In this era of big data, various types of biomedical data for early detection of diabetes have been emerging from electronically generated health records, medical images, IoT sensor data, and simple text data. This streaming data is intricate, diverse, appallingly annotated, and commonly not structured. Early detection of the disease is significant to take timely steps to avoid other health risks and complications. However, the earlier studies depict that the ML algorithms need structured data for classification, have less prediction accuracy, prone to overfitting, and require more computational time to predict the disease. While DL models are more promising, as DL networks are flexible, making them suitable for structured and unstructured data (33), they can process the data than the shallow architecture.

Further, their accuracy can be improved by appropriate feature selection techniques (34, 35). Thus, DL approaches could employ big biomedical data to improve human health (36). For example, most of the recent research (20) concluded that DL performs better for early detection of diabetes as compared to Artificial Neural Network (ANN), Naive Bayes (NB), and Decision Tree (DT).

In literature, various techniques like linear regression feature selection, logistic regression feature selection, Correlation-value based feature selection, Chi- square-based feature selection, F-score based feature selection, decision tree feature selection and random forest feature selection are used for selecting relevant features.

Table 1 below summarizes the methodology used and the limitations of some of the pertinent recent works.

Chen et al. (42) concluded that feature extraction might improve the performance of deep neural networks. In their work, Motwani et al. (43) suggested a framework based on a deep neural network for intelligent patient monitoring. Motwani et al. (44) used DL with cost optimization for remote patient monitoring and recommendation. Authors in (45) compared various feature selection techniques and concluded that the random forest algorithm performs better than the other algorithms. Trapping this advantage of the tree-based technique for selecting relevant features based on feature importance, the proposed approach uses the Extra tree ensemble feature selection technique to

TABLE 1 | Methodology and limitations of recent relevant work.

S.No	Author	Methodology used	Limitations
1	Cho et al. (37)	A model which combines Linear SVM classifiers and wrapper or embedded feature selection methods	Wrapper methods for feature selection have high computational costs and are generally prone to overfitting. They are also dependent on the classifiers used.
2	Le et al. (38)	A novel model utilizing Gray Wolf Optimization (GWO) and an Adaptive Particle Swam Optimization (APSO) to optimize the Multilayer Perceptron (MLP) to reduce the number of required input attributes.	In MLP, computations are complex and time-consuming.
3	Lukmanto et al. (39)	A classification framework to identify and classify diabetes datasets using F-Score Feature Selection and Fuzzy SVM.	A disadvantage of the F-score is that it does not reveal mutual information among features. Instead, it only captures the linear relationships between features and labels.
4	Putri et al. (40)	Learning Vector Quantization (LVQ) to classify the diabetes dataset with Chi-Square for feature selection.	Chi-Square for feature selection does not take into consideration the feature interactions. It is best suited only for categorical variables
5	Sneha and Gangil (41)	Classification by selecting the optimal features based on the correlation values.	Correlation values for feature selection uncover only relationships and do not determine what variables have the most influence. Thus, it can be a time-consuming process.

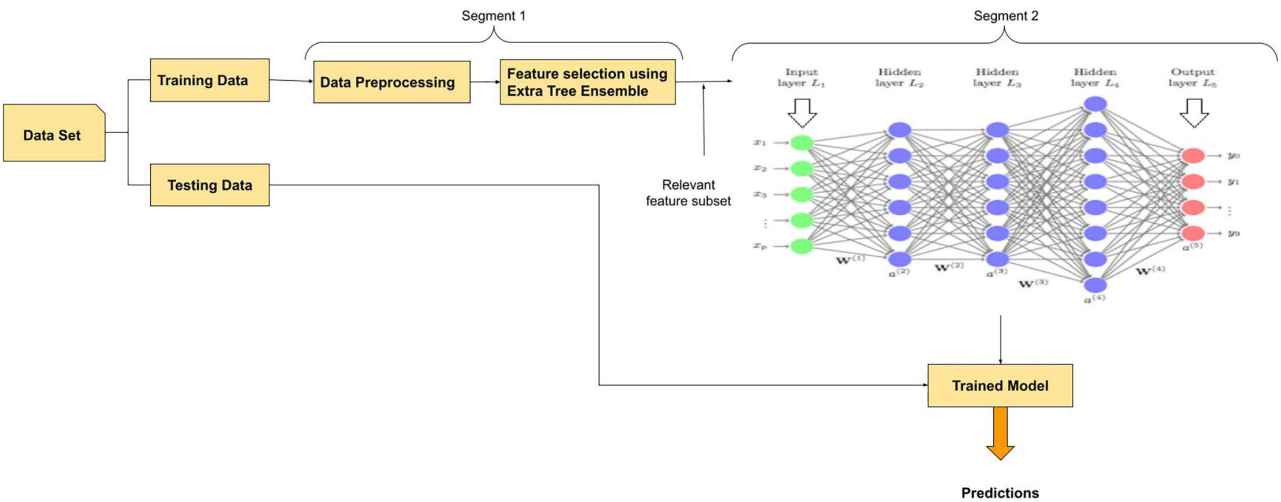

FIGURE 1 | Flowchart for the proposed framework.

retrieve the optimal feature set. Furthermore, a single feature selection method may produce a local optimal or sub-optimal feature subset for which a learning method's performance is compromised. Therefore, multiple feature subsets are combined in the ensemble-based feature selection method to select an optimal subset of features using a combination of feature ranking that improves classification accuracy.

Thrust by these facts, this paper proposed an Extra-Tree Ensemble optimized DL framework (ETEODL) to predict the likelihood of diabetes. This approach is a combination DL approach for prediction and an Extra Tree ensemble technique for selecting the best features based on feature importance. The DL approach extracts lower-level information and feeds them to the next higher layer. The dropout technique is

used with hidden layers of DNN to prevent the overfitting of the model.

The proposed model performs better in the following aspects:

(1) Prediction accuracy and computational time
(2) Prevent overfitting.

The framework is compared with traditional ML techniques and recent works for various parameters like Accuracy, F1-Score, Precision, Recall, and Computation time and thus concluded that the efficiency of the proposed framework is better than the compared works.

The paper has the following sections. First, in section Methodology and Algorithm of the proposed framework are discussed. Then, in section 5, Experimental Setup, including Dataset description, Experiment Environment setup, Experiments, and results, has been discussed. In the last, the proposed work is concluded, and directions for future research are suggested.

METHODOLOGY AND ALGORITHM

The DL framework used in this paper for the early prediction of diabetes is called ETEODL. The framework is divided into two segments. The first segment performs the data acquisition, pre-processing, and feature extraction, while the second segment performs the prediction using a DL model. First, data is acquired from the UCI repository. The acquired data is pre-processed to make it ready for further processing. Next, the data set is split for training and testing purposes. It is followed by feature extraction, where relevant features are extracted to reduce the data set's feature space and prevent model

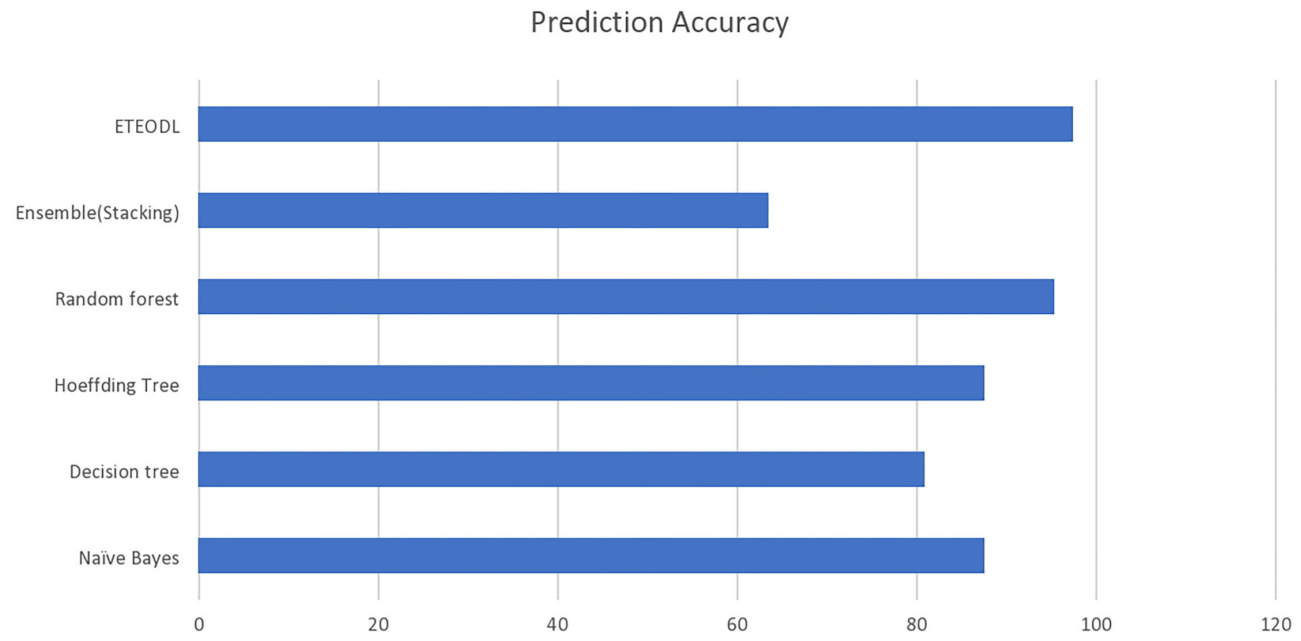

FIGURE 2 | Accuracy (%) comparison with existing methods.

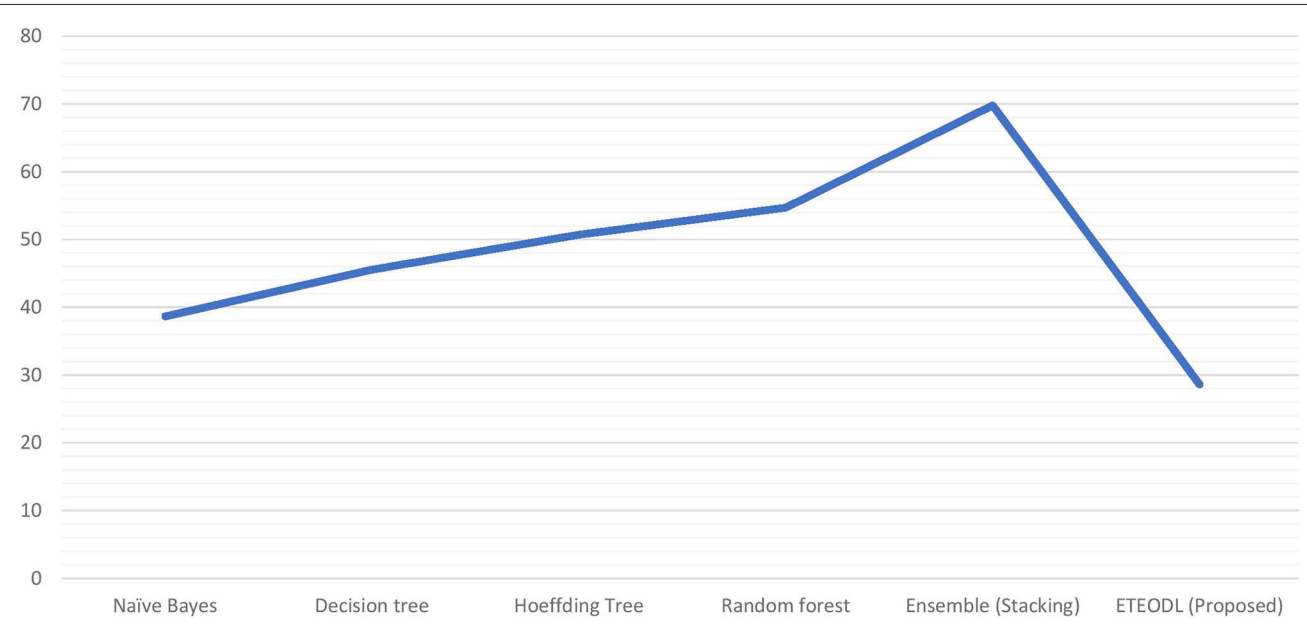

FIGURE 3 | Comparison of computation time (in sec).

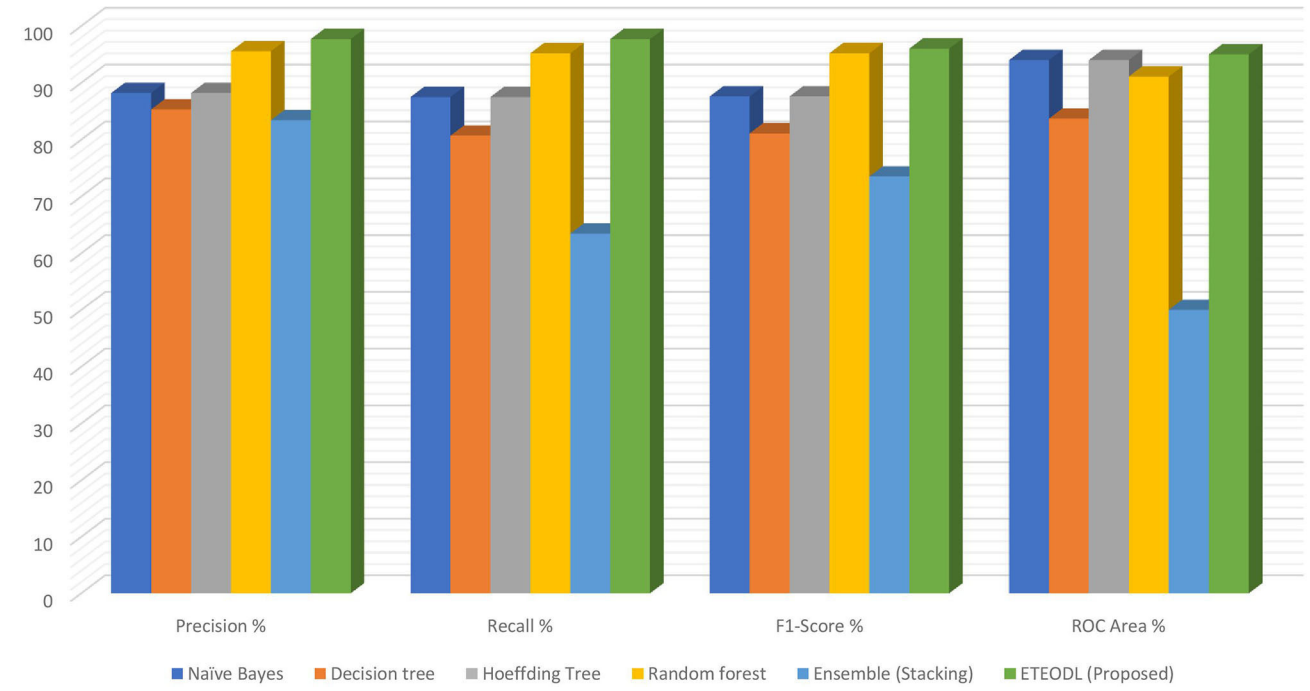

FIGURE 4 | Comparison of precision, recall, F1-score, and ROC area.

overfitting. The extra tree feature extraction technique is used in the proposed work. The output of the first segment is fed in a DL model for classification and prediction. The functions of the two segments are explained in detail in the following section.

Segment-1

Data Acquisition and Data Pre-processing

Data is acquired and pre-processed in the first phase of the framework to clean, transform, and reduce the dimensions. Then, the missing values are discarded. Finally, the normalization process does data transformation. The dataset is divided in a ratio of 80:20 for training and testing purposes for ensuring the learning process only from the training data. After training the model, the performance is tested using testing data.

Data Feature Selection Using Extra Tree Ensemble

After data pre-processing, feature selection is made using Extra Tree Ensemble technique. In this step, the subset of the most relevant features is selected. The choice of the most pertinent features influences the model performance greatly. In the proposed framework, feature importance property is utilized for feature selection. In this method, each feature is given a score. The score ranges from zero and one. The leading score indicates more relevancy of the feature toward the targeted output. These relevant features are thus chosen for model building with improved predictive accuracy and controlled overfitting. A subset of randomly selected n features is supplied to each test node of the tree. Further, the best feature is chosen by the decision tree from this subset to split the data based on Gini Index. The output features of segment one are used as input in segment 2.

Segment-2

DL Model With Dropouts

The DL model consists of three types of layers:

The Input layer is where the selected features are passed. No computation occurs in this layer. The Hidden layers are present between the input and output layers. For choosing the number of Hidden Layers following basic rules are followed;

(1) If the data is linearly separable, then no hidden layers are required.
(2) Using neural networks with one to two hidden layers would be appropriate if the data is less complex and has fewer dimensions or features.
(3) If the data has many dimensions or features, it is possible to use three to five hidden layers to achieve the best possible result.

The input data is not linearly separable and is complex as obtained from various heterogeneous sources; the proposed model consists of three hidden layers. The hidden layers one and two utilize the Rectified Linear Unit (ReLU) as activation.

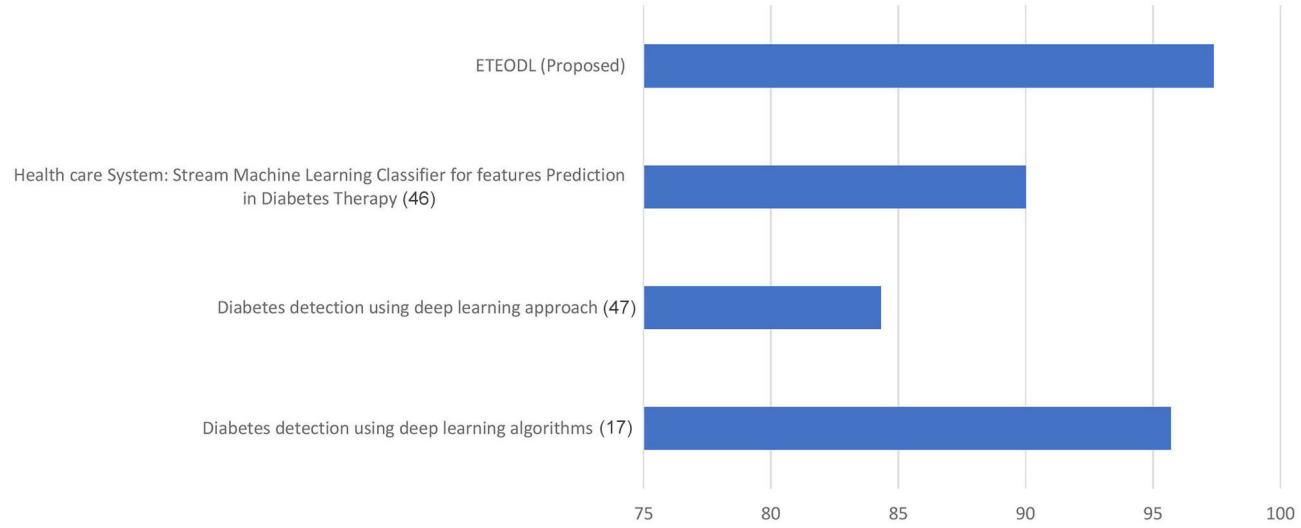

FIGURE 5 | Comparison of prediction accuracy.

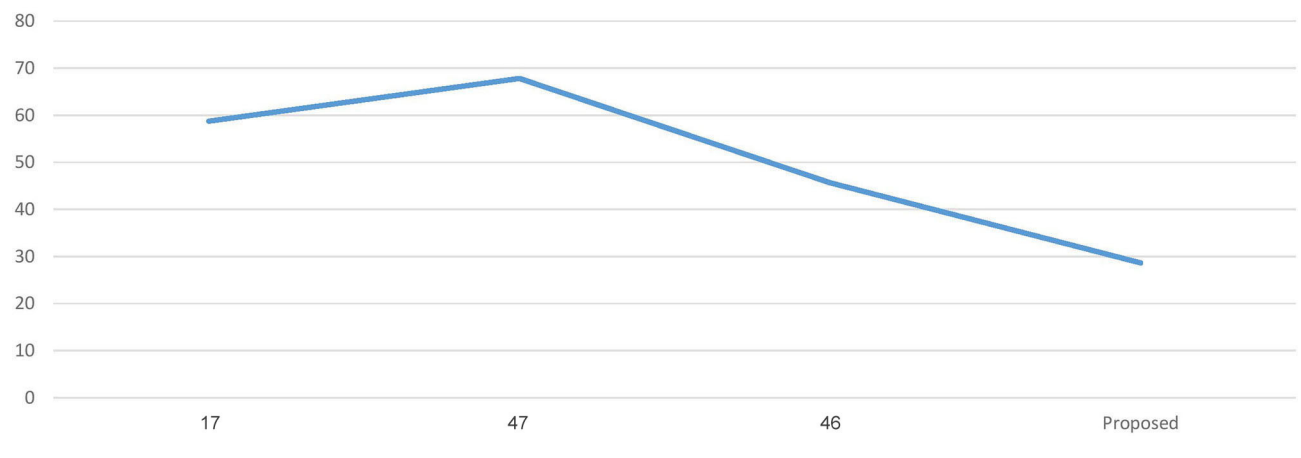

FIGURE 6 | Comparison of computation time.

Mathematically, it is defined as

$$y = max(0, x) \tag{1}$$

And at hidden layer three uses the sigmoid as an activation function. The sigmoid is mathematically represented as:

$$f(x) = 1/(1 + e^{\wedge}(-x)) \tag{2}$$

These hidden layers perform the computation and pass the information to the output layer in the end.

The output layer is responsible for producing the out variable and giving the result.

The cost or loss function is binary cross-entropy/log loss represented using E(W).

$$[E(W)] = -\frac{1}{m}\sum_{i=1}^{m} y_i \log(\gamma) + (1 - y_i)\log(1 - \gamma) \tag{3}$$

A dropout layer is added to the model after each hidden layer to prevent overfitting. During the training phase, the dropout layer deactivates a random set of fractions "i" neurons. The value of p is set to 0.8, where p is the probability of retention used in the input layers and is set to 0.5 in the hidden layers. The value of c is set to 4 in all the layers, where c is the Max-norm constraint. The step-wise methodology of the framework is shown in **Figure 1**.

The algorithm of the proposed framework is given in below.

Algorithm 1| Extra Tree Ensemble Optimized DL Algorithm

Input: X: Training Data set $\tilde{y}$
Y: Class Label of *X*
x: Unknown sample
Output: Label k for unseen sample x
1: Call Algorithm-2 for ETE on Dataset X;
2: Ensemble $x_n = h(\hat{y}_1, \hat{y}_2, \ldots\ldots \hat{y}_n)$
3: Transform Input Features: x_n *to Tensor* Tx_n
4: for each hidden layer, l do

a. $r_j\,(\,l\,) \sim$ *Bernaulli* (p)
b. $\tilde{y}(\,l\,) = r\,(\,l\,)\,{}^{*}y\,(\,l\,)$
c. $z_i\ (\,l+1\,) = w_i\,(\,l+1\,)\,{}^{*}\tilde{y}\,(\,l\,) + b_i\ (\,l+1)$
d. $y_i\,(\,l+1\,) = f\,(z_i\,(\,l+1\,))$

5: Calculate the probability score for predicting the class of transaction:

$$\hat{y} = \sigma(\,Wo\,[Td_m\,] + b_f\,)$$

6: Calculate objective function such as Error Function: E(W) is calculated as

$$[E\,(W)] = -\frac{1}{m}\sum_{i=1}^{m} y_i \log(\gamma) + (1-y_i)\log(1-\gamma)$$

7: Predict diabetes for the given feature set.

Algorithm 2| ETE

Input: F
Output: A Split [f < fc] or none
1: if ($|F| < n_{\min}$) then
return SS=True;
2: if all features are constant in F
return SS=True;
3: if the output is constant in F
return SS=True;
else
return SS=false;
Endif
4: if (SS) is TRUE
return none;
else

a) Select k features $\{f_1, f_2, \ldots\ldots\ldots\ldots f_k\}$ from all f_c that is variable (in F);
b) Take k splits $\{s_1, s_2, \ldots\ldots s_k\}$ where s_i = call Algorithm-3 Rand_Split (s, f_i) $\forall_{\ i}$ =1,2,...k;
c) return a split s* such that Score (s*, F) = max i=1 to k Score (s*, F);

End if

Algorithm 3| Rand_Split(s,f)

Input: s and f
Output: a split
1: Draw a random cut point f_k uniformly in $[fs_{\min}, fs_{\max}]$;
2: return the split $[a < a_c]$;

EXPERIMENTAL SETUP AND RESULTS

Data Set

The dataset used in the research is taken from the UCI repository (34). It contains 520 instances and 16 attributes. The missing values have been pre-processed by discarding the tuples with incomplete values.

Experiment Environment Setup

The experimental setup includes an Intel Core i5 processor with 16 GB RAM. The software configuration includes Keras, Google Tensorflow, and other required libraries such as Scikit-Learn, Numpy, and Pandas installed over Python.

Results and Discussion

The proposed ETEODL model was implemented over Python. The parameters to evaluate the model. The model efficiency was evaluated based on essential metrics like prediction accuracy, precision, recall, f1-measure, ROC, and RMS Error (14). The proposed model is compared with conventional techniques (13) like Naïve Bayes, Decision Tree, Random-forest, Hoeffding tree, and ensemble classifier-like stacking and also with the recent three related works (17, 18, 46). The comparisons are with conventional work is summarized in **Table 2**, and comparison with recent existing work is summarized in **Table 3**.

Table 2 shows the comparison of the proposed framework and conventional ML algorithms.

The outcome of the comparison in **Table 2** can be concluded as follows:

i The DL-based framework outperforms traditional algorithms for the early detection of diabetes (21).
ii The Extra-Tree ensemble feature extraction technique prevents the overfitting of the DL model (28).

The graph in **Figure 2** compares the prediction accuracy of conventional ML algorithms with the ETEODL (proposed).

Figure 3 represents the graphs comparing the computation time of conventional ML algorithms with the ETEODL (proposed).

Figure 4 represents the graphs comparing the precision, recall, and F1 score.

Table 3 shows the performance comparison of the proposed framework with Recent work.

The proposed work is less computationally complex and requires less computation time than previous related work while improving performance.

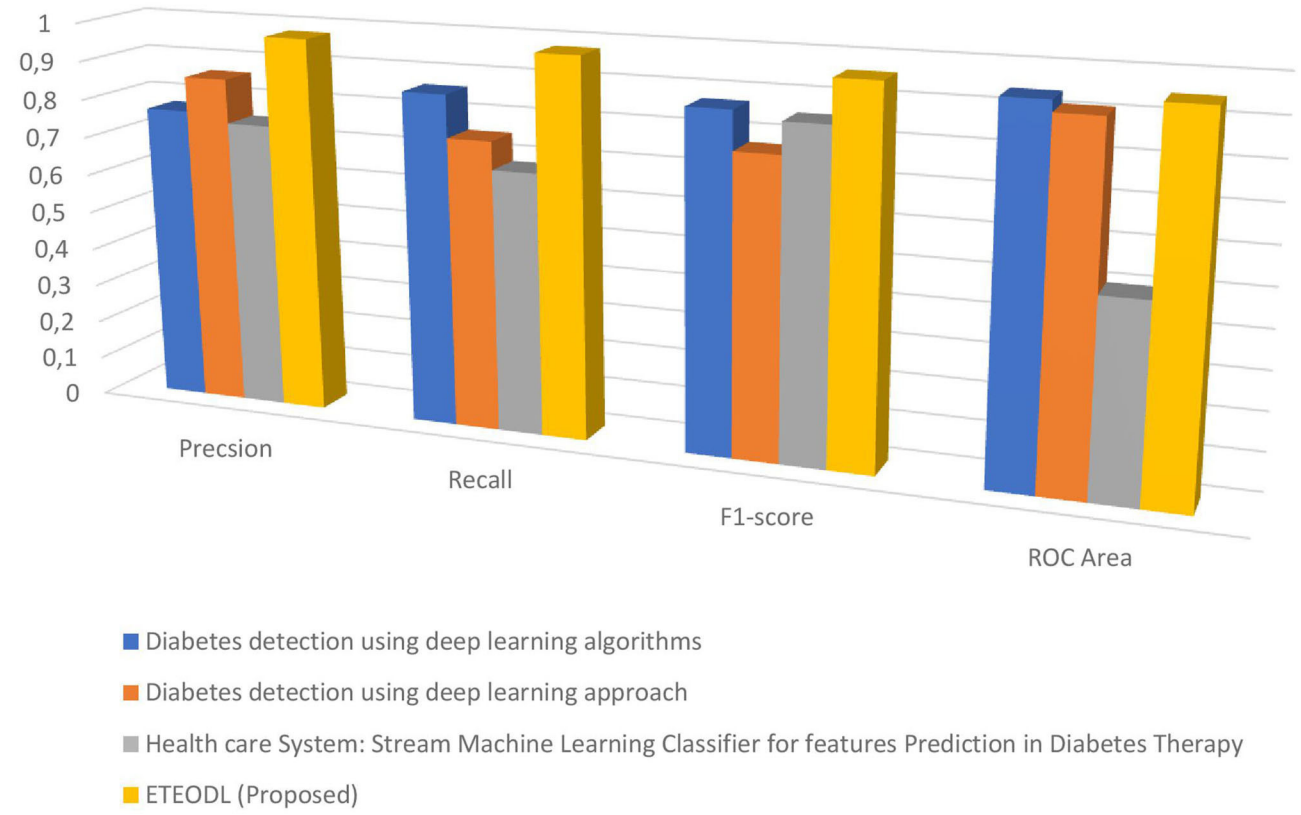

FIGURE 7 | Comparison of precision, recall, f1-score, and roc area.

Figure 5 represents the graph comparing the accuracy of the proposed model with Recent works (17, 46, 47).

Figure 6 represents the graph Comparing the computation time of the Proposed model with three Recent works.

Figure 7 represents the graph Comparing the proposed model's Precision, Recall, and F1 score with Recent works.

Table 4 compares the training and testing accuracy of ETEODL over hundred epochs.

The graph in **Figure 8** shows the comparison of training and testing accuracies.

The comparison graph shows that the proposed work prevents overfitting as it maintains good training and testing accuracies.

EPOCHS	Average training accuracy	Average testing accuracy
01–10	0.836	0.954
11–20	0.877	0.962
21–30	0.922	0.968
31–40	0.934	0.971
41–50	0.952	0.973
51–60	0.964	0.976
61–70	0.965	0.977
71–80	0.966	0.977
81–90	0.968	0.978
91–100	0.968	0.978

CONCLUSION

Detecting diabetes at an early stage is very consequential to take well-timed steps to avoid other health risks and complications. The proposed work demonstrates the application of the Extra Tree ensemble for optimization and DL for classification and prediction for diabetes. The proposed ETEODL is compared against the conventional ML techniques and ensemble algorithms and similar recent works. The accuracy obtained using ETEDOL was approximately 97.38% which is better than contemporary and traditional techniques. The information thus predicted can provide a caution signal for the patient and the doctor to take precautions and control measures. The proposed method is limited to numerical and categorical data and can also be developed

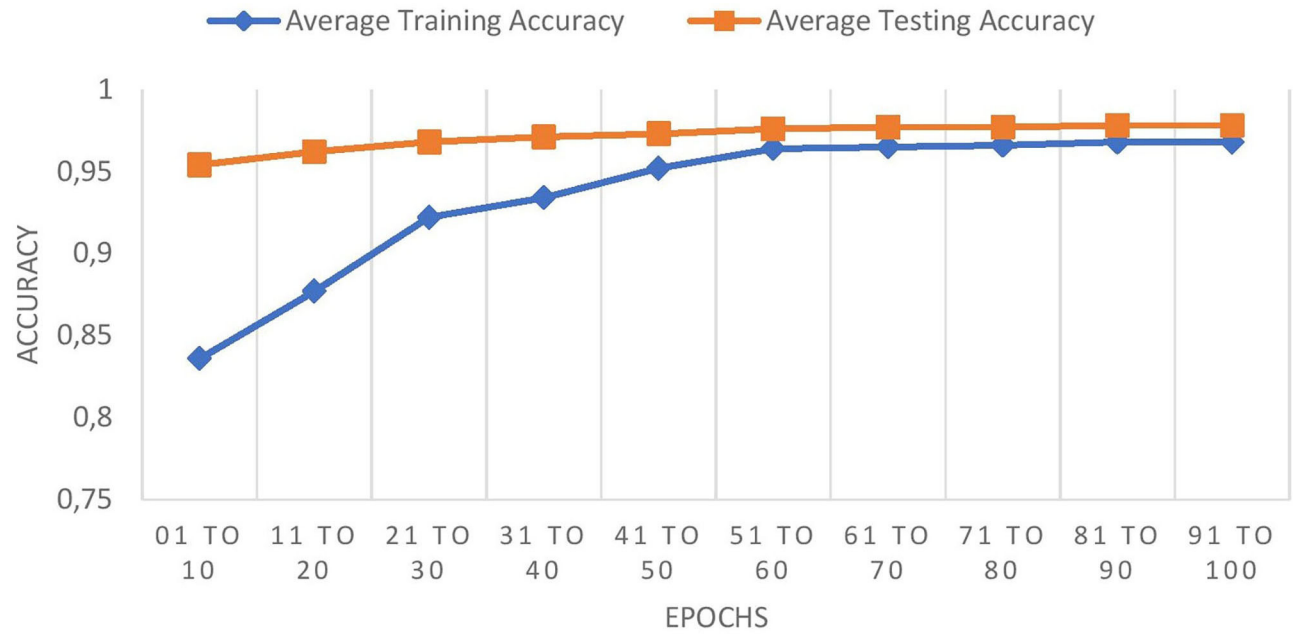

FIGURE 8 | Comparison of training and testing accuracy.

for image data. In the future, the proposed model can be extended as an integral part of an automated system for diabetes prediction.

Background: Renal cell carcinoma (RCC) is the most common renal malignancy in adults, and chromophobe renal cell carcinoma (chRCC) is the third most common subtype of RCC. We aimed to construct a competitive risk model to predict cancer-specific survival (CSS) in elderly patients with chRCC.

Methods: The clinicopathological information of the patients was downloaded from the SEER database, and the patients were randomly divided into the training and validation cohorts. Patients' risk factors for cancer-specific death (CSM) were analyzed using proportional subdistribution hazard (SH). We constructed a competitive risk model to predict the CSS of elderly chRCC patients. Consistency index (C-index), the area under receiver operating curve (AUC), and a calibration curve were used to validate the model's accuracy. Decision curve analysis (DCA) was used to test the clinical value of the model.

Results: A total of 3,522 elderly patients with chRCC were included in the analysis. Patients were randomly assigned to either the training cohort (N = 2,474) or the validation cohort (N = 1,048). SH analysis found that age, race, T, N, and M stage, tumor size, and surgery were risk factors for CSM. We constructed a competitive risk model to predict patients' CSS. In the training set, the model predicted patients' 1-, 3-, and 5-year CSS with C-indices of 82.2, 80.8, and 78.2, respectively. The model predicted patient 1-, 3-, and 5-year CSS in the validation cohort with C-indices of 84.7, 83.4, and 76.9, respectively. The calibration curve showed that the model's predicted value is almost consistent with the observed value, which indicated that the model has good accuracy. The AUC of the training set and validation queue also suggested that the model has good discrimination. The clinical utility of the DCA model in predicting patients' CSS is higher than that of traditional TNM staging.

Conclusions: We constructed a competitive risk model to predict CSS in elderly patients with chRCC. The model has good accuracy and reliability, which can help doctors and patients to make clinical decisions and follow-up strategies.

Keywords: competitive risk model, nomogram, elderly, chromophobe cell renal carcinoma, SEER

INTRODUCTION

Renal cell carcinoma (RCC) is the most common renal malignancy in adults, with more than 400,000 cases diagnosed each year (1). According to its pathological classification, it is mainly divided into clear cell renal cell carcinoma (ccRCC), papillary renal cell carcinoma (pRCC) and chromophobe cell renal cell carcinoma (chRCC), etc. In 2016, The World Health Organization (WHO) defined chRCC as the third common subtype of RCC (2). ChRCC accounts for about 5–7% of RCC, with the same proportion in males and females, and the first diagnosis age of most cases is after 65 years old (3). Most patients are sporadic, and a few are hereditary, including BIRt-Hogg-Dube (BHD) syndrome (4) and tuberous sclerosis (TSC) (5). Comprehensive genomic analysis of chRCC showed a low mutation rate in its somatic cells, and the most common mutated genes were identified as TP53 and PTEN (6). ChRCC originates from the epithelial cells of the distal renal tubules, especially the α-intercalated cells of the renal collecting tubules. CcRCC derived from proximal renal tubular epithelial cells, which provided evidence for the heterogenesis of the two. ChRCC has a good prognosis, with a 5-year survival rate of 78–100% and a 10-year survival rate of 80–90% (7), which is significantly better than other RCCs, including ccRCC. So to this day, research on chRCC remains extremely rare. However, it is worth noting that 5% of chRCC patients are complicated with severe renal venous carcinoma thrombi (8), while nearly 10% of patients develop metastasis (9). The prognosis of these patients is similar to that of clear metastatic renal cell carcinoma, and the 5-year survival rate is only 14% (10). In addition, according to previous reports, factors determining the survival of chRCC patients also vary greatly (11, 12). Therefore, it is of great significance for the treatment and prognosis of chRCC patients to study influential prognostic factors, establish a high-precision prediction model and improve clinical treatment strategies for the particular group of the elderly, the central disease.

In recent years, with the broad application of the nomogram prediction model, traditional TNM staging has been gradually replaced. The prognosis of patients is also affected by many non-anatomic factors, such as age, gender, race, marital status, surgical methods, etc. (13). Nomogram is a data-based graphical computing tool that can estimate the risk of a disease based on staging systems such as the American Joint Commission on Cancer (AJCC) and other key risk factors related to prognosis (14). Today, many nomograms have been developed and applied to RCC, but mainly for patients with ccRCC and pRCC (15–18). However, there is still a lack of adequate and reliable nomograms to predict the prognosis of elderly patients with chRCC.

At present, artificial intelligence has been widely used in human health. Gadekallu et al. (19, 20) used deep learning to detect diabetic retinopathy. Kutia et al. (21) also discussed the great convenience that e-health systems bring to people. Kumar et al. (22) used neural networks to predict COVID-19. Iwendi et al. (23) use machine learning model for product recommendation. At present, there is no survival prediction model for chromophobe cell carcinoma in elderly patients. The existing prediction models are suitable for most of the population, but their accuracy is low.

Based on the above situation, we developed a competitive risk prediction model. We validated its accuracy in evaluating the cancer-specific survival rate (CSS) of elderly chRCC patients, providing a reference for clinical diagnosis and treatment.

METHODS

Data Source and Data Extraction

We collected clinicopathological data from patients in the Surveillance, Epidemiology, and End Results (SEER) program of the National Cancer Institute. The SEER database is the national cancer database of the United States, covering ∼28% of the US population and containing 18 cancer registries. Patient demographic information, clinicopathological information, and follow-up data can be obtained from the SEER database. Because the SEER database is a public database, we cannot identify patients' data, so our study does not require ethical approval and informed consent. Our methodology follows the rules of the SEER database.

We collected clinicopathological information for all chRCC patients, including age, sex, year of diagnosis, race, marital status, tumor size, laterality, histological tumor grade, TNM stage, surgical method, radiotherapy, chemotherapy, survival status, and cause of death. Inclusion criteria: (1) Pathological diagnosis of chromophobe renal cell carcinoma (ICD-O-3 code: 8317); (2) Age $\geq$ 65; (3) Unilateral renal tumor. Exclusion criteria; (1) TNM staging is unknown; (2) Unknown tumor size; (3) Unknown surgical method; (4) Survival time $<$1 month. The screening process for all patients is shown in **Figure 1**.

Patients were divided into years of diagnosis from 2004 to 2010 and 2011 to 2018. Patients were categorized as white, black, and other (American Indian /AK Native, Asian/Pacific Islander). Histological grades of tumors include grade I (highly differentiated), grade II (moderately differentiated), grade III (poorly differentiated), and grade IV (undifferentiated). Patients' surgeries were classified into three categories, including local tumor excision (codes 10–27), partial nephrectomy (codes 30), and radical nephrectomy (codes 40–80).

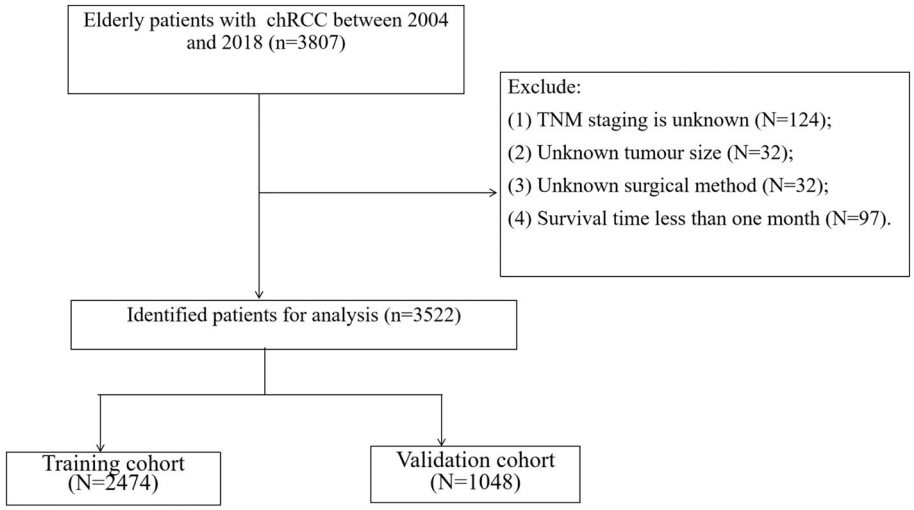

FIGURE 1 | Flow chart of patient screening.

Construction and Validation of the Competitive Risk Model

At present, the main research methods of competitive risk include cause-specific risk model and cumulative risk model. The cumulative risk model takes into account other competing endpoint events when calculating a related endpoint event, which is closer to reality (24). All patients were randomly assigned to a training cohort (70%) or a validation cohort (30%). In the training cohort, the primary outcome was cancer-specific mortality (CSM), and the competing risk event was other causes of mortality (OCM). In the case of competition risk, the cumulative risk model is used to estimate the cumulative occurrence rate of interest events. Based on the proportional sub-distribution hazard model proposed by Fine and Gray, the influencing factors of cancer-specific death in patients were analyzed. At the same time, we used the risk factors of CSM to construct a competitive risk model to predict CSS. Consistency index (C-index), the area under the receiver operating curve (AUC), calibration curve were used to validate the accuracy and discrimination of the model.

Clinical Utility

Decision curve analysis (DCA) was used to validate the clinical value of the model. We compared it with traditional TNM staging. All patients were divided into high-risk and low-risk groups based on competitive risk model scores. Log-rank test and Kaplan-Meier (K-M) curve were used to analyze survival differences between groups.

Statistical Analysis

Measurement data (age and tumor size) were described by mean and standard deviation, and a non-parametric *U*-test analyzed differences. Count data were characterized by frequency (%), and the Chi-square test performed difference analysis or non-parametric *U*-test. We analyzed risk factors for CSM and death from other causes with proportional subdistribution hazard (SH). Log-rank test and Kaplan-Meier curve were used to analyze the difference in survival between groups. All statistical methods were analyzed by R software 4.1.0 and SPSS 26.0. A P-value < 0.05 was considered statistically significant.

RESULTS

Clinical Features

A total of 3,522 elderly patients with chRCC were included in the analysis. Patients were randomly assigned to either the training cohort ($N = 2{,}474$) or the validation cohort ($N = 1{,}048$). The average age of the patients was 73.2 ± 6.11 years, and 2,907 (82.5%) were white, 2,035 (57.8%) were male, and 2,185 (62.0%) were married. There were 1,749 (49.7%) patients with tumors at the left side, and histological grades included 192 (5.45%) of grade I, 1,097 (31.1%) of grade II, 617 (17.5%) of Grade III, and 110 (3.12%) of grade IV. There were 2,974 (84.4%) patients in T1-T2, 3,470 (98.5%) patients in N0, and 3,452 (98.0%) patients in M0. The mean tumor size was 49.2 ± 35.0 mm. Local tumor excision was performed in 214 (6.08%) patients, partial nephrectomy was performed in 1,264 (35.9%) patients, and radical nephrectomy was performed in 1,903 (54.0%) patients. Fifty-five (1.56%) patients received chemotherapy and 23 (0.65%) received radiotherapy. The clinicopathological information of all patients is shown in **Table 1**. There was no significant difference between the training cohort and the validation cohort.

Construction of the Competing Risk Model

The training set analyzed the risk factors of CSM and OCM using SH and cumulative survival rate. The results showed that the risk factors of CSM in patients included age and race, T stage, N stage, M stage, tumor size, operation. Risk factors for OCM were age, sex, marital status, year of diagnosis, and tumor size (**Table 2**). We used patient risk factors for a cancer-specific

end to construct a competitive risk model that predicted patient CSS (**Figure 2**). We developed a web page utility to calculate a patient's probability of CSS. Visit https://chenghao.shinyapps.io/DynNomapp/ to enter the site and a patient's clinicopathological features to obtain a CSS rate.

Validation of the Competitive Risk Model

We use the C-index to validate the model's training and validation set accuracy. In the training set, the model predicted patients' 1-, 3-, and 5-year CSS with C-indices of 82.2, 80.8, and 78.2, respectively. The model predicted patient 1-, 3-, and 5-year CSS in the validation cohort with C-indices of 84.7, 83.4, and 76.9, respectively. The results show that the model has good discrimination. In addition, the model's calibration curve showed that the model's predicted value is almost consistent with the actual observed value, indicating that the model has good accuracy (**Figure 3**). The AUC of the training set and validation cohort also suggested that the model has good discrimination (**Figure 4**).

Clinical Application of the Competitive Risk Model

DCA showed that in both the training and validation set, the clinical utility of the model in predicting patients' 1-, 3-, and 5-year CSS was higher than that of traditional TNM staging (**Figure 5**). We classified patients into the high-risk group based on their competitive risk model score (total $>$ 54.1) and low-risk group (total score $\leq$ 54.1). K-M curve showed that the 1-, 3- and 5-year survival rates of patients in the high-risk group were 96.1, 92.3, and 88.2%, respectively, while the 1-, 3-, and 5-year survival rates of patients in the low-risk group were 99.1, 97.3, and 95.0%, respectively. In the training and validation sets, survival was significantly higher in the low-risk group than in the high-risk group (**Figure 6**). In addition, we analyzed surgical procedures in the high-risk and low-risk groups. In the low-risk group, all patients underwent surgery, and there were no significant differences in CSS between the types of surgery (**Figure 7A**). Most patients chose radical nephrectomy in the high-risk group, and patients with a partial nephrectomy and local tumor excision had significantly higher survival rates (**Figure 7B**).

DISCUSSION

chRCC is a new type of renal cell carcinoma (RCC) discovered by Thoenes et al. (25). The etiology of ChRCC is not clear yet, and some studies have claimed that it is closely related to chromosome variation. All chromosome loss is common in chRCCs, especially chromatids 1, 2, 6, 10, 13, and 17 (26). The inactivation of the TSC2 gene and the activation of MTOR is the most critical molecular changes (6). Under the pathological microscope, chRCC is characterized by large polygonal cells, pale cytoplasm, protruding cell membrane accompanied by raisin-like shrinkage (27). Ultrastructural analysis showed many abnormal mitochondria in the chRCC cytoplasm, with different sizes and shapes, accompanied by external swelling (28). In immunohistochemistry, CK7 is an important marker, expressed in more than 75% of chRCC, which can be preliminarily diagnosed by combining the diffuse positive expression of CD117 and KSP-cadherin (29).

However, it still needs to be differentiated from eosinophilic carcinoma. ChRCC has a clear boundary and no capsule, only occurs in the kidney, and the section is gray or light brown. Eosinophilic carcinoma can occur in any part of the body, and the cut surface is peach-red (30, 31). ChRCC lacks typical clinical manifestations. A characteristic triad of low back pain, hematuria and abdominal mass rarely occurs in the early stage of ChRCC and is considered a marker of disease progression (32).

At present, the nomogram of renal cell carcinoma has been widely established. For example, Wang et al. (15) established a nomogram to predict the medium- and long-term prognosis of patients with papillary cell carcinoma. Peng et al. (16) established a nomogram to predict the prognosis of patients with clear cell carcinoma and renal cell carcinoma. Yan et al. (17) established a nomogram to predict cancer-specific survival in patients with papillary renal cell carcinoma. Chen et al. established a nomogram to predict the prognosis of chromophobe RCC patients, but did not involve competitive risk. Although these nomgorams can be used to predict survival in patients with renal cell carcinoma, they are not accurate enough. The competitive risk of survival

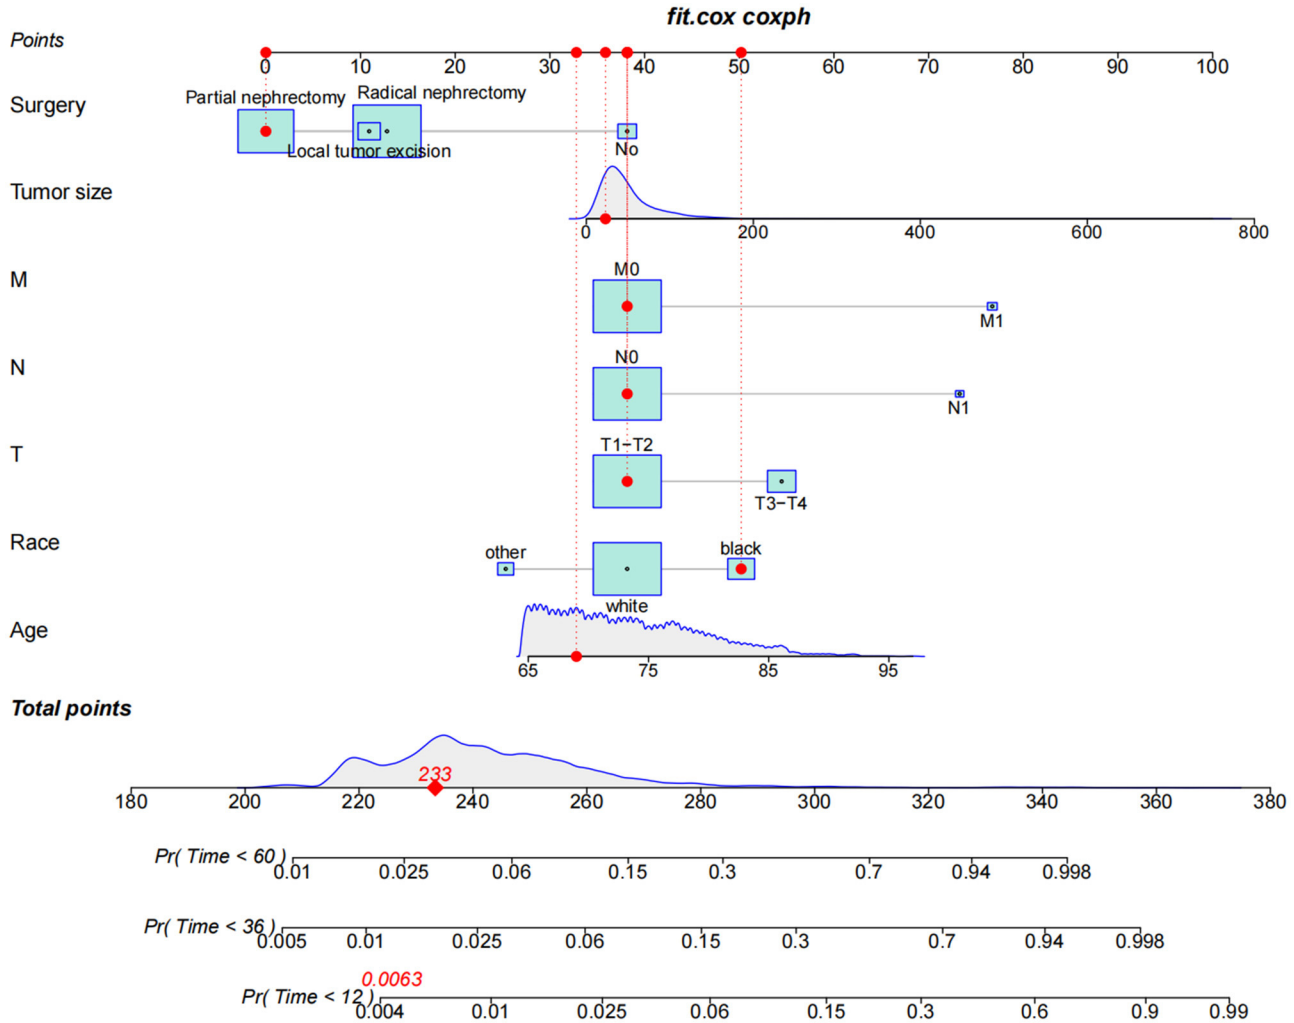

FIGURE 2 | The competitive risk model nomogram of CSS in elderly patients with chRCC at 1-, 3-, and 5-year.

in elderly patients with chRCC requires a more accurate prediction model.

The arrival of artificial intelligence makes big data medical care a reality. Maddikunta et al. (33) explore the potential application of artificial intelligence in industry 5.0. Healthcare 5.0 aims to use medical big data combined with artificial intelligence to assist human health. This study is to use the big data of cancer patients to establish a prediction model to predict the survival of patients.

Age is a critical factor in developing all cancers, and as we age, the risk of genetic mutations that could trigger cancer increases. Somatic mutations are generally considered the first step in the occurrence of cancer. They are associated with aging and highly reproducible DNA methylation changes, which help explain the higher prevalence of malignant tumors in the elderly (34). There is no consensus on defining the age of elderly patients, but more than 60% of initial cancer diagnoses and more than 70% of cancer deaths occur in patients over 65 years old (35). To improve the accuracy and representativeness of the prediction model, chRCC patients over 65 years old were included in this study. Escudier et al. (36) found that under the condition of the same stage and grade, there was a massive difference in the survival rate of patients and believed that clinical factors such as age were more critical than pathological and metastatic factors. Dias-Santos et al. (37) also showed that age is closely related to the survival rate of various cancers.

Surgery is a crucial measure for the treatment of chRCC, and tumor size based on clinical T-stage directly affects the choice of surgery and surgical method. Currently, the primary surgical procedures for chRCC include radical nephrectomy, partial nephrectomy, and local tumor excision represented by thermal ablation (TA), radiofrequency ablation (RFA), and cryoablation (CA). Current guidelines indicate that PN is still the standard recommended procedure for stage cT1a

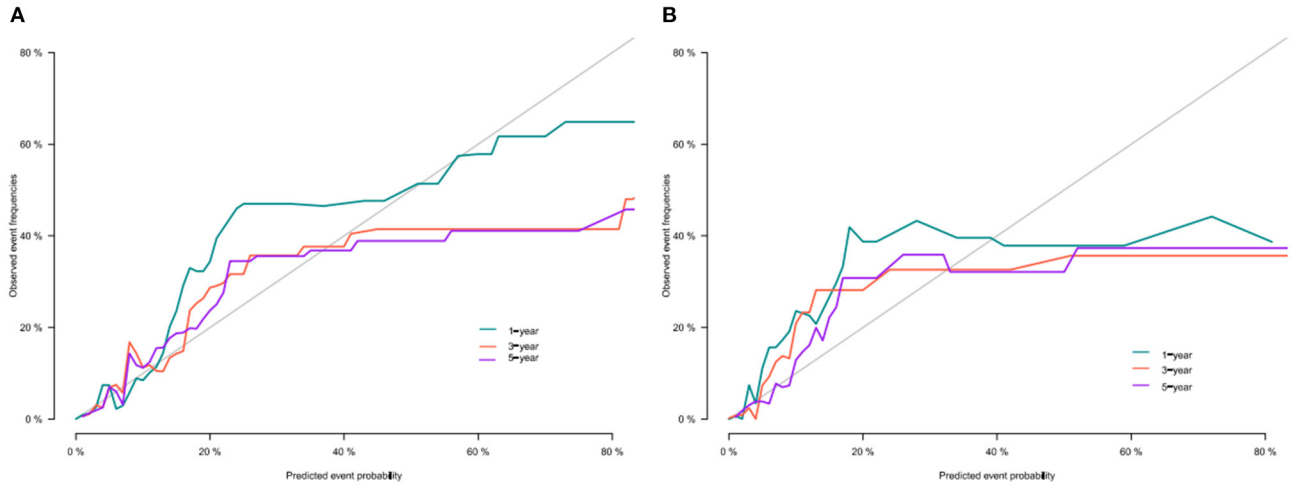

FIGURE 3 | Calibration curve of the nomogram in training cohort **(A)** and validation cohort **(B)**.

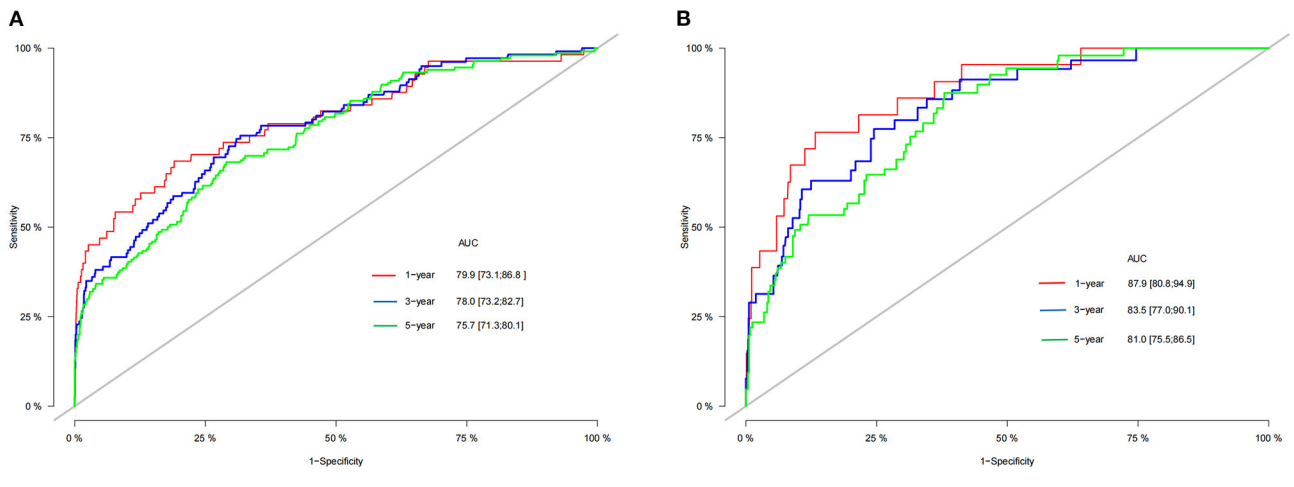

FIGURE 4 | AUC for predicting 1-, 3-, and 5-year CSS in training cohort **(A)** and validation cohort **(B)**.

tumors, while there is controversy for stage cT1b, and RN is recommended for stage cT2 (38). However, with the increasing reports of chronic kidney disease (CKD) induced by RN and PN surgery, more and more attention has been paid to the requirement of nephron preservation, and tumor resection represented by TA is recommended to be used in cT1a stage RCC (39). TA is theoretically feasible for tumors larger than 4 cm, but it requires multiple puncture operations at various sites, and the probability of bleeding and other complications is significantly increased (40). At the same time, based on the solid support of extensive sample prospective studies, active surveillance (AS) is recommended for renal tumor patients with cT1 stage (41), with metastasis rates of 0–6% and CSS of 0–18% (42). It is worth noting that Huang et al. (43) found that in elderly chRCC patients over 65 years old, the mortality rate of the RN group was significantly higher than the PN group, which was presumed to be due to the risk of surgery and anesthesia caused by cardiovascular and cerebrovascular diseases and chronic kidney disease. Thompson et al. (44) also found a significant positive correlation between RN and mortality; therefore, AS has particular advantages in elderly patients.

In addition, the mean tumor size of ChRCC was 6.0 cm, which was significantly more significant than the other subtypes of RCC. However, the degree of malignancy was not higher than that of other RCCS, indicating no correlation between tumor growth and malignancy among different RCC subtypes (45). However, for the chRCC subtype, there was a linear relationship between tumor size and recurrence (46), which was consistent with this study. This study showed that the larger the tumor,

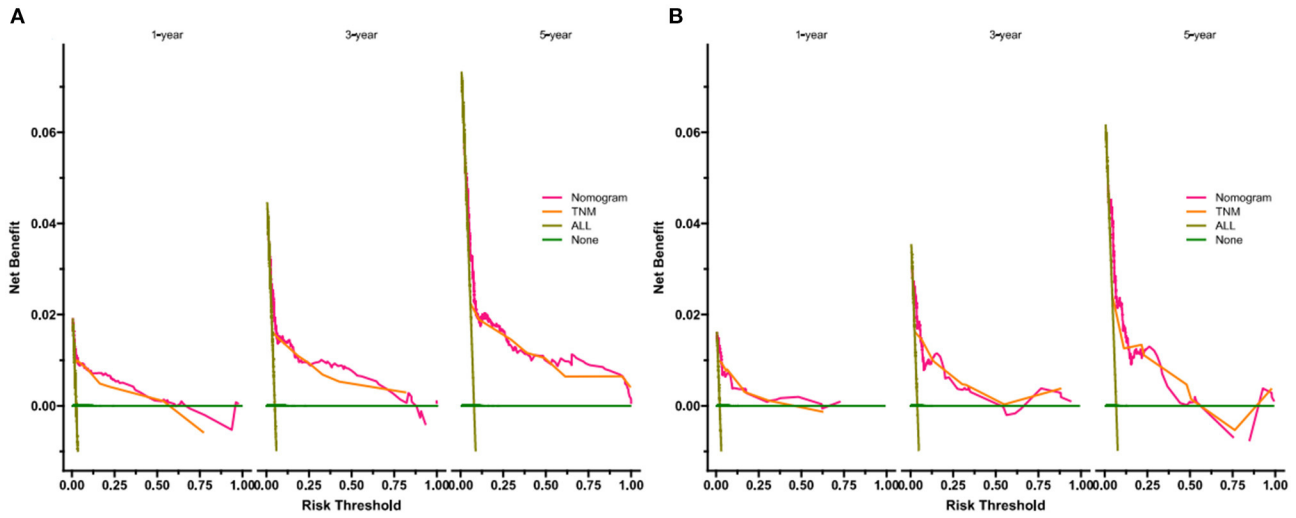

FIGURE 5 | DCA of the nomogram in training cohort **(A)** and validation cohort **(B)**. The Y-axis represents a net benefit and the X-axis represents threshold probability. The green line means no patients died and the dark green line means all patients died. When the threshold probability is between 20 and 100%, the net benefit of the model exceeds all deaths or none.

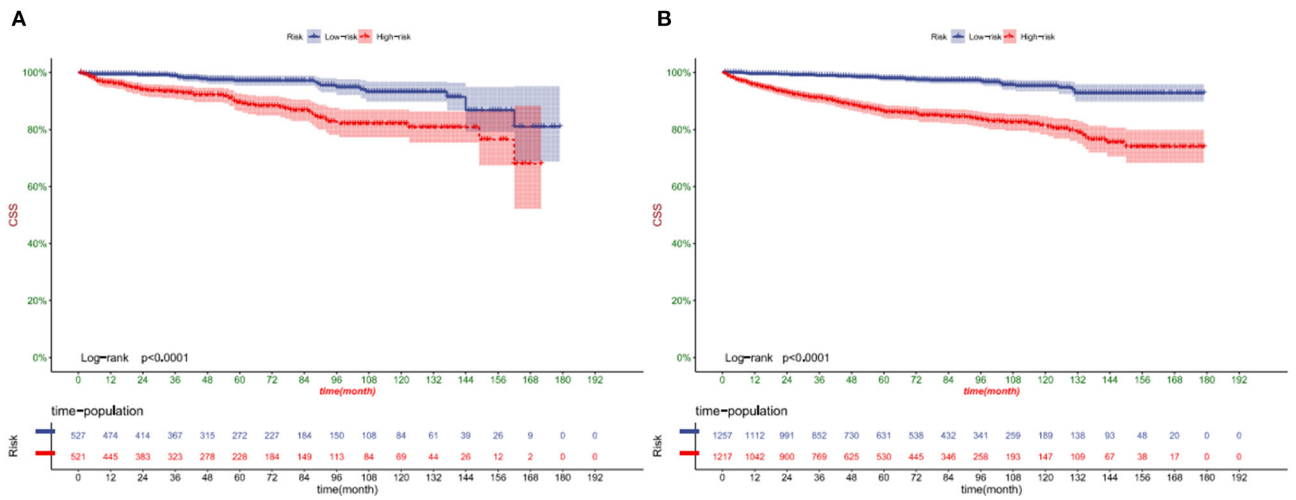

FIGURE 6 | Kaplan-Meier curves of patients in the low-risk and high-risk groups in training cohort **(A)** and validation cohort **(B)**.

the lower the patient's survival rate and could affect death from other causes.

This study is the first to construct a competitive risk model to predict cancer-specific survival in elderly patients with chromophobe cell carcinoma. This model has good accuracy and reliability through internal verification. However, there are still some shortcomings in our research. First of all, this study is a retrospective study, so it is challenging to avoid selection differences, which may cause a particular bias. Secondly, we did not include some key variables, such as BMI, smoking, drinking, hypertension, etc., which could improve the model's accuracy. Finally, our model has only undergone internal validation, and further external proof and future clinical application are necessary. Next, we will conduct the next prospective study to validate our prediction model.

CONCLUSION

We identified age, race, TNM stage, tumor size, and surgery as risk factors based on competitive risk in elderly patients with chRCC. We constructed a competitive risk model to predict CSS in elderly patients with chRCC. The model has good accuracy and reliability, which can help doctors and patients to make clinical decisions and follow-up strategies.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://seer.cancer.gov/.

ETHICS STATEMENT

The data of this study is obtained from the SEER database. The patients' data is public and anonymous, so this study does not require ethical approval and informed consent.

AUTHOR CONTRIBUTIONS

JW and CZ designed the study. CZ, JW, JL, ML, LJ, and XT collected and analyzed the data. JW drafted the initial manuscript. CZ, TM, JL, ZZ, and DH revised the article critically. CZ, JL, DH, ML, and XT reviewed and edited the article. All authors approved the final manuscript.

FUNDING

This work was supported by Special Key Project of Chongqing Technology Innovation and Application Development (No. Cstc2019jscx-tjsbX0003).

Wen C, Tang J and Luo H (2022) Development and Validation of a Nomogram to Predict Cancer-Specific Survival for Middle-Aged Patients With Early-Stage Hepatocellular Carcinoma. Front. Public Health 10:848716. doi: 10.3389/fpubh.2022.848716

Background: Hepatocellular carcinoma is a common cause of death in middle-aged patients. We aimed to construct a new nomogram to predict cancer-specific survival (CSS) in middle-aged patients with hepatocellular carcinoma at an early stage.

Method: We collected clinicopathological information on early middle-aged patients with hepatocellular carcinoma from the SEER database. Univariate and multivariate Cox regression models were used to screen the independent risk factors for prognosis. These risk factors were used to construct predictions of CSS in patients with hepatocellular carcinoma. Consistency index (C- index), calibration curve, area under the receiver operating curve (AUC) were used. A decision analysis curve (DCA) was used to evaluate the clinical utility of the predictive model.

Results: A total of 6,286 patients with hepatocellular carcinoma in early middle age were enrolled. Univariate and multivariate Cox regression analysis showed that sex, marriage, race, histological tumor grade, T stage, surgery, chemotherapy, AFP, and tumor size were independent risk factors for prognosis. All independent risk factors were included in the nomogram to predict CSS at 1-, 3-, and 5-years in early middle age patients with hepatocellular carcinoma. In the training cohort and validation cohort, the C-index of the prediction model was 0.728 (95%CI: 0.716–0.740) and 0.733 (95%CI: 0.715–0.751), respectively. The calibration curve showed that the predicted value of the prediction model is highly consistent with the observed value. AUC also suggested that the model has good discrimination. DCA suggested that the nomogram had better predictive power than T staging.

Conclusion: We constructed a new nomogram to predict CSS in middle-aged patients with early-stage hepatocellular carcinoma. This prediction model has good accuracy and reliability, which can help patients and doctors to judge prognosis and make clinical decisions.

Keywords: nomogram, cancer-specific survival, middle-aged patients, hepatocellular carcinoma, SEER

INTRODUCTION

Primary liver cancer is the sixth most commonly diagnosed cancer and the third leading cause of cancer-related death worldwide, with ∼906,000 new cases and deaths in 2020, and hepatocellular carcinoma (HCC) accounts for the vast majority (75–85%) of primary liver cancers (1). Although some risk factors such as hepatitis B virus (HBV) and aflatoxin B1 (AFB1) are declining in many regions due to public health measures, the incidence of liver cancer is still rising, possibly because of the increasing prevalence of obesity and diabetes (2). Due to a variety of diagnostic methods, including ultrasonography, serum alpha-fetoprotein (AFP), computed tomography (CT), and magnetic resonance imaging (MRI) being widely used, a more significant proportion of early HCC patients are diagnosed (3). Besides, a majority of HCC patients are aged between 40 and 60. Hence, the survival prognosis of this group of patients with early HCC remains a significant concern.

Many risk factors are affecting the survival prognosis in patients with HCC, including age (4), race (5), histological grade (6), chemotherapy (7), surgery (8), tumor size (9), and so on. To the best of our knowledge, numerous nomogram prediction models based upon the above factors for HCC have been constructed (10–12), as well as prognostic nomogram for early-stage HCC (13). However, there have been no clinical studies and statistical tools that evaluated the predictive factors for early-stage HCC patients aged between 40 and 60. Considering the earlier the stage and the younger the patient, the better the prognosis and the more meaningful the prediction, we aim to extract data from the Surveillance, Epidemiology, and End Results (SEER) database to develop and validate a practical nomogram for predicting the cancer-specific survival (CSS) of patients with early HCC aged between 40 and 60 by integrating some significant variables so that clinicians can make better decisions.

At present, artificial intelligence has been widely used in human health care. Shubham et al. (14) used deep learning methods to identify glomerulus in human kidney tissue images. Movassagh et al. (15) used a new method to train neural networks. Mohan et al. (16) used machine learning to predict heart disease. Iwendi et al. (17, 18) used machine learning to classify COVID-19 patients and make health predictions. Kumar et al. (19) used neural networks to predict COVID-19. Ngabo et al. (20) use machine learning architectures to tackle urban pandemics. In this study, we used conventional nomogram to construct a new predictive model to predict the survival of middle-aged HCC patients. This prediction model can help HCC patients and doctors to develop clinical and follow-up strategies.

PATIENTS AND METHODS

Data Source and Data Extraction

We downloaded clinicopathological information of all patients with HCC from 2010 to 2018 from the SEER database. We collected social and demographic information (age, sex, race, year of diagnosis, and marriage), tumor information (tumor stage, tumor profile, tumor size, and histological grade), and treatment information (radiation, chemotherapy, and surgery). Because SEER is a public database, patient information is not identifiable, so our study does not require ethical approval and patients' informed consent. Our analysis follows the data usage rules of the SEER database.

Inclusion criteria: (1) Pathological diagnosis of HCC; (2) Aged 40–60; (3) The years of diagnosis were 2010–2018. Exclusion criteria: (1) Surgical method unknown; (2) Unknown tumor size; (3) The cause of death is unknown; (4) Survival time $<$1 month. The patient inclusion and exclusion procedures are shown in **Figure 1**.

Patients were categorized as white, black, and others (American Indian/AK Native, Asian/Pacific Islander). The histological tumor grading of the patients was divided into grades I to IV, which were highly differentiated, moderately differentiated, poorly differentiated, and undifferentiated. The surgical methods of patients are divided into three categories: local tumor destruction, lobectomy, and transplant. AFP can be positive or negative.

Construction and Validation of the Nomogram

All patients were randomly assigned to a training cohort (70%) or a validation cohort (30%). Univariate Cox regression analysis was used to identify prognostic risk factors in middle-aged patients with early-stage HCC in the training cohort. Multivariate Cox regression analysis analyzed the independent risk factors for prognosis. All independent risk factors were included in a nomogram to predict patients' CSS. A series of validation methods were used to validate the accuracy and discrimination of the prediction model, including Consistency index (C-index), calibration curve, area under the receiver operating curve (AUC).

Clinical Utility

A decision analysis curve (DCA) is a method to evaluate the practical value of the model by calculating the net income under different thresholds. We used DCA to assess the clinical utility of the nomogram prediction model and compared it with conventional T staging. At the same time, we divided all patients into low-risk and high-risk groups based on each patient's nomogram score. Log-rank test and Kaplan-Meier (K-M) curve were used to compare survival differences among patients in different groups.

Statistical Analysis

Counting data were expressed as frequency (%), and differences between groups were analyzed by Chi-square or non-parametric U-tests. Measurement data (age and tumor size) were described using mean and standard deviation, and differences between groups were analyzed using non-parametric U-tests. Univariate and multivariate Cox regression models examined the survival and prognostic factors of the patients. Log-rank test and Kaplan-Meier (K-M) curve were used to compare survival differences between groups. R software 4.1.0 and SPSS 26.0 were used for statistical analysis. A P-value < 0.05 was considered statistically significant.

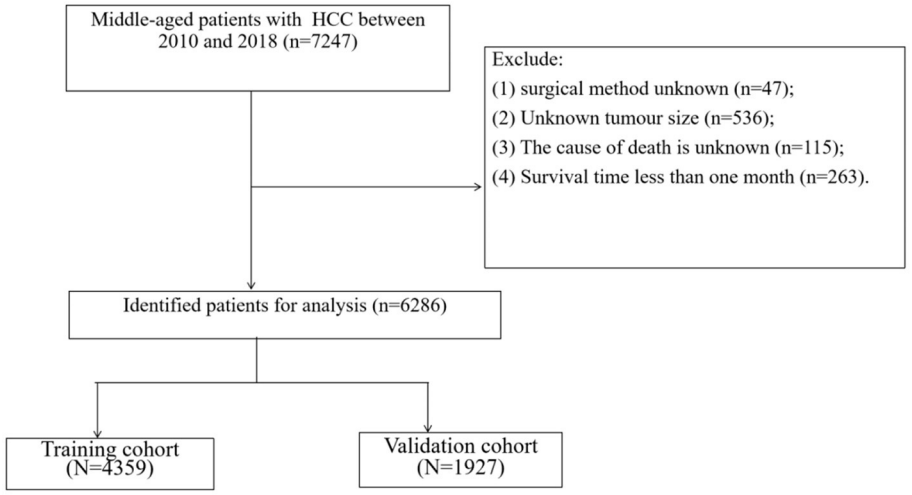

FIGURE 1 | Flow chart of patient screening.

RESULTS

Clinical Features

A total of 6,286 patients with early-stage HCC aged between 40 and 60 were included in the study. The mean age of all patients was 54.4 ± 4.1 years, 4,298 (68.4%) patients were white, 5,005 (79.6%) patients were male, 2,799 (44.5%) patients were married, and 3,386 (53.9%) patients were AFP positive. The histological grades were 666 (10.6%) in grade I, 1,050 (16.7%) in grade II, 309 (4.92%) in grade III, and 16 (0.25%) in grade IV. There were 3,976 patients (63.3%) with stage T1 tumors, with a mean tumor size of 35.5 ± 32.2 mm. Partial tumor destruction was performed in 1,183 (18.8%) patients, lobectomy was performed in 702 (11.2%) patients, and liver transplantation was performed in 769 (12.2%) patients. Two thousand nine hundred and fourteen (46.4%) patients received chemotherapy, and 507 (8.07%) received radiotherapy. The clinicopathological information of all patients is shown in **Table 1**. There was no significant difference between the training cohort and the validation cohort.

Univariate and Multivariate Cox Regression Analysis

In the training cohort, univariate Cox regression analysis suggested that sex, marriage, year of diagnosis, race, histological tumor grade, T stage, surgery, chemotherapy, AFP, and tumor size were correlated with prognosis. All related risk factors were included in multivariate Cox regression analysis. The results showed that sex, marriage, race, histological tumor grade, T stage, surgery, chemotherapy, AFP, and tumor size were independent risk factors for patient prognosis. The univariate and multivariate results are shown in **Table 2**.

Construction and Validation of the Nomogram

All independent risk factors were included in the nomogram to predict 1-, 3-, and 5-year CSS in early middle-aged HCC patients (**Figure 2**). Tumor size and operation were the most important factors influencing patient survival, followed by histological tumor grade, AFP, and T stage. In addition, race, marriage, and sex also influenced the prognosis of patients. In the training and validation cohort, the C-index of the prediction model was 0.728 (95%CI, 0.716–0.740) and 0.733 (95%CI, 0.715–0.751), respectively, indicating that the model had good discrimination. Calibration curves of the training cohort and validation cohort showed that the predicted value of the prediction model is highly consistent with the actual observed value (**Figure 3**), indicating that the model has good accuracy. In addition, the AUC of the training cohort and validation cohort also suggested that the model had good discrimination (**Figure 4**).

Clinical Application of the Nomogram

DCA suggested that the nomogram had better predictive power than the T-staging (**Figure 5**). All patients were assigned to the high-risk group based on their nomogram scores (total >133.2) and low-risk group (total ≤133.2). In the training and validation cohort, patients in the low-risk group had significantly higher survival rates than those in the high-risk group (**Figure 6**). In the high-risk group, the 1-, 3-, and 5-year survival rates were 78.2, 53.5, and 43.3%, respectively. In the low-risk group, the 1-, 3-, and 5-year survival rates were 84.7, 67.9, and 59.8%, respectively. In the low-risk group, survival was highest among patients who received liver transplantation and lobectomy (**Figure 7A**). Survival of patients who received liver transplantation was highest in the high-risk group (**Figure 7B**).

DISCUSSION

Predictive models for cancer patients have been widely established, including nomograms for predicting survival in HCC patients. Yan et al. (13) constructed a nomogram to predict cancer-specific survival in early hepatocellular patients. Kong et al. (21) constructed a nomogram to predict survival in young patients with hepatocellular carcinoma. Hu et al. (22) developed a nomogram to predict survival in bone metastatic hepatocellular carcinoma patients. Liu et al. (23) constructed a nomogram to predict cancer-specific survival in all patients with hepatocellular carcinoma. Similarly, Ni et al. (24) constructed nomograms to predict survival in all hepatocellular patients. Nevertheless, prognosis and risk of death in HCC patients vary greatly with age. Middle-aged people have a high incidence of hepatocellular carcinoma, and their prognostic survival factors are different from those of other age groups. For example, marriage and race can affect the survival of patients, so a special nomogram is needed to predict patient survival.

Our study extracted information on early-stage HCC patients aged between 40 and 60 from the SEER database. We split the entire cohort into training and validation groups. Differences between the two groups regarding various essential variables such as marriage status, AFP level, grade, stage, and treatments were tested. All tests showed p-values > 0.05, indicating no significant difference between the training and validation groups. Univariate and multivariate Cox analysis found that numerous factors significantly affected CSS, including sex, race, marital status, AFP level, grade, T stage, tumor size, surgery, and chemotherapy. At the same time, other variables such as age and year of diagnosis were not identified as prognostic significance. That is partly because the population we selected is strictly defined, and there was so little difference between patients about age and year of diagnosis.

Social and demographic variables (age, race, and marital status) were identified as prognosticators of HCC. In our study, marital status is a relatively important factor for survival prediction, parallel to many previous studies (13, 25). This is partly because most single, separated, and

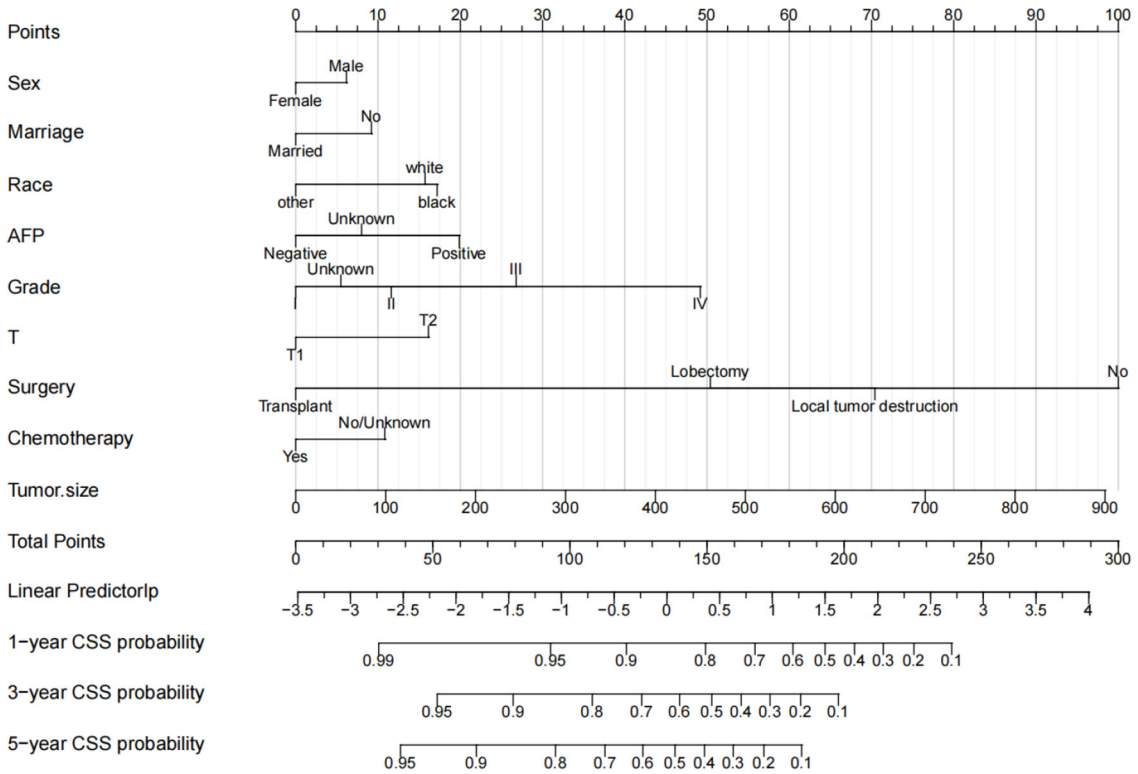

FIGURE 2 | The nomogram of CSS in middle-aged patients with HCC at 1-, 3-, and 5-year.

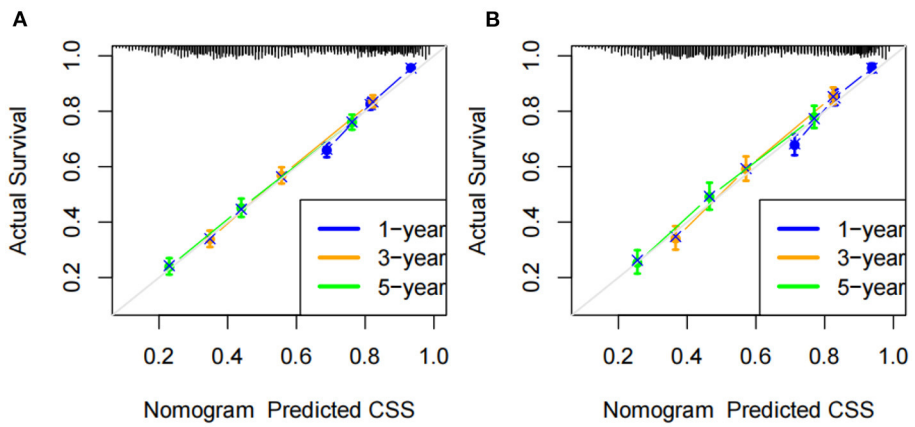

FIGURE 3 | Calibration curve of the nomogram. **(A)** Calibration curves of 1-, 3-, and 5-year CSS in training cohort; **(B)** calibration curves of 1-, 3-, and 5-year CSS in the validation cohort.

divorced cancer patients experience more stress and pain than married patients (26). Besides, married patients have better adherence to prescribed treatments than unmarried patients, leading to better cancer control (27). Furthermore, several biological, psychological, and social theories can also explain this phenomenon. A systematic review and meta-analysis indicated significant racial disparities in HCC prognosis in the United States, with Black patients having worse overall survival and Hispanic and Asian patients having better overall survival than White patients (28). Nikita Sandeep Wagle et al. found that Black patients receive curative treatment more minor than White because of social and economic situations (29), which may partly explain this phenomenon. Consistently, we found Black patients having worse CSS, closely followed by the White ($P = 0.589$), and other races having better CSS ($P < 0.001$; **Table 2**).

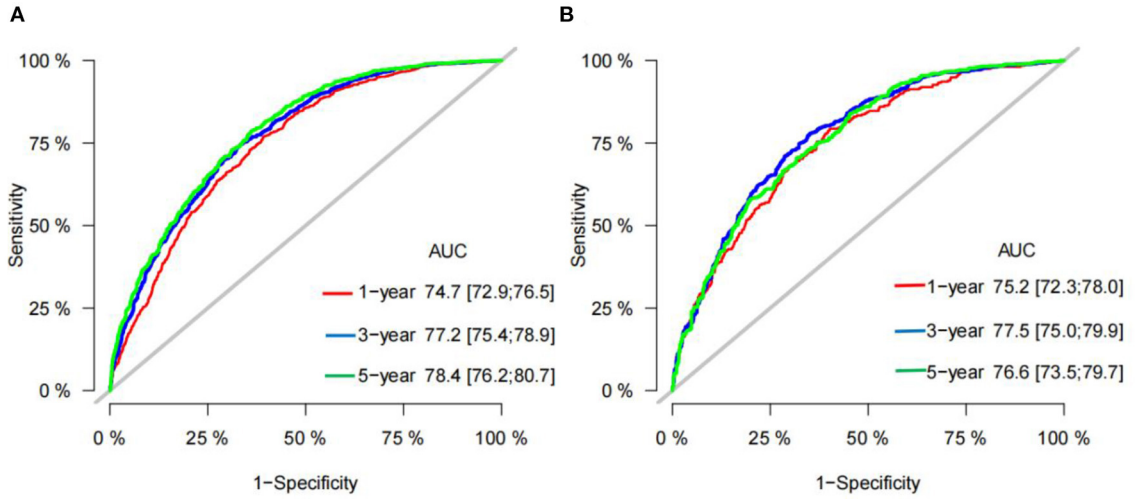

FIGURE 4 | AUC for predicting 1-, 3-, and 5-year CSS in training cohort **(A)** and validation cohort **(B)**.

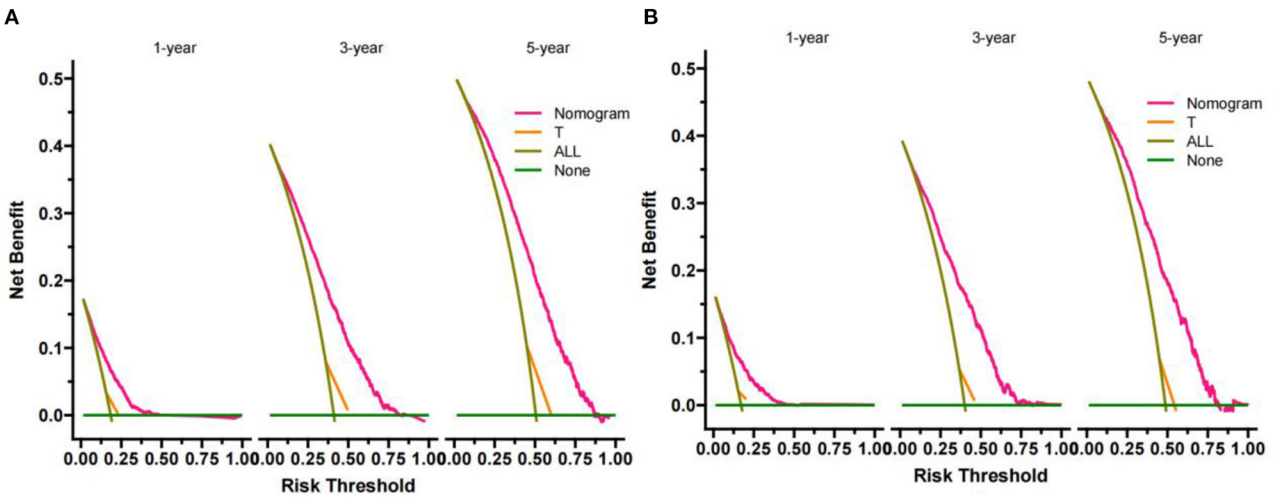

FIGURE 5 | DCA of the nomogram in training cohort **(A)** and validation cohort **(B)**. The Y-axis represents a net benefit, and the X-axis represents threshold probability. The green line means no patients died, and the dark green line means all patients died. When the threshold probability is between 0 and 75%, the net benefit of the model exceeds all deaths or none.

As for the tumor features (pathological grade, T stage, and tumor size) variables included in the nomogram, the tumor size has the most significant effect for CSS. A retrospective study suggests that tumor size is a vital independent prognostic factor in T2 solitary HCC after curative liver resection (30). In addition, the Milan criteria of liver transplantation strictly limited tumor size, which means that tumors with smaller diameters can be treated in more ways and get better treatment (31). Our results consistently reflected the relationship between tumor size and CSS and quantified its impact on CSS of a specified population compared with previous studies.

There are several kinds of treatment methods for patients with early-stage HCC, including liver resection (LR), ablation, and orthotopic liver transplantation (OLT) (32). Liver transplantation is considered an ideal treatment for selected patients with HCC, as it removes both the tumor and potential cirrhosis, with a 5-year survival rate exceeding 70% (33). Our results once again confirmed its superiority in the treatment of early-stage HCC, and its score is the lowest in the nomogram, which indicated the best outcome. However, the shortage of donor organs has severely limited the utilization of liver transplantation (34). In our results, lobectomy is inferior to liver transplantation but superior to local tumor destruction such as ablation. A systematic review of randomized controlled trials with Meta-analysis and sequential trial analysis found no statistical difference between radiofrequency ablation (RFA) and hepatic resection (HR) in

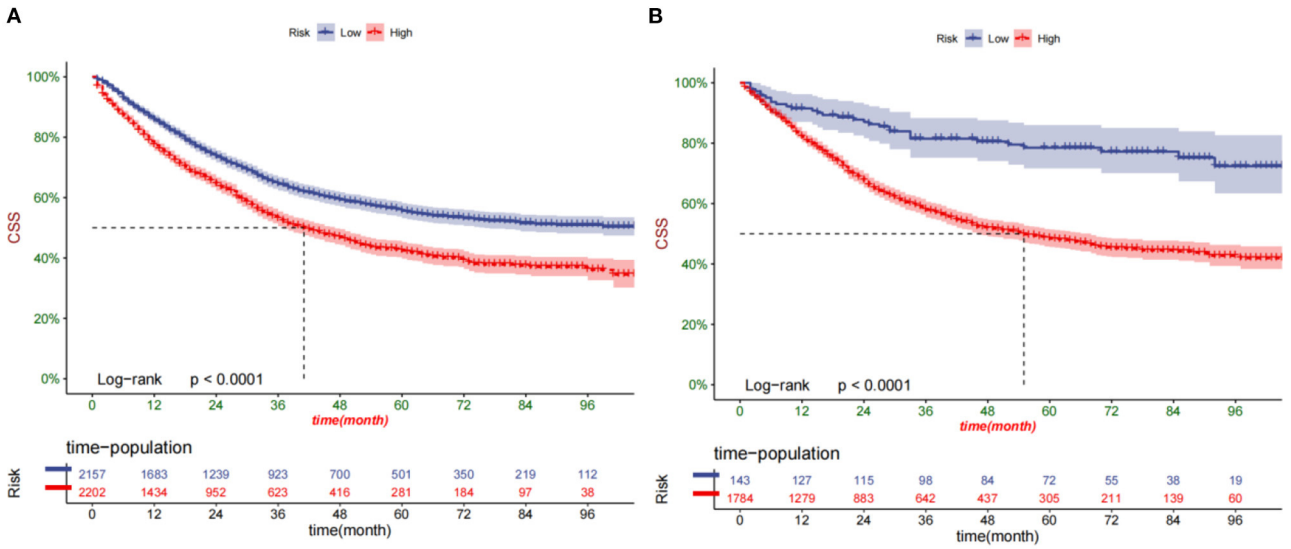

FIGURE 6 | Kaplan-Meier curves of patients in the low-risk and high-risk groups in training cohort **(A)** and validation cohort **(B)**.

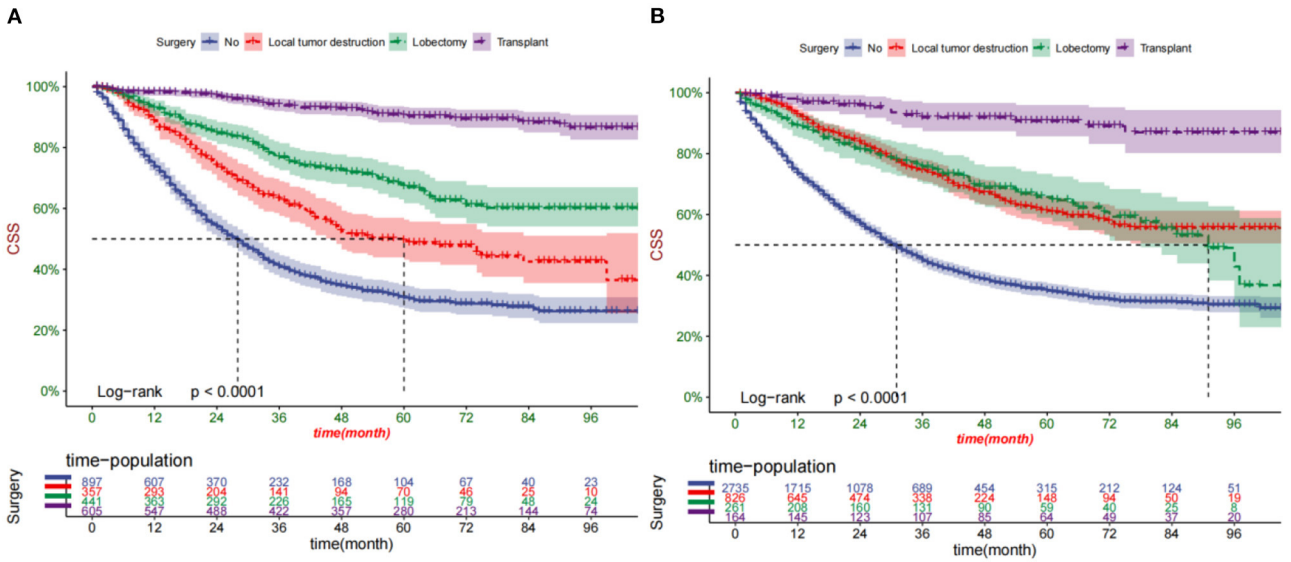

FIGURE 7 | Kaplan-Meier curves of patients with different surgical procedures in the low-risk group **(A)** and high-risk group **(B)**.

overall survival at 1 and 3 years. Still, RFA is resulted in decreased overall survival compared with HR at 5 years (35). A retrospective study showed that lobectomy has better overall survival and higher cancer-specific survival than thermal ablation (36). Moreover, chemotherapy such as sorafenib and lenvatinib is also an effective treatment for HCC (32). Therefore, it is suggested that surgery (OLT, LR, or RFA) combined with chemotherapy is an ideal choice for early-stage HCC patients aged between 40 and 60.

In our prediction model, the AUC of 1-, 3-, 5-year CSS is 0.747 (95%CI: 72.9–76.5), 77.2 (95%CI: 75.4–78.9), and 78.4 (95%CI: 76.2–80.7), respectively, in the training cohort. In the validation cohort, the AUC of 1-, 3-, 5-year CSS is 0.752 (95%CI: 72.3–78.0), 77.5 (95%CI: 75.0–79.9), and 76.6 (95%CI: 73.5–79.7), respectively (**Figure 4**). It indicates that our nomogram has relatively high accuracy in predicting CSS of early-stage HCC patients aged between 40 and 60. In addition, we also drew DCA curves to assess the clinical practicability of the nomogram, which suggested that the prediction model has better clinical application value than the traditional TNM staging system and can more accurately predict the 1-, 3-, 5-year CSS of early-stage HCC patients aged between 40 and 60.

However, our study has limitations. First of all, the nomogram was constructed based on the SEER database. It neither necessarily represents the rest of the world nor includes important factors such as alcohol intake, viral infection, cirrhosis, and liver function. Besides, our study was performed by retrospective analysis, which inevitably has a selection bias that is difficult to adjust. Moreover, our prediction model has only been validated internally, and external validation or further prospective studies are necessary. It is suggested that a multicenter study including more liver function variables be conducted.

CONCLUSION

We explored cancer-specific survival factors in early middle-aged patients with HCC. We found that sex, marriage, race, histological tumor grade, T stage, surgery, chemotherapy, AFP, and tumor size were independent risk factors for patient prognosis. We constructed a new nomogram to predict CSS in patients with early-stage HCC in middle age using these risk factors. This prediction model has good accuracy and reliability, which can help patients and doctors to judge prognosis and clinical decisions.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://seer.Cancer.gov/.

AUTHOR CONTRIBUTIONS

JT and CW designed the study, revised the article critically, reviewed, and edited the article. CW, JT, and HL collected and analyzed the data. CW drafted the initial manuscript. All authors approved the final manuscript.

Alzheimer's disease (AD) is the leading cause of dementia in older adults. There is currently a lot of interest in applying machine learning to find out metabolic diseases like Alzheimer's and Diabetes that affect a large population of people around the world. Their incidence rates are increasing at an alarming rate every year. In Alzheimer's disease, the brain is affected by neurodegenerative changes. As our aging population increases, more and more individuals, their families, and healthcare will experience diseases that affect memory and functioning. These effects will be profound on the social, financial, and economic fronts. In its early stages, Alzheimer's disease is hard to predict. A treatment given at an early stage of AD is more effective, and it causes fewer minor damage than a treatment done at a later stage. Several techniques such as Decision Tree, Random Forest, Support Vector Machine, Gradient Boosting, and Voting classifiers have been employed to identify the best parameters for Alzheimer's disease prediction. Predictions of Alzheimer's disease are based on Open Access Series of Imaging Studies (OASIS) data, and performance is measured with parameters like Precision, Recall, Accuracy, and F1-score for ML models. The proposed classification scheme can be used by clinicians to make diagnoses of these diseases. It is highly beneficial to lower annual mortality rates of Alzheimer's disease in early diagnosis with these ML algorithms. The proposed work shows better results with the best validation average accuracy of 83% on the test data of AD. This test accuracy score is significantly higher in comparison with existing works.

INTRODUCTION

Alzheimer's Disease (AD) is a progressive neurological condition that leads to short-term memory loss, paranoia, and delusional ideas that are mistaken for the effects of stress or aging. In the United States, this Disease affects about 5.1 million people. AD does not have proper medical treatment. In order to control AD, continuous medication is necessary. AD (1) is chronic so that it can last for years or the rest of your life. Therefore, it is most important to prescribe medication at the appropriate stage so that the brain is not damaged to a great extent. Early detection of this Disease is a tedious and costly process since we must collect a lot of data and use sophisticated tools for prediction and have an experienced doctor involved. Automated systems are more accurate than human assessment and can be used in medical decision support systems because they are not

subject to human errors. Based on previous research on AD, researchers have applied images (MRI scans), biomarkers (chemicals, blood flow), and numerical data extracted from the MRI scans to study this Disease. As such, they were able to determine whether a person was demented or not. In addition to shortening diagnosis time, more human interaction will be reduced by automating Alzheimer's diagnosis. In addition, automation reduces overall costs and provides more accurate results. For example, we can predict whether a patient is demented by analyzing MRI scans and applying prediction techniques. If a person has early-stage Alzheimer's Disease, they are considered demented. By doing so, we can achieve better accuracy.

When a person has Alzheimer's Disease in the early stages, they can usually function without any assistance. In some cases, the person can still work, drive, and partake in social activities. Although this is the case, the person may still feel uneasy or suffer from memory loss, such as not remembering familiar words and locations. People close to the individual notice that they have difficulty remembering their names. By conducting a detailed medical interview, a doctor may identify problems with memory and concentration in the patient. Common challenges in early stage of Alzheimer's Disease include,

- It's hard to remember the right word or name.
- Having difficulty remembering names when meeting new people.
- Working in social settings or the workplace every day can be challenging.
- Having forgotten something that you have just read in a book or something else.
- Having trouble finding or misplacing a valuable object.
- Tasks and activities are becoming increasingly difficult to plan or organize.

Alzheimer's symptoms become more persistent as the Disease progresses. When people suffer from dementia, their ability to communicate, adapt to their environment, and eventually move is lost. It becomes much more difficult for them to communicate pain through words or phrases. Individuals may need substantial assistance with daily activities as their memory, and cognitive skills continue to decline. At this stage, individuals may:

- Personal care and daily activities require 24/7 assistance.
- The consciousness of their surroundings, as well as recent experiences, is lost.
- As you age, you may experience changes in your physical abilities and walking, sitting, and eventually swallowing.
- Communication with others is becoming increasingly difficult.
- Infections, specifically pneumonia, become more prevalent.

Motivation

Under the current conditions, human instinct and standard measurements do not often coincide. In order to solve this problem, we need to leverage innovative approaches such as machine learning, which are computationally intensive and non-traditional. Machine learning techniques are increasingly being used in disease prediction and visualization to offer prescient and customized prescriptions. In addition to improving patients' quality of life, this drift aids physicians in making treatment decisions and health economists in making their analyses. Viewing medical reports may lead radiologists to miss other disease conditions. As a result, it only considers a few causes and conditions. The goal here is to identify the knowledge gaps and potential opportunities associated with ML frameworks and EHR derived data.

Contribution

In our research work, people affected by Alzheimer's Disease are identified and we aims at finding individuals who potentially have Alzheimer's at an early stage. The datasets for Alzheimer's Disease is available on both OASIS and Kaggle which is used for training all patient's data using various machine learning algorithms such as SVM, Random Forest classifier, Decision tree classifier, XGBoost and Voting classifier to effectively distinguish the affected individuals with high degree of efficiency and speed. Finally, an overview of how the Disease has affected the population according to various criteria is analyzed.

Organization

Following are the different sections of our work: Section Related Works address the recent papers on detecting Alzheimer's Disease using Machine learning and Deep learning models. Section Materials and Methods discusses the exploratory data analysis, and different Machine learning classifier models. Results and Discussion section address the performance measures of different Machine Learning models. Finally Section Conclusion concludes the work and discusses the future work.

RELATED WORKS

Alzheimer's Disease is predicted using ML algorithms by using a feature selection and extraction technique, and the classification is conducted based on the oasis longitudinal dataset. The different techniques (2) involved in analyzing brain images for diagnosing diseases of the brain to provide a brief overview. Several major issues are discussed in this article relating to machine learning and deep learning-based brain disease diagnostics based on the results of the reviewed articles. The most accurate method of detecting brain disorders was found in this study and can be used to improve future techniques. Using machine learning and deep learning platforms, this study aims to combine recent research on four brain diseases: Alzheimer's disease, brain tumors, epilepsy, and Parkinson's disease. By using 22 brain disease databases that are used most during the reviews, the authors can determine the most accurate diagnostic method.

Martinez-Murcia et al. (3) uses deep convolutional autoencoders to explore data analysis of AD. Data-driven decomposition of MRI images allows us to extract MRI features that represent an individual's cognitive symptoms as well as the underlying neurodegeneration process. A regression and classification analysis are then performed to examine the distribution of the extracted features in a wide variety of combinations, and the influence of each coordinate of the autoencoder manifold on the brain is calculated. MMSE or

ADAS11 scores, along with imaging-derived markers, can be used for over 80% accuracy to predict AD diagnosis.

A deep neural network is used with layers (4, 5)) that are all connected to perform binary classification. Each hidden layer is activated by a different activation function. A model with the best performance is chosen after k-folds validation Researchers at the Lancet Commission found that about 35% of Alzheimer's risk factors can be modified. The following factors can contribute to these risks: a lack of education, hypertension, obesity, hearing loss, depression, diabetes, lack of physical activity, smoking, and social isolation. Regardless of the impact of these factors at any stage of life, it is beneficial to eliminate them. Studies have suggested (6) that early intervention and treatment of modifiable Alzheimer's risk factors can prevent or delay 30% of cases of Alzheimer's (7). According to the Innovative Midlife Intervention for Alzheimer's Deterrence (In-MINDD) project (8) one way to calculate Alzheimer's risk based on risk factors is by using the Lifestyle for Brain Health (LIBRA) index (9–12). According to the National Academy of Medicine (13, 14) cognitive training, hypertension management, and increased physical activity were the three main categories of dementia intervention. The most common type of Alzheimer's is Alzheimer's Disease (AD). Among the types of Alzheimer's, Vascular Alzheimer's (VaD) is the second most common, followed by Alzheimer's with Lewy bodies. A few other types of Alzheimer's are associated with brain injuries, infections, and alcohol abuse. Tatiq and Barber (15) in their study suggested that Alzheimer's can be prevented by targeting modifiable vascular risk factors because these two types often co-exist in the brain and share some modifiable risk factors. Williams et al. (16) obtained predictions of cognitive functioning based on neuropsychological and demographic data using four different models: SVM, Decision Tree, NN, and Naïve-Bayes. In this case, average values were substituted for the missing values; the accuracy of Naive Bayes was the highest. Data from ADNI study are applied using ten-fold cross-validation (17, 18) and show high correlation between genetic, imaging, biomarker, and neuropsychological outcomes. MRI images from the OASIS dataset (19, 20) are analyzed using voxel-based morphometry. **Table 1** summarizes the recent work on prediction of Alzheimer's disease.

MATERIALS AND METHODS

The proposed approach consists of three basic steps. Firstly, the Alzheimer's disease dataset (24–26) was loaded into pandas for data preprocessing. This study utilized a longitudinal dataset, so a timeline of the study was necessary to gain further insight into the data. Our first step was to determine how cross-sectional the data appear to be, if either at a baseline or at a particular time. A complete analysis of the data was then conducted, including a comparison of the main study parts and the corresponding data collected during each visit. In this work, longitudinal MRI data is our primary data source. MRI data from 150 patients aged from 60 to 96 were included in the study. We scanned each patient at least once. Everyone is right-handed. Throughout the study, 72 of the patients were classified as "non-demented". At the time of their initial visits, 64 patients were classified as being "Demented," and they remained in this category throughout the study. **Table 2** shows the dataset description of MRI data.

The Machine Learning techniques (26, 27) were applied to Alzheimer's disease datasets to bring a new dimension to predict Disease at an early stage. The raw Alzheimer's disease datasets are inconsistent and redundant, which affects the accuracy of algorithms (28, 29). Before evaluating machine-learning algorithms, data must be effectively prepared for analysis by removing unwanted attributes, missing values, and redundant records. Building a machine-learning model requires splitting the data into training and testing sets. In the following data

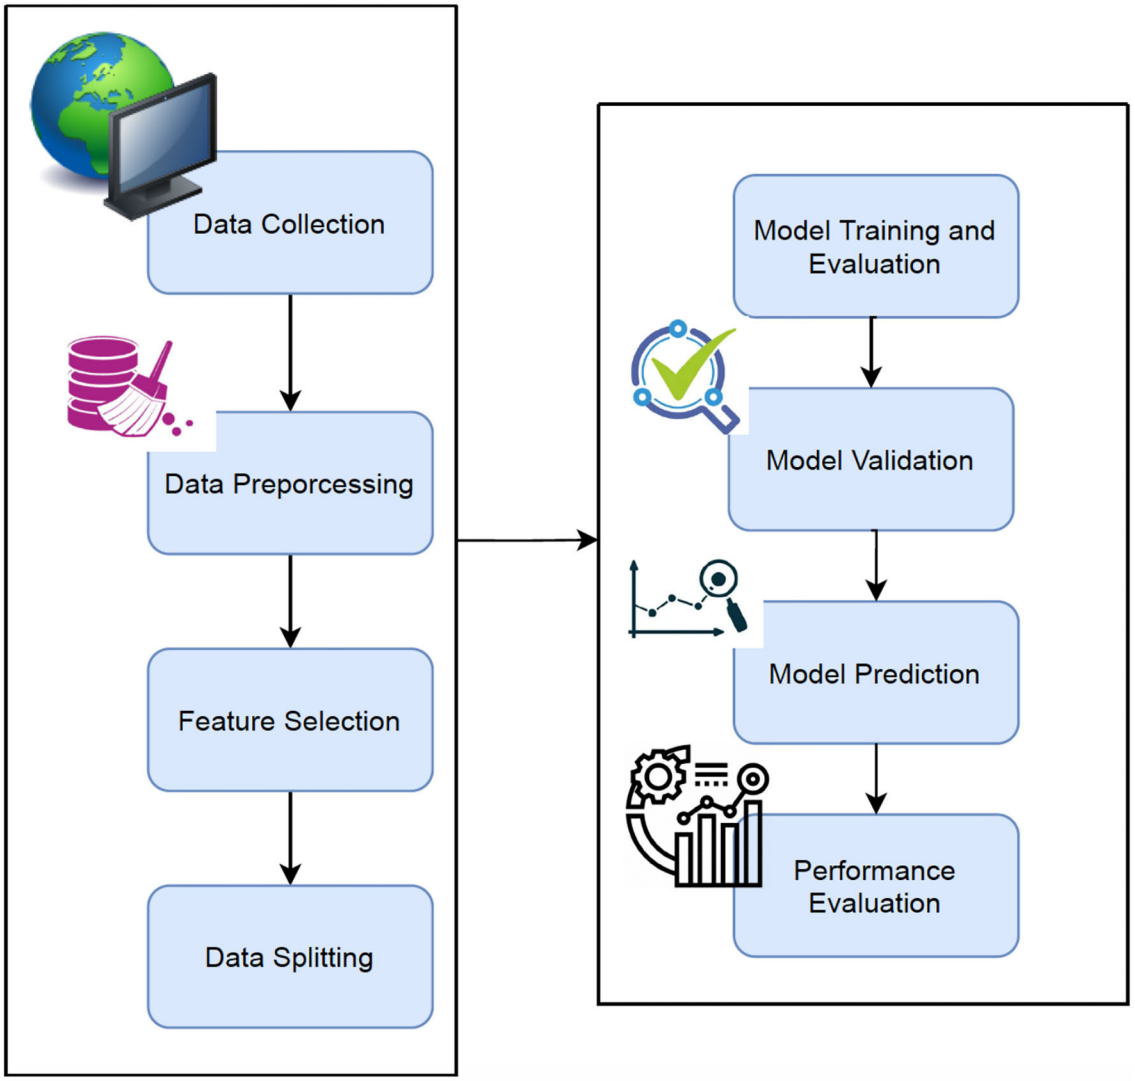

FIGURE 1 | Proposed workflow.

preparation step, the training data were used to create a model, which was then applied to test data to predict Alzheimer's Disease (28, 30, 31). The model was trained from training set data, and test set data were used to test unseen data. Cross-validation was carried out by dividing the dataset into three subsets. Model predictions are made using one subset of the data (test data) and model performance is evaluated using the other subsets (training and validation) of the data. The data had been preprocessed, and we randomly divided it into an 80:20 ratio, with 80% going to training and 20% gone to testing. **Figure 1** describes the system workflow for predicting the Alzheimer's Disease at early stage (32, 33).

Data Preparation

Various data-mining techniques were used to clean and preprocess the data in this phase. As part of this, missing values are handled, features are extracted, and features are transformed, and so on. In the SES column, we identified 9 rows with missing values (34, 35). This issue is addressed in two ways. The simplest solution is to drop the rows with missing values. The other way to fill in missing values is by Imputation (21), which refers to replacing them with their corresponding values. The model should perform better if we impute since we only have 140 measurements. The 9 rows with missing values are removed in the SES attribute and the median value is used for the imputation.

Data Analysis

We have discussed the relationships between each feature of an MRI test and dementia in this section. In order to formulate the relationship of data explicitly using a graph, we conducted this Exploratory Data Analysis process (36, 37) to estimate the correlations before extracting data or analyzing it. The

TABLE 3 | Min, max, and median values of each attribute.

	Min	Max	Mean	Median
EDUC	7	22	14.2	
SES	2	6	2.3	
MMSE	16	30	26.2	
CDR	0	1	0.3	
eTIV	1,120	1,990	1,450	
nWBV	0.55	0.81	0.7	
ASF	0.87	1.43	1.3	

information could be used to interpret the nature of the data later on and to determine what method to use to analyze it. **Table 3** shows the Min, Max and median values of each attribute.

Feature Selection

Feature selection is very important in machine learning. In this work, feature selection is applied to the clinical data of Alzheimer's disease where we have thousands of samples. Feature selection (22) has three methods such as: Filter methods, Wrapper methods, and embedded methods. Filter method is a common method used in the stage of pre-processing. Wrapper methods is another method which core the feature subset. Finally, Embedded method combines the filter and wrapper methods.

The most common and popular feature selection methods are chosen in this work are Correlation coefficient, Information gain, and Chi-Square.

Correlation Coefficient

The covariance between the two variables X and Y is defined as

$$\rho_{X,Y} = \frac{Cov(X, Y)}{\sigma_X \sigma_Y}$$

The covariance between two variables measures the linear relationship between them. Using correlation coefficients, it is easy to find a correlation between the various stages of Alzheimer's. The problem with this method is that the data is collected from a broad range of sources, so it becomes very sensitive to outliers.

Information Gain

The entropy of the lower node is subtracted from the entropy of upper node to obtain the Information gain value when the attribute D is selected.

$$Gain\,(D) \;=\; I\,(s1, s2, s3, \ldots\ldots .sn) - E\,(Feature\,D)$$

Chi-Square: Using this method, we can examine categorical variables such as the relationship between food and obesity.

$$Chi - Square \;=\; \frac{(Observed - Expected)^2}{expected}$$

Preparation and Splitting the Data

Figure 2 shows the schematic representation of data splitting stage

1. Select Data: M.F, Age, EDUC, SES, MMSE, eTIV, nWBV, ASF, CDR
2. Train_Data <- round(0.8 * nrow(data)) #Select 80% of train data
3. TrainData_indices <- sample(1:nrow(data), Train_Data). #Vector is created with random indeces
4. TrainML <- data[TrainData_indices,] #Training dataset is generated
5. SplitFormula<- CDR ~ M.F + Age + EDUC + SES + MMSE + eTIV + nWBV
6. N = 5
7. Split<- nWayCrossValidation(nrow(data), n). #5-fold cross validation is generated

Classifier Models

Decision Tree (DT)

An overview of the decision tree gives a tree-based model for dividing the data repeatedly based on the cutoff values of the features. Splitting creates subsets by separating instances into subsets. Intermediate subsets are referred to as internal nodes, while leaves are referred to as leaf nodes. A decision tree is most useful when there is significant interaction between the features and the target.

Random Forest (RF)

A random forest model performs better than a decision tree because it avoids the problem of overfitting. Models based on random forests consist of various decision trees, each slightly different from the others. Using the majority voting algorithm, the ensemble makes predictions based on each individual decision tree model (bagging). As a result, the amount of overfitting is reduced while maintaining the predictive ability of each tree.

Support Vector Machine (SVM)

This method involves determining the class of data points by appropriate hyper planes in a multidimensional space. By using SVM (25), we aim to find a hyperplane that separates cases of two categories of variables that take up neighboring clusters of vectors, one on one side, the other on the other side. Support vectors are those that are closer to the hyperplane. Training and test data are used in SVM. Training data is broken up into target values and attributes. SVM produces a model for predicting target values for test data.

XGBoost

XGBoost stands for eXtreme Gradient BOOSTting. It refers to the process of implementing gradient-boosted decision trees for maximum speed and performance. Due to the sequential nature of model training, gradient boosting machines are generally slow in implementation

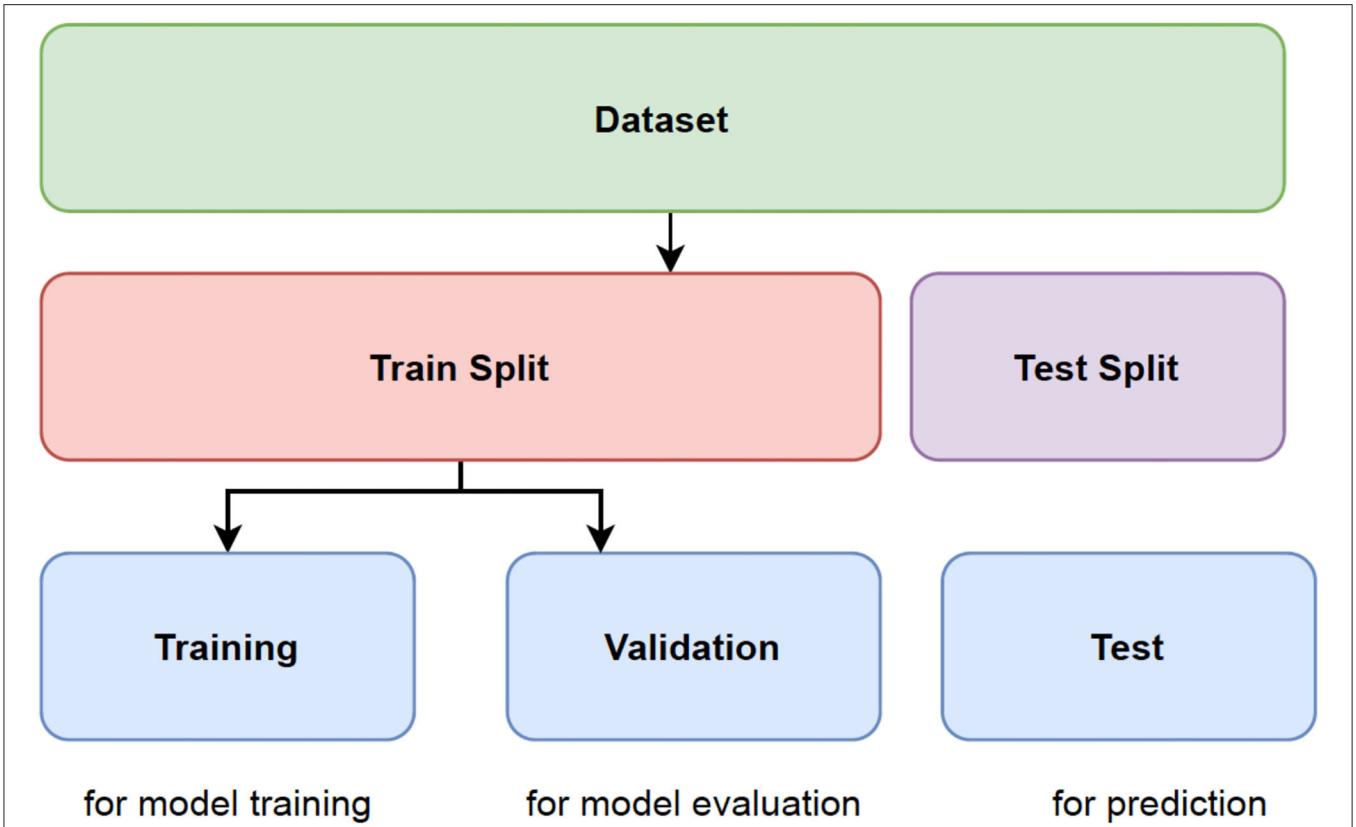

FIGURE 2 | Representation of data splitting.

and not very scalable. XGBoost is focused on speed and performance.

Voting

Voting is one of the simplest ways of combining the predictions from multiple earning algorithms. Voting classifiers aren't actually classifiers but are more like wrappers for multiple ones that are trained and evaluated concurrently in order to benefit from their specific characteristics. We can train data sets using different algorithms and ensembles then to predict the final output. There are two ways to reach a majority vote on a prediction:

Hard voting: The simplest form of majority voting is hard voting. The class with the most votes (Nc) will be chosen in this case. Our prediction is based on the majority vote of each classifier.

Soft voting: This involves adding up the probability vectors for each predicted class (for all classifiers) and choosing the one that represents the highest value (recommended only when the classifiers are well calibrated).

Model Validation

Model validation reduces the overfitting problem. Cross Validation is done to train the ML model and are used to calculate the accuracy of the model. It is a challenging task to make the ML model from noise free. Hence, in this research work, Cross validation is performed which divides the whole dataset into n divisions which is of equal in size. The ML model is trained for every iteration with the n-1 divisions. The performance of the method is analyzed by the mean of all *n*-folds. In this work, the ML model was trained and tested 10 times by applying ten-fold cross validation to the model.

RESULTS AND DISCUSSIONS

We evaluate various performance metrics like accuracy, precision, recall and F1 score. To determine the best parameters for each model, we perform 5-fold cross-validation: Decision Tree, SVM, Random Forests, XGBoost and Voting. Finally, we compare accuracy of each model. Several metrics and techniques were used to identify overfitting and parameter tuning issues after the models were developed. Performance evaluations can either be binary or multiclass and are described using the confusion matrix. A learning model was developed to distinguish true Alzheimer's disease affected people from a given population and a novel Machine Learning classifier was developed and validated to predict and separate true Alzheimer's disease affected people. The following evaluation measures were calculated using these components: precision, recall, accuracy,

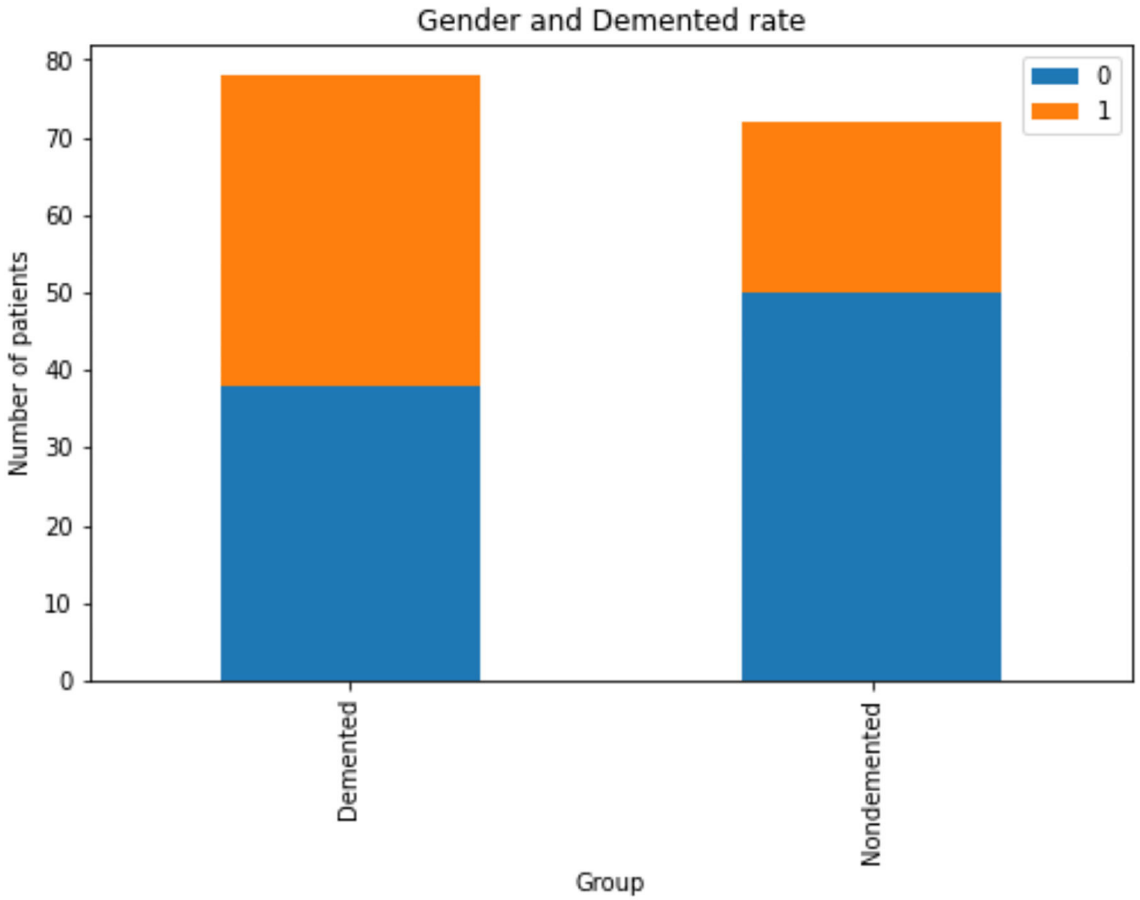

FIGURE 3 | Analysis of demented and non-demented rate based on gender, Gender group Female = 0, Male = 1.

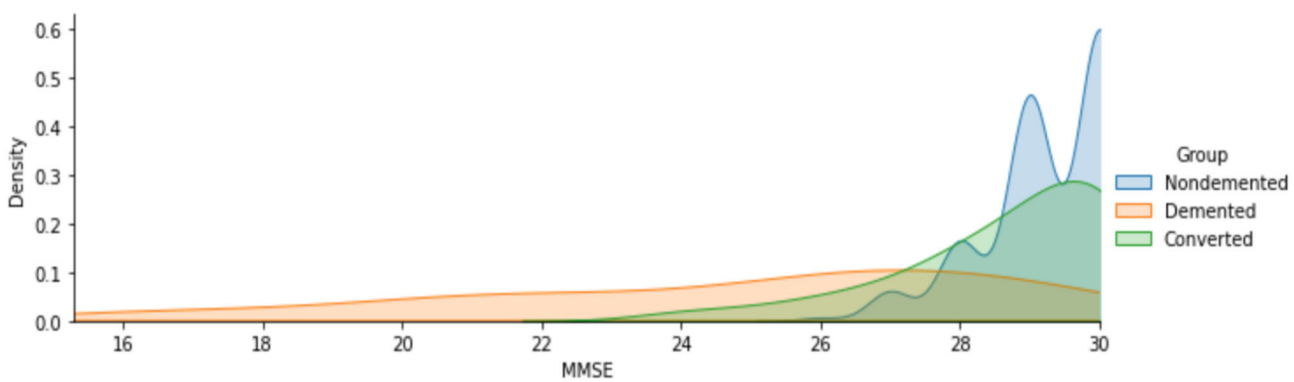

FIGURE 4 | Analysis of MMSE scores for demented and non-demented group of patients.

and F-score. Based on this study, recall (sensitivity) is the proportion of people accurately classified as having Alzheimer's. The precision of Alzheimer's diagnosis is the rate of people correctly classified as not having the disease. Alternatively, F1 represents the weighted average of recall and precision, while accuracy represents the proportion of people correctly classified. According to the results, the patient receives a report that tells him or her what stage of Alzheimer's Disease he or she is currently in. It is very important to detect the stages because the stages are based on the responses of the patients. In addition, knowing the stage helps doctors better understand how the Disease is affecting them. This research used these environments, tools, and libraries to conduct its experiments and analysis:

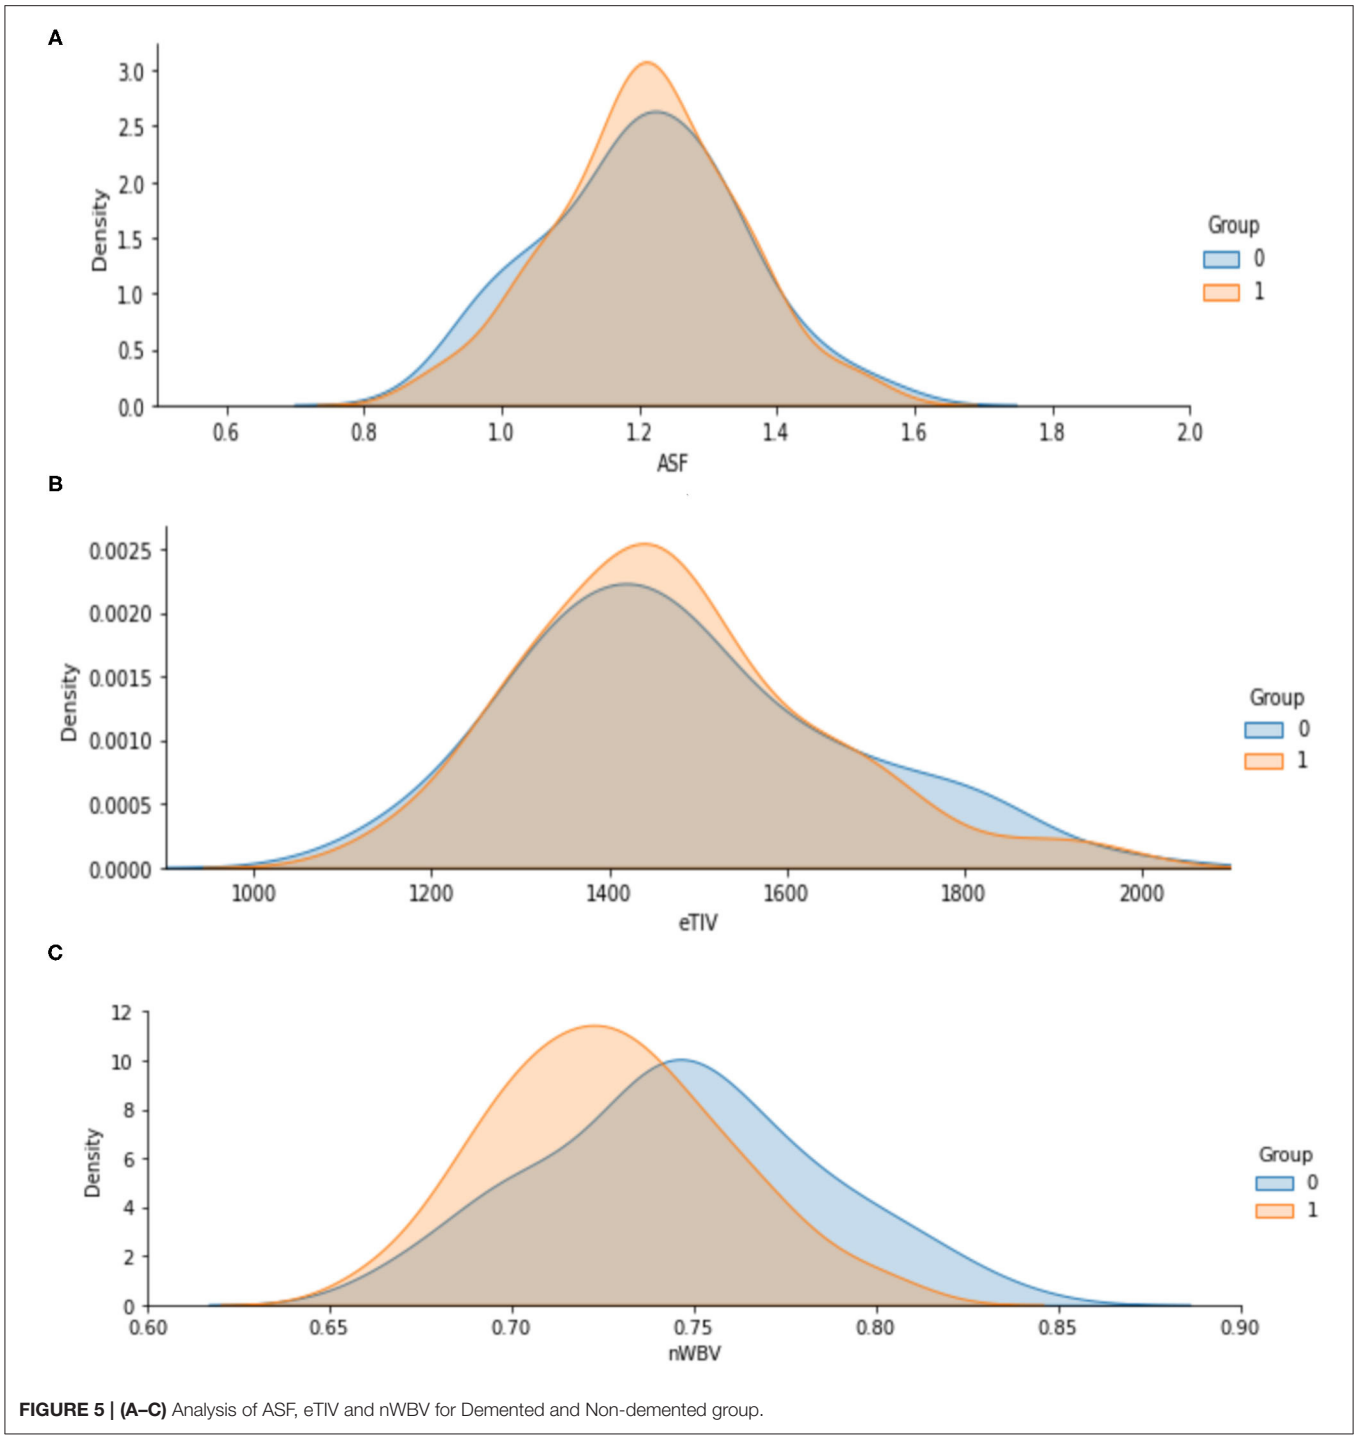

FIGURE 5 | (A–C) Analysis of ASF, eTIV and nWBV for Demented and Non-demented group.

a) Environments Used: Python 3
b) Scikit-learn libraries for machine learning

The **Figure 3** indicates that men are more likely than women to have dementia. **Figure 4** that the non-demented group had much higher MMSE (Mini-Mental State Examination) scores than those with dementia.

The **Figures 5A–C** shows the analyzed value of ASF, eTIV and nWBV for Demented and Non-demented group of people. As indicated by the graph in **Figure 5**, the Non-demented group has a higher brain volume ratio than the Demented group. The reason for this is that the diseases influence the brain tissues causing them to shrink. **Figure 6** shows the analyzed results of EDUC for Demented and Non-demented people.

Figure 7 shows the analysis on age attribute to find the percentage of people affected based on the demented and non-demented group. It is observed that a higher percentage of Demented patients are 70-80 years old than non-demented

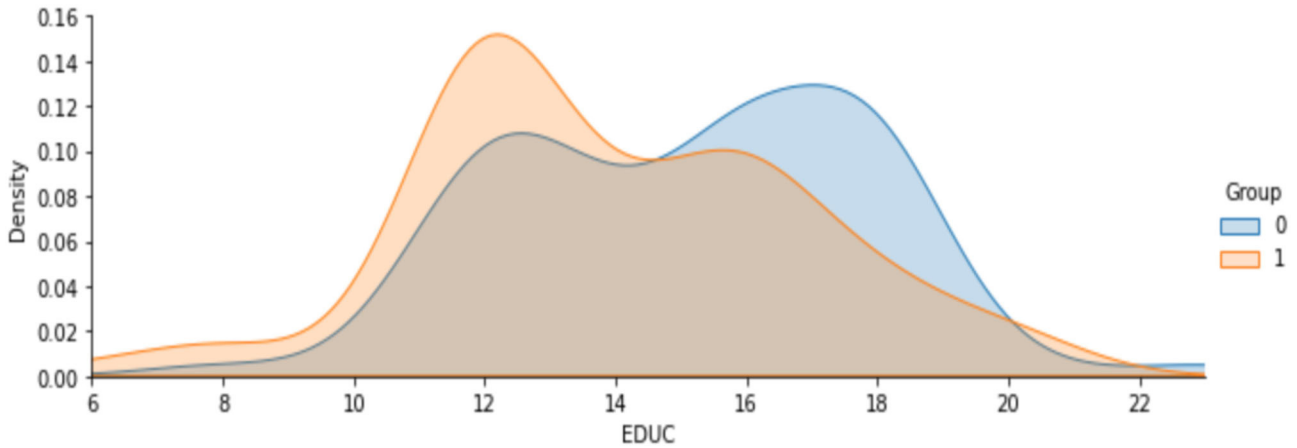

FIGURE 6 | Analysis on years of education.

FIGURE 7 | Analysis on people affected by demented and non-demented group based on age.

TABLE 4 | Performance comparison of different ML models.

Model	Accuracy	Precision	Recall	F1-score
Decision tree classifier	80.46%	0.80	0.79	0.78
Random forest classifier	86.92%	0.85	0.81	0.80
Support vector machine	81.67%	0.77	0.70	0.79
XGBoost	85.92%	0.85	0.83	0.85
Voting classifier	85.12%	0.83	0.83	0.85

patients. It is likely that people with that kind of Disease have a low survival rate. Only a few people are over 90 years old.

From the above all analysis on the attributes, the following are the summary on intermediate results.

1. It is more likely for men to have demented, or Alzheimer's Disease, than for women.
2. In terms of years of education, demented patients were less educated.
3. Brain volume in non-demented groups is greater than in demented groups.
4. Among the demented group there is a higher concentration of 70-80-year-olds than in the non-demented patients.

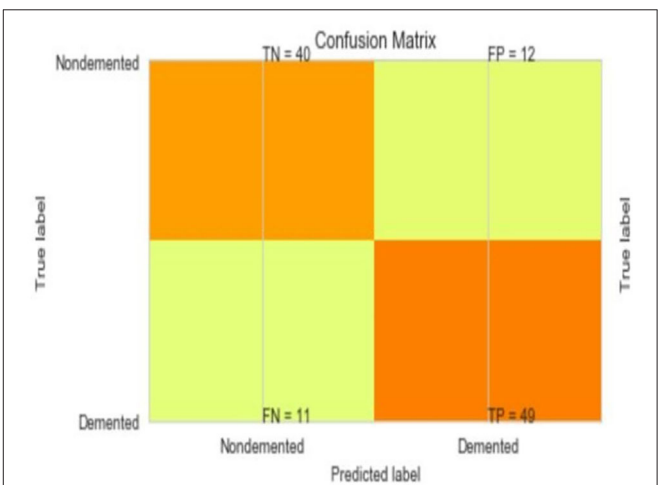

FIGURE 8 | Confusion matrix for decision tree.

Table 4 shows the performance comparison of accuracy, precision, recall, and F1 score for different ML models. The performance measures are defined as,

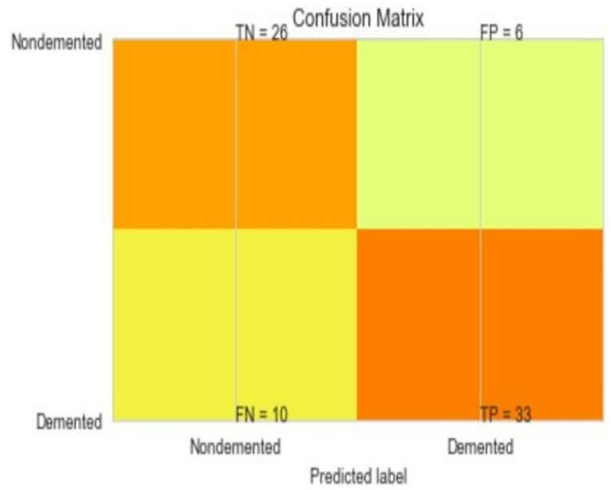

FIGURE 9 | Confusion matrix for random forest.

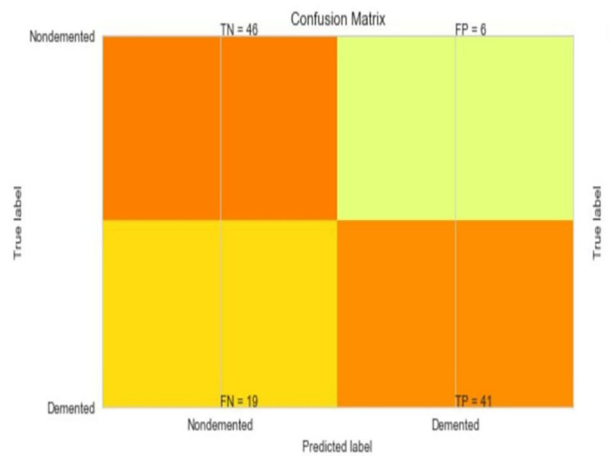

FIGURE 10 | Confusion matrix for SVM.

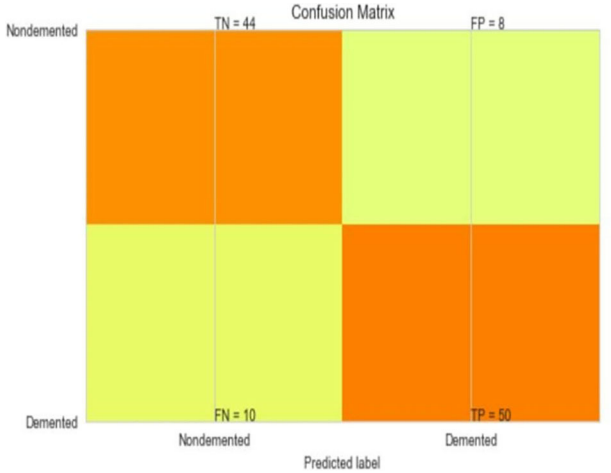

FIGURE 11 | Confusion matrix for XGBoost.

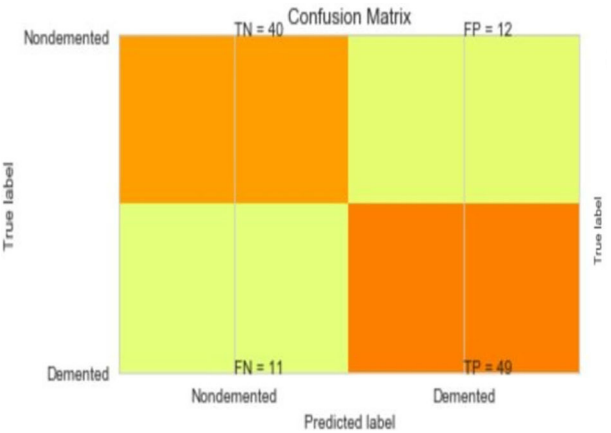

FIGURE 12 | Confusion matrix for soft voting classifier.

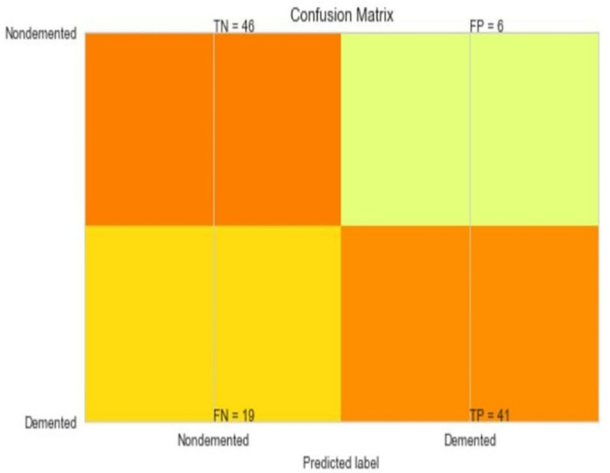

FIGURE 13 | Confusion matrix for hard voting classifier.

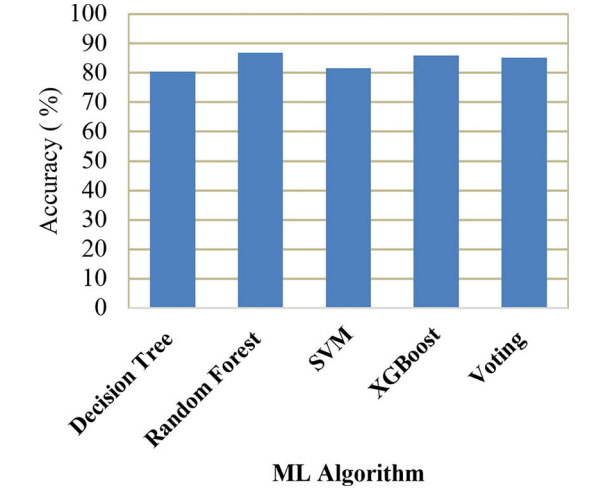

FIGURE 14 | Comparison of accuracy.

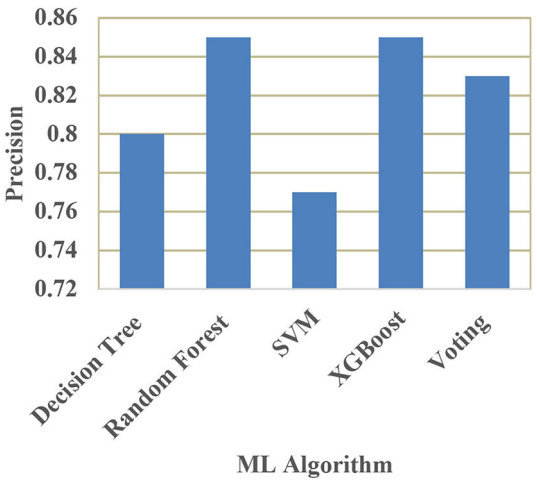

FIGURE 15 | Comparison of precision.

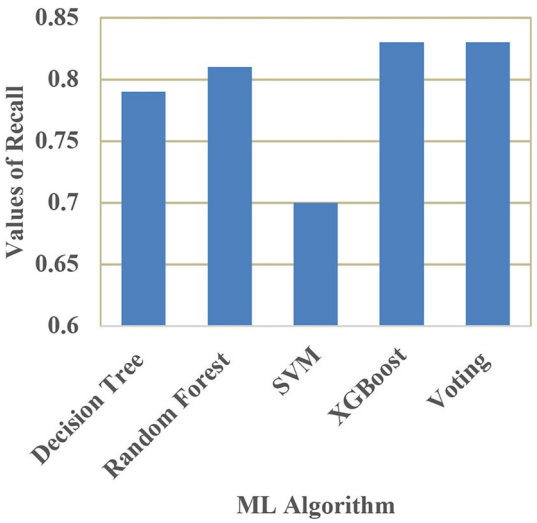

FIGURE 16 | Comparison of recall.

Accuracy: It is the measure of finding the proportion of correctly classified result from the total instances.

$$Accuracy(inPercentage) = \frac{TN + TN}{TP + TN + FP + FN} \times 100$$

Precision: This measures the number of correctly predicted positive rate divided by the total predicted positive rates. If the Precision value is 1, it is meant as a good classifier.

$$Precision = \frac{TP}{TP + FP}$$

Recall: Recall is a true positive rate. If the recall is 1, it is meant as a good classifier.

$$Recall(inPercentage) = \frac{TP}{TP + FN}$$

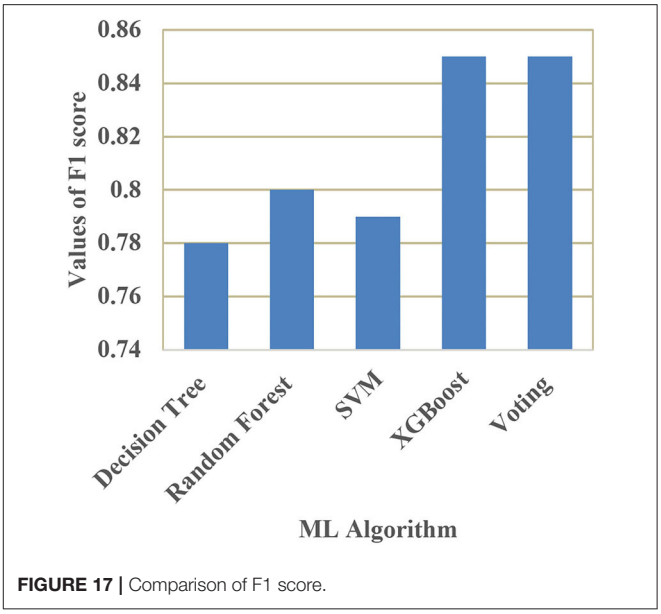

FIGURE 17 | Comparison of F1 score.

F1 Score: It is a measure which considers both Recall and Precision parameters. F1 score becomes 1 only when both the measure such as Recall and Precision is 1.

$$F1Score(inPercentage) = 2^* \frac{Recall^* Precision}{Recall + Precision}$$

The most common metrics are the conversions of the True Positive (TP), the False Positive (FP), the True Negative (TN), and the False Negative (FN) metrics. **Figures 8–13** shows the confusion matrix for Decision tree, Random Forest, SVM, XG boost, Soft, and Hard Voting classifier ML models.

A comparison of training and testing accuracy has been conducted for each model to eliminate overfitting. For each model, precision, recall, accuracy, and F1-score are shown in **Table 3**. Based on the analysis showed in the **Table 3**, the results approved that the best and ideal techniques, which have a good performance, are random forest, and XGBoost. The accuracy value of Voting classifier model is also closer to the random forest, and XGBoost models. All the experimental results (the average accuracy, precision, recall, and F measure of each model) were collected for extra analysis. The comparative analyses among all the Machine Learning models in terms of accuracy, precision, recall, and F1 score are presented graphically in **Figures 14–17** respectively.

CONCLUSIONS

Alzheimer's is a major health concern, and rather than offering a cure, it is more important to reduce risk, provide early intervention, and diagnose symptoms early and accurately. As seen in the literature survey there have been a lot of efforts made to detect Alzheimer's Disease with different machine learning algorithms and micro-simulation methods; however, it remains a challenging task to identify relevant attributes that can

detect Alzheimer's very early. The future work will focus on the extraction and analysis of new features that will be more likely to aid in the detection of Alzheimer's Disease, and on eliminating redundant and irrelevant features from existing feature sets to improve the accuracy of detection techniques. By adding metrics like MMSE and Education to our model, we'll be able to train it to distinguish between healthy adults and those with Alzheimer's.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found at: https://www.kaggle.com/jboysen/mri-and-alzheimers?select=oasis_cross-sectional.csv.

In the last decade, smart computing has garnered much attention, particularly in ubiquitous environments, thus increasing the ease of everyday human life. Users can dynamically interact with the systems using different modalities in a smart computing environment. The literature discussed multiple mechanisms to enhance the modalities for communication using different knowledge sources. Among others, Multi-context System (MCS) has been proven quite significant to interlink various context domains dynamically to a distributed environment. MCS is a collection of different contexts (independent knowledge sources), and every context contains its own set of defined rules and facts and inference systems. These contexts are interlinked *via* bridge rules. However, the interaction among knowledge sources could have the consequences such as bringing out inconsistent results. These issues may report situations such as the system being unable to reach a conclusion or communication in different contexts becoming asynchronous. There is a need for a suitable framework to resolve inconsistencies. In this article, we provide a framework based on contextual defeasible reasoning and a formalism of multi-agent environment is to handle the issue of inconsistent information in MCS. Additionally, in this work, a prototypal simulation is designed using a simulation tool called NetLogo, and a formalism about a Parkinson's disease patient's case study is also developed. Both of these show the validity of the framework.

Keywords: healthcare system, NetLogo, web ontology, multi-agent system, medical internet of things (IoT)

1. INTRODUCTION

Ubiquitous computing deals with invisibly interweaving the real world with various agents embedded seamlessly in everyday objects of lives and connected through dedicated networks and media to make our everyday life easier and more efficient (1–3). When the agents were initially designed, they were used solely to detect user location, however, with technological advancements, they gradually were able to adapt to interfaces, increase the precision of information retrieval, discover services users may require, and most importantly build smart environments (4). Smart environments are the physical environments used in daily human life that are seamlessly embedded with tiny smart devices equipped with sensors, actuators, and computational elements (agents).

These physically embedded devices are connected through a continuous data collection and processing network to enable various pervasive applications, services, and smart environments to perform efficiently. The usage of various connected agents for data retrieval, processing, and exchanging make up a system called Multi-Agent System (MAS) (5).

A multi-agent system is a computerized system comprising multiple interacting intelligent agents (6). These intelligent agents can collect data, process it, and then send it to the controller/central system for further analysis. While this level of intelligence and functionality is more than enough for some applications, for others, this is not. These are the applications or systems that needed information from multiple resources (domains) to execute their required operations (4). This problem leads to a solution termed Multi-Context Systems (MCS).

Equilibrium is defined as a belief state that comprises a belief set, consisting of beliefs of each context in the MCS, such that an MCS is said to be in equilibrium if all the heterogeneous contexts have consistent beliefs (7). Inconsistency is a significant concern depriving MCS of reaching its full potential. Inconsistency makes it impossible for the system to conclude from the provided data. Suppose a system cannot derive a decision, then it is considered a failure. This work tries to ensure that the system maintains its equilibria state. This is the state in which each element of the system has a single belief, i.e., the decision should be the same according to each element of the system. The equilibria are lost whenever the system receives contradictory or inconsistent information. This makes the overall system not provide a conclusion, causing it to become purposeless. This becomes a severe issue, especially in the safety-critical system dealing with life and death situations in healthcare systems (8).

The proposed system uses a case study about a Parkinsons' disease patient to show its correctness. The system includes a Multi-Context system (MCS) consisting of several heterogeneous contexts. Several agents acquire information, process data, and perform reasoning accordingly in each context in MCS. As physical implementation of such a system is not feasible due to financial and technological constraints, virtual agents model the proposed smart environment. It is assumed that these virtual agents are intelligent; thus, they are intelligent virtual agents. Virtual agents can also be considered a type of software that collects, processes, and shares data just like a physical sensor and agent. It is assumed that data is acquired from virtual sensors for data acquisition. In the proposed framework, intelligent agents acquire contextual information from the sensors and perform reasoning accordingly. For each domain, an ontology is developed using Protégé, a free, open-source ontology editor and management system. Each of these ontologies is connected using mapping rules. These ontologies are mapped on their corresponding description logic. These description logic-based ontologies are then linked together using distributed description logic (DDL) formalism. Once the system gets settled, the flow of information begins due to the communication between the heterogeneous contexts. After this, the system's conflicting information is dealt with using CDL (9). Contextual defeasible reasoning can handle inconsistencies occurring due to contradictory information (8).

The rest of this article is structured as follows. Section Related Work presents the related work. Section Contextual Defeasible Reasoning (CDL) Based Multi-Agent Formalism presents the extensive description of the architecture of the framework proposed and the inclusion of Contextual Defeasible Reasoning in it. Section Framework Development discusses the contexts developed for the framework and their corresponding ontologies. Section Temporal Logic Formalism covers the formalism of the proposed work using temporal logic. Section Simulation of Proposed System discusses the simulation of the system done using NetLogo. In section Algorithm the proposed algorithm for the system is discussed in detail. Finally, this work is discussed overall and concluded in sections Limitations and Future Scope and Conclusion, respectively.

2. RELATED WORK

Authors in (9) proposed a methodology for handling inconsistency produced in a Multi-Context System (MCS) by utilizing the consistency-based and abduction-based techniques. In the first approach, pairs of sets of mapping rules are considered, such that deactivating the rules in one set and forcing the rules in the other to be active allows to re-establish consistency. While in the second approach, a pair of rules were considered whose joint (de-)activation reproduced the observed inconsistency. In (8), the authors proposed a framework based on Contextual Defeasible Logic (CDL) for distributed MCS. The authors deployed the Meta-rules technique to perform reasoning on the system-acquired data.

In (10), the authors present a smart city ontology called KM4City (Knowledge Model for City). This ontology includes data coming from various heterogeneous sources and mapped onto it. Since ontologies are flexible, therefore, the addition of new information can easily be managed. Static and dynamic data from various heterogeneous sources is obtained and stored in RDF syntax, accessed using SPARQL queries. This data was from public and private sources, such as people sending information from their devices. The primary purpose of the author's KM4City is to help citizens on roads, mainly those stuck in traffic, and especially helping the ambulances find an optimal path to their destinations, be it the hospital or the location of a patient. The proposed work, according to the authors, overcomes the gap of combining public and private data from various heterogeneous sources. Various applications like those of public administrations and enterprises can be made using this framework. The information collected for the scope of the proposed paper was limited to road graphs, services available on the roads, and traffic sensors.

In (11), the authors have used an RPI-CAM-V2 pi camera, soil moisture sensor, and a temperature sensor and connected them to a Raspberry pi microcontroller. A raspberry pi is a circuit board that can be attached to a computer monitor through the USB port. This system has especially been developed for the farmers or the caretakers of agricultural lands to increase the efficiency of the agricultural systems by automating the irrigation process. It then sends the data to the Thingspeak mobile application (an android application available on the play

TABLE 1 | Analysis of related work.

store of all android devices), where the farmers can easily have access to the environmental conditions of the fields without being in the area. The authors have also used the Telegram mobile application for fetching data from raspberry pi when in remote locations. Telegram application is a messaging application similar to Whatsapp, except for creating bots that interact with both humans and machines.

In (12), the authors have presented a survey on the application of technologies of industry 5.0 in different domains. Industry 5.0 is mainly used to increase the efficiency and effectiveness of large-scale product manufacturing. However, like any other technology, this also comes with many drawbacks, mainly privacy and security dilemmas. In (13), the authors have presented a grid and place neuron model in cognitive tasks applications. The 2D virtual environment was created to deploy this system, which resulted in 92.27 % localization accuracy.

In (14), the authors have highlighted the usage of ML algorithms for the diagnosis, analysis, and prediction of stroke. Moreover, the authors used the Antlion optimization (ALO) algorithm using a deep learning model in minimal time consumption for optimal hyper-parameters selection. The training time for the proposed model is 38 % as a positive outcome considered for the experimental superiority results.

In (15), the authors have proposed a novel pairing-free certificateless scheme using blockchain technique and a CLS scheme using a smart contract. After this, they simulated the Type-I and Type-II adversaries to verify their scheme. After a thorough analysis, the authors deduced that their work reduced 40.0% computation cost and 94.7% communication cost. In (16), the authors have highlighted the emergence of heterogeneous Internet of Medical Things (IoMT) (e.g., for smart healthcare systems) that is used for sending huge bulk of patient's data for disease analysis to central cloud servers. However, it is prone to many security issues that can be overcome using AKA p. The authors have proposed an authentication protocol using blockchain technology and physically unclonable functions (PUF) in their work. In addition, biometric information is dealt with using a fuzzy extractor scheme. Their analysis proved that their work requires the most negligible computation and communication cost among the compared schemes.

This work is novel in the way that it proposes a smart decision-making healthcare system based on formalism technique that can help the medical professionals in their everyday routine and the patients living in far-off areas. The modeling of the system was done using ontologies so a clear picture of the system and the flow of information in it can be obtained. In order to check the validity of this work, a simulation was created using the NetLogo simulation tool. The existing approaches are summarized in **Table 1**. This work is different from others such that it uses contextual defeasible logic to resolve inconsistencies in multi-context systems. This technique is helpful when the entire system needs to be controlled automatically with the help of rule-based formalism in order to allow the system to reach a conclusion about the patient's health and provide the medical authority about the current situation.

3. CONTEXTUAL DEFEASIBLE REASONING (CDL) BASED MULTI-AGENT FORMALISM

This section covers the CDL based on multi-agent formalism. In the context-aware MAS, every agent has a set of defeasible rules in their knowledge base where the contextual information and reasoning strategy is stored. Multi-context system notions are used for modeling heterogeneous systems (18–20). Multiple ontologies can send contextual information (e.g., rules, and facts). Each knowledge source sends the contextual information to its corresponding agents. After that, agents perform their reasoning mechanism based on the pre-defined rules. Reasoning types are two called, locally and globally. In local reasoning, the rules are performed by obtaining, through a single ontology. In distributed reasoning, multiple ontologies extract the sets of rules and facts by which each agent performs its reasoning. A framework of contextual defeasible reasoning based on heterogeneous formalism is proposed in this thesis. The framework uses the data acquired by sensors and analyzed and shared by agents, working in various heterogeneous contexts/domains with their respective systems. The following case study has been developed, which will form the basis of framework modeling and development.

Figure 1 shows the working of the proposed system. First, the virtual sensors continuously send data to a database. This database contains additional information about the patient, his allergies, and insurance. The information from the database (which also contains data from the sensors) is sent to the proposed system, which is the intelligent system responsible for making a decision. The intelligent system responsible for making a decision acquires this information and tries to derive a conclusion. In case of no inconsistency during conclusion making, then the system prescribes the treatment for the disease and keeps a record of the severity level of the patient. But if an inconsistency does occur, then the system first handles this inconsistency by using contextual defeasible logic and then prescribes treatment and severity level. After allotting severity

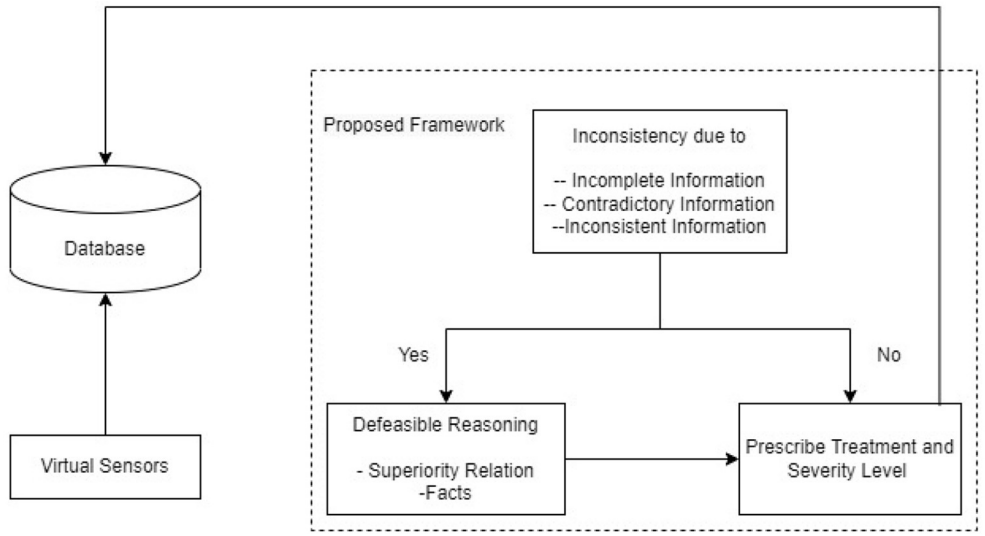

FIGURE 1 | Architecture diagram.

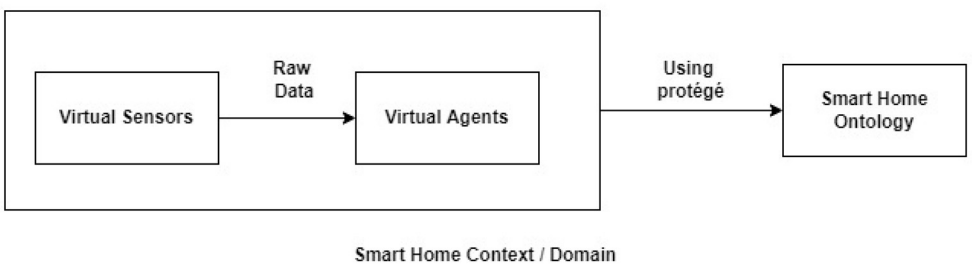

FIGURE 2 | Smart home system.

level and treatment, the system sends this information back to the database. The hospital has complete access to this database and will take action accordingly.

These systems, which are a smart home system and smart hospital system, then send their received data to the smart decision-making system embedded in the smart hospital system so that the smart decision-making system could form a diagnosis of the patient's current health and the necessary treatment. Since multiple heterogeneous contexts/systems/domains are involved in this framework, structuring the overall system and data is crucial. Therefore, ontology is used for this purpose. To conclude, the smart decision-making system needs some reasoning mechanism. For this purpose, contextual defeasible reasoning is used. The flow/sharing of information between heterogeneous contexts is done and maintained using rules. **Figure 2** explains the data acquisition and sharing in a smart home environment. The virtual sensors embedded in the smart home or worn by the patient inside the smart home collect raw data and send it to the virtual agents in a continuous manner. The virtual agents, which are intelligent, use their reasoning capabilities to generate an alert if a certain reading is obtained which is above or below a certain threshold. The agents alert the smart hospital domain's smart decision-making system.

Figure 3 explains the collection and transfer of data in a smart hospital environment. The virtual sensors embedded all over the hospital collect raw data and continuously share it with the virtual agents. The virtual agents use their reasoning capabilities and generate an alert if a particular acquired data reading is beyond or below a certain threshold. This alert generated is sent to the smart decision-making system by the agents implemented in the smart hospital domain. Databases containing information about the patient's allergies, and insurance, are also involved in this context or domain. They send the relevant data to the smart decision-making system whenever needed.

Intelligent virtual agents carry out the step that includes data acquisition of the MCS. The virtual agents take into account all data that real physical agents measure. The proposed system includes Multi-Context Systems consisting of several heterogeneous contexts. After this, in order to map the acquired data into the different domains of the system, ontologies are developed with their own set of rules. The developed ontologies are then mapped to their correlated description logic. Ontologies

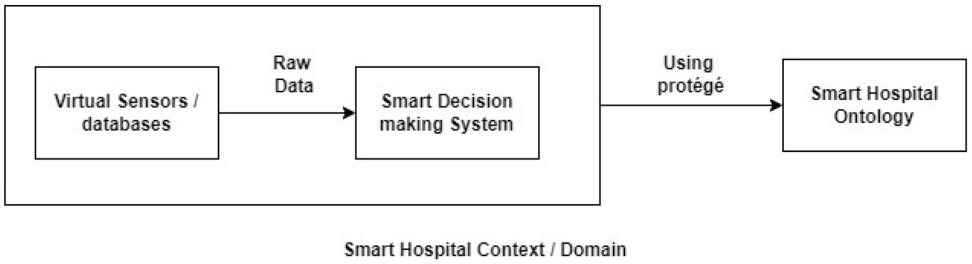

FIGURE 3 | Smart hospital system.

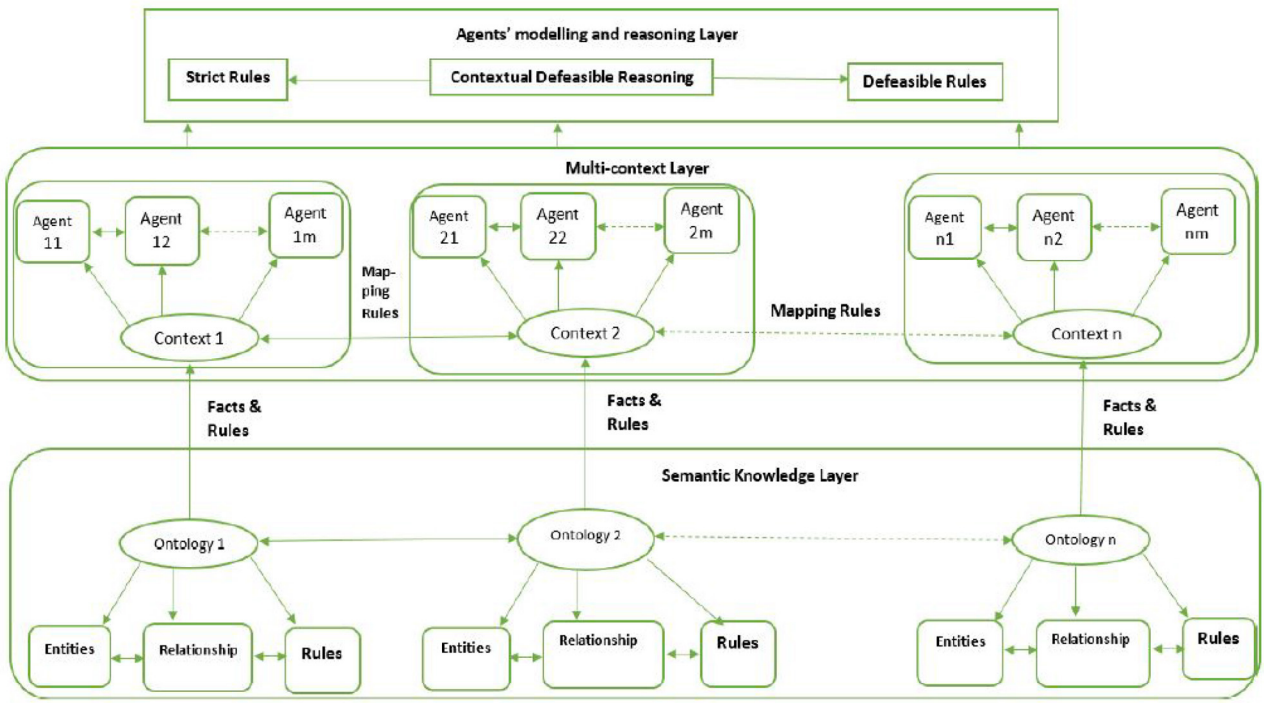

FIGURE 4 | Proposed system layered architecture.

based on descriptive logic use the distributed description logic for interconnection *via* mapping rules. Once the system gets settled, the flow of information begins by heterogeneous contexts interactivity. Contextual defeasible reasoning (CDL) is applied to the system after the information flow and used to handle any inconsistencies.

After this, contextual defeasible reasoning is applied to the system to handle any inconsistencies. CDL uses its facts, strict, defeasible, and defeater rules and preferences to solve these issues. The proposed framework verification is achieved by intending to develop a prototype or with the help of simulation. At the moment, implementing the proposed system is difficult due to financial and technical constraints. Our emphasis is mainly on research and partially on development. The development done is mainly for testing purposes. We are assuming that sensors are collecting the data. This data is modeled using agents. The reasoning performed on this system is done through contextual defeasible reasoning. Since our system is heterogeneous, therefore, initially, the agents are defined in different heterogeneous contexts. These heterogeneous contexts communicate with each other *via* mapping rules. **Figure 4** explains the overall layered architecture of the proposed framework.

4. FRAMEWORK DEVELOPMENT

4.1. Context Development

To check the correctness of this work, we have developed a case study about a person who has Parkinson's disease (a

Agent 11: Room Temperature Agent
Initial Facts: Person (‘Alice), Patient_ID(‘E001), has_Patient_ID(‘Alice, ‘E001), RoomTemp(’21), Location(‘Kitchen, ‘Room, ‘LivingRoom), hasRoomTemp (‘Location, ‘RoomTemp), HighRoomTemp(‘21, ‘?),LowRoomTemp(‘21, ‘?)
R111: person(?p), has_Patient_ID(?p, ?PID), Patient_ID(?PID) → Patient(?p) **R112:** Location(?L), hasRoomTemp (‘?L, ‘?rt), RoomTemp (‘?rt), HighRoomTemp(‘?rt, ‘35) →hasRTSituation (‘?RT, ‘high) **R113:** Location(?L), hasRoomTemp (‘?L, ‘?rt), RoomTemp (‘?rt), LowRoomTemp(‘?rt, ‘15) →hasRTSituation (‘?RT, ‘low)

FIGURE 5 | Example rules of context 1 smart home.

neurodegenerative disease). The following two contexts have been developed for this case study.

4.1.1. Context 1: Smart Home

Since memory loss is the dilemma of Parkinson's disease, Alice's house has been embedded with various sensors. One of them is the motion detector sensor for sensing the current position of Alice, i.e., whether she is sitting, standing, has fallen over, or is showing symptoms of Slowed movement (bradykinesia) (21) one of the cardinal manifestations of Parkinson's disease, and for determining the current location of Alice in her house, i.e., Alice is in which room of her house is currently. This sensor is embedded in every room of her house. There are also smoke detection sensors to detect the presence of smoke or fire in the house. Another sensor being used is the carbon monoxide (CO) detection sensor that helps in alerting about emergencies, such as a person has turned on the gas of the stove but forgot to light it. Carbon monoxide is an extremely gas, and interaction with it for an extended period can be injurious to health (22). The smoke detectors are embedded everywhere in the house. However, the carbon monoxide detector is embedded in the kitchen only. On average, the carbon monoxide level recorded in houses with gas stoves is between 0.5 and 5 parts per million (ppm). However, in houses with gas stoves that are properly fixed, the normal recorded level is between 5 and 15 ppm, but the level may be 30 ppm or higher if the gas stoves are not correctly fixed (22). **Figure 5** shows some example rules for the smart home context.

4.1.2. Context 1: Smart Hospital

In addition to home embedded sensors, some sensors are worn by Alice. These sensors are the heart rate monitoring sensor to detect fluctuations in heart rate, body temperature sensors for measuring changes in body temperature, and surface electrodes sensors for measuring electrocardiography (ECG), electromyography (EMG), or electroencephalography (EEG). They are used to monitor the electrical activities of the heart, muscles, and brain, respectively, directly from the skin's surface, eventually providing information about rigidity in the skin and detecting body tremors, both of which are prevalent symptoms of Parkinson's disease.

It must be mentioned here that a specific range of "normal" values is associated with each of these sensors. In case a reading value of a sensor goes above or below this range, an alert is issued by the sensor. The normal range for a heart monitoring sensor is 60–100 bpm (precisely 82 bpm). Usually, an adult has a body temperature between 97 and 99 F (22). For ECG sensors, normal electrocardiography intervals are 0.6–1.2 s. Based on the muscle, the normal EMG range is between 50 μV and 30 mV. An average adult has EEG readings between 8 Hz and higher. For EMG, a reading of 7 Hz or less is considered abnormal in awake adults. However, they are considered normal in children, or sleeping adults (23). **Figure 6** shows some example rules for the wearable device context.

4.2. Agent Development

Nine intelligent virtual agents are designed for the proposed framework. Their description is provided below.

- Systolic Blood Pressure (BP) Agent: For monitoring the systolic BP
- Diastolic BP Agent: For monitoring the diastolic BP
- Body Temperature Agent: For monitoring the body temperature
- Heart-Rate-Agent: For monitoring the Heart Rate
- EEG-Agent: For monitoring the EEG
- ECG-Agent: For monitoring the ECG
- EMG-Agent: For monitoring the EMG
- Carbon Monoxide-Agent: This agent monitors the carbon monoxide level
- Carbon Dioxide-Agent: This agent monitors the carbon dioxide level
- Room-Temperature-Agent: This agent monitors the room temperature

4.3. Ontology Development

For system modeling, contextual information is obtained from multiple ontologies.To model distributed domains for the

Agent 21: Body Temperature Sensor
Initial Facts: Person (‘Alice), Patient_ID(‘P002), has_Patient_ID(‘Alice, ‘P002), Body_Temperature(‘99.5), has_Body_Temperature(‘Alice, ‘99.5), Greater_Than_Equal(‘99.5, ‘100.9), Less_Than_Equal(‘99.5, ‘95.0)
R211: person(?p), has_Patient_ID(?p, ?PID), Patient_ID(?PID) →Patient(?p) **R212:** person(?p), has_Body_Temperature(‘?p, ‘?temp), Body_Temperature(‘?temp), Greater_Than_Equal(‘?temp, ‘100.9) → has_Fever(‘?p, ‘high) **R213:**has_Fever(‘?p, ‘high) → Tell (31, 54, (has_Fever(‘?p, ‘high)) **R214:** person(?p), has_Body_Temperature(‘?p, ‘?temp), Body_Temperature(‘?temp), Less_Than_Equal(‘?temp, ‘95.0) → has_Hypothermia(‘?p, ‘high) **R215:**has_Hypothermia(‘?p, ‘high) → Tell (21, 54, (has_Hypothermia(‘?p, ‘high)) **R216:** person(?p), has_Body_Temperature(‘?p, ‘?temp), Body_Temperature(‘?temp), ~Greater_Than_Equal(‘?temp, ‘100.9), ~Less_Than_Equal(‘?temp, ‘95.0) →Current_Body_Temperature(‘?p, ‘normal)

FIGURE 6 | Example rules of context 2 smart hospital.

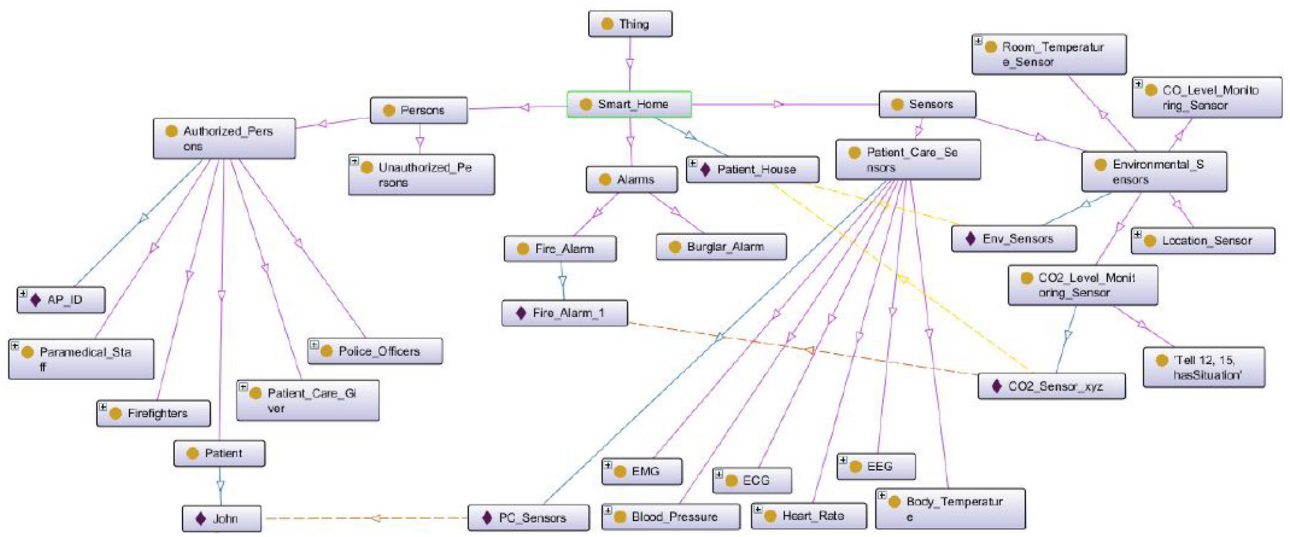

FIGURE 7 | Smart home ontology.

proposed system, a smart home ontology and a smart hospital ontology are developed for modeling the proposed framework. Fragment of the smart home ontology is shown in **Figure 7**.

The smart home ontology describes the flow of information in this context. The second ontology developed is the smart hospital ontology. This ontology describes the structuring of the smart hospital context and expresses the relations between different smart hospital context entities. It also describes the flow of information in this context. Fragment of the smart hospital ontology is shown in **Figure 8**.

In the proposed framework, agents acquire contextual data either from a single ontology or multiple ontologies based on the system's design. Mapping rules have been designed to model the flow of information between the contexts involved in the framework. To manage inconsistencies in such systems, priorities are assigned to the mapping rules, with the rule having the

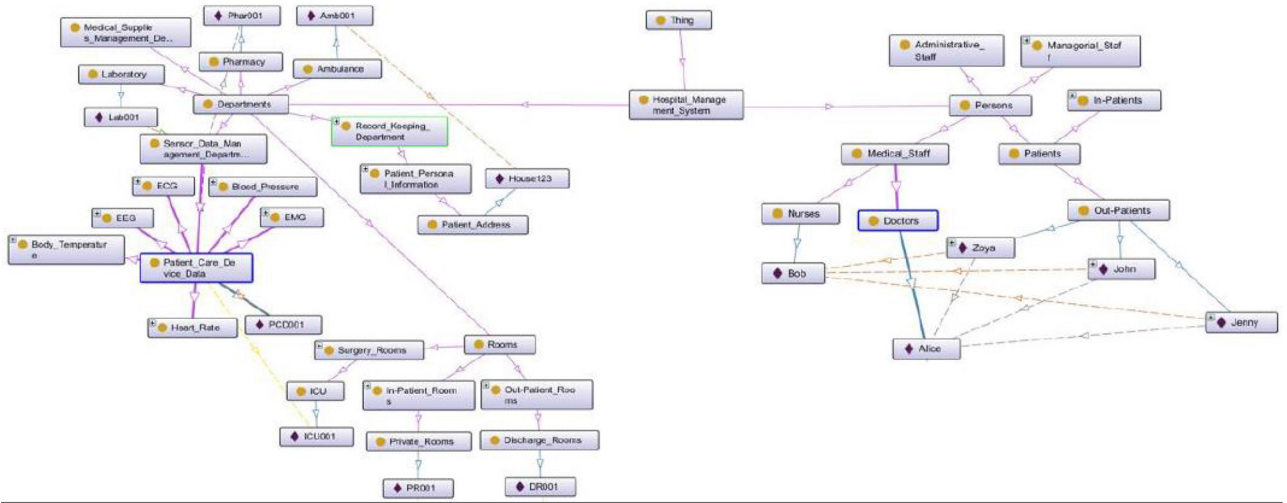

FIGURE 8 | Smart hospital ontology.

higher priority being fired. Class hierarchies of the developed two ontologies are also shown in **Figure 7**.

5. TEMPORAL LOGIC FORMALISM

There are two types of models in temporal logic. Linear temporal logic (LTL) and computational tree temporal logic (CTL*) (24). In our work, we use CLT* instead of LTL because LTL is based on a single computational path (25).

The semantic of TL is defined by CLT* (26). The changing of the current state, i.e., state to -> state from and state from -> state to, is represented by the ω-tree shape (27). The states correspond to the agent knowledge base and communication mechanism. The agent fires multiple rules in a multi-agent system to reach the required state that is acceptable as an outcome. Each agent may drive new context whenever it matches the pre-defined rules. When the agent acts on its actions, the system moves to the next state. If the agent did not acquire the data, the agent tells its corresponding agent about the context, and then the system moves to the other state.

5.1. Current Situation Observation

When an agent gets something from its corresponding sensor, it checks it to map the acquired context with the internal knowledge.

5.1.1. Pre-defined Rules

- G Ag^i (ϕ, t1) where $\phi \in IK^i$ - (i)
- G Ag^i ($\neg\phi$, t1) where $\phi \in IK^i$ - (ii)

In the rule mentioned above i and ii, globally, agent i gets information from the environment which belongs to the agent's internal knowledge IK or information has not been detected by agent i but belongs to internal knowledge. Here, IK^i represents internal knowledge. For instance, when the fire information is acquired to the agent thus the fire context belongs to the agent's internal knowledge; else, not fire belongs to it.

- F [$\ni$ Tell (i, j, ϕ)] - (iii)

In rule iii, it states in the future, on some existing states s' $agent^i$ believes in telling $agent^i$ about some acquired context information, so the $agent^i$ can be auto-trigger.

- Ag^i (ϕ, t1) where $\phi \in$ HI - (iv)

$Agent^i$ acquired the state formula concerning t1, and it is true, and that state formula belongs to acquire HI. For example, after selecting the optimal plan, $agent^i$ has the information about calling the humanitarian assistance for human involvement to give the alert related to the unauthorized entity, as shown in rule iv.

5.1.2. Successful Events

- ϕ i ε ψ i - (v)

When $agent^i$ acquires the context ϕ about one state formula or $agent^i$ acquires the context ψ about other state formula or both. In every way, it would be a successful case. For example, if $agent^i$ gets the information about an animal who is on-site where the camp of soldiers are, or $agent^i$ gets the information about detecting the unauthorized entity or both. It would be a successful case, as shown in rule v.

- Agi ($\neg\phi$, t1) where $\phi \epsilon IK^i$ -(vi)

Agent i has not detected any information, and it does belong to internal knowledge; therefore, it is the case of partial success, e.g., an agent did not get the information about detecting any unauthorized entity, is still a partial success case, as shown in rule vi.

- Ask (j, i, ϕ) ε Tell (i, j, ϕ) - (vii)

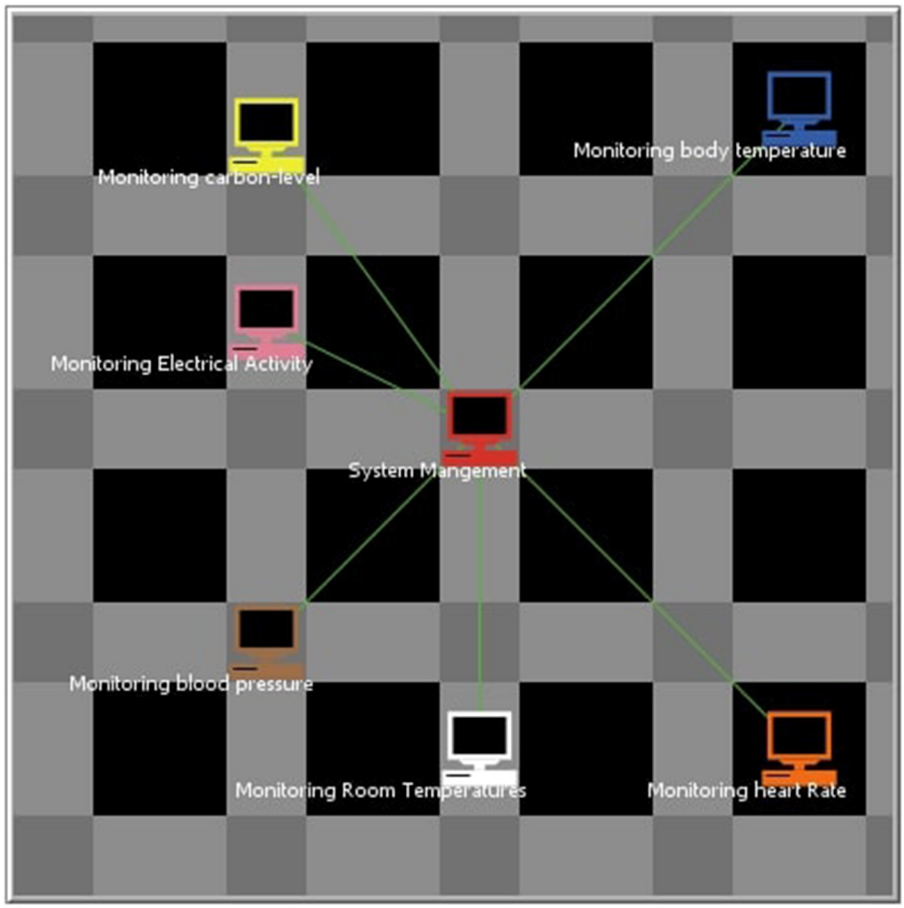

FIGURE 9 | System interface.

In rule vii, agent^i can ask agent^i about the specific context, or agent^i has the pre-defined rule to tell the specific context to agent^i. For example, agent^i has the rule to ask agent^i about detection, or agent^i has the rule to tell agent^i about the detected entity.

5.1.3. Current Situation Step of Actions

After the agent checks the acquired information is true or not, it has the step of actions to follow to act efficiently.

- Xi (α, ti) - (viii)

In rule viii, after matching the predefined rules, the very next thing is, agent^i has to perform θ certain actions α. For instance, if the unauthorized entity context detection is true, then agent^i has actions α to perform θ in a specific time t_i.

- F [$\ni$ i (α (HI), t_i)] - (ix)

After matching the pre-defined rules, in the future, in some existing states, an agent^i has the actions to perform HI requirements. After selecting the optimal plan, agent^i would contact the HI to prevent the situation from any damage, as shown in rule xi.

5.1.4. Task Priorities

- DL (H) iff ϕ i $\cup$ ψ j - (x)
- DL (S) iff ϕ i $\wedge$ ψ j - (xi)

The danger level DL is always high (H). If the one-state formula is detected ϕ unless the other state formula ε is detected, DL changes to severe (S). For example, unauthorized entity ϕ with any weapon at the site ψ is severe DL, as shown in rules x and xi.

6. SIMULATION OF PROPOSED SYSTEM

This section explains the case study, we have developed for the validation of our system. For its implementation, we have used the Netlogo simulation tool. Netlogo is used for modeling, and it teaches the concept of agents like turtles, patches, observers and links, etc., it is used in different kinds of scenarios like in gaming, or if people built a model for a war to check it whether it is correct or not, or/ and in disaster management scenarios, etc. It is open-source software that includes an interface, commands to create an agent model and execute them. It has built-in commands and reports that they call primitive, and the command reports created

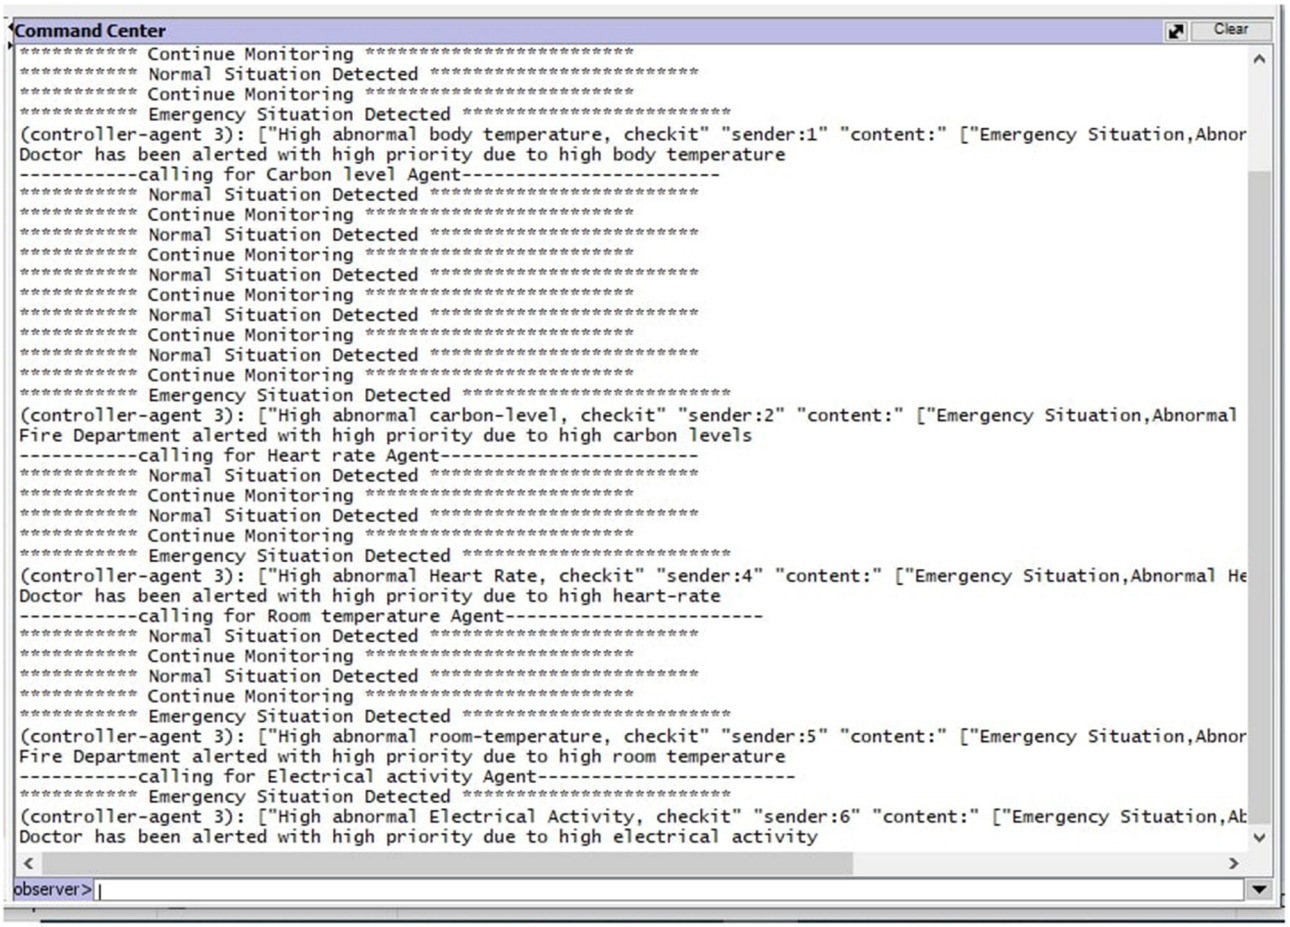

FIGURE 10 | System interface.

by a programmer called procedure (28, 29). To achieve the perfect communication between agents, FIPA protocol was used (30).

For example, agent 1 tells agent two about an "Emergency Situation" by sending "Abnormal BP detected" in the message.

["Emergency Situation" "sender:1""content:" "Abnormal BP Detected" "receiver:2."]

Figure 9 shows the interface of our system. We created seven context-aware agents named controller agent, BP agent, body temperature agent, heart-rate agent, electrical-activity agent, carbon-level agent, room-temperature agent. Each of them has their unique functionality based on their own set of facts and rules, also perform reasoning and take decisions intelligently. These agents can communicate in NetLogo as they are connected by creating a link.

Figure 10 shows the execution of the system. During the execution, the system continuously monitors the patient's situation as "Continuously Monitoring." When any "Emergency Situation" is detected controller agent gets to inform a respective agent that is highly abnormal body temperature detected. After that controller agent sends a message to the doctor by alerting the situation "Doctor has been alerted with high priority due to high body temperature."

7. ALGORITHM

The algorithm has two parts. The first part (**Algorithm 1**) is invoked as soon as the system begins. However, invoking the second part of the algorithm (**Algorithm 2**) depends on obtaining an abnormal value (above or below the pre-defined normal range). In **Algorithm 1**, the agents collect contextual information from their environment. Until that contextual information remains within a specific range (the value obtained is above the lower pre-defined range and below the upper pre-defined range), the system generates no alert and usually works. However, if any agent obtains a value that does not fall within the pre-defined normal range (the value obtained is either below the lower or above the upper pre-defined range), the system generates an alert (**Algorithm 2**) invoked.

In **Algorithm 2**, the priority of the rule instances is fired, and the rule with the highest priority is chosen. The following action, alerting the corresponding authority, depends on the rule instance fired. In the case of PC_Agents rule instances, the

Algorithm 1: Obtaining of Data.

Input:

- Contextual_Info^{xi}: contextual data acquired by an agent^{i} from the environment
- high_value^{i}: the maximum value of given range
- low_val^{i}: the minimum value of given range
- flagVar: flag will be 0 when system continues and 1 and when the system stops
- r^{i}: the fired rule instance

Output: Alert when out of the given range Contextual_info$^{i}_{x}$ is obtained
Start ∀ *Agent*^{i} ∈ agents{*n*}
∃ (*Env_Agents*^{i} ∈ agentsn || PC_Agents^{i} ∈ *agents*{*n*})
if (Contextual_Info^{xi} < high_val^{i} && Contextual_Info^{xi} > low_val^{i}) **then**
  return Contextual_Info^{xi} is normal
else
  invoke Algorithm 2 (Situation abnormal)
end
if some act done **then**
  flagVar = = 1
else
  flagVar = = 0
end
if Flag = 1 **then**
  System Stops
else
  Flag = 0
  System continues as normal
  Invoke Algorithm 1
end

doctors, caretakers, and the next of kin are alerted. On the other hand, when the rule instances fired are from Env_Agents, then the fire department, emergency response unit, and the police department are alerted.

This alert is sent to the corresponding authority by the controller agent of the system. The controller agent is the primary agent of the system controlling all information flow. All the contextual information obtained by any agent is sent directly to the controller agent. In case of an emergency (an abnormal value), the agent sends an alert to the controller agent, and the controller agent then contacts the corresponding authority. The contact can be made in any number of ways, and it can be a text message, an email, a notification, a phone call, or a WhatsApp message. The mode of communication is chosen by the corresponding authority and then included as a command in the memory of the controller agent.

Once an alert has been generated, it is up to the corresponding authority to either take action or not do anything. The corresponding authority solely takes this decision. The reason for this decision goes beyond the scope of this work and the author's domain. If the corresponding authority believes action must be taken, it alerts the system, and the flag's value is set to 1. The flag is a variable that can have only two values, either 1 or 0. each value corresponds to a separate course of actions. If the flag's value becomes 1, the system knows that the corresponding authorities have taken over. In such a case, the system will halt and wait to be rebooted by the corresponding authority. However, if the corresponding authority believes that no action needs to be taken, it does not alert the system, and the flag's value is set to 0. If the flag's value becomes 0, then the system knows that the corresponding authorities have not taken over now, and they will continue to work as usual (continue gathering contextual information). In such a case, the system will not halt. The working of the algorithm in case a single rule is fired or in case multiple rules are fired simultaneously is described below. It must be mentioned here that by default, the priority of patient care agents (PC_Agents) is more than environmental agents (Env_Agents).

7.1. Case 1: Single Rule Instance Fired

When a single rule is fired, the system will function according to that rule without any conflict or issue.

7.2. Case 2: Multiple Rules Instances

When multiple rules are fired, then the set CRS_{pri} will be developed. All the conflicting rules will be included in the CRS_{pri} set, and ultimately the rule with the highest priority will be selected.

8. LIMITATIONS AND FUTURE SCOPE

Since the inconsistencies in heterogeneous knowledge sources systems usually do not have a single reason for occurrence but arrive from the interaction of heterogeneous knowledge bases, therefore, conflicting, or contradictory information is a major

Algorithm 2: Conflicting Rule Set Creation

Input:

- Contextual_Info^{xi}: contextual data acquired by an agent^{i} from the environment
- high_value^{i}: the maximum value of the given range
- low_val^{i}: the minimum value of the given range
- flagVar: flag will be 0 when system continues and 1 and when the system stops
- r^{i}: the fired rule instance
- r$_{pri}{}^{i}$: the priority of the rule
- r^{j}: the other fired rule instance
- r$_{pri}{}^{j}$: the priority of the other rule
- CRS^{pri}: Prioritized rules set of conflicting rules
- CRS^{ord}: Ordinary rules set of conflicting rules

Output: CRS with all those rules conflict the fired rule

Start
if r^{xi} && r^{j} ∈ PC_Agents **then**
  r$_{pri}{}^{i}$ == r$_{pri}{}^{j}$ == prioritized CRS^{pri} = m ← r^{i} && r^{j} **if** r$_{pri}{}^{i}$ > = r$_{pri}{}^{j}$ **then**
    Return r^{i}
  else
    Return r^{j}
  end
else
  invoke Algorithm 2 (Situation abnormal)
end
if r^{xi} && r^{j} ∈ Env_Agents **then**
  r$_{pri}{}^{i}$ == r$_{pri}{}^{j}$ == ordinary CRS^{ord} = m ← r^{i} && r^{j} **if** r$_{ord}{}^{i}$ > = r$_{ord}{}^{j}$ **then**
    Return r^{i}
  else
    Return r^{j}
  end
else
  invoke Algorithm 2 (Situation abnormal)
end
if r^{xi} ∈ PC_Agents && r^{j} ∈ Env_Agents **then**
  r$_{pri}{}^{i}$ == prioritized
  CRS^{pri} = m ← r^{i}
  r$_{pri}{}^{j}$ == ordinary
  CRS^{ord} = m ← r^{j}
  Return r^{i}
else
  invoke Algorithm 2 (In case of a situation that is not normal)
end
if some act done **then**
  flagVar = = 1
else
  flagVar = = 0
end

reason for an inconsistent system. According to the best of our knowledge, the existing approaches propose no hard and fast method for assessing inconsistencies in MCS as so far, no proposed method is flexible enough to accommodate the criteria of various applications. A new approach is needed to provide a single platform to overcome the issues of inconsistency due to conflicting or contradictory information. This new approach must have a reasoning mechanism to handle the issues while having a solid logical base to perform sound reasoning. Since these issues occur due to knowledge sharing among heterogeneous contexts, a mechanism is needed to represent the knowledge formally. There can be multiple heterogeneous

contexts in a multi-context system. Thus having a mechanism for structuring such a system in an organized manner is extremely necessary. The proposed framework fulfills all the requirements mentioned above by using ontology to structure the system, description logic for knowledge representation, and contextual defeasible reasoning for performing reasoning. This work is beneficial for patients who require continuous monitoring of their health, but they cannot afford to stay in a monitoring facility or do not have enough resources to accommodate all their patients. In such cases, this system can be helpful as it will allow the patient to be under supervision continuously by the agents, and in case of an emergency, the authorities will be instantly notified. Another implementation of this system is for those patients who may not need continuous monitoring but are suffering from terminal illnesses such as Parkinson's disease. In these cases, the disease can act up at any moment. The exact time of such situations cannot be predicted. In these scenarios, the patients can be monitored in the safety of their homes, and in case of emergencies, the medical authorities will be notified immediately. In other domains, this system can also be implemented. In disaster management systems, this system can be used to manage disasters such as fire eruptions, carbon dioxide or carbon monoxide leakage, the occurrence of flood, etc.

9. CONCLUSION

In this work, an ontology-driven formalism has been proposed for handling inconsistency in a highly dynamic environment. The proposed framework and application differ from other approaches because it uses contextual defeasible logic to solve inconsistencies. The proposed framework can provide a single platform to overcome the issues of inconsistency occurring due to contradictory information in a multi-context system. Contextual defeasible reasoning has been chosen to perform reasoning on the system as it can handle inconsistency issues by providing a solid logical base to perform sound reasoning. Since the issue occurs due to sharing knowledge among heterogeneous contexts, description logic (DL) and distributed description logic (DDL) mechanisms represent the knowledge being shared formally. While an ontology-based modeling approach has been adopted to model the multiple heterogeneous contexts in a multi-context system. Thus, the proposed framework provides a formalism of multi-agents based on that can handle conflicting information in an environment that is highly decentralized in nature.

Diagnosis is a crucial precautionary step in research studies of the coronavirus disease, which shows indications similar to those of various pneumonia types. The COVID-19 pandemic has caused a significant outbreak in more than 150 nations and has significantly affected the wellness and lives of many individuals globally. Particularly, discovering the patients infected with COVID-19 early and providing them with treatment is an important way of fighting the pandemic. Radiography and radiology could be the fastest techniques for recognizing infected individuals. Artificial intelligence strategies have the potential to overcome this difficulty. Particularly, transfer learning MobileNetV2 is a convolutional neural network architecture that can perform well on mobile devices. In this study, we used MobileNetV2 with transfer learning and augmentation data techniques as a classifier to recognize the coronavirus disease. Two datasets were used: the first consisted of 309 chest X-ray images (102 with COVID-19 and 207 were normal), and the second consisted of 516 chest X-ray images (102 with COVID-19 and 414 were normal). We assessed the model based on its sensitivity rate, specificity rate, confusion matrix, and F1-measure. Additionally, we present a receiver operating characteristic curve. The numerical simulation reveals that the model accuracy is 95.8% and 100% at dropouts of 0.3 and 0.4, respectively. The model was implemented using Keras and Python programming.

Keywords: machine learning, convolution neural networks, transfer learning, MobileNetV2, COVID-19

INTRODUCTION

The coronavirus disease (COVID-19) has endangered social lives and created disturbing financial costs. Many studies have attempted to find a way to manage its spread and the resulting death. Moreover, many research propositions have been made to evaluate the existence and seriousness of pneumonia triggered by COVID-19 (1–4). Compared to CT, although radiography is easily accessible in hospitals worldwide, X-ray images are considered less delicate for examining patients with COVID-19. Primary analysis is crucial for instant seclusion of the infected individuals. Moreover, it decreases the rate of infection in a healthy population because of the accessibility of sufficient therapy or vaccination for the virus.

Chest radiography is an essential method for identifying pneumonia. This is easy to accomplish with rapid medical identification. Upper body CT has a high level of susceptibility for the identification of COVID-19 (5). The X-ray image reveals aesthetic keys associated with the virus (6, 7). They considered the tremendous rate of suspected individuals and a minimal variety of trained radiologists. These automated identification methods with refined abnormalities help diagnose diseases and raise early medical identification quality with high accuracy.

A therapeutic image in the form of a chest X-ray is crucial for the automatic clinical identification of COVID-19. A clinical approach for identifying COVID-19 based on artificial intelligence (AI) can be as precise as a human, conserve the radiotherapist period, and perform clinical identification less expensively and faster than standard techniques. AI explanations can be influential approaches for dealing with such problems. A machine learning structure was used to predict COVID-19 from a chest X-ray image. In contrast to classic medical image category approaches, which stick to a two-phase treatment (handmade function abstraction plus identification), we used an end-to-end deep determining structure that directly discovers COVID-19 from raw pictures without any pre-processing (8–14). Deep learning (DL)-based variations, specifically convolutional neural networks (CNNs), have been shown to perform better than timeless AI approaches. Recently, various processing system ideas and clinical image evaluation tasks have been utilized in several issues, including categorization, dissection, and face identification (15–19).

Convolutional neural network (CNN) is considered among the finest therapeutic imaging applications (20), particularly for categorization. CNN is better suited for large databases and requires computational assets (storage and memory). In most cases (as in this research), the database is inadequate; therefore, it is insufficient for building and training a CNN. Thus, obtaining the benefit of the CNN's power and transfer learning can reduce the computational cost (21, 22). A proficient CNN on a large and varied image database can perform specific classification tasks (23). Hence, many pre-trained designs such as VGG-Net, (24), Resnet (25), NAS-Net (26), Mobile-Net (27), Inceptions (28), and Xception (29) have won many of the world image classification competitions.

Recently, Bhattachary et al. in (30, 31) presented a survey of most of the DL models in the last five years, used to identify COVID-19 with different data sets. Kermany et al. (32) used the DL framework with transfer learning, Rajaraman et al. (33) used a customized CNN model- VGG16, Wang, et al. (34) proposed AI and DL based Frameworks, Shan et al. (35) presented Human-In-the-Loop Strategy and DL Based Segmentation Network VBNet, Ghoshal and Tucker (36) used Drop weights-based Bayesian Convolutional Network, Apostolopoulos and Mpesiana (37) presented Transfer Learning based on CNN, Esmail et al. (38) used CNN Architecture. Khan et al. (39) presented COVIDX-Net comprising Deep CNN Models. Sahiner et al. (40) proposed Deep CNN Models – ResNet50, InceptionV3, and Inception-ResNetV2.

How can the researchers in poor and developing countries quickly and appropriately contribute to stopping the spread of the virus and thus contributing to the economy's growth? Using AI and machine learning models with transfer learning

can contribute to answering this question. This article, which we contribute to, is considered to prevent the spread of the virus.

Because of the absence of a public image database of patients with COVID-19, numerous research studies reporting on the choices for the adaptive discovery of COVID-19 from X-ray images were not easy. This is because they are difficult to train, and many images are required to discover these networks without overfitting. In

this work, data augmentation of the training/testing data set was applied.

In this study, we present a COVID-19 X-ray classification technique based on transfer learning with Mobile NetV2, present in the appendix, which is a pre-trained design (without segmentation). This technique addresses the COVID-19 image deficiency issue. As an alternative to training the CNN from the beginning, our method fine tunes the last layer of the design pre-trained variation on Image-NET (presented in Section The Proposed Architecture net and Strategies for Using the Transfer Learning). The above methods assisted in training the versions with conveniently not easily offered images and they attained excellent efficiency.

The MobileNet model proved to be highly efficient in fruit classification with 102 varieties (41, 42) and the classification of systemic sclerosis skin (43). After reviewing the latest modern studies, the latest (30, 31) studies, and to the best of my knowledge, the MobileNet was not used to identify the coronavirus.

The main contribution of this paper is to investigate and evaluate the performance of MobileNetv2 as a lightweight

convolutional neural with transfer-learning and augmentation data for the early detection of coronavirus, to propose and adopt a new model structure for MobileNetv2 for binary classification, and to investigate the COVID-Computer-aided diagnostic (CCAD) tool based on the MobilenetV2 developed.

This paper is organized as follows: The methods and materials are described as the general projected framework in Section Materials and Methods. The results and discussions in Section Experimental Results and Discussion describe the database, experimental research studies, and measurement tools. Finally, the conclusions and future work are presented in Section Conclusion and Future Work.

MATERIALS AND METHODS

We utilized a CNN to extricate highlights from COVID-19 X-ray images. We took on an extraordinary CNN called a pre-trained show wherever the arrangement is already prepared on the Image-NET database, and it comprised numerous images (creature, plants, …on 1,000 courses). Transfer learning was utilized by exchanging weights obtained and booked right into a pre-trained adaptation system Mobile NetV2.

Transfer Learning

We had few images in the present task to conduct the training, particularly in the COVID-19 category. Thus, transfer learning

```

B

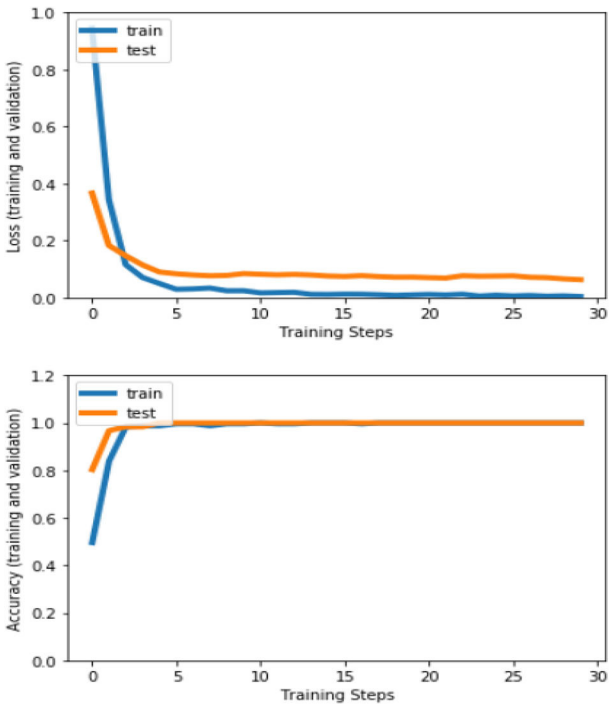

FIGURE 8 | (A) Accuracy and loss (training and validation)–Database B. **(B)** Accuracy and loss (training and validation)–Database B.

is essential. Transfer learning enhances learning in a new job by moving expertise from previous works that have already been reviewed. That is, we used techniques that have been pre-trained on image classification tasks rather than learning a new design. The advantages of transfer learning are as follows:

1. ***Higher begin:*** The first ability (before fine adjustment of the creation) on the resource design is more significant.
2. ***Higher slope:*** The rate of ability enhancement throughout the training of the source design is steeper.
3. ***Higher asymptote:*** The converged skill of the skilled version is much better. When transfer learning is applied to the design, higher precision degrees are quicker.

Description of Deep CNN

The application system is illustrated in **Tables 1**, **2**, changing the highlights from the M to N channels, with walk s and advancement perspective t. This blockage incorporates a 1 × 1 convolution layer and sometimes the depth-wise convolutional layer. In addition, in requiring the advantage of serial actuation rather than the non-linear actuation included after the pointwise convolutional layer, it fulfills its objective down-sampling by setting basis s within the depth-wise convolutional layer. The entire organized Mobile-NetV2 system (**Figure 1**) is summarized in **Table 2**. The two-dimensional (2D) convolution (conv2d) layer is the essential complication, avg-pool is the average pooling, c is the number of the result channels, and n is the copied numbers. CNNs have 19 layers; the center layers are utilized for extricating capacities and the final layers are utilized for categorization. Based on the exchange learning guideline, we utilized Mobile-NetV2 pre-trained by Image-NET as a settled separator.

The mobile-NetV2 network is a base model without top classification layers, a deal for attribute abstraction. A conv2d layer with a dropout and soft-max categorizer layer is added to the basic design in **Figure 2**.

The design of the proposed model is summarized in **Figure 2**; we notice that the total number of coefficients is 2,260,546 for the new model. Only 2,562 coefficients are trainable.

Table 3 shows the differences between the MobileNetV2 model and the other models regarding requirements and efficiency.

EXPERIMENTAL RESULTS AND DISCUSSION

Database Description

The first dataset includes 309 chest X-ray images (102 were infected with COVID-19 and 207 were normal) see **Figure 3**. The second dataset includes 516 chest X-rays images (102 were infected with COVID-19 and 414 were normal). All Data sets are organized in two folders, one for training and the second for testing /validation. In each folder of the two (training and testing), two open folders equal to the number of classes, then in each class, the images examples of this class are put. The dataset was obtained from two different open-source databases:

1. GitHub database [https://github (44)].
2. https://kaggle.com/c/rsna-pneumonia-detection-challenge.

They include 8,851 normal samples and 6,012 samples infected with pneumonia, and the chest X-ray image dimension is adjusted to 224 × 224 to satisfy the input conditions of the Mobile-NetV2 model.

Open-source CNN versions are readily available for training from scratch and transfer learning (customizing parts of an extant design for a new job). These versions are frequently tested on the ImageNet dataset of more than 1 million classifieds. The following section presents the proposed structure based on the MobileNetV2.

The Proposed Architecture Net and Strategies for Using the Transfer Learning

1. **Building the generator of the training data.**

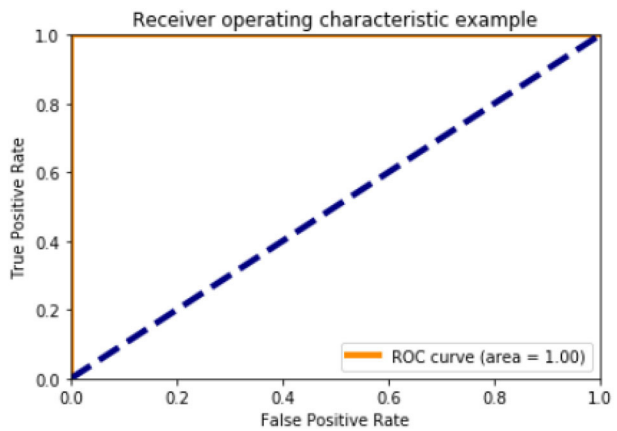

FIGURE 10 | ROC curve (Case B).

The batches of tensor image data were generated using the class ImageDataGenerator(); also, this class is used as real-time data augmentation with different parameters. With the flow_from_directory() method, which receives two arguments, the directory(from which the images are loaded for creating the batches) and target size (we Adapt the: Target size of the loaded image, which is (256, 256) by default. To (128, 128). In addition, the method receives 3 other arguments (color_mode: RGB, class_mode:' "categorical", batch_size:32).

2. **Building the validation data generator (is like building the generator of the training data).**

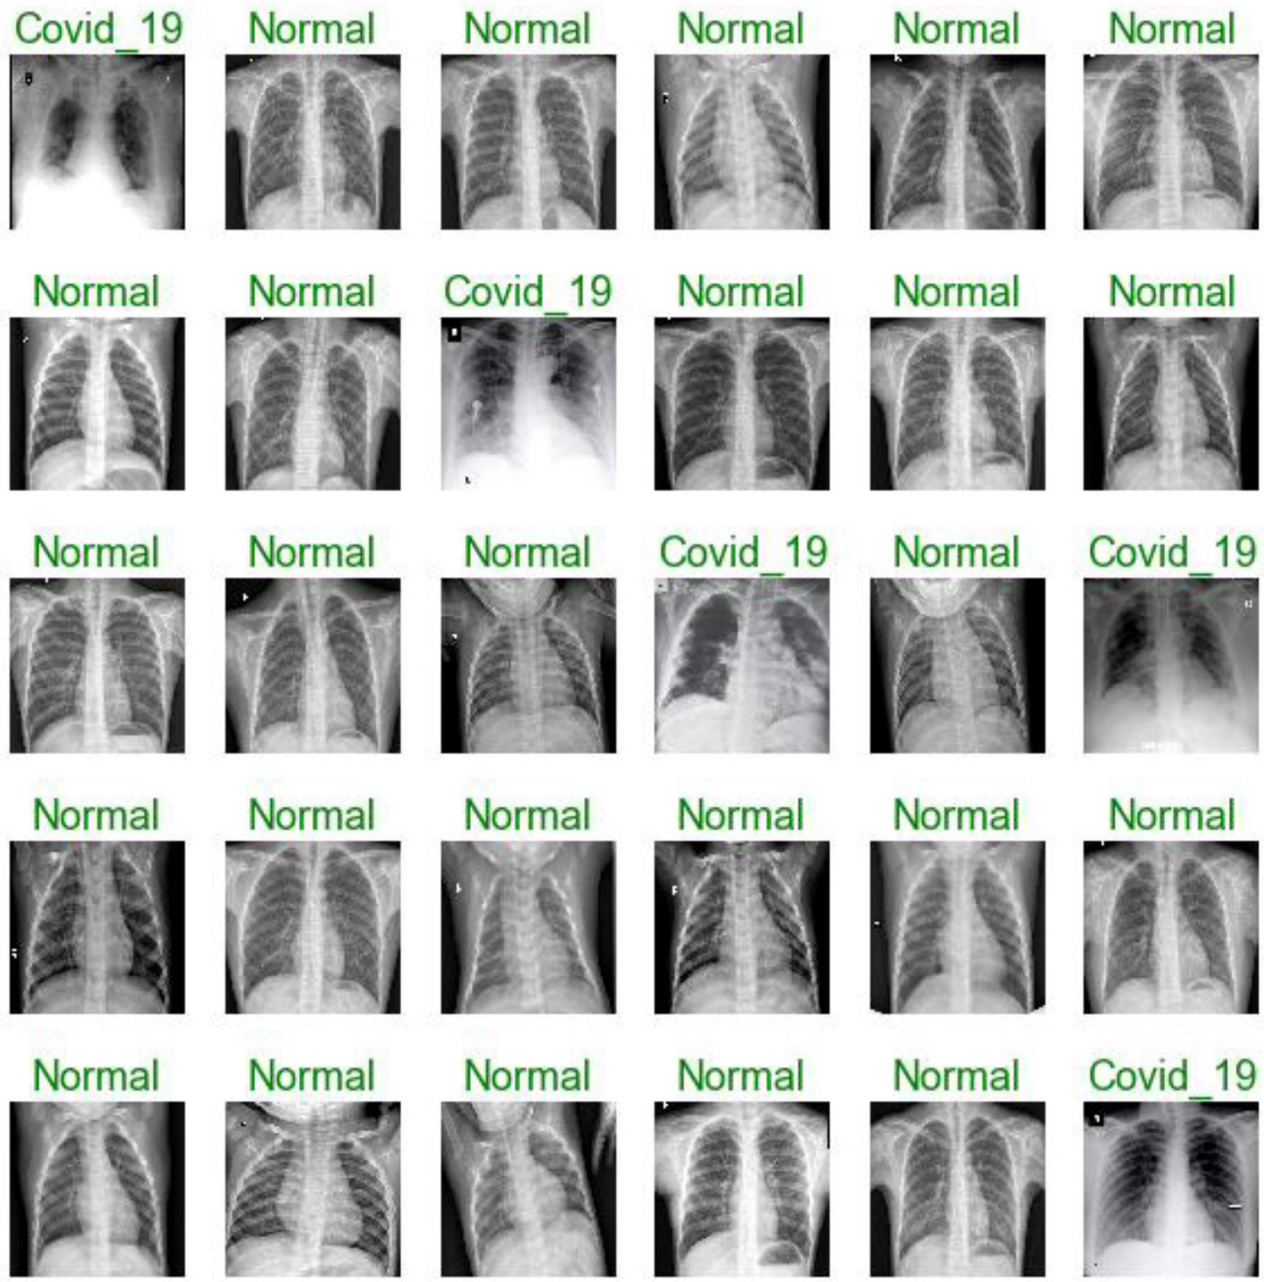

FIGURE 11 | Model predictions (green: correct, red: incorrect).

3. **Loading the MobileNetv2.**

Load the MobileNetv2 from the TensorFlow.Keras.Applications and store in the COVID19Model. Then, remove the last Final conect (FC) layers from the original model. The number of classes is 1,000, and the number of parameters is 4,231,976 trainable parameters in the network. To make this model suitable for working with our data set (Covid19) in two classes: change the size image from (224, 224, 3) to (128, 128, 3). we set in the MobileNet() function argument input_shape = (128, 128), and include_top = False (meaning load the model without FC layers) then make the model return just a vector of length equal to the number of classes. Also, the trainable argument of the loaded model is set to False.

4. **Adding new FC Layers to the modified model.**

We do not need to build a new architecture but use the architecture in the modified model stored in the COVID 19 model. Using the Sequential class in Keras, two layers were added

```
In [13]: #Use hub.KerasLayer to load a MobileNetV2 model from TensorFlow Hub
         #classifier_model ="https://tfhub.dev/google/tf2-preview/mobilenet_v2/classification/4"
         model = tf.keras.Sequential([
          hub.KerasLayer("https://tfhub.dev/google/tf2-preview/mobilenet_v2/feature_vector/4",
          output_shape=[1280],
          trainable=False),
          tf.keras.layers.Dropout(0.5),
          tf.keras.layers.Dense(train_generator.num_classes, activation="softmax")
         ])
         model.build([None, 224, 224, 3])
         model.summary()

         Model: "sequential"
         _________________________________________________________________
         Layer (type)                 Output Shape              Param #
         =================================================================
         keras_layer (KerasLayer)     (None, 1280)              2257984
         _________________________________________________________________
         dropout (Dropout)            (None, 1280)              0
         _________________________________________________________________
         dense (Dense)                (None, 2)                 2562
         =================================================================
         Total params: 2,260,546
         Trainable params: 2,562
         Non-trainable params: 2,257,984
```

FIGURE 12 | Case B with 10 epochs.

at the top of the modified Mobile Net architecture, which are the: a) Average pooling layer b) FC layer with two neurons using the Dense class. (Note that an FC layer is also called a dense layer, and therefore the class used for building the FC layer is called Dense.) Adapting two layers is better than adapting one layer. Adapting three layers is better than just adapting 1 or 2 layers.

5. **Compiling the new model.**

Use the **compile ()** method with the arguments optimizer, loss and metrics as: optimizer=tf.keras.optimizers.RMSprop (lr=0.0001), loss ="binary_crossentropy" and metrics=["accuracy"]).

6. **Finally, MobileNet transfer learning over the COVID-19 dataset.**

   The **fit–_generator()** method is used. With the argument: generator: Train generator. steps_per_epoch: set to ceil (number of training samples/batch size). epochs: Number of training epochs. validation_data: Validation generator. validation_steps: calculated as ceil (number of validation samples/batch size.

7. **Finally, save the model with extension.h5,** which is a format for saving structured data.

Data Augmentation

In machine learning (ML) and deep learning (DL) applications, the availability of large-scale, high-quality datasets plays a major role in the accuracy of the results. Keras ImageDataGenerator class provides a fast and simple method to increase your images. It offers various augmentation strategies like standardization, rotation, shifts, turns, brightness modification, etc. Data augmentation of the training/testing data set was applied to each image. For this, we use used the Keras ImageDataGenerator () class with the flowing set of constructor parameters: **Table 4**.

Experimental Environment

To survey the execution of Mobile-NetV2 with exchange learning, TensorFlow 2 (Tensorflow free) was introduced on Windows-10, a 64-bit working framework. Mobile-NetV2 was run using Python (Python free), and it was pre-trained using the Image-NET database. The exploratory framework is as follows: Intel R Center i7-8250U CPU @1.70 GHz, 1900 MHz 7 Core(s). 9 consistent Pr. and the memory was 16 GB. We used the Keras guide (45) and TensorFlow backend (46) in the implementation model.

Evaluation Metrics

In the classification Models, most researchers used only accuracy as a performance metric. But the accuracy in some cases is not enough because of the imbalance problem in the data. To measure the model's performance and avoid the problem of data imbalance in the classes, we used more than one performance metric, such as the confusion matrix, F1, Precision, Recall, and Area Under Curve (AUC), which is one of the highest used metrics for evaluation. It is used for binary classification problems. The performance of the classification models can be assessed using various metrics, such as classification precision, sensitivity, specificity, F1-score, and accuracy. Sensitivity and specificity can be calculated using the following equations (45–47): Precision: measure the true patterns correctly predicted from the total predicted patterns in a true class. Accuracy: measure the ratio of correct predictions over the total number

B

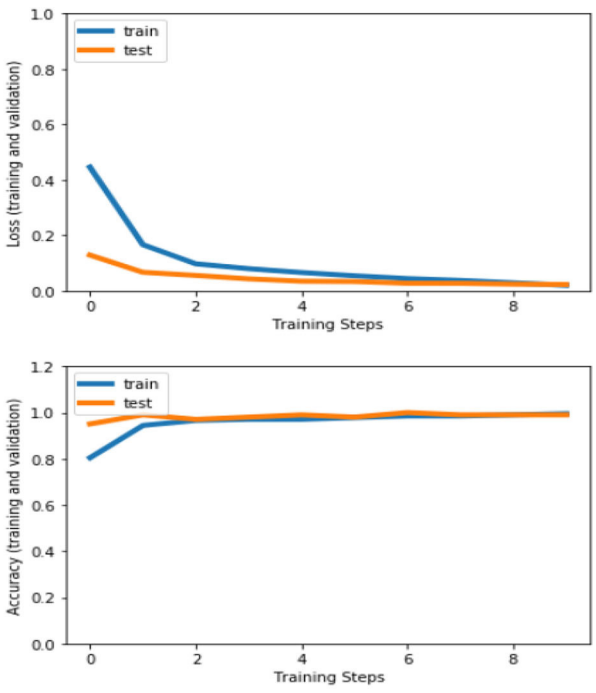

FIGURE 13 | (A) Accuracy and loss (training and validation)–Database B with 10 epochs. **(B)** Accuracy and loss (training and validation)–Database B with 10 epochs.

of examples evaluated, Recall: used to measure the fraction of positive examples that are correctly classified, and F1: a measure that provides the absolute average between accuracy and recall.

$$\text{Accuracy } (\text{for each category}) = \frac{TN + TP}{TN + TP + FN + FP},$$

$$\text{Specificity} = \frac{TN}{TN + FP}, \text{Sensitivity} = \frac{TP}{FN + TP},$$

$$, \text{Precision} = \frac{TP}{FP + TP}, \text{and} F1 = \frac{2^{*}TP}{2^{*}TP + FP + FN}$$

where true positive (TP) is the correctly categorized number and false positive (FP) is the incorrectly recognized number. False-negative (FN) is the image of a category that is found as an additional class and true negative (TN) is an image that does not belong to any category and is not categorized as any class.

Evaluation Results

We prepared the experiment with our database utilizing the Adam optimizer and a batch measure of 30. We performed our exploration by selecting a dropout rate (0.4, 0.5). Additionally, we utilized a learning rate rise to 1e-3 for the Adam optimizer and prepared for ten epochs within the pre-training organization; in any case, we select a much lower preparation rate e^{-5} for 31 epochs during the fine-adjustment phase.

set B, and Dataset B with only 10 epochs and a dropout of 0.5, respectively.

Figures 6, **10**, **15** and **Table 8** represents the receiver operating characteristic (ROC) Curve for data set A, Data set B, and Dataset B with only 10 epochs and a dropout of 0.5, respectively (see **Figure 12**).

Figures 7, **11**, **16** are present the model predictions results (green: correct, and red: incorrect) for data set A, Data set B, and Dataset B with only 10 epochs and a dropout of 0.5, respectively.

Based on the results (all figures and tables), it is shown that the proposed classification strategy DL MobileNetV2 might considerably influence the automated detection and extraction of essential features from X-ray images associated with the medical diagnosis of COVID-19.

The preparation of a deep CNN (D-CNN) takes days and hours, and it requires a large database to induce significant precision. Most assignments or information were related. The model coefficients learned can be utilized within the modern demonstration through transfer learning to accelerate and maximize the learning execution of the modern model. We observed from our tests that preparing D-CNNs, particularly for Mobile-NetV2, with a transfer learning strategy could hasten the preparation method.

TABLE 7 | Confusion matrix for all data set.

Data set	Confusion matrix
A	19 2 0 11
B	25 0 0 7
B with only 10 epochs and Dropout of 0.5	25 7 0 7

TABLE 8 | Roc curve area for all data sets.

Data set	Roc curve area
A	0.95
B	1.0
B with only 10 epochs and Dropout 0.5	1.0

Moreover, distinct profundity convolutions and modified remaining direct blockages can diminish the number of coefficients. Thus, Mobile-NetV2 can be rapidly sent in versatile and inserted apparatus. Because the database utilized in this study is small, we trained our model utilizing dropout, which is a proficient strategy for minimizing overfitting in neural systems by dodging sophisticated adaptations on preparing information.

DL Challenge in the Diagnosis of COVID19 Chest Xray

Some limitations of the study research can be overcome in future research, specifically, a more in-depth analysis that requires much more patient data. Establishing models to identify COVID-19 cases from similar viral cases, such as severe acute respiratory syndrome (SARS), and a higher range of common pneumonia is needed. Nonetheless, this work contributes to the possibility of an affordable, fast, and automated diagnosis of the Coronavirus disease.

In the last two years, much DL research on X-rays has been conducted to promote and propose a primary diagnostic tool for COVID-19. These studies have shown good performance results and the best DL algorithm models. These studies have proven that DL algorithms can classify or differentiate between normal and COVID19 chest X-rays. Hence, to keep the study more reliable and to be part of the primary diagnosis tool, perhaps, now is the time to move the study to classify the severity level of COVID-19 where the levels of COVID-19 severity infection are classified into five stages. They are beginning from stage 1 up to stage 5. Stage 1 is defined as the early stage of infection, where these levels classify based on SpO2 level respiratory frequency and difficulty of breathing symptoms. **Table 10** shows the severity level and its common symptoms. To certify this future works, deep learning researchers and medical doctors must work together to recognize or build the actual image samples for the algorithm.

CONCLUSION AND FUTURE WORK

This study presents a recognizable verification framework for COVID-19 based on a light neural network, Mobile-NetV2, with a transfer-learning procedure and chest X-ray images. We utilized the pre-trained neural system, Mobile-NetV2, which was prepared using the Image-NET database. The conventional

TABLE 9 | Compare the results obtained using the proposed network with other networks (37).

Network		Accuracy 2-class (%)	Sensitivity (%	Specificity (%)	F1 %
VGG19 (48)		98.75	92.85	98.75	-
MobileNet v2 (28)		97.40	99.10	97.09	-
Inception (49)		86.13	12.94	99.70*	-
Xception (50)		85.57	0.08	99.99*	-
Inception ResNet v2 (49)		84.38	0.01	99.83*	-
Proposed Network	A	93.75	100	100	95.0
(Based on MobileNetv2)	B	99.2 and 100	100	100	100

*The asterisk * denotes the measurements corresponding to sensitivity and specificity, which obtained not meaningful values due to data imbalance. In our work, Data augmentation is used in the training/testing data set using Keras ImageDataGenerator () class.*

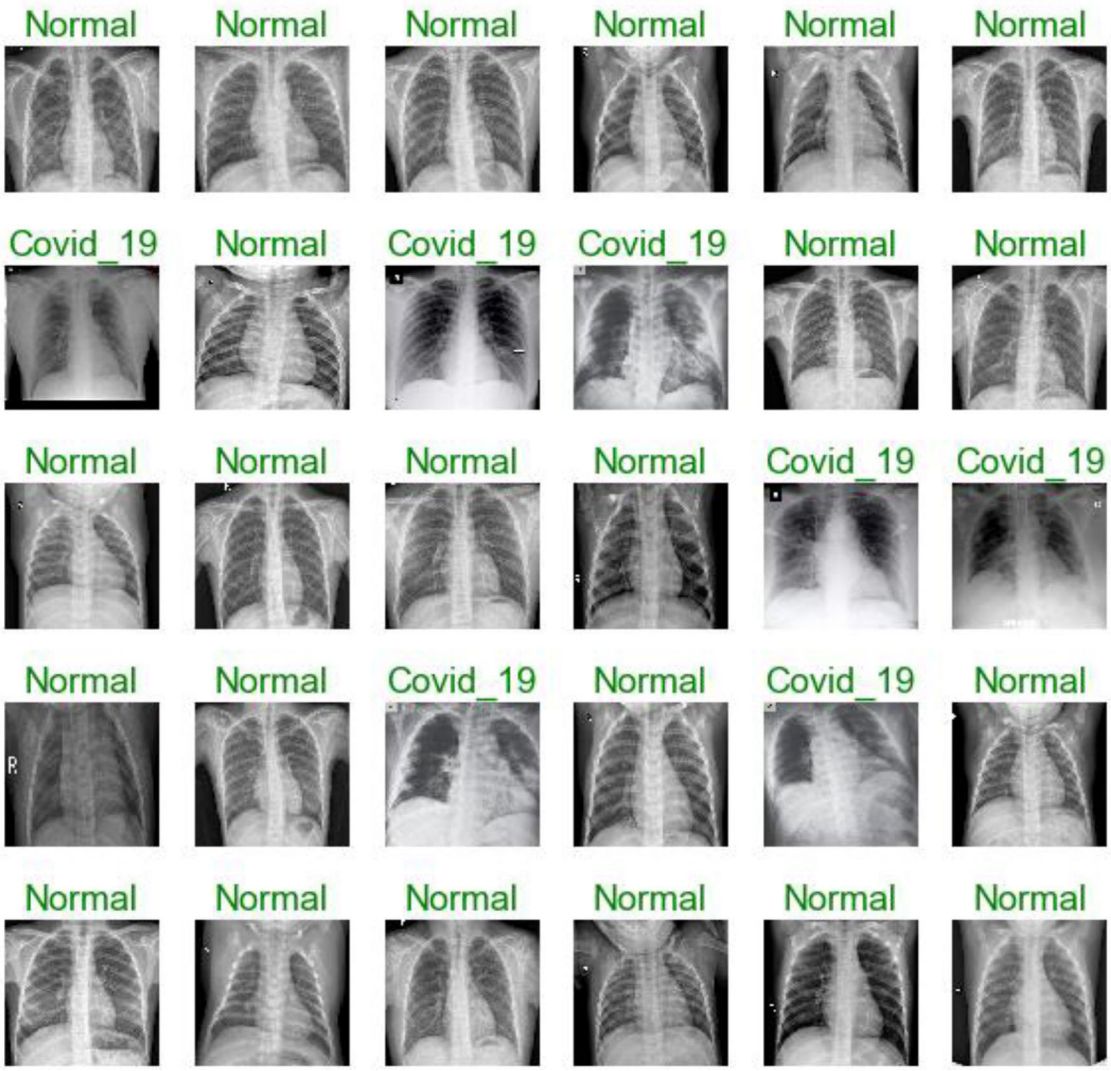

FIGURE 16 | Model predictions (green: correct, red: incorrect).

TABLE 10 | Severity level of COVID-19 (51).

Severity level	Name	Description/Individuals who
1	Asymptomatic	Have no symptoms that are consistent with COVID-19
2	Mild	Have light symptoms
3	Moderate	Show evidence of lower respiratory (SPO2 ≥94%)
4	Severe	Have SPO2 < 94%, and other conditions
5	Critical	Have respiratory failure/multiple organ dysfunction

convolution layer was used as the beat layer of a recent study. To reduce overfitting, we connected the recession to the recently included conv2d layer. Mobile-NetV2 demonstrates employment to extricate highlights, and the soft-max categorizer is employed to categorize highlights.

The performance rates indicate that computer-aided diagnostic models based on the convolutional neural MobilenetV2 networks may be employed to diagnose COVID-19. The proposed strategy achieved a distinguishing proof accuracy of 99.9 and 100% in our chest X-ray pictures database, with 309 and 512 images (102 infected with COVID-19, 207 normal; 102 infected with COVID 19, 414 normal, respectively) (see **Table 9**). The proposed framework can be employed in limited computing and low power devices such as smartphones because Mobile-NetV2 is a lightweight neural arrangement.

In the future, we plan to promote a hybrid system based on MobileNetV2 as a feature extractor with the Whale Optimization Algorithm (WOA) for efficient feature selection and other classifiers such as sport vector machine or Extra Randomized Tree (ERT) algorithm (52).

DATA AVAILABILITY STATEMENT

The datasets analysed in this study are available at: GitHub database [https://github (30)] and https://kaggle.com/c/rsna-pneumonia-detection-challenge. Further inquiries can be directed to the corresponding author/s.

ETHICS STATEMENT

Ethics approval and written informed consent were not required for this study in accordance with national guidelines and local legislation.

AUTHOR CONTRIBUTIONS

MR supervised the project. GA, HA, and SA designed the model, the computational framework, and analysed the data. AN and MR carried out the implementation. GA and HA performed the calculations. GA and SA wrote the manuscript with input from all authors. All authors provided critical feedback and helped shape the research, analysis and manuscript. All authors contributed to the article and approved the submitted version.

FUNDING

This project was supported financially by Institution Fund projects under Grant No. (IFPRC-215-249-2020).

ACKNOWLEDGMENTS

We extend their appreciation to the Deputyship for Research and Innovation, Ministry of Education in Saudi Arabia for funding this research work through the project number (IFPRC-215-249-2020). and King Abdulaziz University, DSR, Jeddah, Saudi Arabia.

Background: An increasing number of geriatric patients are suffering from degenerative lumbar spondylolisthesis (DLS) and need a lumbar interbody fusion (LIF) operation to alleviate the symptoms. Our study was performed aiming to determine the predictors that contributed to unfavorable clinical efficacy among patients with DLS after LIF according to the support vector machine (SVM) algorithm.

Methods: A total of 157 patients with single-segment DLS were recruited and performed LIF in our hospital from January 1, 2015 to October 1, 2020. Postoperative functional evaluation, including ODI and VAS were, performed, and endpoint events were defined as significant relief of symptom in the short term (2 weeks postoperatively) and long term (1 year postoperatively). General patient information and radiological data were selected and analyzed for statistical relationships with the endpoint events. The SVM method was used to establish the predictive model.

Results: Among the 157 consecutive patients, a postoperative unfavorable clinical outcome was reported in 26 patients (16.6%) for a short-term cohort and nine patients (5.7%) for a long-term cohort. Based on univariate and multivariate regression analysis, increased disc height (DH), enlarged facet angle (FA), and raised lateral listhesis (LLS) grade were confirmed as the risk factors that hindered patients' short-term functional recovery. Furthermore, long-term functional recovery was significantly associated with DH alone. In combination with the SVM method, a prediction model with consistent and superior predictive performance was achieved with average and maximum areas under the receiver operating characteristic curve (AUC) of 0.88 and 0.96 in the short-term

cohort, and 0.78 and 0.82 in the long-term cohort. The classification results of the discriminant analysis were demonstrated by the confusion matrix.

Conclusions: The proposed SVM model indicated that DH, FA, and LLS were statistically associated with a clinical outcome of DLS. These results may provide optimized clinical strategy for treatment of DLS.

Keywords: degenerative lumbar spondylolisthesis, clinical outcome, machine learning, predictor, lumbar interbody fusion

INTRODUCTION

As the aging society comes, degenerative lumbar spondylolisthesis (DLS) with symptomatic stenosis presents a serious challenge to healthcare (1, 2). After struggling with the dilemma of decompress treatment, spine surgeons have recognized that it will cause inferior postoperative outcomes without fusion, including persistent pain, pseudarthrosis, and progressive degenerative changes (3–5). Therefore, lumbar interbody fusion (LIF), in combination with decompression, has become the main surgical options for the treatment of DLS.

We noted that the negative feedback from the patients is the main reason for the increased reoperation rate and decreased treatment satisfaction, which result in contradictions or bothers between doctors and patients and heavy substantial burden on the healthcare systems (6).

The current dominant functional scales for evaluating symptoms of degenerative spinal diseases are the Visual Analog Scale (VAS) and the Oswestry Disability Index (ODI) (1, 7–9). However, there are few studies on surgical efficacy evaluation based on patient-reported outcomes (PROs) at present (7).

Machine learning (ML) has proved to be an effective data-driven automatic modeling mechanism in processing numerous problems in the biomedical field (10–13). Support vector machine (SVM) is a well-established classifier, which was applied for accurately patients' classification and treatment options improvement (14).

Considering there is a lack of superior predictive models, the purpose of this study was to investigate the clinical distribution of PROs and to establish a predictive model to evaluate the risk of unfavorable clinical outcomes in short- and long-term postoperative cohorts using the SVM algorithm.

METHODS

Study Design and Participants

The diagnosis of DLS required a minimum 3-mm vertebral displacement observed in lateral X-rays, and patients were selected from January 1, 2015 to October 1, 2020 at our institution. Inclusion criteria: (1) age ranged from 50 to 80 years old, (2) patients diagnosed with symptomatic DLS, (3) single-level spondylolisthesis and LIF, (4) traceability of clinical parameters, radiological variables, and surgical records, (5) at least 1 year of follow-up available. Exclusion criteria: (1) American Society of Anesthesiologists (ASA) rating of III or higher, (2) multi-level decompression and LIF with pedicle screws, (3) previous lumbar surgical intervention, (4) revision surgery, (5) spinal tumor, deformity, fracture, infection or other spine diseases, and (6) rejection of implants.

The Ethics Committee of our hospital approved this study. All data were extracted from hospital electronic system.

Data Collection

General patient information was recorded, including age, sex, body mass index (BMI), smoking, diabetes, Oswestry Disability Index (ODI), Visual Analog Scale (VAS), fusion technique, operation level, bone graft methods, cement augmentation, and surgical complications.

All patients received a complete imaging evaluation, including standard anteroposterior and lateral X-rays, CT, dual-energy X-ray (DEXR), and MRI. Based on X-rays results, we recorded and analyzed the following radiological variables: sacral slope (SS), the angle between the sacral plate and the horizontal axis. Draw the line connecting the midpoint of the femoral head to the midpoint of the sacral plate, which formed an angle with the vertical line of the sacral plate as pelvic incidence (PI) and an angle with the longitudinal axis as pelvic tilt (PT) (**Figure 1A**). Slip degree (SD), the horizontal distance of posterior wall between the slipped and upper vertebrae; lumbar lordosis (LL), the angle between the upper endplate of L1 and the upper endplate of S1; segment lordosis (SL), the angle between the upper endplate of the upper vertebrae and the upper endplate of the lower vertebrae of the slipped segment; disc height (DH), the average of anterior disc height and a posterior disc height (**Figure 1B**); lateral listhesis (LLS) was defined the distance between vertebral bodies (**Figure 1C**). Insertion depth, as 60% of the vertebral depth, was treated as the minimum screw purchase at our institution; the patients were assigned to the S group and the L group (**Figure 2**). The facet angle (FA) between the facet line and the line connecting the bilateral dorsal points was measured on CT (**Figure 3**). Osteoporosis was defined as T-score < -2.5 SD on dual-energy X-ray absorptiometry.

PROs were determined as function evaluations. ODI was used to describe the patient's quality of life; a smaller value

suggested better function. VAS was chosen to measure the patient's back pain; a decreased value suggested reduced pain. Based on practical experience and literature review, significant symptomatic improvement was observed in patients with lumbar spondylolisthesis after decompression and fusion. (7) We defined the short-term endpoint event as a 60% improvement in VAS and ODI 2 weeks postoperatively, and long-term endpoint event as a 90% improvement in VAS and ODI 1 year postoperatively.

Surgical Technique

All recruited patients were operated by the same surgeon. Prone position after general anesthesia has taken effect. The transforaminal lumbar interbody fusion (TLIF) group and posterior lumbar interbody fusion (PLIF) group designed their individual landmarks separately with the assistance of C-arm fluoroscopy. The TLIF group used a percutaneous fixation approach to implant screws *via* the pedicle, and PLIF used a conventional open approach. If the primary surgeon felt it necessary (preoperative diagnosis of osteoporosis or intraoperative finding of bone weakness), the tip of the vertebroplasty needle was inserted into the central point of the vertebral body under fluoroscopic guidance, and, approximately, 2–3 ml of polymethylmethacrylate (PMMA) bone cement was injected. The corresponding lamina is removed and retained for bone grafting, and the upper and lower cartilage endplates of the intervertebral disc are scraped with a ring curette after debridement of the annulus fibrosus and nucleus pulposus. The rods are inserted bilaterally, and traction is applied to

lift the slipped segment and ensure uniformity with the upper and lower vertebrae as much as possible. Some patients might receive cement augmentation due to screw retraction at this stage. After fluoroscopic demonstration of satisfactory correction of the slippage, an appropriately sized cage is filled with allograft and/or autologous bone, and the processed interbody fusion cage is inserted into the interbody space to support the vertebral body (**Figure 4**).

Support Vector Machine

VAPNIK first conceived the SVM technique as a classification method for both linear and non-linear data two decades ago. The input vectors were mapped to a high-dimensional feature space *via* preselected non-linear mappings, and the optimal classification hyperplane was constructed in this space. The support variables eventually obtained are exactly the nearest sample points. The data input format was recorded as "csv" or "xlxs" and analyzed depending on the Python programming language (Python 3.8.0, Python Software Foundation).

Statistical Analysis

For continuous variables, normal distribution was subject to Student's *T*-tests, and non-normal distribution was subject to Mann–Whitney test. Chi-square test was adopted to analyze categorical variables. Continuous variables and categorical variables are presented as means ± standard deviations (SD) and relative frequencies and percentages, respectively. In addition, we applied logistic regression analysis to identify the predictors of unfavorable clinical outcomes within 2 weeks postoperatively. The statistically significant variables obtained from the univariate regression analysis were again subjected to multivariate regression analysis. Furthermore, the selected variables were put into the SVM classifier. Statistical differences were defined as $p < 0.05$. All statistical analysis was performed with SPSS version 22.0 (IBM SPSS, Armonk, New York).

RESULTS

From January 2015 to October 2020, a total of 157 consecutive patients met the inclusion criteria after excluding three patients due to follow-up loss. The demonstrative information of the patients was observed in **Table 1**. The mean age of the patients was 63.84, and the majority was females (approximately two times of males). Based on the selection basis of degenerative disease, 43 patients (27.39%) were diagnosed with osteoporosis, and 52 patients (33.12%) received intraoperative cemented augmentation. All the patients underwent single-segment fusion, with the primary level of fusion at L4/5 and TLIF as the dominant fusion approach. Autograft bone was the preferred bone graft method. Two patients had intraoperative screw retraction, and subsequent short-term poor functional recovery was observed during follow-up. The fusion rate was 95.54%, and, among the seven patients who achieved inadequate fusion, three exhibited consistent low back pain and one underwent revision surgery as the result. According to the PROs, 26 patients and nine patients were eventually assigned to the short- and long-term unfavorable cohorts; the score summary is shown in **Table 2**. Serious complications, such as neurological deficits, deep vein thrombosis, and wound infection, did not occur in this series of patients. However, we identified two patients with postoperative urinary retention and one patient who underwent revision surgery for persistent low back pain.

Table 3 compared the preoperative and postoperative radiological parameters. There were no statistically significant differences both in the short- and long-term cohorts, including

SD, LL, and PI. In the present study, we found that DH, LLS, PT, and FA were significantly higher in the long-term unfavorable cohort than in the counterpart, and a higher proportion in the short screw group. In evaluating the long-term clinical efficacy, the differences of DH, LLS, and FA in the unfavorable group were statistically significant.

Univariate and multivariate regression analyses indicated that preoperative LLS ($p = 0.005$), postoperative DH ($p = 0.004$), and FA ($p = 0.030$) were independent risk factors in a short-term adverse outcome (**Table 4**), while only postoperative DH ($p = 0.038$) was independently associated with a long-term outcome (**Table 5**).

To predict the risk of an adverse outcome in patients with spondylolisthesis, we developed SVM models based on the above-mentioned independent predictors. We evaluated the ROC curve of the model and calculated the area under the ROC curve. Furthermore, 10-fold cross-validation was performed to evaluate the predictive power of the algorithm. For patients who fed back adverse PROs in the short term, the SVM model showed satisfactory classification performance with mean and maximum AUC values of 0.88 and 0.96, respectively (**Figure 5**). Among all routine indicators, the only predictor of a long-term outcome (1 year) was postoperative DH, and the long-term SVM model showed slight weakening of performance compared to the short-term SVM, with mean and maximum AUC values of 0.78 and 0.82, respectively (**Figure 6**). Based on the confusion matrix, these indices provide evidence for performance evaluation, and the following equations are presented:

$$Accuracy\ (ACC) = \frac{TP + TN}{TP + TN + FP + FN}$$

$$Precision = \frac{TP}{TP + FP}$$

The confusion matrix showed the models were excellent at predicting the risk of unfavorable clinical outcomes in patients with spondylolisthesis with the ACC of 93.7% and precision of 88.5% in the short-term cohort and the ACC of 86.7% and precision of 66.7% in the long-term cohort.

DISCUSSION

No consensus has been achieved on whether to perform interbody fusion for degenerative lumbar spondylolisthesis. Chan et al. (15) concluded that their evidence that supported decompression alone was a more beneficial intervention to minimize surgery-related trauma and postoperative morbidity, and had comparable efficacy to additional interbody fusion, especially for low-grade spondylolisthesis. Ghogawala et al. controverted this conclusion (5). After 4-year follow-up, they found decompression with lumbar fusion was associated with a significant improvement in physical health-related quality of life compared to laminectomy alone. The abnormal sagittal alignment of the lumbar spine can lead to increased energy demands in non-resting positions, resulting in early fatigue and exercise intolerance (9). Therefore, the aim of DLS surgery is to restore the normal anatomical sequence and stability of the lumbar spine based on the removal of spinal stenosis (7). In the present study, all the patients underwent decompressive laminectomy and instrumented lumbar spinal fusion to achieve the above-mentioned treatment goals. PROs were direct and convenient evidence to measure the quality of DLS surgeries. Meanwhile, the VAS and ODI scores were regarded as the primary evaluation tools; these subjective data offered "real world" insights into guiding and improving surgical techniques (15, 16). Moreover, a series of reported model evaluation metrics indicate that the deep learning can provide satisfactory performance in distinguishing target patients, demonstrating good clinical application (17, 18). A broad application prospect requires additional data science techniques to support, including supervised dimensionality reduction for big data (19), deep learning networks for diabetic retinopathy (20), and identification of malnourished patients (21). the SVM model, postoperative DH, FA, and preoperative LLS were eventually identified as risk factors in unfavorable clinical outcomes at short-term follow-up, whereas only postoperative DH predicted clinical efficacy at long-term follow-up.

A large number of studies have demonstrated the importance of maintaining DH for achieving vertebral stability either in decompression alone or decompression with interbody fusion (3, 9). Our study indicated that the patients that attained a <6-mm DH intraoperatively were more likely to derive a sustained benefit from the decompression with a fusion procedure than the patients reporting poor clinical outcomes. The mean DH was higher in the short-term adverse group (8.11 vs. 7.84), which could be acceptably explained by progressive degeneration at the operated segment. The definition of the pathological change is adjacent segment disease (ASD), which was the condition responsible for half of the reoperations (3, 22, 23). Although PROs suggested that ASD was an unavoidable healthcare concern, we still feel encouraged by a reoperation rate of <1%. Sato et al. reported a reoperation rate of 2.2% in their 1-year follow-up (3), while this incidence reached a staggering 10% in the study by Deyo et al. (24). Furthermore, classifying patients with > 60% improvement in functional evaluation as the definitive efficacy group at 2 weeks postoperatively, we considered 6 mm as an effective threshold associated with clinical outcomes, which was consistent with previous studies (3, 25, 26). Considering the intervertebral space could serve to guide the selection of an interbody fusion cage, a careful fluoroscopic image review after restoring the slipped vertebra is necessary. Interestingly, Yen et al. reported the intradiscal vacuum phenomenon (IVP) occurring after interbody fusion was associated with increased disc height and vertebral instability (27). An intensive biomechanical analysis of this susceptible anatomy seems imperative.

The structure, locating on the posterolateral region of the vertebral body and connecting the adjacent vertebral arch, is the facet joint, which constitutes the classic triple-joint complex with

the intervertebral disc (28). In the current study, outcomes in consecutive patients suggested that increased FA limits functional recovery in the short term without impacting on long-term outcomes. It was worth noting that 5–90% of chronic low back pain was triggered by facet joint pain (29). For symptomatic DLS, lumbar degenerative changes and facet joint misalignments are mutually anatomically predisposing factors (30). Thus, the facet joints, which bear approximately a quarter of the relevant axial load, play an important but neglected role in reflecting the PROs (29), and this was particularly evident in the case of short-term assessments. This variable conceals its function when focusing on and attempting to improve long-term PROs. Assuming FA does not actually worsen surgical outcomes (31), a more convincing association was acknowledged. Due to the local fixation with pedicle screws, the altered facet joint stress accelerated disc degeneration, leading to an additional influence of disc height in predicting long-term outcomes (28). This explanation was also corroborated in this study. The finite element analysis from Park et al. externally verified the homogeneity between DH and FA (32). Moreover, in the current healthcare system, pain management has become an important part of surgical intervention, especially in the treatment of degenerative spinal diseases, and has shown promising results (28, 33–35). Nevertheless, for postoperative patients, pain is a generalized clinical symptom. It is necessary for the spine surgeons to cautiously analyze the etiology of the patient's adverse PROs to achieve precise management.

In general, successful surgery is largely dependent on acquiring a solid fusion and re-establishing normal local sagittal and coronal balance. The short-term postoperative outcome was correlated with preoperative LLS but independent of postoperative LLS. In other words, the difference between the two groups postoperatively was not statistically significant (1.93 vs. 2.24, $p = 0.172$), and measurement of preoperative coronal imbalance was more valuable. The role of sagittal lumbar alignment in assessing disease grade and deciding on individualized surgical strategies was well recognized in published articles (1–3, 7), but coronal malalignment was an equally important issue to be treated with caution (1, 36, 37). Although we identified the presence of LLS preoperatively and targeted the restoration of normal lumbar coronal balance by obtaining greater lumbar lordosis intraoperatively (38), the consideration was reflected in the comparison of postoperative data, but an inferior PRO was still observed. There were several conceivable reasons for the poor outcomes. First, asymmetric degenerative changes lead to disc collapse and laxity of the paravertebral ligaments, manifested by LLS of vertebral body and lateral displacement of the disc (1). This complicated deformity had more severe pathological changes than a mere sagittal imbalance. A limited surgical benefit was observed in DLS with LLS, including an elevated and persistent back pain due to the coronal displacement of the slipped segment (36). Second, purposeful surgical strategies and instruments were recommended to correct vertebral slippage in patients with lateral slippage, including preserving the lumbar lordosis, implanting a larger cage and laterally distracting the displaced vertebral body (1, 39). However, higher restoration requirements were frequently associated with increased risk of major complications, including extensive soft tissue injury and intraoperative blood loss, all of which can reduce short-term PROs (9). Therefore, alleviating the symptoms of DLS with LLS through a modified surgical approach remained a challenge that required an all-out effort to address.

Combining SVM machine learning technique to analyze predictors of short- and long-term adverse clinical outcomes from routinely available variables was the innovation of this study. Ten-fold cross-validation AUC and confusion matrix suggested that our model performed well. However, there were several limitations in our study. First, selection bias may exist

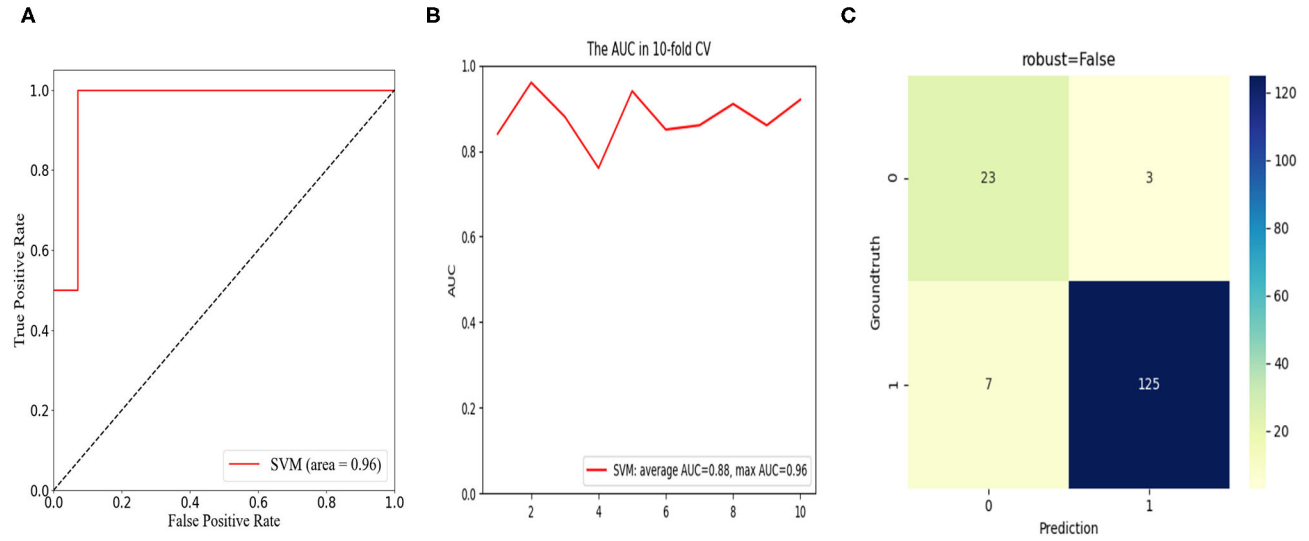

FIGURE 5 | In the short-term cohort, receiver operation characteristic (ROC) curve analysis of the SVM model with the maximum value of 0.96 **(A)**; ROC curve analysis of 10-fold cross validation of the SVM model for predicting the risk of unfavorable clinical outcomes following LIF with average AUC of 0.88 and max AUC of 0.96 **(B)**; confusion matrix of the SVM model **(C)**.

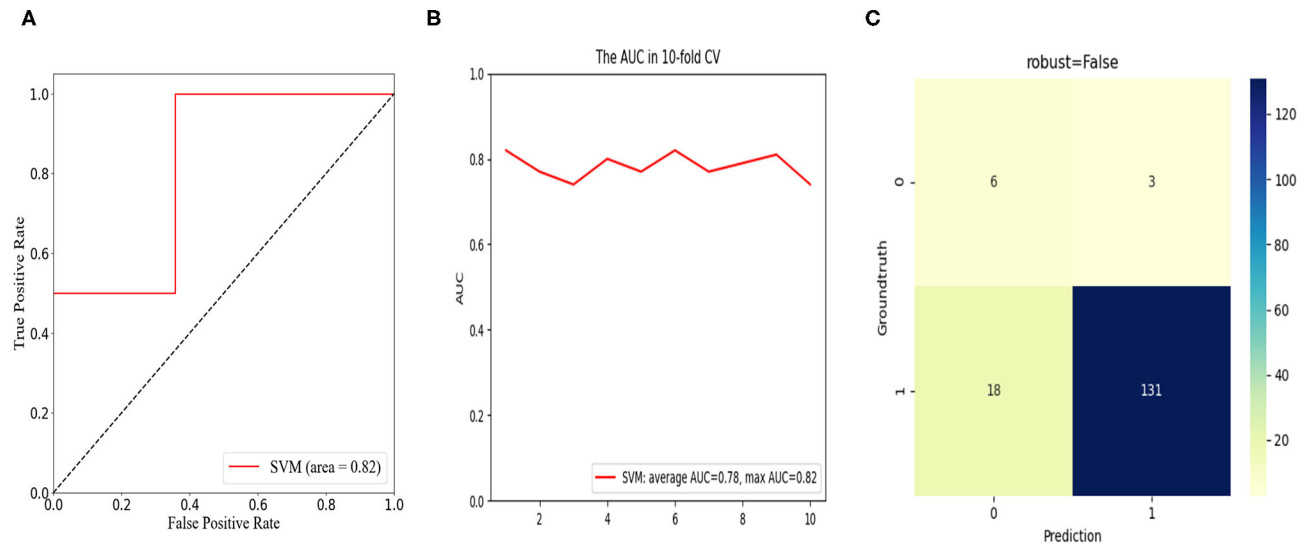

FIGURE 6 | In the long-term cohort, receiver operation characteristic (ROC) curve analysis of the SVM model with the maximum value of 0.82 **(A)**; ROC curve analysis of 10-fold cross validation of the SVM model for predicting the risk of unfavorable clinical outcomes, following LIF with average AUC of 0.78 and max AUC of 0.82 **(B)**; confusion matrix of the SVM model **(C)**.

due to the inherent flaw of retrospective studies. Second, the analyzed data were from our single institution, resulting in a lack of adequate training of the SVM model. Therefore, future studies may require a multicenter prospective randomized controlled design to assist in externally validating the credibility of our conclusion. Finally, despite an attempt to analyze extensive patient information, spinal degeneration is a multidimensional and progressive disease that still left some data unaccounted for.

CONCLUSION

In conclusion, both TLIF and PLIF are practicable surgical strategies to improve symptoms in patients with DLS. Postoperative DH, FA, and preoperative LLS were statistically associated with the short-term clinical outcome, while only postoperative DH accurately predicted the long-term clinical outcome with an average follow-up time

of 1 year. The proposed SVM model showed superior predictive performance.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

ETHICS STATEMENT

The study was approved by an Institutional Ethics Committee at the First Affiliated Hospital of Dalian Medical University. Considering that this work was a retrospective study, the Ethics Committee waived the requirement for informed consent from patients.

AUTHOR CONTRIBUTIONS

SD and YZ completed the study design. SD, YZ, HY, and NT performed the study and collected and analyzed the data. SD, YZ, and GH drafted the manuscript. JL and KT provided the expert consultations and suggestions and conceived the study, participated in its design and coordination, and helped to embellish language. All the authors reviewed the final version of the manuscript.

FUNDING

Alzheimer's disease (AD) is a neurodegenerative disease involving the decline of cognitive ability with illness progresses. At present, the diagnosis of AD mainly depends on the interviews between patients and doctors, which is slow, expensive, and subjective, so it is not a better solution to recognize AD using the currently available neuropsychological examinations and clinical diagnostic criteria. A recent study has indicated the potential of language analysis for AD diagnosis. In this study, we proposed a novel feature purification network that can improve the representation learning of transformer model further. Though transformer has made great progress in generating discriminative features because of its long-distance reasoning ability, there is still room for improvement. There exist many common features that are not indicative of any specific class, and we rule out the influence of common features from traditional features extracted by transformer encoder and can get more discriminative features for classification. We apply this method to improve transformer's performance on three public dementia datasets and get improved classification results markedly. Specifically, the method on Pitt datasets gets state-of-the-art (SOTA) result.

INTRODUCTION

Alzheimer's disease (AD) is a nervous degenerative disease with an insidious and irreversible onset, which is difficult to be detected in every stage. AD can influence patients' daily living ability and social communicate ability and may even lead to disability (1, 2). Researchers have found that AD has a profound impact on patients' language function (3) in addition to mood, attention, memory, movement, and so on. Language is the representation of mental activities, which can clearly reflect the relationship among language, cognition, and communication (4). Language interference is a common manifestation of patients (5) with AD which may even earlier than orientation and memory difficulties (6, 7). Picture description task, taken from Boston Aphasia Diagnostic Test (8), has already been verified sensitive to subtle cognitive deficits (9); therefore, valuable clinical information can be obtained from spontaneous speech to recognize AD. The transcripts of speech can be used to detect AD effectively.

The problem of AD recognition can be regarded as text classification problem in natural language processing (NLP). Deep learning models manifest better in classification as they can extract deep semantic features by effective model architecture automatically. For example, RNN can capture long-term dependencies within sentence, but it may neglect some important local words which may important for classification (10), and CNN can capture local and position-related features (11) but cannot give enough weight to some discriminative or special words. To solve the problem, attention mechanism was introduced. Transformer gives different weights to different words using attention mechanism, the performance of which is better than CNN and RNN. Although transformer has made great progress in producing discriminative features by powerful representation learning, there is still room to improve. There are few studies nowadays in this area to improve representation learning of deep learning. Based on GRL (12–17) in extracting common features which are not discriminative for classification, this paper proposes a novel feature purification method to improve the representation learning of transformer to get a more discriminative feature vector to diagnose AD.

The original transcripts of speech are the description of a picture, which should be comprehensive and integrated for a normal individual. That is to say, the discriminative words or sentences, with relevant and less vague words, should be included. For example, accurate descriptive words, such as "mother", "tap", "the stool is tipping", etc., are usually a better cognitive sign. Words or sentences such as "I do not know", "um", and "pause" should be an indicative of a bad cognitive condition, and they are discriminative for AD recognition. But some equivocal, inconsequential, and even irrelevant descriptions are unhelpful and may even interfere with the final classification, such as "is not that enough?", "It is great", "there may be a little breeze coming in", et al. They can disturb the representation learning of deep learning by producing suboptimal representations. To solve this problem, transformer proposes a self-attention mechanism to give weight to words and usually can get better performance than RNN and CNN. Though attention may alleviate the influence by giving a higher or lower weight for those more or less relevant words, the classification problem cannot be solved properly with inaccurate attention mechanism or specificity of data. To solve the above problems, our study, inspired by the paper (17) which used feature projection method to purify the representation learning of deep learning, proposes a novel feature purification method to improve representation learning of transformer to get more discriminative features, which is GP-Net. It has two subnetworks, a common feature learning network called G-Net and a purification network called P-Net. G-Net uses gradient reverse layer (GRL) (12, 13, 18) to extract common features which are shared by classes and have no or few roles for classification. P-Net first uses transformer encoder to extract traditional feature vector for the sentence. Then, it rules out the common features from traditional feature vector to generate more purified features. It is clear that this operation gets rid of the effect of common features and makes the system only focus on discriminative features. We will explain the principle in Method Section.

The experiments on three datasets with our method get an improved performance which prove that the purified features are more discriminative. To the best of our knowledge, there have been still no studies to recognize AD from spontaneous speech by purifying representation learning of deep learning up to now.

The key contributions we have made in this work include the following:

(1) A whole process of AD screening method, based on linguistic data, was designed and implemented.
(2) We propose a novel feature purification network to improve representation learning of transformer and get state-of-the-art (SOTA) result on Pitt dataset.
(3) The proposed method has the advantage of low cost, reliable, and convenience, which can provide a feasible solution for the screening of AD with a better performance.

RELATED WORK

Existing studies on AD diagnosis across spontaneous speech mainly focus on two aspects. One is feature extraction manually including acoustic features (19–21), linguistic features (22–25), or their combinations (21). This method is subjective and needs more professional knowledge. They are generally associated with a specific task scenario; once the scenario changes, these artificially designed features and prior settings cannot adapt to new scenarios and need to be redesigned, so the model has a low universality. The other is deep learning method which can extract deep semantic features automatically. Based on its powerful representation learning ability, the performance of deep learning is usually better than the first method. Additionally, deep learning improves the generalization ability of the classifiers which can be utilized further in different clinical environments. Deep neural network can process representation learning to extract deep semantic features using cascaded data of multilevel non-linear processing units without the need for feature engineering manually.

AD Detection Based on Deep Learning

There are many studies to detect AD from oral speech with deep learning methods (26–29), such as RNN, long–short-term memory (LSTM) networks [e.g., ELMo (30)] and CNN. Recurrent convolutional neural Networks (RCNN) (31) uses Bi-LSTM to get contextual information and then concedes the hidden output of Bi-LSTM and word embedding for classification. DPCNN (32) is a simple network with 15 layers which likes a deep CNN, and it increases network depth of CNN but does not increase the computational cost. Attention mechanism is used in many NLP tasks such as text classification (33–36). Transformer architecture [e.g., Bert (37)] uses attention mechanism to extract deep semantic features. Enhanced representation through knowledge integration (ERNIE) (38, 39), proposed in 2019 by Baidu corporation, is optimized further based on Bert model. They usually have better performance than CNN, RNN, and LSTM.

Public Dementiabank datasets or ADReSS challenge (40) datasets are often used to recognize AD. For example, Orimaye et al. (41) proposed the combination of deep language models and deep neural network to predict mild cognitive impairment (MCI) and AD. The datasets used were public Dementiabank transcript with 37 healthy elderly and 37 MCI transcripts. The study did not use any handcrafted features; just the original transcripts were fed to the model, and n-gram word embedding method combined with deep neural network (DNN) got a best AUC of 0.83. Different from our dataset and classification, there was no comparability with our method. Karlekar et al. (23) used four types of interviews: story recall, sentence construction, cookie-theft picture description, and vocabulary fluency; the dataset included 243 normal controls and 1,017 AD transcripts. Three classifiers were used for comparison, that is, LSTM-RNN, CNN, and CNN-LSTM, and achieved a best accuracy of 91.1%, but the results were somewhat questionable as mentioned in the Discussion. These methods used deep learning algorithms or their linear combinations to recognize MCI and AD. Our work is much different clearly as none of these existing studies improve representation learning of deep learning by feature purification method.

Studies Related to GRL

Our study is related to some former work. Ganin and Lempitsky (13) first introduced GRL to extract common features which were sentiment-sensitive and domain shared in domain adaptation (DA). It embeds DA to the process of representation learning in order that the final classification result is more discriminative for the domain changes. Though we use GRL to extract common features, we do not use it in the area of DA, and they also do not use for feature purification. Belinkov et al. (14) used adversarial learning to encourage the model to process representation learning on SNLI dataset. Combining with aspect attention and GRL, Kai Zhang et al. (16) studied cross domain text classification problem, and common features across domains were extracted from the aspects for text classifications. The idea of generative adversarial networks (GANs) (42) was used to ensure that the common feature space did not mix with private features and only contained pure task-independent common feature representation. In these studies, they all used GRL to extract common features inseparable for two domains, and domain-shared features were generated in the shared space according to adversarial training, whereas our study is different from them clearly as this existing work does not improve representation learning of the model. The study (17) proposed a feature projection method to further improve representation learning of deep learning from a novel angle. The method projected existing features into the orthogonal space of the common features, so the resulting projection is perpendicular to the space that common features located in and thus more discriminative for text classification. Different from this study (17) which only deletes a section of common features, we rule out the influence of whole common features, which we believe that a better classification performance should be achieved. Also, we did the experiment with the method of study (17) on Pitt dataset, and the performance is not better than our method, just as shown in **Table 1**.

TABLE 1 | Relationship between predicted and true classes.

	True class	
Predicted class	Positive	Negative

Negative	False negative (FN)	True negative (TN)

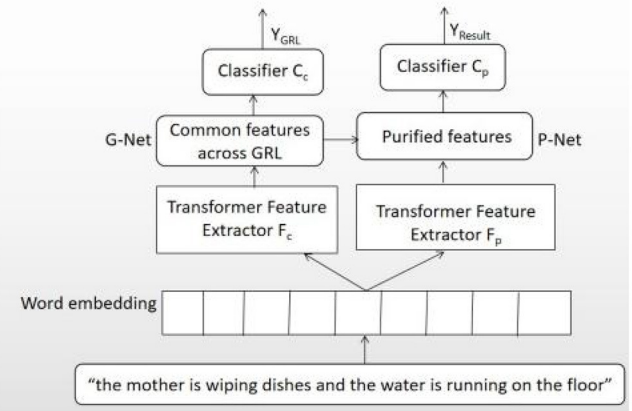

FIGURE 1 | The architecture of GP-Net.

METHODS

In this study, we propose a novel GP-Net framework to recognize AD from normal controls, which is indeed a binary classification problem in NLP.

Feature Purification Network: GP-Net

This paper proposed a novel architecture, named GP-Net, to recognize AD, the network structure of which is shown in **Figure 1**. The whole network includes two sections: G-Net and P-Net. The aim of G-Net is to extract common features by reversing the gradient direction in the training process, and these common features are shared by both classes and have no discriminative for classification. The aim of P-Net is to purify the features further by deleting the common features from traditional features extracted from transformer model. G-Net includes four sections, that is, the input layer X, feature extractor F_c, GRL, and classifier layer C_c. P-Net also includes four sections, which include the input layer X, feature extractor F_p (the features extracted by F_c and F_p have no share parameters), purification network, and classifier layer C_p. The main idea of proposed network is as follows: the feature vector, extracted by the feature extractor F_p, deletes the common features got from G-Net, and then, more discriminative purified features have got for the final classification. Two operations, including G-Net and P-Net, are required in order for feature purification operation.

Transformer Extractor

This study uses transformer encoder as the feature extractor. Transformer is a SOTA model which has a novel architecture to solve sequence to sequence tasks. The model can capture long-distance dependencies and learn global semantic features of input text thoroughly through multihead self-attention mechanism. As transformer has some mechanisms as self-attention and location code, it has excellent feature extraction and semantic abstract competence. Like most Seq2Seq model, transformer model also uses encoder–decoder structure, the encoder of which is a better feature extractor with multihead attention and feed forward neural network.

Supposing G-Net and P-Net have the same input X, the feature extractors of G-Net and P-Net are F_c and F_p, which can get the advanced features f_p and f_c from the input layer, respectively, but there are not any shared parameters between them. We refer to the features of P-Net and G-Net, respectively, as

$$f_p = Transformer_p(X), \tag{1}$$
$$f_c = Transformer_c(X), \tag{2}$$

Additional details of G-Net and P-Net will be introduced in G-Net and P-Net module.

G-Net Module

The main goal of G-Net module is to extract common features among datasets, which is not discriminative for the classification. As common features are those shared by all the classes, the classifier cannot use them to distinguish different classes effectively. To get common features, GRL (12, 13, 18) is added between the feature extractor F_c and the classifier to reverse the gradient direction. The common features that are shared among different classes are obtained after the training module. G_λ can be thought as two incompatible equations that describe the forward and back propagation behaviors:

$$G_\lambda(x) = x, \tag{3}$$
$$\frac{\partial G_\lambda}{\partial x} = -\lambda I, \tag{4}$$

where λ is a hyper parameter. We process feature vector f_c through GRL and get f_c', for example, G_λ (f_c) = f_c'. To make f_c' close to real common features, GRL acts as identity transform during the forward propagation and then takes the gradient from subsequent level and changes the value (i.e., multiplies it by -λ) before passing it to the next layer during back propagation, and this operation can ensure that the feature distributions are similar and as indistinguishable as possible for the classifier. Only in this way we can get the common features sharing among classes. Finally, f_c' is fed to classifier C_c.

$$Y_{GRL} = softmax(W_c^* f_c' + b_c), \tag{5}$$
$$Loss_c = CrossEntropy(Y_{True}, Y_{GRL}), \tag{6}$$

where W_c and b_c are the weight and bias of classifier C_c. By optimizing $Loss_c$, the feature extractor F_c can extract common features of different classes.

P-Net Model

The goal of P-Net is to extract the semantic information from input example first and then purify features for the classification. Supposing the traditional feature vector we extracted by transformer is f_p, the common feature vector is f_c. The final feature vector for classification is f_w.

$$f_w = f_p - f_c, \tag{7}$$

As f_c disturbs the classification result, we delete f_c from f_p to eliminate the influence of nondiscriminative feature vector (i.e., common features), so the feature vector f_w is more discriminative than f_p. Finally, the purification feature vector f_w is fed to classifier C_p.

$$Y_{Result} = soft\ max(W_p * f_w + b_p), \tag{8}$$
$$Loss_p = CrossEntropy(Y_{True}, Y_{Result}), \tag{9}$$

where W_p and b_p are the weight and bias of classifier C_p. By optimizing $Loss_p$, the feature extractor F_p can purify the features, $Loss_c$ and $Loss_p$ are trained simultaneously, but they use different optimizers. $Loss_c$ use moment SGD optimizer because Ganin and Lempitsky (13) also used moment SGD, and $Loss_p$ use Adam optimizer. We also conducted the experiments using Adam optimizer for both G-Net and P-Net and found that the results made no difference when using two different optimizers. In terms of optimization targets of feature extractor F_c, though the two losses are opposite to each other, a balance can be found to make the extracted feature f_c closer to real common features. The algorithm description of the whole training process is shown in **Algorithm 1**:

Algorithm 1 GP-Net

1: Input:
Supposing the datasets are $D = \{(x_i, y_i)\}_{i=1}^N$, x_i is the embedding matrix of deep learning, $X_i \in R^{Lk}$, y_i is the corresponding classes; randomly initialized the parameters of GP-Net.

EXPERIMENT

Datasets

Three datasets are used to carry out the experiments which are all the dialogues of picture description task, including English and Chinese.

Pitt Datasets

This is a Pitt corpus (43) from Dementiabank dataset (43), which comes from a study at School of Medicine in Pittsburgh University and is gathered longitudinally every year. More detailed description about the dataset can refer to the study (43). After deleting some unqualified datasets such as unknown label, memory impairment, and other dementia diagnose, for example, vascular dementia, there are 498 participants enrolled in our study after data preprocessing, which is composed of 242 controls and 256 possible or probable AD. Both categories are balanced basically.

ADReSS Datasets

The datasets include 78 dementia patients and 78 normal controls from ADReSS challenge in 2020. The speech is segmented using a voice activity detect method based on signal energy value. All datasets have already been preprocessed by removing noise.

iFLY Datasets

The Chinese datasets include 111 CTRL and 68 AD, with 60 women and 51 men in CTRL group and 38 women and 30 men in AD group, respectively. More details can refer to the website: http://challenge.xfyun.cn/2019/gamedetail?blockId=978.

Feature Parameters

In the training stage of GP-Net module, a stochastic gradient of 0.9 is used as momentum, and annealing learning rate can be calculated by the following formula:

$$l_p = \frac{l_0}{(1 + \alpha^* p)^\beta} \tag{10}$$

where $l_0 = 0.01$, $\alpha = 10$, $\beta = 0.75$, p is training progress linearly changing from 0 to 1. In Equation (4), the parameter λ is set as [0.05, 0.1, 0.2, 0.4, 0.8, and 1.0]. Transformer encoder is used as the feature extractor, with three blocks and single head specifically.

Experiment Results

For our model, 5-fold cross validation was used for training dataset. The dataset was divided into five parts randomly, of which four parts were used for training, and one part was used for test. We repeat the process five times using different test dataset

TABLE 3 | The result of pre-trained models on Pitt dataset.

Model	Embedding	Classifier	Precision	Recall	Accuracy	F1
BertCNN	Bert	CNN	58.85	56.25	56.25	52.79
BertRCNN	Bert	RCNN	-	50.00	50.00	33.33
BertDPCNN	Bert	DPCNN	41.11	47.92	47.92	35.59
ERNIEDPCNN	ERNIE	DPCNN	-	50.00	50.00	33.33
BertLogistic	Bert	Logistic Regression	88	85	86.20	85.60
Transformer+GP	Transformer	Transformer	94.00	89.00	93.50	91.19

every time. Finally, the results of five times were summarized, and the average value was used as the estimation of model performance index. The classification of our model adopts the following indexes: accuracy, precision, recall, and F1 score are used as the final index (44). The relationship between the actual class and predicted class is shown in **Table 1**, and the evaluate metrics in this study are defined as Equations (11–14).

$$Accuracy = \frac{TN + TP}{TN + FP + FN + TP} \tag{11}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{12}$$

$$\text{Recall Rate} = \frac{TP}{TP + FN} \tag{13}$$

$$F1 - score = \frac{2TP}{2TP + FP + FN} \tag{14}$$

Table 2 is the classification scores for AD and CTRL on Pitt Dementiabank datasets, including handcrafted features extracted methods and deep learning methods. As far as we know, SOTA on Pitt corpus is the study of Roshanzamir et al. (48) in 2021, and our method in this paper performs better than SOTA. Also, transformer+FP[25] is the feature project method for text classification, and we did the experiment with this method on our Pitt datasets; the performance of our method is better than the project method with the same datasets. To further compare with some proposed popular pretrained models in recent years, including Bert (37), ERNIE (38), RCNN (31), and DPCNN (32), we do the comparative experiments with the combination models, including BertRCNN, BertDPCNN, BertLogistic, and ERNIEDPCNN models, which are the combination of Bert + CNN, Bert + RCNN, Bert + DPCNN, Bert + Logistic Regression, and ERNIE + DPCNN, respectively. The former is the feature extractor and the latter is the classifier. The evaluation index is shown in **Table 3**.

From **Table 3**, we can find that the performance of first four models is not better, with an accuracy of only 50% or so, BertLogistic model has a better accuracy of 86.2%, and our method gets the best result than these pretrained models. In the meanwhile, to prove the superior of our method, we also test the method on ADReSS and iFLY datasets. The result is shown in **Table 4**, accuracy is improved by 2.1, 4.3, and 2.1%, respectively, on Pitt, ADReSS, and iFLY dataset, which means that the purified features are more discriminative than the features extracted by transformer encoder. Though we do not get SOTA accuracy on ADReSS and iFLY dataset, the performance of our method is improved than transformer.

TABLE 4 | Accuracy on three datasets.

Model	Pitt	ADReSS	iFLY
Transformer	91.4	74.3	81.6
Transformer+GP	93.5	78.6	83.7

DISCUSSION

Why the performance is better after purification? We know that transformer is superior to RNN, CNN on its long-distance reasoning ability, but it is not easy to understand the deep semantic feature vector extracted by transformer as deep learning is a "black-box." The common features in the study are the vector that cannot differentiate for classification in semantic space. They may be the words or sentences that are unimportant, unmeaningful, and irrelevant that may disturb the final classification. Our original dataset is a dialogue of description. It should include some important people, scenes, and ongoing events in the picture. The study (52) pointed out the seed words of the picture should include the following 23 words: boy, girl, woman, cookie, stool, sink, overflow, fall, window, curtain, plate, cloth, jar, water, cupboard, dish, kitchen, garden, take, wash, reach, attention, and see. The sentences including these words are helpful for the classification. Other unrelated words or sentences such as "Can you tell me", "look, there is no people outside" which are unhelpful words or sentences that cannot distinguish cognitive condition. They are, which we think maybe the common features, unhelpful and may even disturb the final classification. When we rule out these words or sentences (i.e., common features) that disturb the classification, the result can be improved correspondingly. The features extracted manually in this area usually include part-of-speech (POS), fluency, semantic feature, lexical richness, and so on. Now, there is an opinion that the features that deep learning extracted automatically maybe are much like the features that people extract manually, and deleting those unhelpful words for the classification can improve the classification performance.

We know that in transformer model, complexity per layer of self-attention is $O(n^2 * d)$, where d is the representation dimension, and n is the sequence length. Our model includes

two sections, one is transformer encoder, the other is feature purification layer which just multiply (-λ) when running back propagation. Both of them can run concurrently and have the same complexity, so the computational complexity of our model is the same as that of self-attention.

CONCLUSIONS

Nowadays, many medical problems used artificial intelligence method to solve (53, 54). which is low cost and convenient. Two methods, that is, feature extraction manually and automatically by deep learning, are usually used to recognize disease. Features extracted method manually based on machine learning does not generalize well, as it needs many special knowledge and annotation to extract features. Due to high cost of manual annotation, it is not feasible to procure numbers of annotated datasets for most clinical tasks. But deep learning does not need any annotation and can finish the process automatically. This paper combines transformer-based model with a feature purification network to improve the classification performance to a large extent. We pretrain transformer and then fine-tune the model on new datasets to transfer learned knowledge to our text classification task. Our work is obviously different from the former studies in AD recognition because none of the former studies improve representation learning of deep learning in this area, as far as we know. The common features extracted by GRL maybe the words that shared by different classifications, or nonimportant words that have small role for classification, ruling out them from traditional representation vector can improve the performance of the model. In addition, we can develop WeChat procedure or APP in mobile device further in order that the elderly can test their cognitive condition at home. So, large volumes of patient's datasets need to be transferred to central cloud server for data analysis, the safety of which is important, and blockchain technology is a better choice which may ensure the security of medical data (53, 55).

Transformer model is still the most widely used deep learning algorithm, but the time complexity of self-attention is higher, which hinders the development of the model, so the improvement of model efficiency is of great importance in the future. Transformer, as the feature extractor we used in this study, can also be replaced by other deep learning algorithms such as Bert, RNN, CNN, and so on; next, we will perfect the work further. In the meanwhile, we also believe that our feature purification method may predict other diseases that language and cognitive impairment related, such as Parkinson's disease, Aphasia, and Autism spectrum disorder. Aphasia is maybe more pronounced as Aphasia is a disease of the brain tissue associated with language function. Our method provides a feasible solution for detecting patients with AD at the doorsteps. Feature purification method for deep learning, as far as we think, is a promising direction to explore in the future.

DATA AVAILABILITY STATEMENT

The public datasets we used can get from the website: https://sla.talkbank.org/TBB/dementia/English/Pitt, or visit our github website: https://github.com/lzy1012/Public-Pitt-Dementiabank-Dataset.

AUTHOR CONTRIBUTIONS

ZY designed the research. QT analyzed the data and interpreted the analysis. NL and ZY wrote the main manuscript text and revised carefully. All authors reviewed and approved the final manuscript.

FUNDING

This research was funded by grants of Natural Science Foundation of Zhejiang Province (LGF20F020009), Anhui Provincial Natural Science Foundation (No. 2108085QF269), and the 4th Graduate Student Innovation and Entrepreneurship Competition of Hangzhou Normal University.

Background: Clear cell renal cell carcinoma (ccRCC) is expected in the elderly and poor prognosis. We aim to explore prognostic factors of ccRCC in the elderly and construct a nomogram to predict cancer-specific survival (CSS) in elderly patients with ccRCC.

Methods: Clinicopathological information for all elderly patients with ccRCC from 2004 to 2018 was downloaded from the Surveillance, Epidemiology, and End Results (SEER) program. All patients were randomly assigned to a training cohort (70%) or a validation cohort (30%). Univariate and multivariate Cox regression models were used to identify the independent risk factors for CSS. A new nomogram was constructed to predict CSS at 1-, 3-, and 5 years in elderly patients with ccRCC based on independent risk factors. Subsequently, we used the consistency index (C-index), calibration curves, and the area under the receiver operating curve (AUC) and decision curve analysis (DCA) to test the prediction accuracy of the model.

Results: A total of 33,509 elderly patients with ccRCC were enrolled. Univariate and multivariate Cox regression analyses results showed that age, sex, race, marriage, tumor size, histological grade, tumor, nodes, and metastases (TNM) stage, and surgery were independent risk factors for CSS in elderly patients with ccRCC. We constructed a nomogram to predict CSS in elderly patients with ccRCC. The C-index of the training cohort and validation cohort was 0.81 (95% CI: 0.802–0.818) and 0.818 (95% CI: 0.806–0.830), respectively. The AUC of the training cohort and validation cohort also suggested that the prediction model had good accuracy. The calibration curve showed that the observed value of the prediction model was highly consistent with the predicted value. DCA showed good clinical application value of the nomogram.

Conclusion: In this study, we explored prognostic factors in elderly patients with ccRCC. We found that age, sex, marriage, TNM stage, surgery, and tumor size were independent

risk factors for CSS. We constructed a new nomogram to predict CSS in elderly patients with ccRCC with good accuracy and reliability, providing clinical guidance for patients and physicians.

Keywords: nomogram, clear cell renal cell carcinoma, cancer-specific survival, elderly patients, SEER

INTRODUCTION

Renal cell carcinoma (RCC) is a malignant tumor originating from renal tubular epithelial cells. More than 400,000 cases are diagnosed each year, and RCC incidence is about twice as high in men as in women (1, 2). There are several major pathological subtypes of RCC, of which clear cell renal cell carcinoma (ccRCC) accounts for 70–80%, with papillary renal cell carcinoma (PRCC) and chromophobe renal cell carcinoma (CRCC) remaining (3, 4). ccRCC is characterized by rich glycogen and lipids in cells and is manifested as chromosomal 3p deletion and genomic mutation in Von Hippel-Lindau (VHL) tumor suppressor allele (5). Although ccRCC is a disease that can be cured by early surgery, such as radical nephrectomy (RN), partial nephrectomy (PN), and local tumor excision represented by radiofrequency ablation (RFA), recurrence and metastasis occur in up to one-third of cases (6). Moreover, these metastases often suggest poor prognosis, which makes the prognosis of ccRCC significantly different from that of other RCCs (7).

Age is a significant risk factor for cancer. With the increase of age, the probability of cell mutation caused by molecular changes also increases, and cell mutation is generally considered the initiation event of cancer (8). The elderly over 65 years old account for more than 75% of the diagnosed patients with ccRCC. With the aging population and the extension of life expectancy, the incidence rate of renal cancer in the elderly is still increasing year by year (2).

Unfortunately, until today, studies on genetics (9), molecular structure (10), and clinicopathological features (11) have not been able to predict the clinical outcome and prognosis of ccRCC patients accurately. Accurate prediction is crucial in clinical decision-making, patient confidence building, and medical care improvement. In recent years, the application of nomogram prediction models, such as UISS (12), the Stage, Size, Grade, and Necrosis (SSIGN) (13), and Leibovich (14), in the prognosis of cancer patients provides clinicians with a basis for precise and individualized treatment of various cancer patients.

At present, artificial intelligence has been widely used in human health. Awais et al. (15) used texture analysis techniques in fluorescence imaging to help dentists identify areas of oncogenic cavity abnormalities in the oral cavity, and thus, perform biopsies more efficiently to predict the histological diagnosis of epithelial dysplasia. Shah et al. (16) used machine learning to detect the condition and risk of cardiac arrest early to improve survival in patients with heart disease.

However, to our knowledge, no predictive model for cancer-specific survival (CSS) of elderly ccRCC has been reported. Moreover, the prognostic factors of survival in elderly patients with ccRCC remain unclear. We used big data from the Surveillance, Epidemiology, and End Results (SEER) program for the first time to explore factors influencing CSS in elderly patients with ccRCC. Based on the above situation, we developed the nomogram prediction model. We validated its accuracy in evaluating the CSS rate of patients with ccRCC, providing a reference for clinical diagnosis and treatment.

PATIENTS AND METHODS

Data Source and Data Extraction

We downloaded clinicopathological information for all elderly patients with ccRCC from 2004 to 2018 from the SEER program of the National Cancer Institute. SEER database is the National cancer database of the United States, covering about 30% of the population and containing 18 cancer registries. Demographic information, clinicopathological information, and follow-up data for all cancer patients are publicly available from the SEER database. Because patient data are publicly available and cannot be identified, our study needs not require ethical approval or informed consent from patients. Our research methods comply with the regulations of the SEER database.

All the demographic information of ccRCC in elderly patients (age, sex, race, year of diagnosis, and marriage), clinical pathologic information (laterality, tumor size, histological grade, and tumor, nodes, and metastases [TNM] stage), treatment (surgery, radiation therapy, and chemotherapy), follow-up information (survival status, survival time, and the cause of death) were collected. Inclusion criteria were as follows: (1) pathological diagnosis of ccRCC (International Classification of Diseases for Oncology [ICD-O]-3 codes, 8310); (2) age $\geq$65; (3) the years of diagnosis were 2004–2018; and (4) unilateral renal tumor. Exclusion criteria were as follows:(1) tumor histological grade is unknown; (2) tumor size is unknown; (3) unknown surgical method; (4) survival time <1 month; and (5) incomplete follow-up information. The patient screening flow chart is shown in **Figure 1**.

The patients' race was divided into three categories: white, black, and others (American Indian/AK Native, Asian/Pacific Islander). Patients were divided into years of diagnosis from 2004 to 2010 and 2011 to 2018. The patient's tumor histological grades included grade I (well-differentiated), grade II (moderately differentiated), grade III (poorly differentiated), and grade IV (undifferentiated). Patients were classified as non-operative (SEER Operation Code 0), local tumor excision (SEER Operation Code 10-27), PN (SEER Operation Code 30), and RN (SEER Operation Code 40-80).

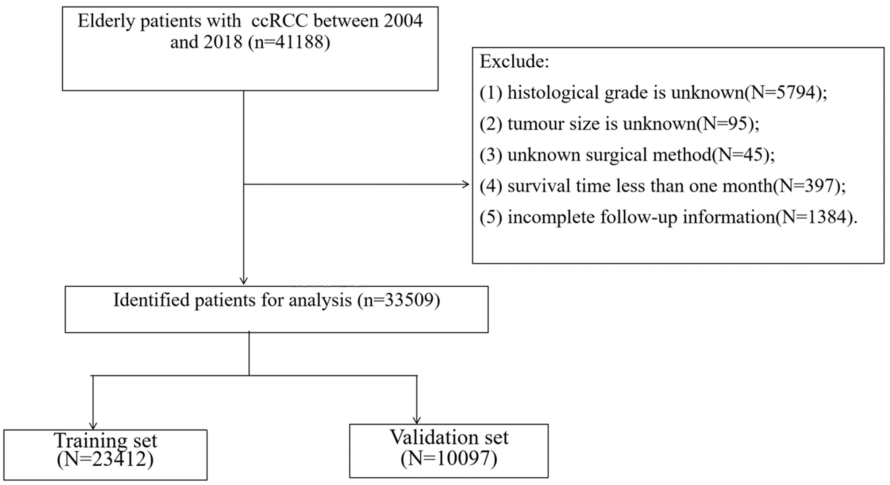

FIGURE 1 | Flowchart for inclusion and exclusion of all patients.

Univariate and Multivariate Cox Regression Analyses

All elderly patients with ccRCC were randomly assigned to a training cohort (70%) or a validation cohort (30%). All variables that might be associated with patient outcomes were included in the analysis. Univariate Cox regression models were used in the training cohort to analyze risk factors associated with in patients with CSS. According to univariate Cox regression analysis, a multivariate Cox regression model was established to identify the independent risk factors for CSS.

Construction of Nomogram

The establishment of the nomogram mainly relies on the multivariate Cox regression model. We developed a new nomogram to predict CSS at 1-, 3-, and 5 years in elderly patients with ccRCC based on independent risk factors for univariate and multivariate screening. Because these independent risk factors are predictors of patient outcomes.

Validation of Nomogram

Subsequently, we used the consistency index (C-index) to test the accuracy and discrimination of the prediction model in the training cohort and validation cohort. Calibration curves of 1,000 bootstrap samples were used to test the accuracy of the prediction model. The area under the receiver operating curve (AUC) was used to test the model's prediction accuracy at 1-, 3-, and 5 years.

Clinical Utility

We used the decision analysis curve (DCA) to validate the clinical potential of the predictive model. DCA is a new algorithm for calculating net benefit under different thresholds and is currently most commonly used to evaluate the clinical application value of models. In addition, we divided patients into high-risk and low-risk groups based on each patient's nomogram score and cutoff values determined by the receiver operating curve. Log-rank test and Kaplan-Meier (K-M) curve were used to compare the survival difference between the two groups. In addition, we analyzed surgical differences between high-risk and low-risk patients based on risk grouping.

Statistical Analysis

Continuous measurement data were described by means and variance, and comparison between groups was performed by Chi-square test or non-parametric *U* test. Count data were characterized by frequency (%), and a chi-square test was used to compare groups. Univariate and multivariate Cox proportional regression models analyzed the survival and prognostic factors. Log-rank test and Kaplan-Meier (K-M) curve were used to analyze the survival differences between the patients. SPSS 26.0 and R Software 4.1.0 were used for all statistical analyses. Values of $p < 0.05$ were considered statistically significant.

RESULTS

Clinical Features

A total of 33,509 elderly patients with ccRCC were enrolled. All patients were randomly divided into the training cohort (N = 23,412) and the validation cohort (N = 10,097). The mean age of all patients was 72.7 ± 5.91 years, 29,034 (86.6%) white, 20,201 (60.3%) men, and 21,239 (63.4%) married. Among all patients, there were 16,447 (49.1%) tumors on the left side, 4,077 (12.2%) tumors at grade I, 17,480 (52.2%) tumors at grade II, 9,595 (28.6%) tumors at grade III, and 2,357 (7.03%) tumors at grade IV. The mean tumor size was 51.8 ± 32.3 mm, the T stage T1a had 14,019 (41.8%), T1b had 8,063 (24.1%), T2 had 2,987 (8.91%), T3 had 8,370 (25.0%), and T4 had 70 (0.21%). There were 32,620 (97.3%) patients in stage N0 and 31,320 (93.5%) patients in stage M0. There were 1,227 (3.66%) patients without surgery, 1,718 (5.13%) patients with local tumor excision, 8,791 (26.2%) patients with PN, and 21,773 (65.0%) patients with RN. There were 1,505 (4.49%) patients who received chemotherapy and 640 (1.91%) patients who received radiotherapy. The clinicopathological

information of the patients is shown in **Table 1**, and there was no significant difference between the training cohort and the validation cohort.

Univariate and Multivariate Cox Regression Analyses

Univariate Cox regression model was used to analyze all variables to screen for variables associated with CSS in elderly patients with ccRCC. Age, sex, race, marriage, year of diagnosis, tumor size, histological grade, TNM stage, and surgery were prognostic factors related to patient survival. We included these factors in a multivariate Cox regression analysis. We found that age, sex, race, marriage, tumor size, histological grade, TNM stage, and surgery were independent risk factors for CSS in elderly patients with ccRCC. In other words, these independent risk factors can be used as factors in predictive models to predict CSS of the patients. The univariate and multivariate analyses results are shown in **Table 2**.

Nomogram Construction for 1-, 3-, and 5-Year CSS

We constructed a nomogram to predict CSS in elderly patients with ccRCC (**Figure 2**). Tumor size was the most significant risk factor for in patients with CSS, as shown in the nomogram. The larger the tumor, the higher the patient's risk of death. Second, surgery is the second most important factor affecting patient survival. Survival was most increased in patients with PN, followed by RN and local tumor excision and was lowest in patients who did not undergo surgery. Tumor TNM stage and histological tumor grade are important risk factors for patient prognosis. Patients with higher TNM stage or histological grade had lower survival rates. In addition, the age of the patients was also a key factor; the older the patient, the greater the risk of death. Finally, married patients, women, and other races had a relatively high survival rate.

Validation of the Nomogram

In the training cohort and validation cohort, we first use the C-index to validate the accuracy of the nomogram. The C-index of the training cohort and validation cohort was 0.81 (95% CI: 0.802–0.818) and 0.818 (95% CI: 0.806–0.830), respectively, indicating the accuracy and discrimination of the nomogram. In the training cohort and validation cohort, the calibration curve showed that the observed value of the prediction model was highly consistent with the predicted value, proving that the prediction model had good accuracy (**Figure 3**). The AUC of the training cohort and validation cohort also suggested that the prediction model had good accuracy (**Figure 4**). In the training cohort, the AUC of the prediction model was 86.8 (95% CI, 85.5–88.0), 84.8 (95% CI, 83.8–85.9), and 82.8 (95% CI, 80.8–84.8) in 1-, 3-, and 5 years, respectively. In the validation cohort, the AUC of the prediction model was 86.0 (95% CI, 84.0–88.0), 85.0 (95% CI, 83.5–86.4), and 83.3 (95% CI, 81.6–85.0), respectively.

Clinical Application of the Nomogram

Decision curve analysis showed a good clinical application value (**Figure 5**). Moreover, DCA results showed that the DCA of the nomogram was significantly superior to the traditional TNM staging system in predicting patient survival. We divided the patients into the high-risk group (overall score ≤67.9) and the low-risk group (overall score > 67.9). The K-M curve showed that in the training cohort and validation cohort, the survival rate of patients in the high-risk group was significantly lower than that in the low-risk group (**Figure 6**). The 1-, 3-, and 5 years survival rates in high-risk group were 0.920 (95% CI, 0.916–0.924), 0.808 (95% CI, 0.802–0.815), and 0.732 (95% CI, 0.724–0.740), respectively. The 1-, 3-, and 5 years survival rates in the low-risk group were 0.992 (95% CI, 0.991–0.994), 0.976 (95% CI, 0.973–0.979), and 0.954 (95% CI, 0.950–0.957), respectively. Based on their risk grouping, we analyzed surgical options for patients in the low-risk and high-risk groups. In the low-risk group, we found that all patients received surgical treatment, and most

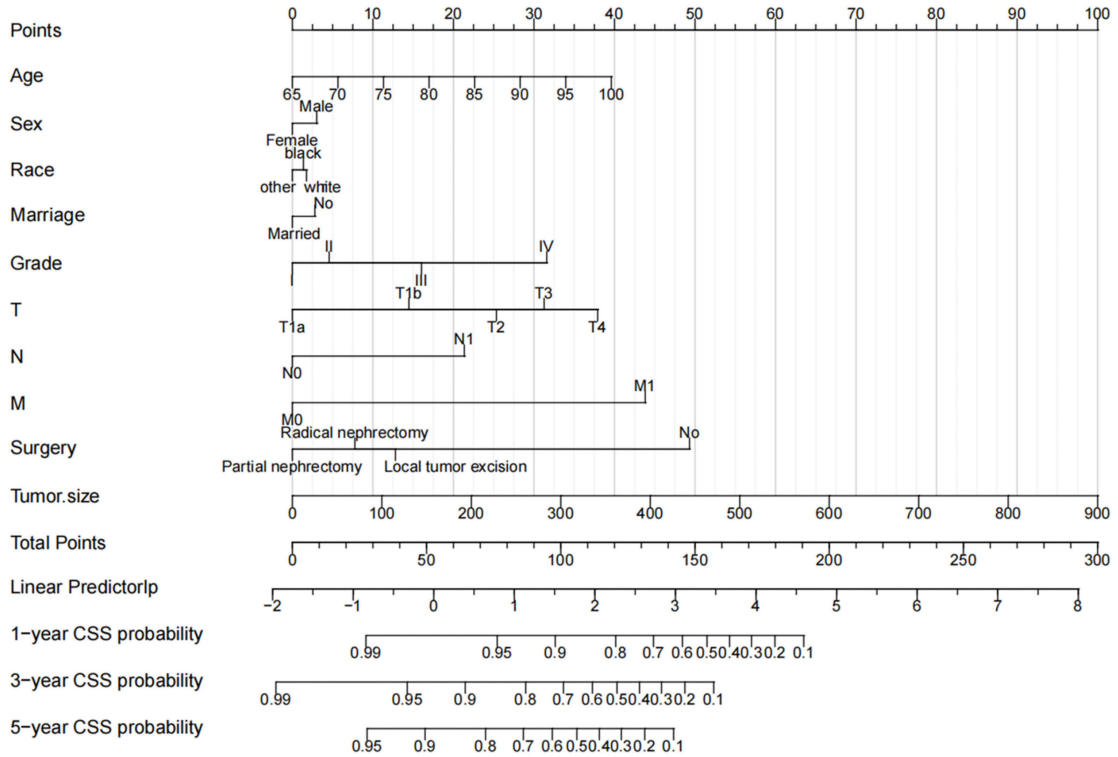

FIGURE 2 | The nomogram predicts CSS in elderly patients with ccRCC at 1-, 3-, and 5 years. CSS, cancer-specific survival; ccRCC, clear cell renal cell carcinoma.

patients received RN and PN, with significantly higher survival rates than local tumor excision. In the high-risk group, most patients who underwent RN had significantly higher survival rates than those who did not, with the highest survival rates among patients who underwent PN and local tumor excision (**Figure 7**).

Online Application of Nomogram

Based on our established programs, we developed a web application to predict 1-, 3-, 5 years CSS in elderly patients with ccRCC. Log on to https://liujiayan.shinyapps.io/DynNomapp/ can enter the website. The survival probability of patients can be obtained by inputting clinicopathological information of patients.

DISCUSSION

Renal cell carcinoma accounts for about 2% of all cancer diagnoses and deaths worldwide, with a higher incidence in developed countries and a severe burden on economic development. RCC is one of the top ten malignant tumors threatening human health (17). CcRCC is a category of RCC with a poor prognosis (7), and its risk factors are controversial. For example, Faramawi et al. (18) found that red meat consumption was an independent risk factor for the prognosis of ccRCC through meta-analysis, while Eun et al. (19) proved no clear correlation through 13 prospective studies. Similar conclusions also appeared when alcohol consumption (20) and exercise (21) were considered risk factors. Therefore, it is crucial to analyze and screen out specific risk factors, establish a predictive model, and accurately predict the prognosis of ccRCC patients.

Age is a critical factor in the occurrence and development of cancer, and so is ccRCC. With age, the probability of genetic mutations leading to cancer also increases. Aging is associated with highly reproducible DNA methylation changes, which helps to explain the higher prevalence of malignant tumors in the elderly (22). There is no consensus on defining the age of elderly patients, but more than 60% of initial cancer diagnoses and more than 70% of cancer deaths occur in patients over 65 years old (8). To improve the accuracy and representativeness of the prediction model, we included patients with ccRCC over 65 years old in this study. It is worth noting that newly diagnosed cases of ccRCC in the elderly are still mainly manifested by renal masses (8), and these masses usually show low-grade malignancy. However, clinicians mostly choose RN to avoid the poor prognosis caused by tumor metastasis, while such excessive treatment leads to more complications and even death in elderly patients (23, 24) and again highlights the crucial clinical value of this study.

Several studies have shown that married patients have increased cancer relative survival, even for untreated tumors (25–27). It may be related to the emotion of marriage and decision-making of medical treatment. Perini et al. (28) found

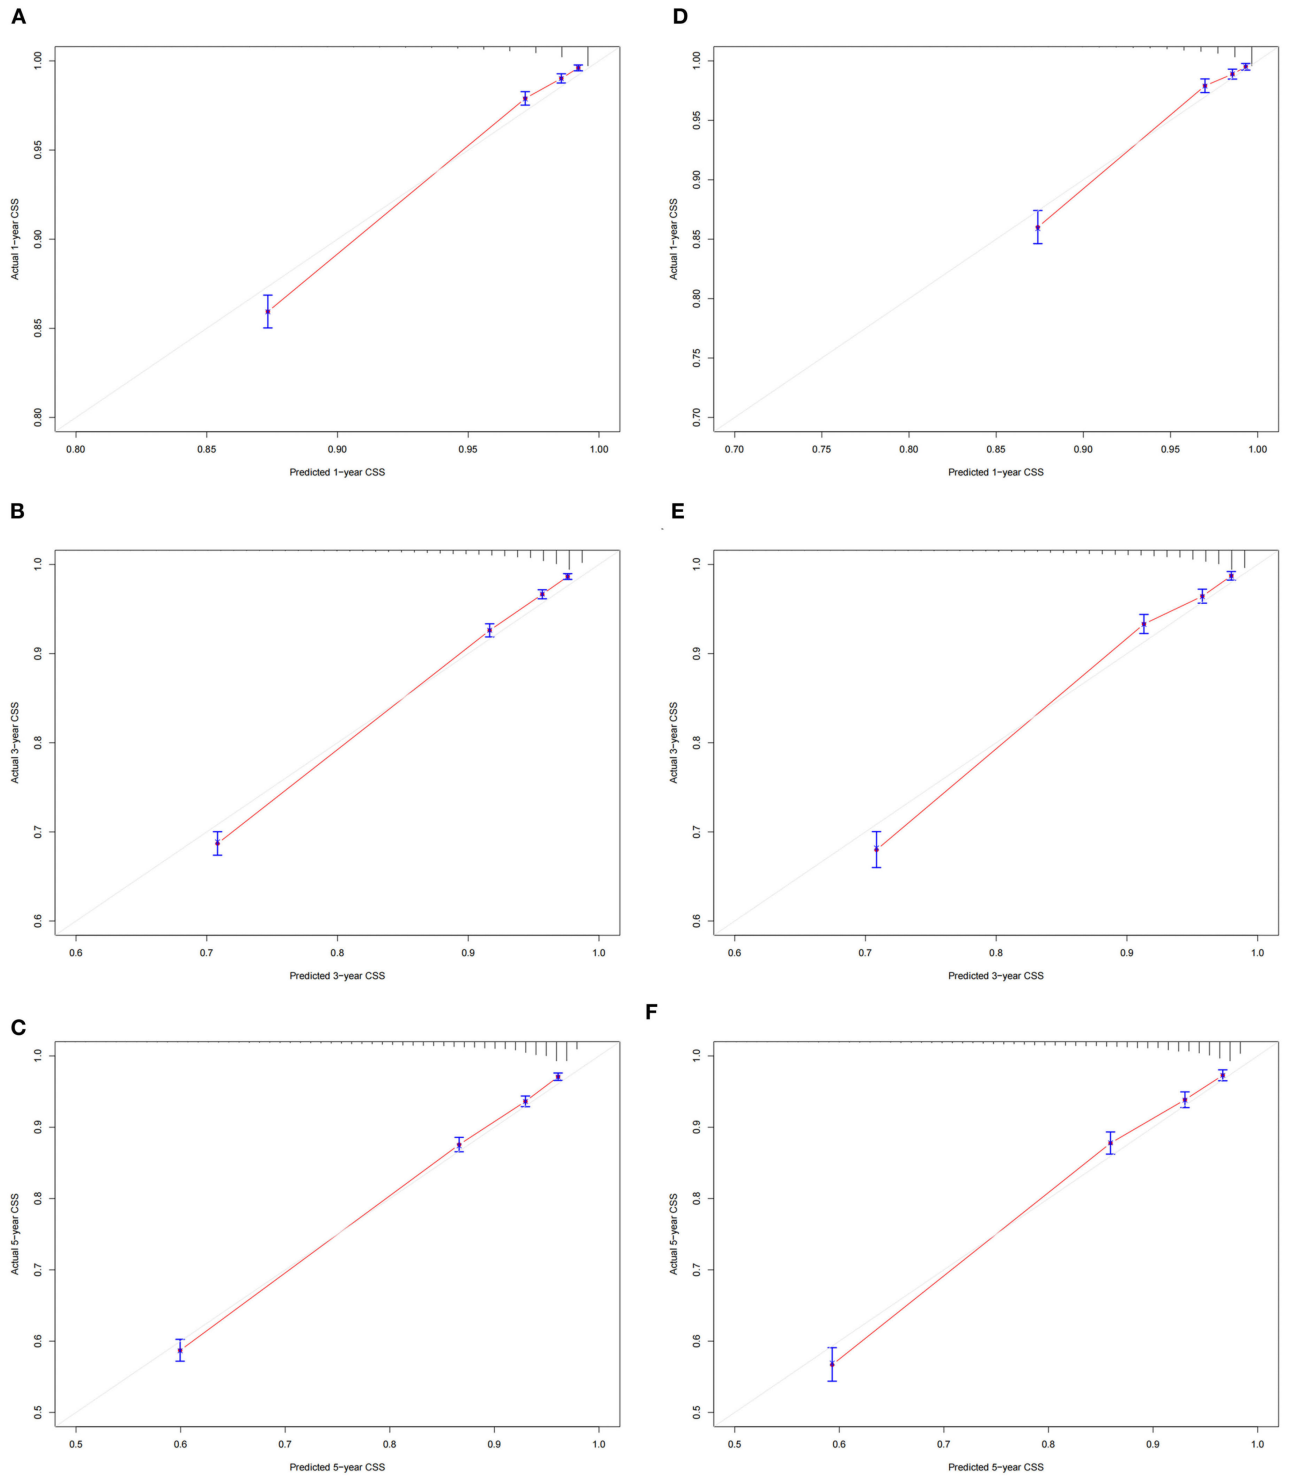

FIGURE 3 | Calibration curve of the nomogram. **(A–C)** Calibration curves of 1 -, 3 -, and 5 years CSS in the training cohort; **(D–F)** calibration curves of 1-, 3-, and 5 years CSS in the validation cohort. CSS, cancer-specific survival.

that depression was a risk factor for the low survival rate of cancer patients, while John et al. (29) found that the incidence of depression in men after marriage was significantly lower than that before marriage, which provided strong evidence for emotional factors. In addition, married cancer patients can detect physical abnormalities early and actively cooperate with

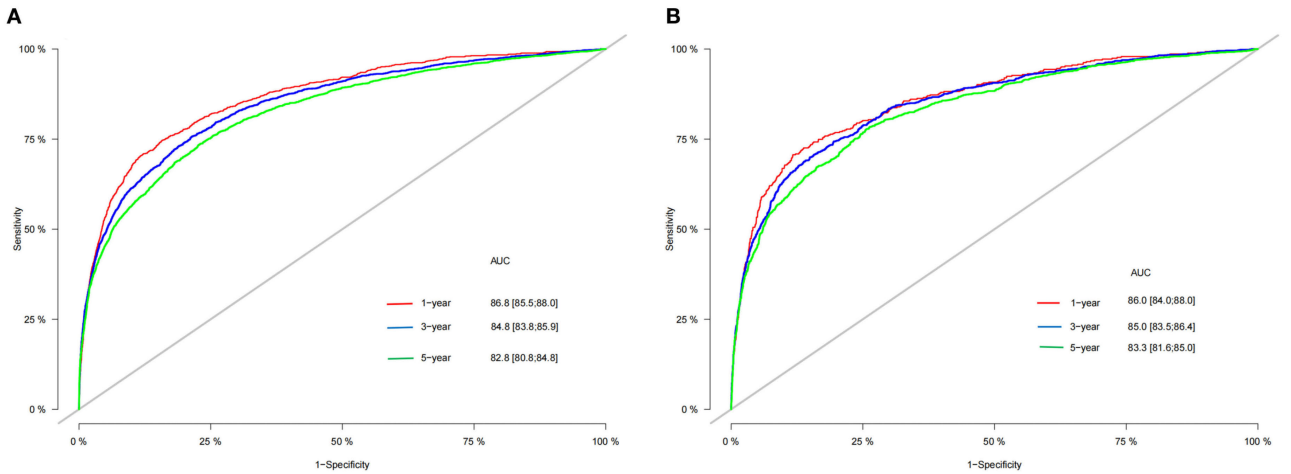

FIGURE 4 | AUC for predicting 1-, 3-, and 5 years CSS in training cohort **(A)** and validation cohort **(B)**. CSS, cancer-specific survival; AUC, area under the receiver operator curve.

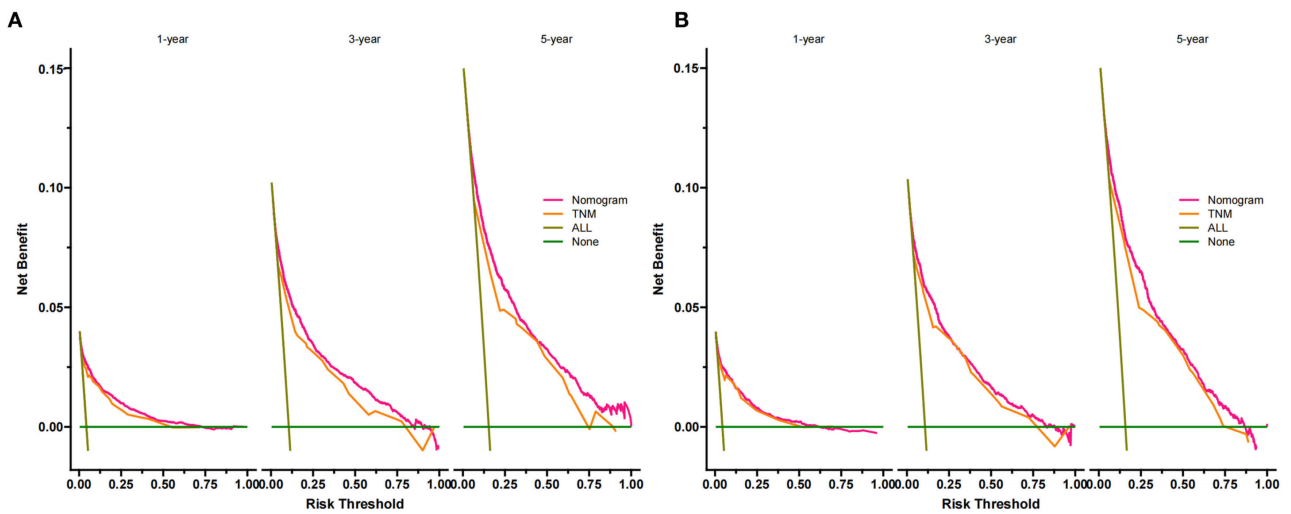

FIGURE 5 | DCA of the nomogram in the training cohort **(A)** and the validation cohort **(B)**. The Y-axis represents a net benefit, and the X-axis represents threshold probability. The green line means no patients died, and the dark green line means all patients died. When the threshold probability is between 0 and 100%, the net benefit of the model exceeds all deaths or none. DCA, decision curve analysis.

treatment, possibly out of the responsibility to the family after marriage (30). In conclusion, married patients showed significant improvement in RR compared with unmarried patients for cancer with a relatively low degree of malignancy, such as patients with ccRCC included in this study. Marriage is not beneficial for highly malignant cancers, such as pancreatic cancer and renal malignant rhabdomyoma tumor (31, 32).

On average, two individuals of the same sex are more than 99.9% alike. However, the genetic similarity between male and female individuals is only 98.5%(33). According to data from the SEER database, men tend to be diagnosed with RCC with higher stage and grade than women (34). Based on data analysis from the Multicenter Society for Renal Oncology Collaborative Study (CORONA) database, women's CSS (hazard ratio [HR] 0.75, $p < 0.001$) and overall survival (OS) (HR 0.80, $p < 0.001$) were significantly better than those of men (35). In this study, the prognosis of female patients with ccRCC was also substantially better than that of male patients (HR: 0.834, 95% CI: 0.796–0.874, $p < 0.001$).

Classical RN involves removing the kidney, perirenal adipose tissue, adrenal gland, and local lymph nodes. It became the preferred treatment for ccRCC for some time. However, the massive loss of nephron caused by surgery can induce chronic kidney disease and cause death (36). Nevertheless, PN can preserve normal nephron to the maximum extent and is widely used in ccRCC cases with tumor sizes <7 cm in length. Nowadays, the biggest challenge for PN is to avoid positive excision margin and reduce postoperative complications, such

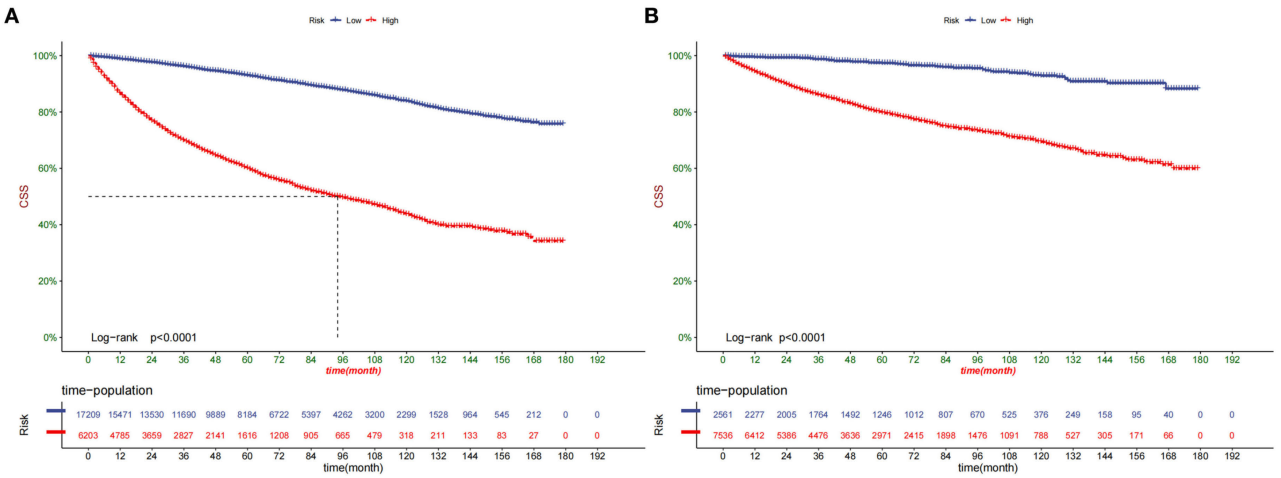

FIGURE 6 | Kaplan-Meier curves of patients in the low-risk and high-risk groups in training cohort **(A)** and validation cohort **(B)**.

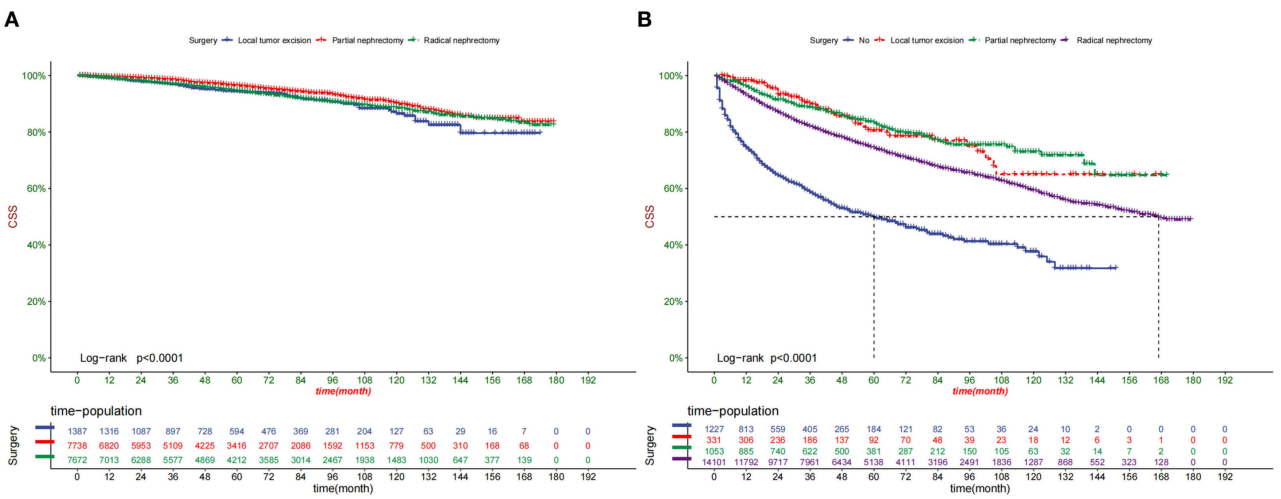

FIGURE 7 | Kaplan-Meier curves of patients with different surgery in the low-risk group **(A)** and high-risk group **(B)**.

as hematuria, perirenal hematoma, and urinary fistula (37). Local tumor excision and active monitoring (AS) represented by RFA have been widely used in elderly patients and achieved good results due to contraindicated comorbidity and short-life expectancy. In a meta-analysis of case studies, Dib et al. (38) showed that cryoablation and RFA efficacy were 89 and 90%, respectively. In addition, RFA and other treatments can be operated under the guidance of ultrasound or CT positioning, effectively avoiding the damage of anesthetics to the heart, liver, and other organs of the elderly. Nevertheless, the surgical recurrence rate of local tumor resection is much higher than that of RN and PN (37). This study found that low-risk patients were more likely to benefit from PN and RN, while high-risk patients were more likely to benefit from PN and local tumor excision.

TNM staging of RCC was based on the 2021 European Association of Urology (EAU) updated criteria (39). The Fuhrman grading system was adopted for tumor classification. According to WHO recommendations, grade I was defined as well differentiated, grade II as moderately differentiated, grade III as poorly differentiated, and grade IV as undifferentiated (36). We found that high TNM staging and histologic grade were associated with poor prognosis, which is consistent with the conclusions of previous studies (40).

In recent years, the broad application of the nomogram prediction model has gradually replaced the traditional TNM staging. First, the c-index of traditional TMN staging for prognosis prediction is about 0.6, which is relatively inaccurate. Second, the prognosis of patients is also affected by many non-anatomic factors, such as age, gender, race, marital status, and surgical methods (41). However, the C-index of this study is 0.81, which is of higher accuracy than the traditional TNM system. Nomogram is a data-based graphical computing tool that can estimate the risk of developing a disease based on staging systems, such as the American Joint Commission on Cancer (AJCC) and

other key risk factors related to prognosis (42). Today, many kinds of nomograms have been developed and applied to RCC, such as Chen et al. (43), who included 6,105 elderly patients with metastatic RCC in the SEER database from 2010 to 2015, indicating the advantages of PN in elderly mRCC. Michele et al. (44) included 4,541 patients with RCC over 75 years of age in the SEER database from 2004 to 2014 and proved that PN did not increase the mortality of elderly patients. With the update of the SEER database and the improvement of patients' clinical information, this study included 33,509 elderly CCRCC patients from 2004 to 2018, which was superior to previous studies on elderly RCC in terms of the number of cases and c-index accuracy.

Still, there are some limitations to our study. First of all, our study was retrospective, and selection bias was inevitable. Secondly, some variables, such as patients' body mass index (BMI), smoking, drinking, heart disease, and other data cannot be obtained from the SEER database. However, we included significant variables, such as tumor stage, surgery, age, and other vital factors. Finally, our prediction model is only validated internally, and further external validation is necessary to validate the model's accuracy.

CONCLUSION

In this study, we explored prognostic factors in elderly patients with ccRCC. We found that age, sex, marriage, TNM stage, surgery, and tumor size were independent risk factors for CSS. We constructed a new nomogram to predict CSS in elderly patients with ccRCC with good accuracy and reliability, providing clinical guidance for patients and physicians.

DATA AVAILABILITY STATEMENT

The data analyzed in this study was obtained from the Surveillance, Epidemiology, and End Results (SEER) Program, the following licenses/restrictions apply: To request access to the SEER Incidence Databases, you will first need to create a SEER*Stat Account and submit a request form. Requests to access these datasets should be directed to: https://service.cancer.gov/seer-data-access. For questions regarding the data access request process, send an email to SEERDataAccess@mail.nih.gov.

ETHICS STATEMENT

Ethical review and approval was not required for the study on human participants in accordance with the local legislation and institutional requirements. Written informed consent from the patients/ participants or patients/participants' legal guardian/next of kin was not required to participate in this study in accordance with the national legislation and the institutional requirements.

AUTHOR CONTRIBUTIONS

JW and CZ designed the study. CZ, JW, JL, LJ, ML, and XT collected and analyzed the data. JW drafted the initial manuscript. CZ, TM, JL, ZZ, and DH revised the article critically. CZ, JL, DH, LJ, and XT reviewed and edited the article. All authors approved the final manuscript.

This study was to explore the application of MRI based on artificial intelligence technology combined with neuropsychological assessment to the cognitive impairment of patients with neurological cerebrovascular diseases. A total of 176 patients were divided into a control group, a vascular cognitive impairment non-dementia (VCIND) group, a vascular dementia (VD) group, and an Alzheimer's disease (AD) group. All patients underwent MRI and neuropsychological evaluation and examination, and an improved fuzzy C-means (FCM) clustering algorithm was proposed for MRI processing. It was found that the segmentation accuracy (SA) and similarity (KI) data of the improved FCM algorithm used in this study were higher than those of the standard FCM algorithm, bias-corrected FCM (BCFCM) algorithm, and rough FCM (RFCM) algorithm ($p < 0.05$). In the activities of daily living (ADL), the values in the VCIND group (23.55 ± 6.12) and the VD group (28.56 ± 3.1) were higher than that in the control group (19.17 ± 3.67), so the hippocampal volume was negatively correlated with the ADL ($r = -0.872$, $p < 0.01$). In the VCIND group (52.4%), VD group (31%), and AD group (26.1%), the proportion of patients with the lacunar infarction distributed on both sides of the brain and the number of multiple cerebral infarction lesions (76.2, 71.4, and 71.7%, respectively) were significantly higher than those in the control group (23.9 and 50%). In short, the improved FCM algorithm showed a higher segmentation effect and SA for MRI of neurological cerebrovascular disease. In addition, the distribution, number, white matter lesions, and hippocampal volume of lacunar cerebral infarction were related to the cognitive impairment of patients with cerebrovascular diseases.

INTRODUCTION

Cerebrovascular disease is one of the main factors to cause vascular cognitive impairment (VCI) (1, 2). With the aging of current society, the incidence of cerebrovascular disease and VCI has increased significantly, ranking second only to Alzheimer's disease (AD), and is an important cause of the cognitive decline in the elderly (3). VCI is a common clinical type. It is the same as other cognitive diseases, and its clinical characteristics are gait, mood, behavior, and urination disorders (4). When the early cognitive impairment occurs, the condition will be mild so that it will often be ignored by others. When it develops into a disorder or even dementia, it is already too late and is not easy to diagnose and treat (5, 6). Therefore, it is very important to detect and find the vascular dysfunction as early as possible.

At present, the diagnosis of VCI is mainly based on the neuropsychological assessment to measure the cognitive function of the patients and to determine the relationship between cognitive impairment and brain disease. If the computer MRI is used as an auxiliary diagnostic method, the diagnosis results will be more reliable (7). With the continuous increase in the breadth and depth of clinical applications of medical images, medical images have become one of the important research directions in medical image processing. The technical difficulty of the brain MRI segmentation is mainly reflected in the following aspects. (1) Due to the principle and technical limitations of MRI and the influence of various factors in the image acquisition process, the image has partial volume effects, field offset effects, noise, motion artifacts, etc. (8, 9). (2) The tissue structure of the brain is complex. Normal tissues in the brain MRI mainly include the cerebral cortex, gray matter, white matter, cerebrospinal fluid, etc.; and the diseased tissues mainly include tumors, edema, and necrosis and cystic transformation within the tumors, and each type of tissue structure is newly transmitted and complex. (3) The space occupation, new transmission, and size of intracranial lesions are uncertain; the gray distribution between different soft tissues or between the diseased tissue and the soft tissue is uneven; and the density distribution is aliased, which is very convenient and very fuzzy. (4) There are big differences in the organizational results of different individuals, even the same person at different ages will have great differences (10–12). Therefore, the automatic segmentation technology using brain tissue MRI plays an important role in the diagnosis and treatment of brain diseases. MRI is the most widely used technique in radio imaging. As a dynamic and flexible technique, MRI can use different parameters for imaging, including longitudinal relaxation time (T1), lateral relaxation time (T2), T1 weighting imaging (T1WI), T2 weighting imaging (T2WI), etc. (13, 14). The imaging of these different parameters can effectively use brain MRI segmentation. Therefore, this study adopts an improved fuzzy C-means (FCM) clustering algorithm to overcome the shortcomings of FCM itself. The clustering-based segmentation method is used to divide the image pixels into several categories according to their similarity. The distance between different individuals and the distance between classes are larger, and the distance between individuals of the same class is smaller. FCM assigns each pixel to each type of organization with a different degree of membership and then has a certain criterion to uniquely divide each pixel into a certain type of organization to obtain the result of segmentation (15, 16).

Therefore, the relevant case data and MRI data of the patients in the Department of Neurology and Physical Examination, Changzhi People's Hospital are selected. In this study, lacunar cerebral infarction, white matter lesions, and hippocampal volume of patients with neurological cerebrovascular disease were studied. Through MRI based on artificial intelligence technology, the neuropsychological evaluation was combined to analyze its correlation with cognitive impairment, aiming to provide a reliable theoretical basis for early diagnosis and the detection, diagnosis, and treatment of vascular cognitive impairment.

MATERIALS AND METHODOLOGY

Information of Research Objects

The relevant case data and MRI data of the patients in the Department of Neurology and Physical Examination, Changzhi People's Hospital from October 1, 2018 to February 1, 2020 were selected. The studies involving human participants were reviewed and approved by Changzhi People's Hospital Ethics Committee. The patients/participants provided their written informed consent to participate in this study. The patients were divided into a control group, a vascular cognitive impairment non-dementia (VCIND) group, a vascular dementia (VD) group, and an AD group according to the Clinical Dementia Rating (CDR) Scale. The classification and diagnostic criteria of VD in the vascular cognitive impairment in China in 2019 were met in the VD group, and the core clinical criteria in the diagnosis of AD revised by the NIA-AA in 2011 were met in the AD group (13). There were 42, 42, and 46 cases in the VCIND, VD, and AD groups, respectively. About 46 cases of healthy patients without memory loss in the Department of Physical Examination were included in the control group, and they had no other related diseases that may affect their cognitive function.

The inclusion criteria: first, completed clinical case and MRI data; second, no acute cerebrovascular disease in at least 1 year; third, meeting the criteria of VD and AD in the diagnostic guidelines for the diagnosis and treatment of vascular cognitive impairment in China Diagnostic criteria for vascular VCI; and forth, no cerebral white matter lesions caused by hydrocephalus, cerebral hemorrhage shown in the MRI.

Exclusion criteria: first, more than 50% of the cranial vascular narrowing shown in the intracranial vascular ultrasonography, head MRI, or head CT angiography; second, having abnormal neurological diseases such as Parkinson's, brain tumors, and encephalitis; third, moderate aphasia, depression, or mental disorders, and other case being unable to complete the investigation; and forth, hereditary small blood vessel disease.

Neuropsychological Assessment

The patients were performed with relevant questions and answers for the test and evaluation in a quiet environment. The test tables included the mini-mental state examination (MMSE), montreal cognitive assessment (MOCA), memory and executive screening (MES), activities of daily living (ADL), and CDR (14). The

neuropsychological assessment was evaluated by an experienced neurologist in the neuropsychological assessment.

MRI Examination Based on the Artificial Intelligence Technology

The MRI examination: the Siemens verio3.0T magnetic resonance scanner was used to scan the patient's head for conventional transverse, axial T2WI, sagittal T1WI, coronary T2 fluid attenuation inversion recovery sequence (FLAIR), and hippocampal volume scan. The results of the MRI examination were identified by 2–3 imaging experienced physicians. For patients being unable to cooperate with the MRI examination temporarily, oral chloral hydrate could be used for sedation.

Improved FCM Image Segmentation Algorithm

The correct segmentation of brain tissue is an important prerequisite for the location and description of lesions. Noise and offset fields, as important factors affecting the quality of brain MRI, often exist at the same time. Therefore, image segmentation algorithms that can remove noise and offset fields are very important for the correct division of brain tissue (17). Therefore, based on the FCM algorithm, an MRI segmentation algorithm that removed noise and corrected the offset field was proposed.

The actual image would be affected by additive noise and multiplicative offset field, which can be expressed as follows:

$$q_i = a_i p_i + c \tag{1}$$

In Equation (1), q_{i} represents a noisy image, a_i represents an offset field, p_i represents an uncontaminated image, and c represents noise. In actual operation, both the offset field and the uncontaminated image are unknown parameters, so the offset field was regarded as a slowly changing and smooth uneven field.

The traditional coherent local intensity clustering (CLIC) algorithm based on the gray correction can be used to evaluate the local neighborhood M_{i} of the offset field, then below equation could be obtained:

$$M_i = \left\{ j : |j - i| \le r \right\} \tag{2}$$

In Equation (2), r represents the radius of the neighborhood. Taking into account the slow change of the offset field, a_j can be replaced by a_i in a small range, so the q_j belonging to the l-th category can be expressed as follows:

$$q_j = a_j d_l + c \tag{3}$$

The cost function of pixel q_i can be expressed as follows:

$$\lambda_i = \sum_{l=1}^{m} \sum_{j \epsilon M_i} \mu_{lj}^{m} K(i-j) \left\| q_i - a_i d_l \right\|^2 \tag{4}$$

In Equation (4), λ_i represents the cost function, and $K(i - j)$ represents the weight coefficient, and Equation (5) could be obtained:

$$K\left(i-j\right) = \begin{cases} \frac{e^{-|i-j|^2}}{v} / 2\sigma^2 & |i-j| \le r \\ 0 & other \end{cases} \tag{5}$$

The total cost function of the CLIC algorithm can be combined with the FCM algorithm to get the equation below.

$$T_c = \sum_{i=1}^{m} \sum_{l=1}^{d} \sum_{j \epsilon M_i} \mu_{lj}^{m} K(i-j) \left\| q_i - a_i d_l \right\|^2 \tag{6}$$

In Equation (6), T_C is the total cost function. The CLIC algorithm can directly process the original data, and the obtained offset field is smooth and changes slowly, without subsequent filtering operations. However, because the objective function does not consider the constraints of domain information, it is more sensitive to noise parameters. In this paper, the spatial information is added to the objective function of the CLIC algorithm, and a new weight coefficient R_{li} is proposed, which is as follows:

$$T_{CR} = \sum_{i=1}^{m} \sum_{l=1}^{d} \sum_{j \epsilon M_i} \mu_{lj}^{m} \left[K\left(i-j\right) \left\| q_i - a_i d_l \right\|^2 + R_{li} \right] \tag{7}$$

In Equation (7), m indicates the existence of m pixels in the image, d indicates the classification of the image into d categories, and μ_{lj} represents the degree to which pixel j belongs to d category. Then the calculated equations for cluster center, membership degree, and offset field can be given as follows:

$$\mu_{lj} = \frac{1}{\sum_{f=1}^{d} \left[\frac{W_{lj} + R_{li}}{W_{fj} + R_{fj}} \right]^{\frac{1}{n-1}}} \tag{8}$$

$$W_{lj} = \sum_{i=1}^{m} K(i-j) \left\| q_i - a_i d_l \right\|^2 \tag{9}$$

$$CC_l = \frac{\sum_{j=1}^{m} \mu_{lj}^{m} q_j \sum_{i=1}^{m} K(i-j) a_i}{\sum_{j=1}^{m} \mu_{lj}^{m} q_j \sum_{i=1}^{m} K(i-j) a_i^2} \tag{10}$$

$$a_i = \frac{\sum_{i=1}^{m} K(i-j) q_j \sum_{j=1}^{m} \mu_{lj}^{m} d_l}{\sum_{i=1}^{m} K(i-j) q_j \sum_{j=1}^{m} \mu_{lj}^{m} d_l^2} \tag{11}$$

Equations (9–11) represent the cluster center, degree of membership, and offset field, respectively. m represents the existence of m pixels in the image, d represents the classification of the image into d categories, and μ_{lj} represents the degree to which pixel j belongs to d category. Based on the possibility of the FCM algorithm MRI segmentation method, the steps were as follows. Step 1: the noise and brain tissue in the brain MRI were removed, and the image was normalized to prepare for the next step. Step 2: the histogram statistics was performed on the three-dimensional MRI data, and the value of 0.707 near the highest value sample was automatically obtained, and the threshold was set to obtain the classification number. Step 3: the initial segmentation was performed through FCM with an uncertain membership relationship to obtain the initial membership degree and cluster center. Step 4:the matrix size of multiple own membership degrees was adjusted. Step 5: the collaborative possibility FCM algorithm was adopted to segment the lesion area to obtain the segmented image. Therefore, the calculation process of the algorithm constructed in this study can be shown in **Figure 1**.

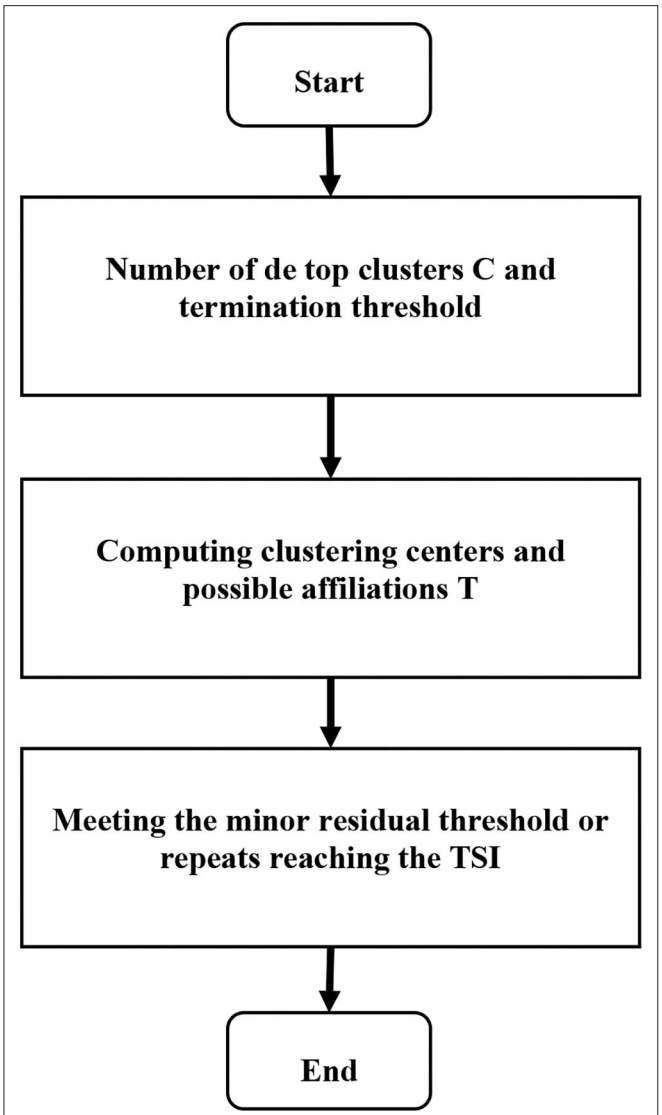

FIGURE 1 | Process of MRI segmentation using the fuzzy C-means clustering (FCM) algorithm.

Assessment of Lacunar Infarction

An MRI examination of the patients' brains was performed. When the sagittal T1WI phase was in a low-signal state, and the axial T2WI and coronary T2 FLAIR were in a high-signal state, it was determined that the diameter was less than 25 mm, and the ischemic infarct lesion is determined. When the diameter was less than 3 mm, it was considered to increase the peripheral blood vessel gap. The numbers of cerebral infarction lesions with a diameter of 3–25 mm were recorded, and the average value was taken as the number of cerebral infarction lesions. The identification and counting were carried out by an experienced radiologist.

Evaluation of White Matter Lesions

An MRI examination of the patients' brains was performed. The T1 weighted was in a low-signal state in the white matter in the bilaterally symmetrical lateral ventricle, whereas the T2 weighted and FLAIR sequence were in a high-signal state with patchy shadows and blurred boundaries. It was determined as the white matter lesion (15). Classification of the white matter lesion was as below: (Level 0: no lesion; Level 1: punctate lesion; Level 2: fusion of lesion; Level 3 lesion merging in large areas).

In this study, segmentation accuracy (SA) and similarity (KI) were used as indicators to evaluate segmentation results. The available equations were given as follows:

$$KI = \frac{2(A \bigcap B)}{2\left(A \bigcap B\right) + (A - B) + (B - A)} \tag{12}$$

$$SA = \sum_{i=1}^{c} \frac{A_i \bigcap B_i}{\sum_{j=1}^{c} B_j} \tag{13}$$

In Equations (12) and (13), A represents the target area pixels obtained by the algorithmic segmentation, and B represents the target area pixels obtained by the standard segmentation.

Statistical Method

In this study, all the experimental data were analyzed by using the SPSS 13.0. The percentage (%) and the mean and SD ($\bar{x} \pm s$) were used to indicate the measured data. The χ^2 test was used to compare the gender, age, and education level of patients in the control, VCIND, VD, and AD groups, and the *t*-test was used to compare the age among four groups. The SPSS Spearman correlation analysis was used to analyze the correlation between the hippocampal volume and age, education level, and ADL, and to understand the relationship of the data. Comparison of data in different groups was analyzed by the one-way ANOVA. If $p < 0.05$, the difference had a statistical significance.

RESULTS

MRI of the Patients

The head MRI of the patients in the control, VD, and AD groups were compared. There was no lacunar infarction, white matter lesions, and hippocampal volume changes for the patients in the control group, as shown in **Figure 2a**. The white matter lesion occurred for the patients in the VD group, as shown in **Figure 2b**. The patients in the AD group had lacunar infarction, white matter lesions, and reduced hippocampal volume, as shown in **Figure 2c**.

Comparison of Algorithm Segmentation Effect

In this study, the standard FCM algorithm was introduced, the bias-corrected FCM (BCFCM) improved based on the global information, and compared the segmentation effect based on the rough FCM (RFCM) algorithm were compared with the algorithm proposed in this study. As shown in **Figure 3**, the improved FCM algorithm used in this study was significantly better than other algorithms in terms of noise removal and detail preservation, and the segmentation effect was the most ideal.

Normal tissues in the brain MRI mainly included cerebral cortex, gray matter, white matter, cerebrospinal fluid, etc.; the

diseased tissues mainly included tumors, edema, and necrosis and cystic transformation inside tumors, and the structure of each tissue was newly transmitted and complex. The space occupancy, new transmission, and size of intracranial lesions were uncertain; the gray distribution between different soft tissues or between the diseased tissue and the soft tissue was uneven; and the aliased density distribution and other factors would affect the image segmentation effect. The MRI of the patient's brain was processed by an algorithm, and the comparison of the white matter, gray matter, and organs of the brain was shown in **Figure 4**.

Further comparison of the quantitative data results (**Figure 5**) showed that the KI and SA of the improved FCM algorithm used in this study were 0.961 and 0.986, respectively; those of the FCM algorithm were 0.755 and 0.809, respectively; those of the BCFCM algorithm were 0.837 and 0.861, respectively; and those of the RFCM algorithm were 0.816 and 0.825, respectively. The KI and SA index data of the improved FCM algorithm used in this study were significantly higher than the standard FCM algorithm, BCFCM algorithm, and RFCM algorithm, showing statistically significant differences ($p < 0.05$).

Comparison of Patients' Basic Information

The sex and education level of the patients in the control, VCIND, VD, and AD groups were compared, as shown in **Figure 6**. It was found that there was no significant difference in gender and education level by the χ^2 test ($p > 0.05$), and there was no significant difference in age by the t-test ($p > 0.05$). After analysis

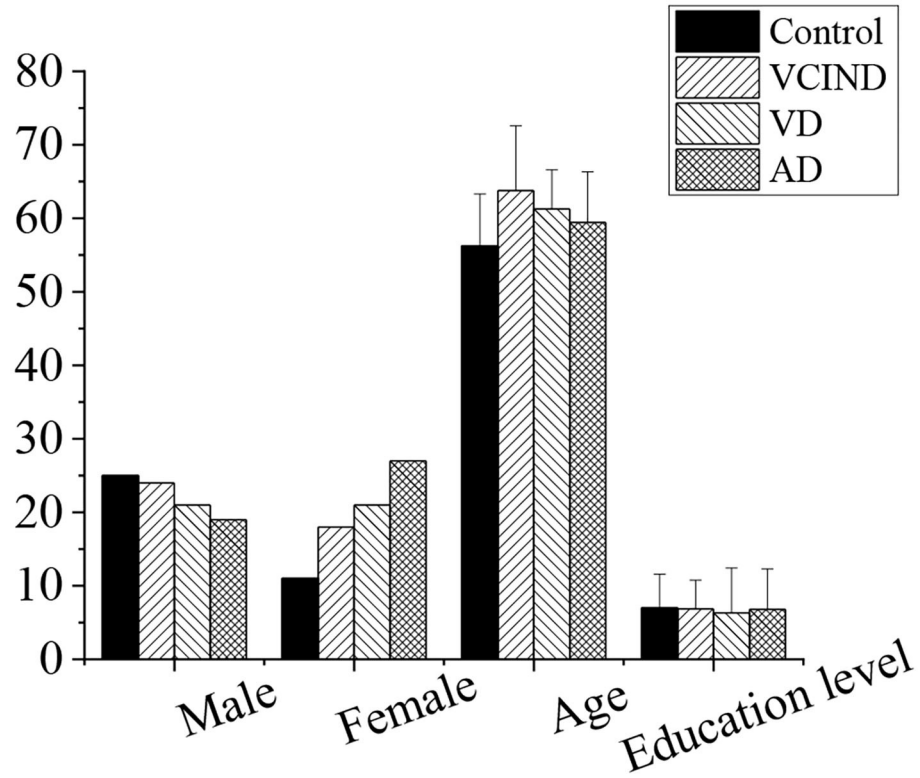

FIGURE 6 | Comparison of patients' basic information in the control, VCIND, VD, and AD groups. There was no statistic difference for the gender, age, and education level ($p > 0.05$). AD, Alzheimer's disease; VCIND, vascular cognitive impairment non-dementia; VD, vascular dementia.

of the patient's basic information and data, it was comparable in gender, age, and educational level ($p > 0.05$).

Analysis of Related Risk Factors of Patients in Four Groups

As shown in **Figure 7**, the hypertension, diabetes, smoking history, drinking history, hyperlipidemia, and coronary heart disease of the patients in the control group (46 cases), VCIND group (42 cases), VD group (42 cases), and AD group (46 cases) were analyzed and compared. It was found that the number of patients with associated hypertension in the VCIND group (22 cases, 52.4%), VD group (30 cases, 71.4%), and AD group (17 cases, 37%) was significantly higher than that in the control group (16 cases, 34.8%) with a statistical difference ($^{*}p < 0.05$). The VD group was significantly higher than that in the VCIND group, which had a statistical difference by comparison ($^{\#}p < 0.05$). There were no significant statistical differences among the other related risk factors ($p > 0.05$).

Evaluation of Cognitive Function of the Patients in Four Groups

MOCA, MES, and ADL were evaluated in the control, VCIND, VD, and AD groups, as shown in **Figure 8**.

First, in the MOCA and MES, the scores of patients in the VD group were 15.09 ± 4.33 and 15.11 ± 5.2, respectively, and were higher than those of the patients in the control group, which were MOCA (25.03 ± 5.2) and MES (24.31 ± 3.67) ($^{*}p < 0.05$). The values in the VD group were also lower than those in the VCIND group, which were MOCA (22.17 ± 4.89) and MES (20.08 ± 5.33), with a statistical difference ($^{\#}p < 0.05$).

Second, in the ADL, the values in the VCIND group (23.55 ± 6.12) and the VD group (28.56 ± 3.1) were higher than that in the control group (19.17 ± 3.67), and it had a statistical difference ($^{\Delta}p < 0.05$). There was no significant difference compared between the VCIND group and the VD group ($p > 0.05$).

Third, there was no statistical difference for MOCA, MES, and ADL in the AD group from the control, VCIND, and VD groups ($p > 0.05$).

Analysis of Distribution of Lacunar Cerebral Infarction and Number of Lesions of Patients in Four Groups

The distribution of lacunar infarction and the number of lesions of patients in the control group (46 cases), VCIND group (42 cases), VD group (42 cases), and AD group (46 cases) were analyzed, as shown in **Figure 9**. The ratios of the lacunar cerebral infarction distribution on both sides of the brain in the VCIND group (22 cases, 52.4%), VD group (13 cases, 31%), and AD group (12 cases, 26.1%) were significantly higher than that in

AD, Alzheimer's disease; VCIND, vascular cognitive impairment non-dementia; VD, vascular dementia. $^{*}p < 0.05$ if compared with distribution of lacunar cerebral infarction in the control group, whereas $^{\#}p < 0.05$ if compared with the VCIND group. $^{\Delta}p < 0.05$ if compared with number of lesions in the control group.

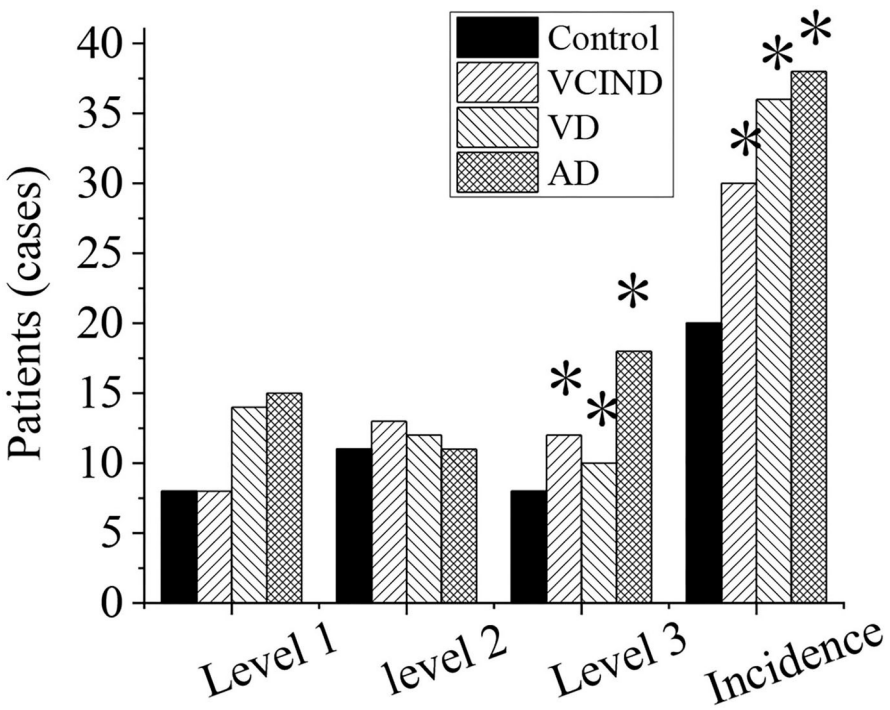

FIGURE 10 | Analysis of white matter lesions and incidence rate of patients in the control, VCIND, VD, and AD groups. AD, Alzheimer's disease; VCIND, vascular cognitive impairment non-dementia; VD, vascular dementia. $^{*}p < 0.05$ if compared with white matter lesions and incidence rate in the control group.

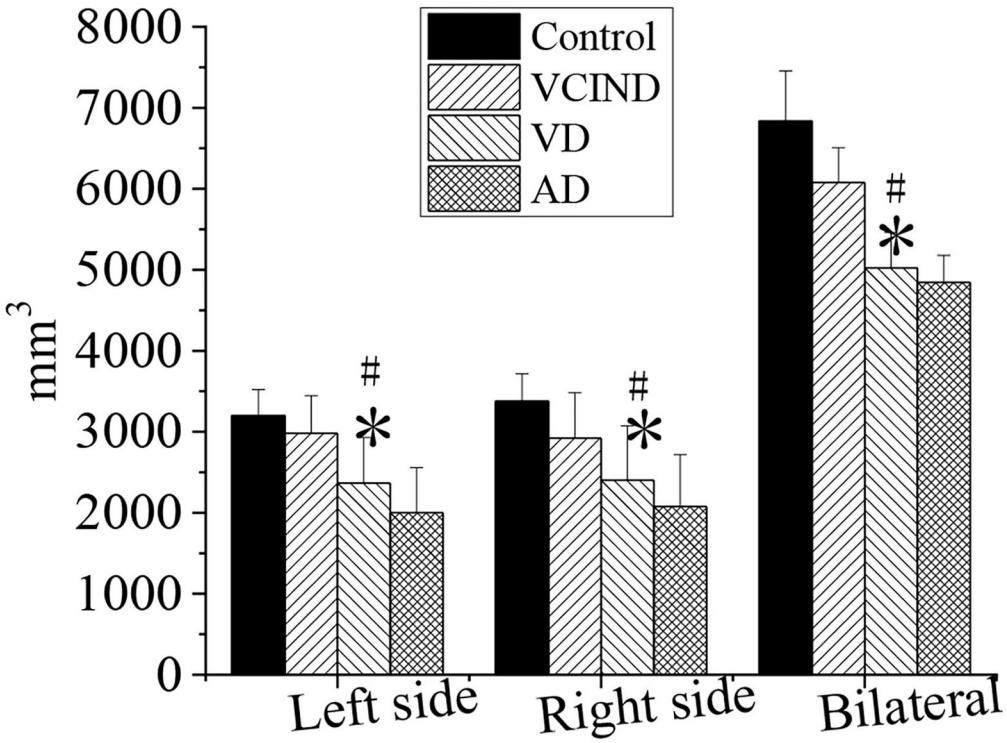

FIGURE 11 | Comparison of hippocampal volumes of patients in the control, VCIND, VD, and AD groups. AD, Alzheimer's disease; VCIND, vascular cognitive impairment non-dementia; VD, vascular dementia. $^{*}p < 0.05$ if compared with the left, right, and bilateral hippocampal volumes in the control group, whereas $^{\#}p < 0.05$ if compared with the VCIND group.

the control group (11 cases, 23.9%), which had a statistical difference ($^{*}p < 0.05$). The proportions of the lacunar cerebral infarction on the left side of the brain in the VD group (28 cases, 66.7%) and AD group (25 cases, 54.3%) were higher than that in the VCIND group (8 cases, 19%), which had a statistical difference ($^{\#}p < 0.05$).

The numbers of lacunar infarction lesions in the VCIND group (32 cases, 76.2%), VD group (30 cases, 71.4%), and AD group (33 cases, 71.7%) were significantly higher than that in the control group (23 cases, 50%), and it had a statistical difference ($^{\Delta}p < 0.05$).

Analysis of White Matter Lesions and Incidence Rate of the Patients in Four Groups

The white matter lesions and incidence rates of patients in the control group (46 cases), VCIND group (42 cases), VD group (42 cases), and AD group (46 cases) were compared and analyzed, as shown in **Figure 10**. Compared with the control group (8 cases, 17.4%), the proportions of 3-grade lesions in the VCIND group (12 cases, 28.6%), VD group (10 cases, 23.8%), and AD group (18 cases, 42.9%) were increased, which had a statistical difference ($^{*}p < 0.05$). Compared with the control group (20 cases, 43.5%), the incidence rates of lesions in the VCIND group (30 cases, 71.4%), VD group (36 cases, 85.7%), and AD group (38 cases, 82.6%) were increased, which had statistical differences ($^{*}p < 0.05$).

Comparison of Hippocampal Volumes of Patients in Four Groups

The hippocampal volumes (left, right, and bilateral hippocampal volumes) of patients in the control, VCIND, VD, and AD groups were compared and analyzed, as shown in **Figure 11**. It compared the left (2,367 ± 563), right (2,401 ± 672), and bilateral hippocampal volume (5,023 ± 437) of patients in the VD group with the left (3,201 ± 321), right (3,378 ± 337), and bilateral hippocampal volume (6,834 ± 621) of patients in the control group. The results revealed that there was a statistical difference ($^{*}p < 0.05$). By comparing the left (2,982 ± 463), right (2,921 ± 564), and bilateral hippocampus volume (6,079 ± 429) of the patients in the VCIND group, the left, right, and bilateral hippocampus volume of the patients in the VD group had a statistical difference ($^{\#}p < 0.05$).

Relationship Between Hippocampal Volume and Age and Education Level

As shown in **Figure 12**, Pearson's correlation analysis was taken for the relationship between the hippocampus volume and age, and it was found that the age and hippocampus volume were negatively correlated ($r = -0.919$, $p < 0.01$). With the increase of age, hippocampus volume tended to decrease.

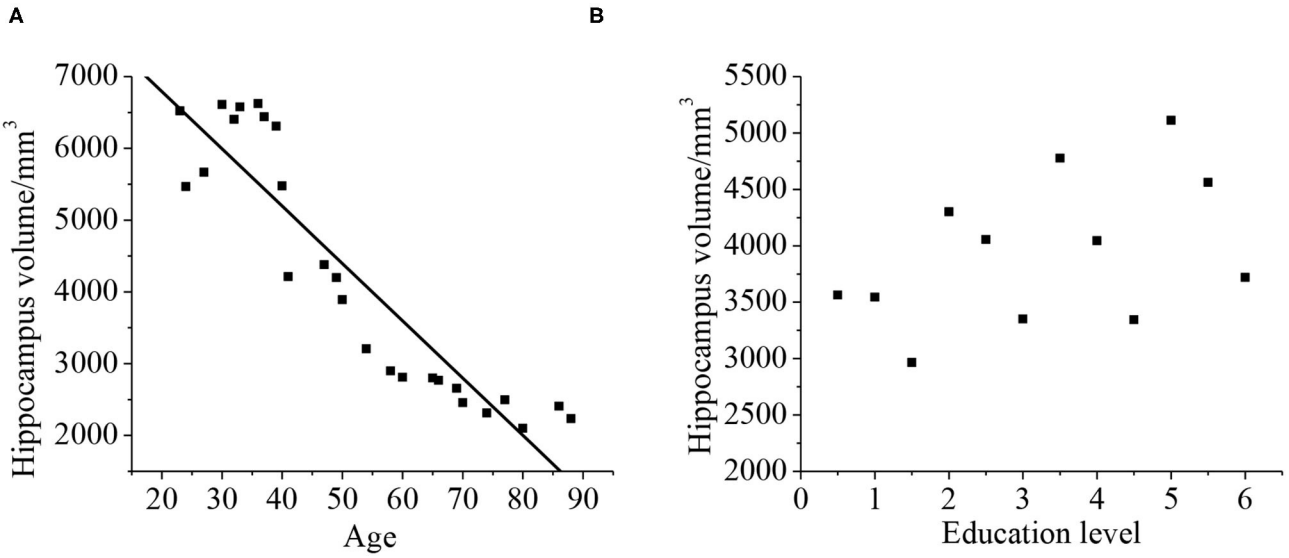

FIGURE 12 | Correlation between the hippocampal volume, age **(A)**, and education level **(B)**. The correlation existed if $p < 0.01$.

The hippocampal volume has no phase relationship with the education level ($p > 0.01$).

Relationship Between Hippocampal Volume and the Neuropsychological Assessment ADL

Pearson's correlation analysis was taken for the relationship between the hippocampal volume and neuropsychological assessment. It was found that the neuropsychological assessment ADL was negatively correlated with hippocampal volume ($r = -0.872$, $p < 0.01$). With less hippocampal volume of the patient, both the cognitive ability and daily living ability of the patient decrease, as shown in **Figure 13**.

DISCUSSION

Among fuzzy clustering, the most commonly used is FCM. However, FCM also has some shortcomings. The sum of the membership degrees of the same sample belonging to all classes is 1, which makes it sensitive to noise and outliers; and it is sensitive to the initial cluster center (18). In order to overcome these shortcomings, some scholars have proposed possible C-means clustering, weighted FCM clustering, and FCM based on the possibility of membership uncertainty. These clustering algorithms are based on the clustering of all special diagnoses in the dataset, and the weight of each special diagnosis is different (19, 20). In order to make the clustering results more accurate, the possibility of collaboration FCM is a method of clustering using the collaborative relationship between different features (12, 21). This method can be combined with other clustering algorithms to improve the clustering effect. The fuzzy partition matrix is obtained by using the synergy coefficient between the different features themselves (22). The detection by the MRI based on artificial intelligence technology will play an important role in the early diagnosis and treatment of diseases related to vascular cognitive impairment. Artificial intelligence can effectively complete the collection of relevant data information by simulating human thinking instead of an artificial collection. In this study, the relevant case data of patients in the Department of Neurology and Physical Examination who entered Changzhi People's Hospital from October 1, 2018, to February 1, 2020 were selected. Combined with the MRI data based on artificial intelligence technology, the risk factors of patients in the control, VCIND, VD, and AD groups were analyzed. It was found that the numbers of patients with associated hypertension in the VCIND group (52.4%), VD group (71.4%), and AD group (37%) are significantly higher than that in the control group (34.8%), which has a statistical difference ($^{*}p < 0.05$). That in the VD group was significantly higher than that in the VCIND group, which had a statistical difference by comparison ($^{\#}p < 0.05$). There were no significant statistical differences among the other related risk factors ($p > 0.05$). It is consistent with the previous results, suggesting that it plays a key role in controlling hypertension in the prevention and control of cognitive impairment (23). If the blood pressure is under high pressure for a long time without any control, the elasticity of small cerebral blood vessels will be reduced accordingly, and the blood circulation will be poor. It will lead to hypoxia in the brain, lacunar cerebral infarction, and white matter lesions and develop into a VD. Some related studies show that diabetes, hyperlipidemia, and coronary heart disease are related to cognitive impairment (24), which is inconsistent with the results of this study. No correlation between gender, age, and education level to the cognitive impairment was found in this study.

In this study, a comprehensive evaluation of the cognitive ability is taken for all patients. It is found the scores of MOCA

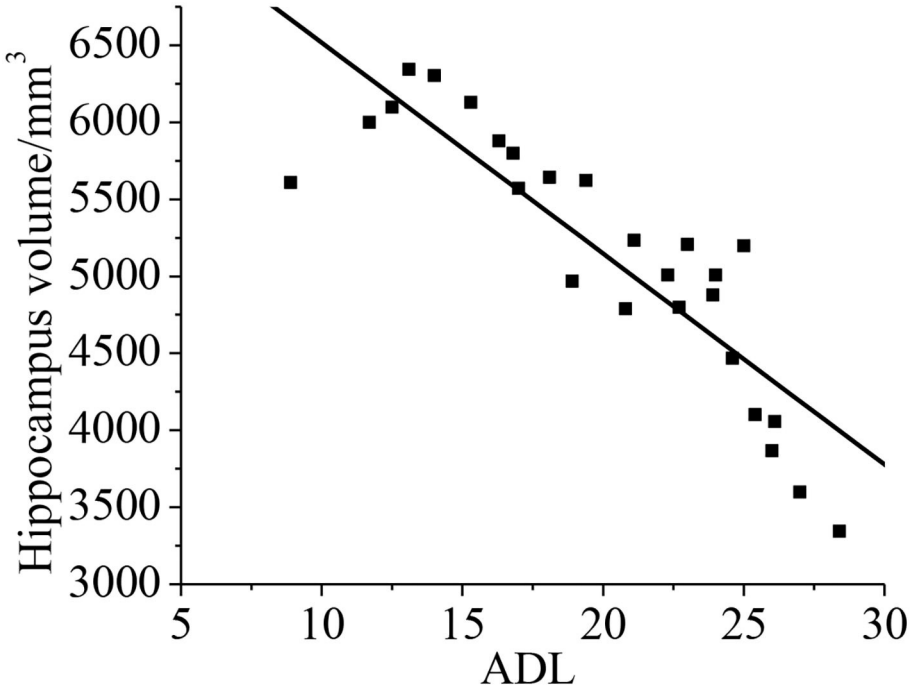

FIGURE 13 | Correlation between the hippocampal volume ADL. The correlation existed if $p < 0.01$.

and MES in the VD group are 15.09 ± 4.33 and 15.11 ± 5.2, respectively. They are lower than that in the control group, and there is a statistical significance ($p < 0.05$). It indicates that compared with the control group, the cognitive level in the VD group decreases greatly, whereas the cognitive level in the VCIND decreases slightly. Such results are consistent with the study of Jadavji et al. (25). In the ADL, the scores in the VCIND group (23.55 ± 6.12) and the VD group (28.56 ± 3.1) are higher than that in the control group (19.17 ± 3.67), which has a statistical difference ($p < 0.05$). It means that compared with the control group, the daily living ability of patients in the VCIND group and the VD group are significantly decreased. The hippocampal volume is negatively correlated with ADL ($r = -0.872$, $p < 0.01$), indicating that the more serious the hippocampus atrophy, the worse the daily living ability of the patient. Such results are consistent with the results of Wierenga et al. (26). The hippocampal volume is negatively correlated with age ($r = -0.919$, $p < 0.01$), indicating that the hippocampus-related neurons may be lost as age increases, causing their volume to shrink.

The distribution of lacunar infarction and the number of lesions of the patients in the four groups were analyzed. It was found that the proportions of lacunar infarction in the brain (52.4, 31, and 26.1%) and the number of multiple lacunar infarction lesions (76.2, 71.4, and 71.7%) in VCIND, VD, and AD groups were significantly higher than those in the control group (23.9% and 50%). It has a statistical difference ($p < 0.05$). With the increase of the infarction, the incidence rate of the cognitive impairment also increases, and the degree of dementia increases. The bilateral and multiple lesions have more serious damage to the executive function of the patient. It may be due to the multiple arterial ischemias, and more neural network structures are also destroyed.

Compared with the control group, the proportions of 3-grade lesions (28.6, 23.8, and 42.9%) and the incidence rate of lesions (71.4, 85.7, and 82.6%) in the VCIND, VD, and AD groups increased, showing statistics differences. When the white matter of the brain suffers some lesion, the white matter fibers will be destroyed, and the cognitive function will be impaired. It is consistent with multiple studies that white matter lesions are related to cognitive impairment in patients with dementia and non-dementia.

CONCLUSION

In this study, the lacunar cerebral infarction, white matter lesions, and hippocampal volume of the patient with the neurological cerebrovascular disease were studied, and the correlation with cognitive impairment of the patient was analyzed through MRI based on artificial intelligence technology combined with the neuropsychological assessment. However, the shortcoming of this study was that the patient samples involved were fewer, which may cause deviations in the results. Therefore, the results needed to be verified further by the multicenter experimental data with more samples. In short, the improved FCM algorithm had a higher segmentation effect and SA on MRI of neurovascular cerebrovascular diseases. The distribution, number, white matter lesions, and hippocampal volume of lacunar cerebral infarction

were related to the cognitive impairment of patients with cerebrovascular diseases.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Changzhi Medical College. The patients/participants provided their written informed consent to participate in this study.

AUTHOR CONTRIBUTIONS

LZ wrote the manuscript. YL, LB, and QL collected and analyzed general data of patients. XZ and BZ were responsible for the follow-up index analysis. BZ helped with statistical analysis. All authors read and approved the final manuscript.

FUNDING

This study was supported by the Scientific Research Project of Shanxi Provincial Health Commission in 2021 (No. 2021012) and the Key Special Project of Four Batches of Science and Technology Innovation Plan of Shanxi Provincial Health Commission (No. 2020XM38).

Background and Objective: According to the WHO, diabetes mellitus is a long-term condition marked by high blood sugar levels. The consequences might be far-reaching. According to current increases in mortality, diabetes has risen to number 10 among the leading causes of mortality worldwide. When used to predict diabetes using unbalanced datasets from testing, machine learning (ML) classifiers and established approaches for encoding categorical data have exhibited a broad variety of surprising outcomes. Early studies also made use of an artificial neural network to extract features without obtaining a grasp of the sequence information.

Methods: This study offers a deep learning-based decision support system (DSS), utilizing bidirectional long/short-term memory (BiLSTM), to accurately predict diabetic illness from patient data. In order to predict diabetes, the BiLSTM hybrid model was used after balancing the data set.

Results: Unlike earlier studies, this proposed model's trial findings were promising, with an accuracy of 93.07%, 93% precision, 92% recall, and a 92% F1-score.

Conclusions: Using a BILSTM model for classification outperforms current approaches in the diabetes detection domain.

INTRODUCTION

With the emergence of AI, data mining applications have become more prevalent in several fields, such as business, education, and healthcare. Healthcare decision support systems are a hot research issue because they allow the finding of exciting patterns and useful data from enormous quantities of healthcare records. Decision support systems might help human medical specialists diagnose illnesses faster by transforming data sources into relevant insights (1). In the fast expanding discipline of data mining known as "deep learning" (DL), a complex mix of feature encoding approaches is used in order to understand from prior data to produce correct estimates (2). There are a number of uses for it, including sentiment classification (3), smart agriculture (4), and more. Recently, neural network models have shown a remarkable capability for content prediction and classification. As shown in Shickel et al. (5) and Miotto et al. (6), deep learning algorithms have figured prominently in healthcare for knowledge discovery and disease diagnosis, such as cardiac diseases, psychiatric disorders, and diabetes disorders, using health data.

A Need for Diabetes Disease Prediction

Diabetes affects more than 34 million people in the United States, accounting for approximately 11% of the population. Diabetes is diagnosed in the United States at a rate of 17 cases per second. Each year, around 1.5 million Americans are diagnosed with diabetes (7). There are several biological indicators and risk factors that must be considered in order to get a definitive diagnosis of diabetes. Some of these indications and variables include age, gender identity, hypertension, and cholesterol levels, among others.

Following China and India, Pakistan has the third highest diabetes prevalence (8). The International Diabetes Federation (IDF) estimates that about 33 million Pakistanis have diabetes. Diabetes diagnoses are crucial since a patient's life is at stake. Diabetics must emphasize early diagnosis and treatment. Numerous complications of diabetes, including nephropathy, retinopathy, neuropathy, cardiovascular disease, stroke, and death, can be delayed or avoided with proper management of elevated blood sugar levels. More effective supervised learning algorithms for disease prediction can significantly reduce these medical errors. The healthcare sector has been supplied with a variety of supervised learning methods by researchers (9). In the health sector, data scientists are encouraged to build useful applications that may help healthcare experts diagnose and manage diabetes illness (10). To effectively predict diabetes illness, it is vital that state-of-the-art deep learning (DL) techniques be researched and applied to health-related patient data.

The Study's Goals

In the past several years, a number of scientists have investigated the possibility of using health data to predict diabetes using computational approaches like machine learning (ML) (9, 10). This research's major goal was to discover ways to detect diabetes before symptoms appear. Additionally, they were constrained by traditional encoders that did not adequately handle the relationship among the disease dataset's predictors. Consequently, the proposed BILSTM-based framework in this research accurately diagnoses diabetes.

Baseline Investigation

Butt et al. developed an ML-based prediction approach for diabetic disease (9). ML was used to better predict diabetes using random forest (RF), support vector machine (SVM), and other classifiers. However, ML classifiers use a traditional encoding strategy that fails to account for the predictors' underlying links. As a result, typical machine learning algorithms are often inefficient at accurately predicting diabetes risk from medical information. Because this study effort had certain limitations (9), we proposed an updated DL model called BiLSTM, which has previously been effectively employed in several fields such as DDoS attack prediction, behavior recognition, and others (2, 11). To predict diabetes, we created the BiLSTM model.

Butt et al. developed an ML-based prediction approach for diabetic disease (9). ML was used to better predict diabetes using random forest (RF), support vector machine (SVM), and other classifiers. However, ML classifiers use a traditional encoding strategy that fails to account for the predictors' underlying links. As a result, typical machine learning algorithms are often inefficient at accurately predicting diabetes risk from medical information. Because this study effort had certain limitations (9), we proposed an updated DL model called BiLSTM, which has previously been effectively employed in several fields such as DDoS attack prediction, behavior recognition, and others (2, 11). To predict diabetes, we created the BiLSTM model.

Problem Statement

The use of traditional feature sets followed by an ML classifier makes it difficult to accurately predict diabetes from patient data (9, 10). Furthermore, the lack of relevant context makes DL models for diabetic illness prediction less effective. Predicting diabetes from patient data is treated as a binary-label prediction problem to handle the aforementioned difficulties. Diabetes is predicted from the supplied illness dataset. There are two classes of data in the dataset: D1 (yes, you have diabetes) and D2 (no, you do not have diabetes). The neural network uses these two classes to predict whether or not someone has diabetes. Using a deep neural network, we want to develop an automated system that can learn from training data and predict the presence or absence of diabetic illness using context information in the healthcare sector.

Research Objectives

We intend to fulfill the following research goals in order to be able to perform an effective diabetic diagnosis.

RO1: To use the BiLSTM deep learning model to make predictions about diabetes based on patient illness data.
RO2: Comparison of the BiLSTM model for diabetes prediction with classical machine learning and deep learning.
RO3. Comparison of proposed method's effectiveness to baseline research for predicting diabetic patients.

Research Contributions

The following are key contributions made by this work:

1. A deep learning (BILSTM) system is being developed to diagnose diabetic disease.
2. The proposed deep learning model for diabetes diagnosis outperforms existing classical machine learning models in terms of prediction performance.
3. To make a diabetes prognosis, two decision classes are employed.
4. Comparing the proposed strategy to existing deep learning and benchmark studies.
5. Using the proposed strategy significantly improves the model's accuracy in predicting diabetes.

The remainder of the study is organized in the following order: Section Related Work gives a review of the current literature, and Section Proposed Methodology discusses the recommended technique. Results and discussion are presented in Section Experimental Results and Discussion, and future applicability of the proposed approach is discussed in Section Conclusions and Future Work.

RELATED WORK

Past studies on diabetes disease prediction are summarized in this section.

Qawqzeh et al. (12) suggested a photoplethysmogram-based regression model for diabetes diagnosis. The framework was validated and evaluated using input from 450 participants and 130 pieces of information. Their suggested approach properly identified 550 non-diabetics with 92% accuracy. But the suggested approach is not compared to current methods. Automated categorization of diabetes using a machine learning technique was given by (13). They employed a SVM classifier using hyperglycemia samples from the UCI Machine Archive. It outperformed Naive Bayes, decision trees, and neural nets. While a contrast of latest systems is provided, there is no discussion of parameter estimation. An SVM-based classifier was employed by Gupta et al. (10) to identify diabetes. They made use of PIMA Indian Diabetes as a resource. Additional methods for improving predictive performance included variable selection and k-fold cross-validation. During the tests, the support vector machine did better than the naive Bayes model. In contrast, there is a lack of current comparability and consistency. Choubey et al. (14) compared numerous diabetes classification systems. The UCI Machine Learning Repository's PIMA Indian collection was integrated with an indigenous hyperglycemia collection. The researchers used SVM, KNN, and NB to identify insulin-dependent individuals from pooled datasets. PCA and LDA feature engineering approaches have been found to improve classification system performance and remove redundant features. Butt et al. (9) looked at utilizing machine learning to diagnose and forecast diabetes. It also showcases an Internet-of-things diabetic tracking device for both normal and sick people. Diabetes was classified using three classification methods: randomized forest, multilayer perceptron, and regression models (LR). They employed SVMs, MA, and linear regression to predict outcomes (LR). The study used the PIMA Indian Diabetes dataset. MLP outperforms similar learners with an accuracy of 86%, whereas LSTM outperforms others with an average of 87%. Zhou et al. (15) proposed a DTP model for glycemic control diagnosis. Each of the data sets contained over 1,000 entries. Smaller epochs in the training step ensure that the technique works rapidly on any smartphone. The findings confirm the effectiveness of the suggested model. Mujumdar and Vaidehi (16) suggested a diabetes prediction model for accurate diagnosis of diabetes that contains a few additional factors that are involved for diabetes in addition to standard indicators such as blood glucose, body mass index (BMI), age, insulin, and so on. Garca-Ordás et al. (17) introduced an algorithm based on deep learning approaches to detect diabetes patients. Variational autoencoders (VAEs) can be used to add data and features, and a CNN can be used to classify the data. Alam et al. (18) diagnosed diabetes utilizing key variables and defined their relationships. Various techniques are utilized for diabetes clustering, prognosis, and association rules. The PIMA dataset was used by Naz and Ahuja (19) to diagnose diabetes. A neural network, Multilayer Perceptron, Logistic Regression, and Deep Learning are all effective classifications that attain 90–98% efficiency. Yuvaraj and SriPreethaa (20) presented machine learning techniques in hadoop clusters for diabetes diagnosis. The results reveal that machine learning techniques can correctly predict hyperglycemia. In their study, Hasan et al. (21) built a comprehensive system for diabetes prognosis that included components such as outlier exclusion, data normalization, extraction of features, K-fold cross-validation, and several machine learning (ML) models (k-nearest neighbor, Decision Trees, Randomized Forest, Xgboost, Bayesian Network, and Gradient boosting) and Lstm. An extensive study of the uses of deep learning in diabetes was published by Zhu et al. (22). Through the exploration, a lot of original scientific papers were found. Prediction models for impaired glucose tolerance in early pregnancy were formed by Liu et al. (23). They used machine learning to make these models. The training dataset was used to build a model for predicting risk based on information gathered at registration. The deep learning classification technique makes use of the ResNet v2 CNN architecture (24), which was trained on tiny patches taken from the entire ear endoscopies before being applied to the complete ear images. A total of four deep learning models were trained for autonomous ascribable diabetic retinopathy detection, dependent on whether or not two criteria were included: DR-related lesions and diabetic retinopathy staging (25). **Table 1** presents a summary of selected works.

Existing Research Gaps

Several deep learning methods based on word embedding have previously been successful in overcoming these limitations. Using deep learning algorithms, it is important to overcome the challenge of remembering extra information in order to make highly accurate diabetes predictions.

PROPOSED METHODOLOGY

It is vital to apply deep learning technology to incorporate current data and experience into a DSS in order to deal with this difficult decision-making challenge. Data, expertise, and models are incorporated into our DSS (see **Figure 1**) so that diabetic professionals may make diagnostic choices based on this information. To further involve the individuals, we sought the advice of medical specialists throughout the design process, as advised by (1). Considering the DSS's nature and the decision issue's complexity, we built the DSS according to Turban et al. (1) recommendations. The DSS has four main subsystems: data management, model management, knowledge-based management, and user interface.

Data Management System

A DSS uses databases and/or datasets to provide relevant data to the decision support system. DSS data can be received from local, public, and customized sources (1), as well as institutional sources. Our decision support system's data management module collects and stores data. In this investigation, the Pima Indians' Diabetes (PID) Data Set (26) was utilized as the data source. UCI's machine learning archive does have this dataset, and it is part of a larger set of data kept by the National Institutes of Health (27). This database contains information on women of Pima Indian

TABLE 1 | Summary of selected works.

References	Technique(s)	Results	Limitations
Butt et al. (9)	Randomized forest, multilayer perceptron, and regression models (LR)	MLP outperforms similar learners with an accuracy of 86%	Dimensionality reduction techniques not applied
Gupta et al. (10)	Support vector machine	Support vector machine did better than the naive Bayes model.	Lack of current comparability and consistency
Qawqzeh et al. (12)	Regression model	92% accuracy	Lack of comparison with the current methods
Pethunachiyar (13)	SVM classifier	Outperformed Naive Bayes, decision trees, and neural nets	There is no discussion of parameter estimation
Choubey et al. (14)	SVM, KNN, and NB	91% accuracy	Performance overhead due to incorporation of extensive feature engineering
Zhou et al. (15)	DTP model for glycemic control diagnosis	Promising results	Execution time needs to be further reduced
Garca-Ordás et al. (17)	Deep learning approach (CNN)	92.31% accuracy	Ensemble learning technique required for more better results
Alam et al. (18)	Association rules	92% accuracy	More effective preprocessing
Naz and Ahuja (19)	Multilayer Perceptron, Logistic Regression, and Deep Learning	90% accuracy	A pipeline of classifiers can produce efficient results
Yuvaraj and SriPreethaa (20)	Machine learning techniques in hadoop clusters	Outperformed baseline methods	Poor selection of predictors
Hasan et al. (21)	k-nearest neighbor, Decision Trees, Randomized Forest, Xgboost, Bayesian Network, Gradient boosting, and Lstm	LSTM exhibited better results (92% accuracy)	Parameter selection is affected by lack of efficient proper preprocessing techniques

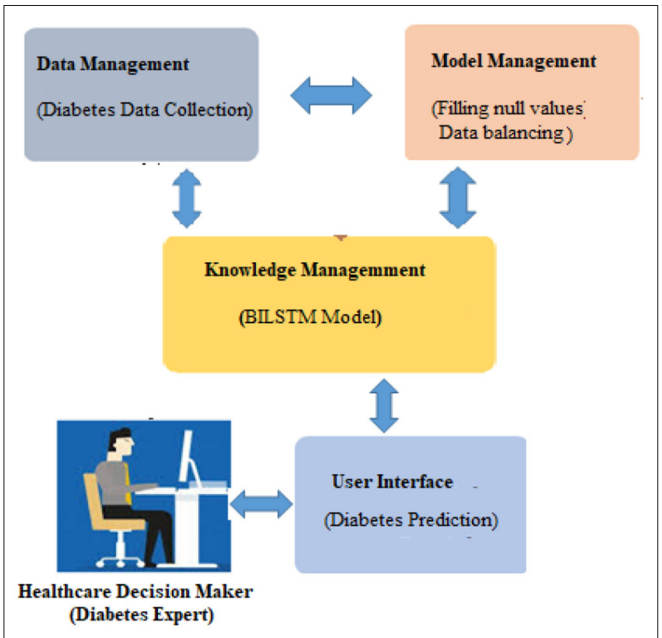

FIGURE 1 | Overview of the proposed system for predicting diabetes disease.

ancestry who were over the age of 20 at the time of data collection and who resided in the United States. The output data parameter accepts either a value of 0 or 1, with value 1 indicating a positive diabetic test and "0" indicating a negative diabetic diagnostic. An overview of the eight diagnostic attributes and their descriptions is provided in **Figure 2**.

How to Use Data

The spreadsheets are converted to CSV files. The "pd.read" command line option reads "csv". This is a key Panda tool. We separated the training and testing sets using the sklearn training (80%) and testing (20%) partition tool (2).

Train Set

During training, around 80% of the training set's data was used (3). The training set includes both result identifiers (dependent variables) and input factors (predictor variables).

Validation Set

Using validation data in the system, efficiency concerns such as overfitting and under fitting may be addressed. Thus, a 10% validation subset is employed for model assessment (2). Both manual and automated parameter changes are possible when using Keras. With the help of automated validation in this research, a more unbiased assessment of the proposed method may be made.

Test Set

In order to evaluate the algorithm's efficacy, the test set includes examples that have never been seen before. This method is applied after extensive usage of the training and testing sets. The model may be evaluated using the testing dataset (11). Ten percent of the test dataset was used, which had nothing to do with the training cases. The training data set is used when the model has been fully trained. It is then checked against real data for correctness. The data is divided into 90/10 ratios by the Scikit-train-test learning division, with 10% of the data being validation data. A validation set was used to

Attribute-id	attribute	description
Diabetes-f1	Age (years)	Age in years
Diabetes-f2	Body mass index	Body mass index (weight in kg/(height in m)2)
Diabetes-f3	Glucose	It takes two hours of oral blood glucose tolerance tests to get the plasma glucose concentration.
Diabetes-f4	Pregnancy	The number of pregnancies
Diabetes-f5	Blood pressure	Blood pressure measured in millimeters of mercury (diastolic, mm Hg).
Diabetes-f6	Skin Thickness	The skinfold thickness of the triceps (mm)
Diabetes-f7	insulin	Two-hour serum insulin (μ U/ml)
Diabetes-f8	Pedigree function of diabetes	Attribute that is used to predict diabetes.

FIGURE 2 | Parameters used to predict the likelihood of diabetes.

make adjustments to the model's parameters and then analyze the results.

Treatment of Data

The model is validated *via* 10-fold cross-validation. At each stage, we collect and keep ten replicas of the training instance. One last "holdout" model was examined in this case. We chose the version with the highest F1 score for the holdout sample.

Model Management System

It works as a data management system. It incorporates a modelbase of statistical and other algorithms that provide sophisticated analytics to DSS. An MMS applies models to DMS data to turn it into information. In order to create a reliable prediction model, the obtained health data must be properly pretreated. The data management system handles unbalanced datasets and null value substitution.

Unbalanced Data Set Management

The underlying dataset is significantly imbalanced and treats both groups unevenly. Two hundred sixty-eight cases (34.9%) are present in class one for a positive test, and five hundred sixty-one cases (65.1%) are present in class zero for a negative test. Whereas, when a model learns from skewed and unequal classed data, the result usually benefits the main class whereas the minor categories are neglected in the classification stage. This is viewed as a class imbalance issue (28). To solve this issue, we use a data processing sampling method called oversampling to equalize all class instances. Oversampling is a method of expanding small classes. Random upsampling merely duplicates minor examples to increase the unbalance percentage (28). This small group replication addition considerably enhanced the classification results. In both the T1:415 and T2:414 classes, the balanced dataset is treated in the same way once random oversampling is used. Instances in total: 829.

Handling Missing Values

In order to increase the model's prediction performance, missing variables should be filled in with accurate data (28). In order to fill in the blanks, one can use an average, choose a random item, or go back and use the prior tier's value as a reference. After settling on the third choice, we went ahead and updated all of the missing numbers with the appropriate higher value.

The Knowledge Management System

When used in conjunction with other DSS modules, this module may be able to provide the most up-to-date information to aid in the resolution of the issue at hand. After information has been found, acquired, and arranged, it must be transformed into knowledge. Data must be categorized, evaluated, and synthesized. The three key components of the proposed technique are: embedding layer-based data representation; bi-LSTM-based forward and backward context information saving; and softmax layer-based classification. With this numeric representation, the second module may encode features. Encoding the context of the data within a sequence using Bi-LSTM In the final module, classification is done using softmax activation (see **Figure 3**). Each component is described below.

Embedding Layer

A numeric array created by embedding items (categories) (vectors). Scalar word embeddings from discrete traits Using neural encoding to reduce attribute values and categorize has several benefits (29). Keras can embed. The diabetes dataset was encoded using attribute-level encoding matrices. Thirty-two Keras layers generate the data embedding vector. A two-dimensional embedding matrix had input data length and a word embedding dimension (feature matrix). This matrix was made by the embedding. The embedding matrices were then shifted.

The BILSTM Layer

The proposed method employs a deep neural network, specifically bidirectional long-short time memory (BiLSTM), to predict diabetes sickness, such as D1 (diabetes disease = yes) or D2 (diabetes disease = no). Long-term dependencies are learned using the Bi-LSTM layer. It assists in preserving the two prior and following contexts in encoded information. Instead of saving information from prior contexts, a single unidirectional LSTM only keeps data that was previously saved (30). Thus, Bi-LSTM is able to analyze encoded reviews in much more detail. Bi-LSTM uses forward and backward

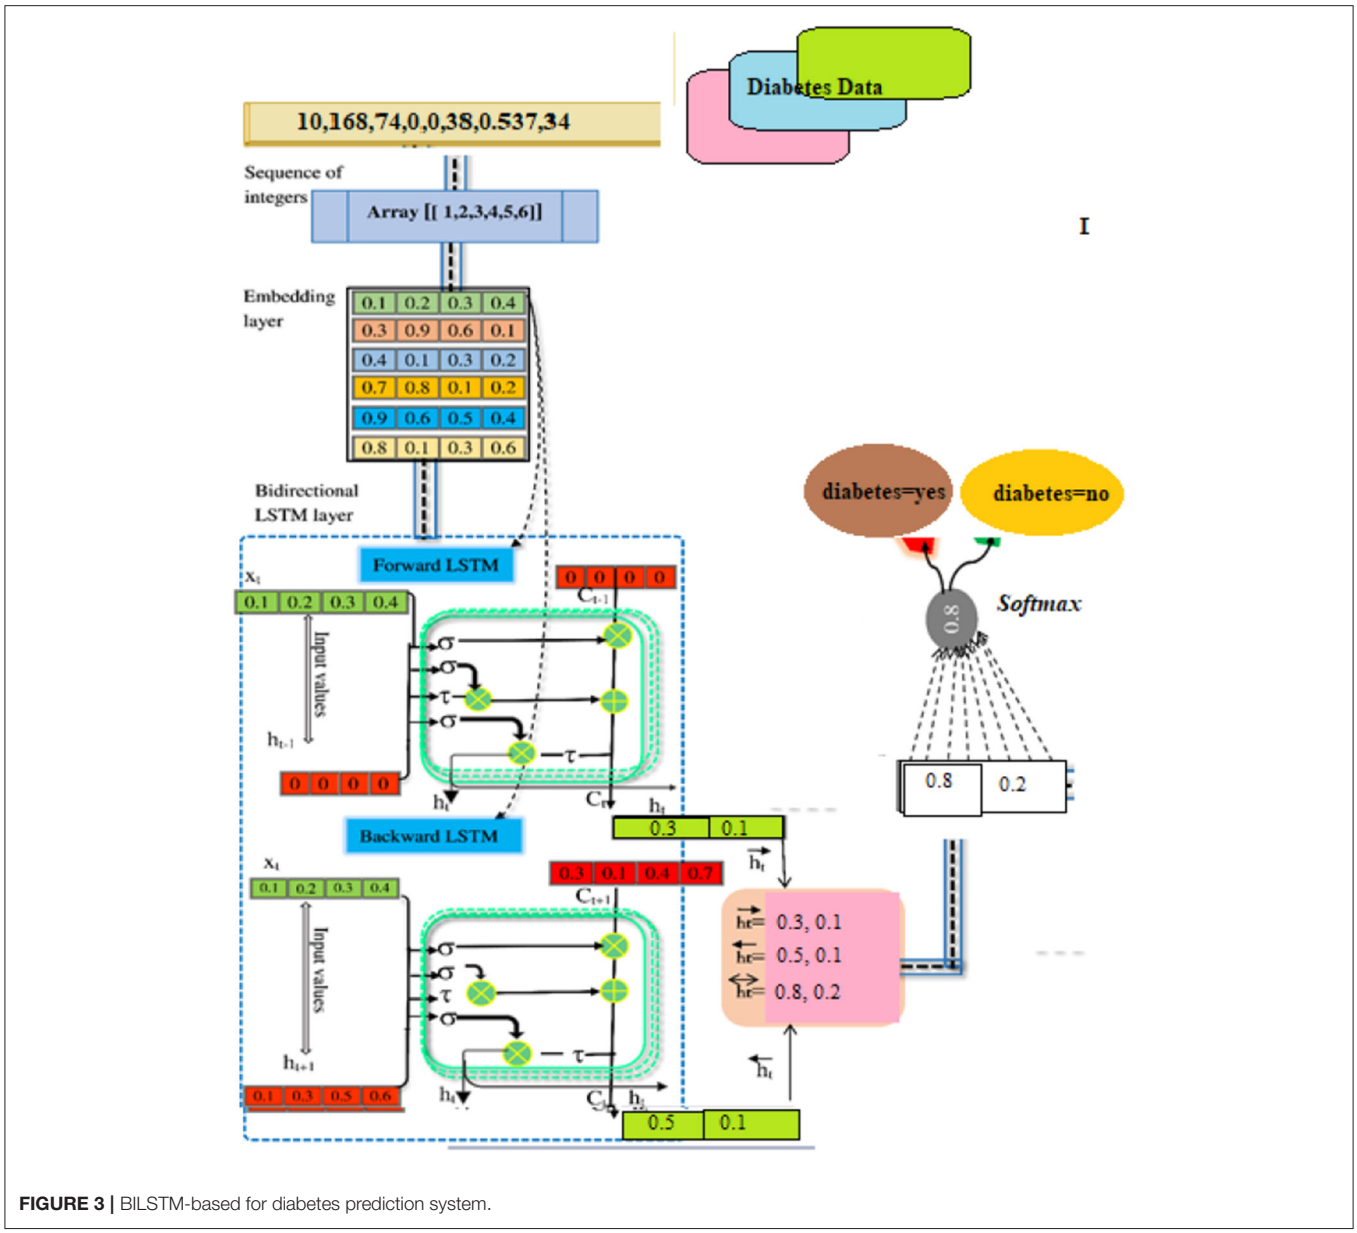

FIGURE 3 | BILSTM-based for diabetes prediction system.

LSTM to learn data's past and future context (2). The following formulas are used to determine the forward and reverse LSTM:

Formulae for forward LSTM

$$f_t = \sigma\left(W_f x_t + U_f h_{t-1} + b_f\right) \quad (1)$$

$$i_t = \sigma\left(W_i x_t + U_i h_{t-1} + b_i\right) \quad (2)$$

$$o_t = \sigma\left(W_o x_t + U_o h_{t-1} + b_o\right) \quad (3)$$

$$c \sim t = \tau\left(W_c x_t + U_c h_{t-1} + b_c\right) \quad (4)$$

$$c_t = f_t \bigodot c_{t-1} + i_t \bigodot c \sim_t \quad (5)$$

$$h_t = o_t \bigodot \tau\left(c_t\right) \quad (6)$$

Formulae for backward LSTM

$$f_t = \sigma\left(W_f x_t + U_f h_{t+1} + b_f\right) \quad (7)$$

$$i_t = \sigma\left(W_i x_t + U_i h_{t+1} + b_i\right) \quad (8)$$

$$o_t = \sigma\left(W_o x_t + U_o h_{t+1} + b_o\right) \quad (9)$$

$$c \sim t = \tau\left(W_c x_t + U_c h_{t+1} + b_c\right) \quad (10)$$

$$c_t = f_t \bigodot c_{t+1} + i_t \bigodot c \sim_t \quad (11)$$

$$h_t = o_t \bigodot \tau\left(c_t\right) \quad (12)$$

SoftMax-Based Prediction

Afterward, SoftMax is being used to figure out how likely it is that target labels will be forecasted (i.e., the diabetes disease).

The formula (Equation 18) explains how to determine the net input value

$$d_i = \sum w_i l_i + b \tag{13}$$

"w" is the weight vector, whereas "l" stands for the input vector. "b" stands for "bias." We can find the SoftMax by plugging it into Equation (19).

$$softmax\ (d_i) = \frac{expd^{d_i}}{\sum_{n=1}^{m} \exp^{d_n}} \tag{14}$$

Applied Example

We performed a number of computations to predict diabetes based on the existing disease data. The BILSTM model's every stage is discussed in detail.

Data Preparation

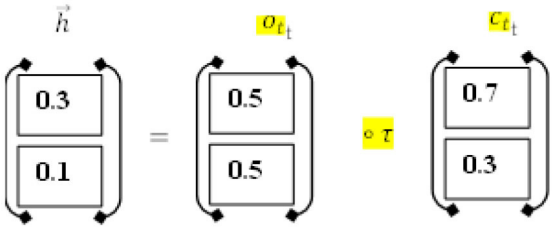
Our model predicts diabetes D1: diabetes Yes, or "D2: diabetes No" for a given patient instance in the illness dataset. Firstly, the illness data for the DL model is acquired through the instance selection module (31). The data was transformed into a matrix of indexes by a parser named Keras and transmitted to the embedding layer of the composite DL model for evaluation. The embedding layer converts each disease indicator into a vector containing streamed numbers. An example of a scalar embedding is [0.2 0.1 0.5 0.4], which encapsulates data about illness with the index [1]. In the end, the matrix packing looked somewhat like this: [0.36, 0.43, 0.85, 0.12], [0.52, 0.61, 0.11,0.25], [0.71, 0.22, 0.54, 0.47], [0.34, 0.48, 0.61, 0.39].

Extraction of Contextual Information

As input for this layer, a rectified feature map derived by the preceding neural network layer serves as input. In BILSTM layer calculations, the primary components are new candidate value ($c \sim_t$), output gate (o_t), forget gate (f_t), and input gate (i_t).

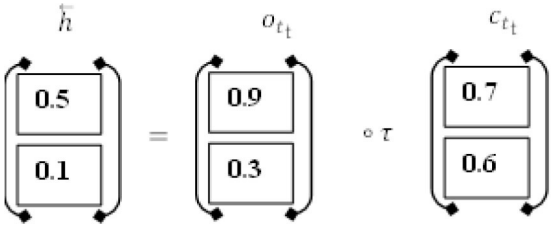
Hidden Layer No. 1

It includes the LSTM's current input (i_t) and prior state (h_{t-1}) The computations are done using Equations (1)–(6). Finally, the first hidden layer computes the "$\overrightarrow{h}$" hidden state (forward pass LSTM).



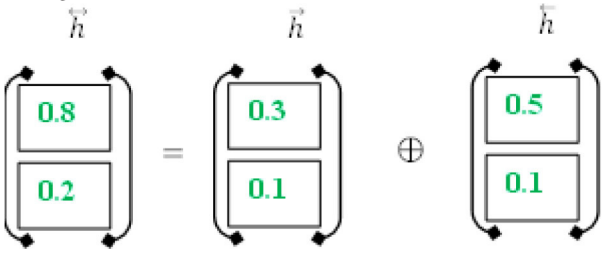
Hidden Layer No. 2

The present input (i_t) and the future state (h_{t+1}). make up the backward pass LSTM. The calculations are carried out by the use of the formulas (7) to (12). Finally, the succeeding layer is used to produce the hidden state $\overleftarrow{h}$ (backward pass LSTM).



BISLTM Outcome

In order to get the final BISLTM "$\overleftrightarrow{h}$" we combine the "$\overrightarrow{h}$" from the LSTM forward pass and the "$\overleftarrow{h}$" from the LSTM backward roll using Formula (5).



Diabetes Prediction

Using the SoftMax approach, it is determined how likely each of the labels "D1" and "D2" actually is. Formula (13) was used to determine the total input, as shown below:

For diabetes-yes, the class label for decision attribute 1 is "D1."

$$d_1 = l_1 \times w_2 + l_2 \times w_2 + b$$
$$d1 = 0.7 \times 0.8 + 0.5 \times 0.2 + 0.5$$
$$d_1 = 0.56 + 0.4 + 0.5 = 1.46$$

For diabetes-No, the class label for decision attribute 2 is "D2."

$$d_2 = l_1 \times w_2 + l_2 \times w_2 + b$$
$$d2 = 0.4 \times 0.8 + 0.4 \times 0.2 + 0.5$$
$$d2 = 0.32 + 0.08 + 0.3 = 0.7$$

To figure out the likelihood of each target class (D1, D2), the SoftMax function (14) is being used.

$$softmax\ (d_1) = \frac{\exp^{d_1}}{\sum_{i=1}^{n} \exp(d_1)}$$
$$softmax\ (d_1) = \frac{\exp^{1.46}}{\exp^{1.46} + \exp^{0.7}}$$
$$softmax\ (d_1) = \frac{4.305}{4.305 + 2.013} = \frac{4.305}{6.318} = 0.681$$

In the same way, the SoftMax function for the second class of diabetes predictions was made as well.

$$softmax\ (d_2) = \frac{\exp^{d_2}}{\sum_{i=1}^{n} \exp(d_2)}$$
$$softmax\ (d_2) = \frac{\exp^{0.7}}{\exp^{1.46} + \exp^{0.7}}$$
$$softmax\ (d_2) = \frac{2.013}{4.305 + 2.013} = \frac{2.013}{6.318} = 0.319$$

In our computations, class D1 diabetes was shown to have the highest likelihood (0.681). Based on such patient details, we can predict that the diabetic chance is "D1" (**Figure 4**).

Using pseudocode, **Algorithm 1** illustrates how the proposed method for forecasting diabetes illness works.

User Interface

The Keras package (1) provides a Python-based user interface for diabetes prediction. Diabetes forecasting software can help doctors and other healthcare providers predict diabetes. The information has been split into segments for simplicity of use and clarity of presentation. The software's body has three basic parts: data collection and preparation, classification and algorithm development, and diabetes diagnosis.

(i) ***Data Collection and Preprocessing Component:*** This component necessitates patient information. After that, the data is preprocessed on the backend. For every patient in the database, a new case patient identity is produced with the new and better data. Using preprocessing findings, a classifier and a model to predict the result of diabetic illness are constructed. The diabetes prediction component makes predictions about a patient's ailment based on the information they've supplied. A unique patient identifier is produced as soon as the required data is entered into the system. Every patient's precise ailment is therefore identified and tracked using this identification. **Figure 5** shows the screen that was used to collect and process the data for a patient registration input. At the software's server, the data is preprocessed in accordance with prior assumptions. As a result of our work, we have a layout that can be adapted to the individual requirements of each patient.

(ii) ***Classifier and Model Development:*** As demonstrated in **Figure 6**, a diabetic dataset may be utilized to train classifiers and build models. When a patient selects the "Model Training" tab, the screen below appears. It displays the imported data for training purposes. Clicking "Model Training" creates and trains a deep learning approach.

(iii) ***Predicting Diabetes:*** It is as simple as entering the necessary patient information and clicking the "Predict Diabetes" option on the site to predict diabetes. Whenever the "update training set" tab is pressed, a new training set is generated. After inputting the patient's disease information and pressing the "predict diabetes" button, the patient's findings are shown as "D1: diabetes Yes," "D2: diabetes No," and a predicted level of acceptance for each choice selected. As shown in **Figure 7**, the likely possibility of a diabetic illness diagnosis for a given set of criteria is "D1: diabetes Yes."

EXPERIMENTAL RESULTS AND DISCUSSION

In this section, we will go through the findings from a series of experiments designed to address the questions posed in Section Introduction of this article.

Addressing Research Objectives

RO1: To Use the BiLSTM Deep Learning Model to Make Predictions About Diabetes Based on Patient Illness Data

We achieved study objective #1 by using multiple BILSTM algorithms for diabetes prediction by modifying the parameters of the recommended BILSTM model. Additionally, there were several other epochs and filtering methods in use. The algorithm has three hidden layers as well as a number of batch sizes and epochs. The number of vocabulary vectors was 62, and the embedding dimension was 128 with the SoftMax activation function being employed (8, 16, and 32). **Table 2** shows the accuracy, recall, and F-score of several BILSTM models. It is 93% accurate with the following parameters: filter number 8, filer size 280, unit size 2, "f1 score" of 92%, recall of 92%, and precision of 92%.

Data balancing greatly increases efficiency, as seen in **Table 3**, compared to not employing data balancing. Using the experimental data, the suggested model may be used to accurately forecast diabetes in real-world contexts.

Table 4 shows the results of 10 BILSTM trials with varied parameter values. We compared the accuracy of each model. The BILSTM-10 model had the greatest accuracy, with eight filter sizes, 16 filters, and 10 LSTM units.

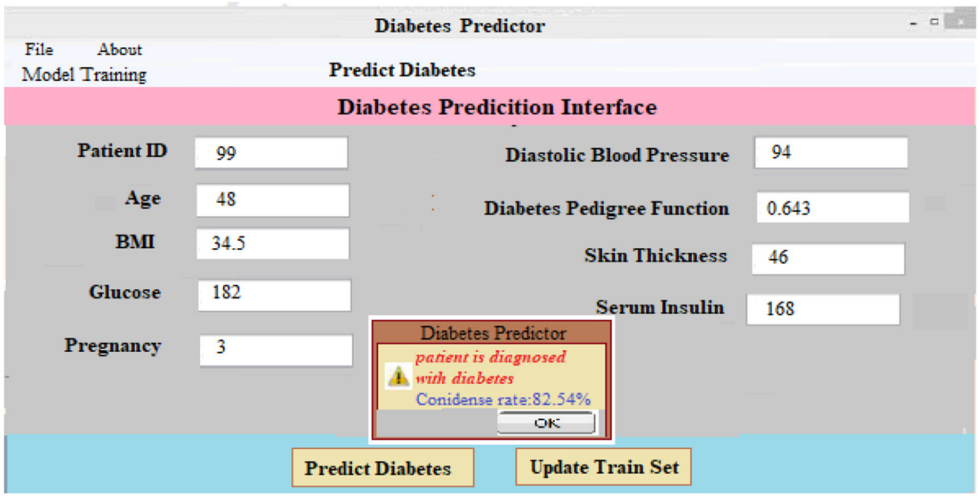

FIGURE 7 | Diabetes prediction interface.

Computational Complexity

Since the input data is routed *via* two LSTM layers, the computational cost of a conventional LSTM model per each stage with a gradient descent optimizer is O (W), where W is the maximum number of variables (21). However, despite the fact that BiLSTM has high computational complexity, it is successful in reducing the volume and complexity of the feature space. BiLSTM takes advantage of the data's inherent properties. Using drop out, we can cut down on the number of features and make sure the model doesn't fit even more than it should.

RO2: Comparison of the BiLSTM Model for Diabetes Prediction With Classical Machine Learning and Deep Learning

The BILSTM results for diabetic disease prediction were contrasted with those from several traditional machine learning approaches as well as deep learning techniques in order to address the second study objective.

Machine Learning vs. Proposed System (BILSTM)

In order to evaluate the suggested approach (BILSTM) with other common machine learning methods, data from patients was employed. Feature representation techniques such as TF-IDF and CountVectorizer are used in machine learning. **Table 5** shows the results of the performance evaluations. The results are summarized below.

- **BILSTM vs. KNN**

  To see how well the suggested BILSTM model stacks up against other machine learning techniques, we used the K-nearest neighbors approach. **Table 5** shows the results of the analysis.
- **BILSTM vs. DT**

  The purpose of this experiment was to compare a BILSTM model against a traditional machine learning classifier (DT). **Table 5** shows that the precision (0.81), recall (0.78), F1-score (0.80), and accuracy (0.78) of DT classifiers were all poorer (80%).
- **BILSTM vs. SVM**

  The results from the BILSTM model were found to be more effective than those from the SVM classification algorithm. **Table 5** displays a lower F1-score (0.79), a lower recall (0.81), and a lower precision (0.79).
- **BILSTM vs. NB**

  BILSTM was tested against a Nave Bayes (NB) classifier in this experiment. **Table 5** shows a lower F1-score (0.70%), lower recall (0.70%), and lower precision (0.70%).

TABLE 2 | BILSTM deep learning models' accuracy, recall, and f1-score.

Model	Precision (%)	Recall (%)	F-score (%)
BILSTM-1	0.74	0.75	0.74

Deep Learning vs. Proposed Technique (BILSTM)

For the purpose of accurately predicting diabetes based on patient data, the suggested method is compared to other deep learning techniques, such as long/short-term memory (LSTM), convolutional neural networks (CNN), and recurrent neural networks (RNN). **Table 6** summarizes the results.

- **LSTM vs. Proposed BILSTM**

  We compared the BILSTM model's performance to that of a single LSTM model throughout this research. The LSTM model has the lowest precision, recall, F1-score, and accuracy among the models shown in **Table 6**.
- **CNN vs. Proposed BILSTM**

  We wanted to see if the suggested BiLSTM method outperformed the CNN model in this trial. **Table 6** shows that the CNN model performed poorly in terms of accuracy, precision, recall, F1 score, and precision.
- **RNN vs. Proposed BILSTM**

  We conducted this test in order to ascertain which method was the most effective. In **Table 6**, the RNN model's precision, recall, F1-score, and accuracy were found to be worse than expected.

TABLE 7 | Comparison of the BILSTM model with other studies.

References	Technique	Results
Butt et al. (9)	Predicting diabetic illness with machine learning	Acc: 85%

Proposed (BILSTM)	Predicting diabetes with deep learning (BILSTM)	93.07

RO3: Comparison of Proposed Method's Effectiveness to Baseline Research for Predicting Diabetic Patients

For the third study question, we compared the proposed BILSTM model's efficacy to similar studies. The suggested system is compared to numerous benchmarking approaches to assess its efficiency. It compares our suggested BILSTM approach to a baseline study and shows that it outperforms the latter (**Table 7**). An exhaustive review of published approaches is challenging for numerous reasons. With so many distinct datasets, it was difficult to compare these methods.

First Study

Butt et al. (9) proposed a supervised ML model for diabetes prediction based on patient data. Data from diabetic patients was collected using a variety of machine learning techniques. The experimental findings demonstrate that the model's performance is unsatisfactory (accuracy: 88%).

Second Study

A ML-based approach for diabetes prediction has been suggested. They used a range of machine learning approaches to analyze diabetes data sets. Combining a DL model with a more effective strategy for data balancing may improve the model's performance.

Work Proposed (Our Model)

A deep neural network is employed in the proposed DL-based diabetes prediction method. The experimental results (**Table 7**) show that the predictor attributes (**Table 7**) chosen have a significant impact on the predicted (target) variable. The main reason for our success in predicting diabetic diseases is the integration of data balancing and the BILSTM deep learning model. With the help of the BILSTM layer, context data may be preserved.

Analyzing Results

Experts' predictions are compared to the forecast provided by the proposed technique, and the proposed method's performance is evaluated. The first 12 patients' workflows are shown in **Table 8**.

TABLE 8 | The human expert's prognosis vs. the suggested system's.

Suspected diabetic patient	Diagnosis by diabetes expert	Prediction by BILSTM model (proposed)
1	Diabetes = yes	Diabetes = yes
2	Diabetes = yes	Diabetes = yes
3	Diabetes = no	Diabetes = no
4	Diabetes = yes	Diabetes = no
5	Diabetes = yes	Diabetes = yes
6	Diabetes = yes	Diabetes = yes
7	Diabetes = yes	Diabetes = yes
8	Diabetes = no	Diabetes = no
9	Diabetes = yes	Diabetes = yes
10	Diabetes = no	Diabetes = no
11	Diabetes = yes	Diabetes = yes
12	Diabetes = yes	Diabetes = yes

Threats to External Validity

As indicated in Section Addressing Research Objectives, the suggested strategy was evaluated internally to assure model stability, and two extra datasets were acquired to externally support the proposed methodology. We collected two more datasets after conducting internal validation of the suggested technique to guarantee the validity of the strategy.

Dataset 2

This dataset comes from the University of Virginia School of Medicine's Department of Medicine (32). It has 1,046 occurrences in two classes. Based on comparisons with the Pima Indians Diabetes Dataset and clinical experience, we chose 12 key features from 19 initial attributes that we thought were most important to look for.

Dataset 3

This data set was compiled *via* responses to an internet questionnaire. There are 14 variables in the questionnaire that we came up with: age, gender, being pregnant, family history, BMI, sleeping habits, quality of sleep, snoring and other snoring-related behaviors, appetite cues, tobacco, drinks, hypertension, sugar levels, and blood sugar. Sixty-eight positive and 316 negative cases make up the dataset, which is broken down into two groups. This data set of people who live in Pakistani let us test our model in a real-world setting.

By comparing it to the multiple datasets provided in this section, we demonstrate that the proposed model for diagnosing diabetes is both effective and exact. In order to evaluate the suggested approach, classifiers are created and tested on the given data sets. On the other hand, models that have been trained on the primary dataset (dataset 1) will be tested on the two new datasets that have been set up.

Table 9 provides a summary of the findings. Both the KNN and LSTM baseline techniques were tested against the proposed model (BILSTM). An average of 82% of the compared techniques (KNN and LSTM) were outperformed by the proposed solution. This study's findings validate the proposed model and its potential to enhance classification accuracy.

TABLE 9 | The external validation of the proposed method.

Dataset	Precision	Recall	Accuracy
Dataset 2	0.723 (KNN)	0.718 (KNN)	0.751(KNN)
	0.761 (LSTM)	0.752 (LSTM)	0.766 (LSTM)
	0.855 (Proposed)	0.819 (Proposed)	0.811 (Proposed)
Dataset 3	0.718 (KNN)	0.817 (KNN)	0.781 (KNN)
	0.726 (LSTM)	0.761 (LSTM)	0.761 (LSTM)
	0.813 (Proposed)	0.834 (Proposed)	0.826 (Proposed)

CONCLUSIONS AND FUTURE WORK

Because of the massive increase in healthcare content, the collection and analysis of such data to identify diabetes disease in patients has become increasingly significant. In order to do this, an effective DL-based DSS model was developed and applied. Get benchmarks for data collection, preprocess, and then use a deep neural network (BILSTM) to forecast diabetes are three components of this model. In addition, the balanced and unbalanced data sets were used in subsequent tests. A BILSTM model was also used to estimate the likelihood of diabetes developing in the future. When compared to previous attempts, the findings are positive. The proposed method does have a few apparent limitations, such as the use of embedding rather than a pre-trained model. In the future, the use of diabetes data sets from many domains (e.g., patient data from several domains) with pre-trained algorithms like word2vec or Fasttext may be investigated.

Early detection of vessels from fundus images can effectively prevent the permanent retinal damages caused by retinopathies such as glaucoma, hyperextension, and diabetes. Concerning the red color of both retinal vessels and background and the vessel's morphological variations, the current vessel detection methodologies fail to segment thin vessels and discriminate them in the regions where permanent retinopathies mainly occur. This research aims to suggest a novel approach to take the benefit of both traditional template-matching methods with recent deep learning (DL) solutions. These two methods are combined in which the response of a Cauchy matched filter is used to replace the noisy red channel of the fundus images. Consequently, a U-shaped fully connected convolutional neural network (U-net) is employed to train end-to-end segmentation of pixels into vessel and background classes. Each preprocessed image is divided into several patches to provide enough training images and speed up the training per each instance. The DRIVE public database has been analyzed to test the proposed method, and metrics such as Accuracy, Precision, Sensitivity and Specificity have been measured for evaluation. The evaluation indicates that the average extraction accuracy of the proposed model is 0.9640 on the employed dataset.

INTRODUCTION

Retinal vessel detection and identifying blood vessel properties, including diameter, shape, bifurcation, and tortuosity, mainly aim to diagnose various eye abnormalities and retinopathies (1). At the same time, the evaluation of bifurcation points and tortuosity assist in diagnosing cardiovascular ailments. Also, analyzing width can result in the prevention of retinopathies induced by hypertension (2). Besides, glaucoma prevention is only possible if fundus retinal images are analyzed regularly to diagnose any abnormal modification of blood vessels around the optic disk (3). Diabetic retinopathy is another disease imposed by blood vessel construction, distribution changes, and fresh vessel evolution. Late diagnosis may also result in adult blindness (4). These critical medical applications highlight the importance of vessel extrication from retinal fundus pictures for ophthalmologists in diagnosing diseases and acting properly for their patients.

Unfortunately, with such a significant role the retinal vessel detection, blood vessels are not visible easily in retinal images taken by the fundus. The red background of the retina alongside the red color of retinal vessels is combined with fading small vessels spread around the retina. Therefore, manual detection of blood vessels is considered a subjective task requiring specific expertise while time-consuming (5). The vessel's width varies subject to the breadth of the vessel and the image resolution. The retinal boundary, optic disc, and diseases such as cotton wool patches, bright and black lesions, and exudate can all be seen in ocular fundus images (3).

Image processing methods have improved the recognition of blood vessels by changing the intensity of images and normalizing the color distribution. These techniques can enhance the reading of retinal images; however, fully automatic extraction requires understanding the properties of the vessel and detecting them in the noisy background of retinal images at which inadequate contrast regions are distrusted non-uniformly. It has been more than three decades where Computer-Aided-Detection (CAD) methods have been employed to diagnose retinopathies. Unfortunately, most traditional methods are not well-suited for recent, accurate sensors. For instance, since the resolution of fundus scanners is increased, standard image-processing methods show their drawback in detecting small faded vessels. Briefly said, the traditional systems underperform the detection due to variations in image properties due to different capture devices that influence the intensity and resolution of retinal images; therefore, machine learning-based approaches are more suitable (6).

For vascular segmentation of retinal pictures, various machine learning (ML) approaches and procedures are available. These methods are divided into supervised and unsupervised approaches. Support vector machine (SVM), neural network, and classification based methods are examples of supervised methods. Matching filter, vessel tracking, and mathematical morphology methods are all examples of unsupervised approaches (7).

The remaining current paper is divided into three sections. In Section Literature Review, a brief review will be conducted on the approaches targeting the objective of the work *via* various techniques. The section is wrapped up by highlighting the importance of fusion approaches taking novel DL methods with successful traditional approaches at once. In the third section, the main idea of the research is proposed, while the user data set and the structure of the employed DL is detailed. Later in Section Results and Discussions, results will be reported, and evaluations will be carried out to identify the strengths and limitations of the suggested approaches compared with the other similar methods. The conclusion is then followed in Section Conclusion and Future Work to wrap up the discussed methodology.

LITERATURE REVIEW

A broad look at the Literature review covering retinal blood vessel detection methodologies reveals that the current methodologies can be categorized into three classes (8) template matching based, tracking-based, and classifying based. In template matching approaches, a kernel is selected, which can be fitted well to a vessel. This kernel is later convoluted with each image. At the final stage, pixels with the highest responses are collected *via* a proper thresholding method to provide a binary map of vessel/background. A Gaussian-shaped curve proposed by Chaudhuri et al. (9) is used to highlight the vessels based on the intensity distribution of the vessel's cross-section (as illustrated in **Figure 1**).

Later improvement has been proposed by Al-Rawi et al. (10) to tune the parameters to increase the Sensitivity and Accuracy and decrease false positive detection. Gaussian, Cauchy, and Gabor distributions have been employed with the same purpose (3).

In contrast to the previous two approaches in which a template of the vessels plays an essential role in the detection, tracking approaches use a model to trace vessels *via* seed growing. Each of the vessels can be traced separately from a starting point (which can be an ending point of the parent vessel) to the ending point at which the vessel is branched. Considering the contrast between vessels and other retina background intensity, Wu et al. (11) determined the mid-line of a vessel from a starting point inside it. Having calculated the vessel's width, tracing the orientation is taken into place automatically by assuming the vessel boundaries are parallel with the middle line. Several discussions have been conducted to detect the initial seed point *via* manual annotation or automatic template matching methods (7). For instance, the methodology proposed by Dizdaro et al. used level-set thresholding to identify an initial seed (12). The work carried out by Zhang et al., which applied active contours started from a seed found *via* Hessian vessel response (13), can be categorized in the second explained group using a tracking approach to detect vessels. Ali et al. used B-COSFIRE filter blending with adaptive thresholding for binarization of retinal blood vessels (14).

In classifying approaches, mostly ML techniques are taken into consideration. ML methods focus on two sets of features: common between pixels belonging to vessels and those that discriminate between background and vessel pixels. Provision of such pixels can increase the accuracy of a model being trained by artificial intelligence (AI) (15, 16).

On the one hand, practical ML approaches with supervised methods target pixel-based feature maps as training to identify vessel patterns. Various methodologies have been proposed to detect vessels using k-Nearest Neighbors (17), Decision Trees (18), SVM (19), and Neural Networks (20, 21). On the other hand, unsupervised methods employ rule-based algorithms, including filters, gradients, and thresholds for the same classification purpose. For instance, the work presented in (22) employs a neural network trained to model a matched filter.

Traditional ML algorithms and recent deep-learning methods can be listed as the third set of approaches. Recent studies on DL comprise two perspectives, in which the first one addresses retinal vessel detection *via* pixel-level classification. The later perspective uses DL to achieve semantic segmentation between the two classes of pixels. An instance can be the pipeline of methodologies proposed by Wang et al. (23). They extract a set

of required features using DL and latterly distinguish each pixel *via* Random Forests.

Ensemble learning has also been used in several investigations. Lahiri et al. (24) suggested using an ensemble of stacked denoising autoencoders. Subsequently, the final conclusion is made *via* voting of a SoftMax layer over autoencoder outputs. In another work, Maji et al. (25) suggested an ensemble of 12 deep Convolutional neural networks (CNN). The final decision is made *via* performing averaging of the output result of the decision over each pixel. Few studies have targeted DNN and formulated the objective into a pixel-to-pixel classification (26, 27); however, these approaches are underperforming the performance by picking each pixel and deciding the proper class in terms of training or testing. A practical solution has been proposed by Dasgupta et al. (28) in which both training and testing phases are carried out over small retinal patches with an end-to-end perspective. These patches are individual from each other, and hence they can be processed simultaneously.

Wu et al. (29) suggested employing a CNN to extract binary masks followed by a generalized particle filtering technique aiming at retinal vessel tree extraction *via* a probabilistic tracking framework. Concerning long-range collaborations between pixels, Fu et al. (30) carried out the vessel detection by Conditional Random Field (CRF) developed based on a multi-level CNN model.

Hybrid methodologies can be suggested *via* a combination of the approaches mentioned above. For instance, the template matching approach can be utilized in the third approach to provide more features for classifying vessels. Studies combine these approaches in sequential order, as template matching has been considered in the preprocessing stage to highlight features that will be used later by the ML approach to discriminate pixels belonging to either retinal tissue or vessel (31, 32). For instance, the work proposed by Gao et al. (33) combines Gaussian matched filter (as a preprocessing stage) with a U-Net CNN to improve vessel detection. In other studies, Zolfagharnasab et al. (34) showed that the Cauchy probability distribution function (PDF) could be a model cross-section of vessels more accurate than the Gaussian. The comparison of Gaussian and the Cauchy curves for generating a template for retinal vessels has been shown in **Figure 2**.

In this way, the conducted study aims to suggest two main contributions in the pipeline of the work proposed by Gao et al. First, supported by the investigation conducted in (33), we will employ Cauchy PDF instead of Gaussian. Second, a novel feature map will be prepared instead of raw pixel intensities by proposing a new three-channel image. Roy and Sharma presented a Residual Y-net design for retinal vessel detection inspired by U-net that help in Diabetic detection (35). Siddique et al. gave a review of U-Net and its variant techniques for image segmentation and specifically highlighted their applications in retinal fundus image segmentation (36). Yuliang et al. propose a retinal blood vessel segmentation model that combines a multiscale matched filter with a U-Net that has been tested on various available public datasets (37). Shabbir et al. describe different types of ML models for glaucoma detection from fundus image like multiscale, texture feature-based, Segmentation-based, CNN, Ensemble Learning approaches in detail (38). Wang et al. proposed a structure using Dense U-net and the patch-based learning approach for clinical applications (39). **Table 1** given below provides a tabular

representation of the related work discussed in the literature review section.

METHODOLOGY

The end-to-end implementation of retinal vessel detection requires introducing a correct set of features per pixel in which the model can find meaningful discrimination between vessels and background. Concerning the intensity of each pixel in the fundus image, $I(x, y)$ can be defined where x and y are the pixel intensity, and I is the content of the pixel intensity reported in the RGB vector. Several studies have suggested a preprocessing step to enhance the brightness of fundus images (29, 40).

Pre-processing

Illustrated in **Figure 1**, the original fundus images present low-intensity differences among the retina tissue and vessels; therefore, it is proposed to use contrast limited adaptive histogram equalization operation (known as CLAHE) to improve the overall image distinction (1). The CLAHE operation was performed for each color channel to normalize the pixel intensity values image *via* (1).

$$I\left(x,y\right) = \frac{I\left(x,y\right) - u}{\sigma} \tag{1}$$

Where μ is mean, and σ is the standard deviation of each channel.

Concerning the red nature of blood vessels, since the retina texture is supplied *via* micro-vessels, the mean intensity of the red channel is mostly higher than other RGB channels. To this end, it has been reported to remove the red channel from the processing of retinal vessels. In contrast, the green channel and the blue one can be used instead to provide more information about the spread of blood vessels. To this end, an initial step comprising the decomposition of the channel is required, and the omitted channel will be replaced with an extra feature channel to highlight the presence of the vessels across the retina texture.

Construction of the Feature Map

As discussed through the literature review, the cross-section can be modeled as a Gaussian curve; however, in (10), it was shown that Cauchy PDF (2) could be fitted better than the traditional Gaussian in case, as they are compared in **Figure 2**.

$$C\left(x\right) = \frac{1}{\pi\gamma\left[1 + \left(\frac{(x-x_0)}{\gamma}\right)^2\right]} \tag{2}$$

Where γ and x stand for scaling parameter (defining the slope of the curve) and pixel intensity, respectively. By selecting non-zero values for x_0, the curve peak is shifted horizontally. To generate the bank of filters, γ is chosen as 1, the template curves trunk value (T) is selected 9, while the length value of each template (L) was chosen 8, upon the recommendations for DRIVE dataset in (2).

The template is then rotated every $\frac{\pi}{12}$ to detect vessels in different orientations. To prepare an image for either training or testing, each pixel is first convolved with the bank of filters, and the highest response is stored. **Figure 3** depicts an image with its response after the convolution.

As the red channel was initially removed from the original image, the matched filter response is inserted in the red channel. To prepare the new feature images (Cauchy-G-B) for creating patches. Since there are few training images (20 for the dataset), a total of 500 overlapped 64 × 64 patches have been generated per training image. Besides, data augmentation has been employed via either flipping patches horizontal and vertically. This operation assured that more than 40k patches are available for the training and validation process. However, for testing purposes, the total ROI of each test image is segmented into 64 × 64 patches with no overlap. It assures that as soon as there is a prediction per each patch, they can be regrouped structurally to form the predicted image entirely. The image preparation pipeline and the patches are presented in **Figure 4**.

U-Net

The U-Net is widely employed among the different CNN architectures used for retinal vessel detection (41). U-net has been proven to have a promising output in various segmentation approaches, especially in retinal vessel segmentation (3, 4). Concerning the end-to-end training of pixels, it uses multi-level decomposition to incorporate low-level features and multi-channel filtering. On the one hand, employing U-net enhances training useful low-level features. Yet, on the other hand, through the testing, it discards the trained feature, which results in degradation of learning ability.

The employed U-net model is based on a fully connected network structure comprising an input layer, a convolutional layer, a pooling layer, and an up-sampling layer followed by the output layer. Bach to the encoding stage includes four down-sampling steps where there are two convolutional layers and one pooling layer in each. The encoding stage consists of four up-sampling steps, while each one consists of two convolutional layers and one up-sampling layer. The input layer is set to accept patches of the size of 64 × 64 × 3, while the output is designed to generate a 64 × 64 × 1 floating point image. The architecture consists of 32 filters with padding for the size equal to the input for the first and second convolutional layers in the internal layers. The Rectified Linear Unit (ReLU) activation function was used in the whole model except the last layer where SoftMax was employed presented in (3).

$$p_k\left(x\right) = \frac{exp\left[a_k\left(x,y\right)\right]}{\sum_{k'=1}^{K} exp\left[a_k\left(x,y\right)\right]} \tag{3}$$

where $a_k\left(x\right)$ stands for the activation in feature channel k at the pixel position of $\left(x,y\right)$. The number of classes is shown by K and $p_k\left(x\right)$ shows the approximated maximum function. The U-net structure is depicted in **Figure 5**.

RESULTS AND DISCUSSIONS

Database

The DRIVE database contains 40 pictures with 768 × 584 pixels captured digitally via a Canon CR5 camera at 45 fields of view (42). Total seven images show some lesions corresponding to degrees of retinopathy. Besides, binary maps containing manual segmentation of vessels are provided, and masks cover retina boundaries. Unfortunately, the images are provided in a lossy compression format (JPEG), which has affected some small

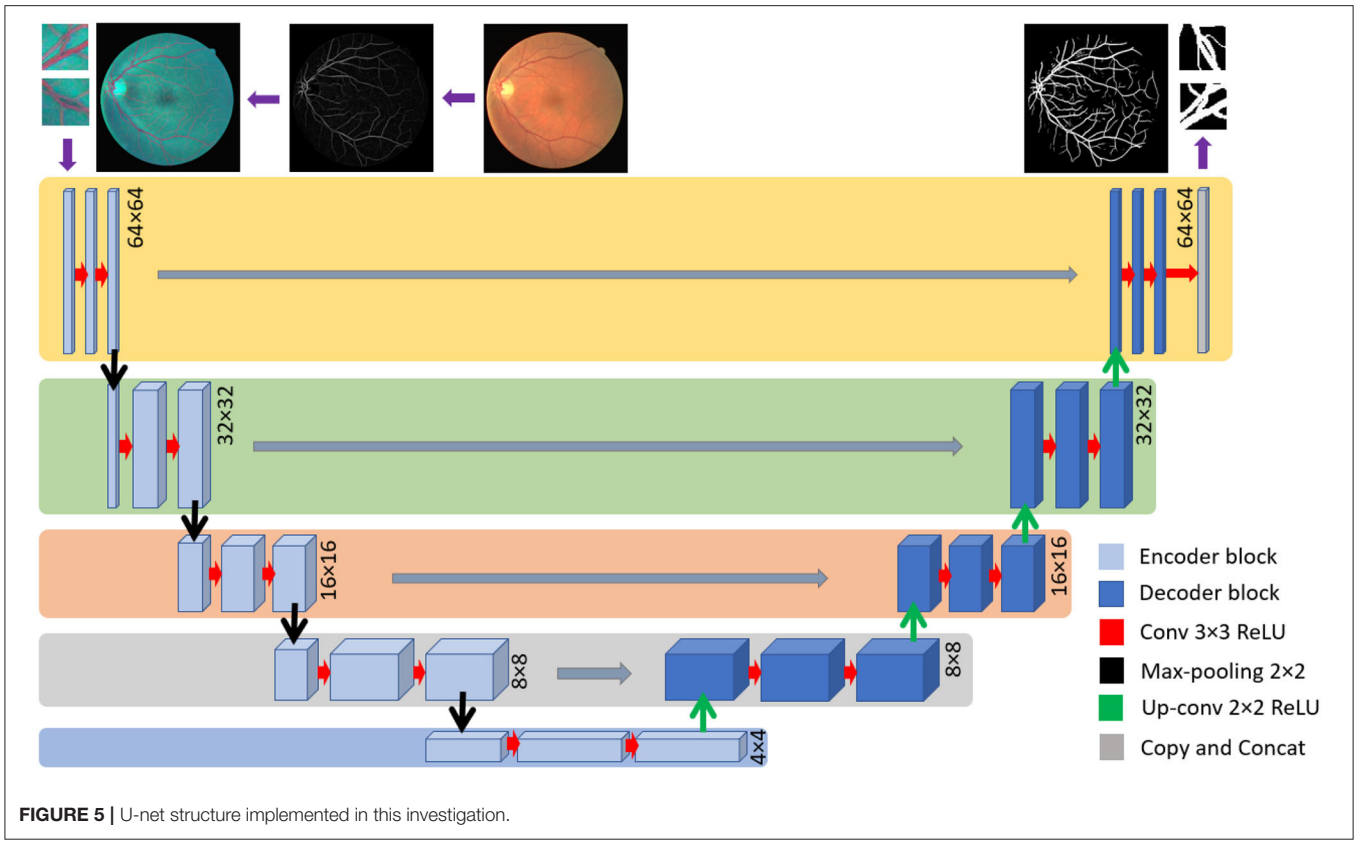

FIGURE 5 | U-net structure implemented in this investigation.

details; however, most researchers have used this dataset as a reference for evaluation. The images are split into two groups, training and test, each containing 20 images with three images presenting retinopathy symptoms.

Implementation Details

We first extracted patches from DRIVE retinal images to train a DL model. Later, we fed them as the input of the designed network and the corresponding label patches obtained from ground truth data. In other words, With the approach used to train a U-net with the end-to-end strategy, the preprocessed patches and their corresponding ground truth extractions were employed to obtain a specific training model for DRIVE database images. Data splitting was carried out by considering 90% of all extracted patches for training and 10% for validation. This strategy has been adopted in several previous studies, including in (42–44), and (33). A total number of 200 epochs were considered for the training process, as well.

Training Details

Adam optimizer was employed to speed up the training process and avoid trapping on local minima while training. It included setting $\beta_2 = 0.9$ and $\beta_2 = 0.999$ to handle sparse gradients on noisy (45). While the initial learning rate was set to $\eta = 0.01$, and it was set to decrease with the shrinking rate of $\eta_i = 0.9\eta_i - 1$ per each 10 epochs when the value of loss function is saturated.

The system configuration used for the training and testing process includes an Intel Core i7-7300 CPU with 64GB of memory. The code was developed in Python 3.7 using Anaconda and Keras as the DL framework and TensorFlow. The preprocessing, including the preparation of multi-channel feature images, was quite fast per each image (<10 s), but instead, each training epoch required more than 2 h to complete.

Evaluation Metric

Retinal vessel segmentation is commonly looked at as a binary classification task. The predicted labels for each pixel are compared with the ground truth classes to fit vessel (positive) or retinal tissue (negative) categories. Binary classification requires determining a true or false class (vessel or retinal tissue) class per pixel. Therefore, a predicted pixel can be represented in four groups:

- True Positive (T_P) are those pixels predicted as vessels and belong to vessels in ground truth images (correct prediction).
- True Negative (T_N) pixels are predicted as non-vessels and belong to retinal tissue (correct prediction).
- False Positive (F_P) indicates the predicted pixels as retinal background but instead belong to vessels (incorrect prediction).
- Finally, False Negative (F_N) are non-vessel pixels, but they have been classified as retinal vessels (incorrect prediction).

For the evaluation purposes, the performance of the trained models is obtained through measuring Sensitivity (Sen), specificity (Spc), accuracy (Acc), and Precision (Prc), which are

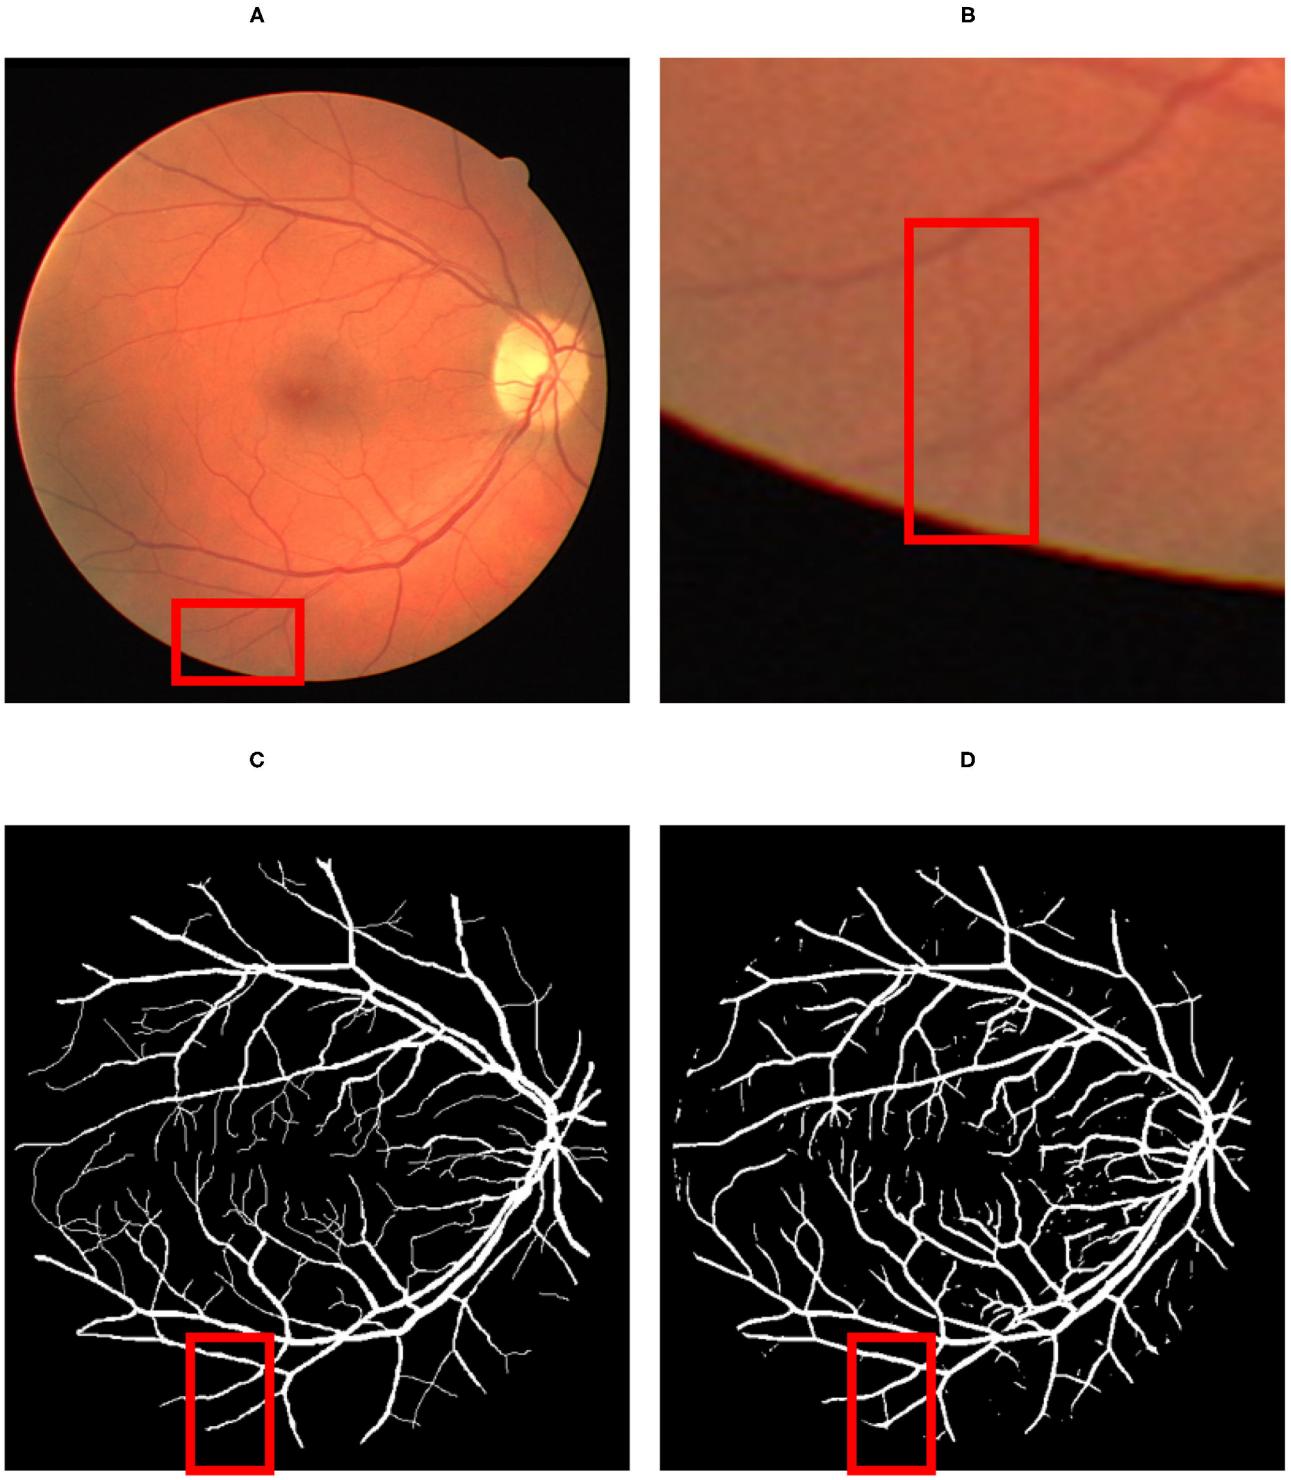

FIGURE 6 | The result of the detection: **(A)** Original fundus image; **(B)** a thin vessel; **(C)** the corresponding ground truth map which does not contain the vessel; **(D)** the thin vessel being detected by the proposed model. The red color square box part in **(A)** has been reflected by respective identified image in **(C)** by proposed map. Similarly the red square part reflected in **(B)** has been identified by red square box part in image **(D)**.

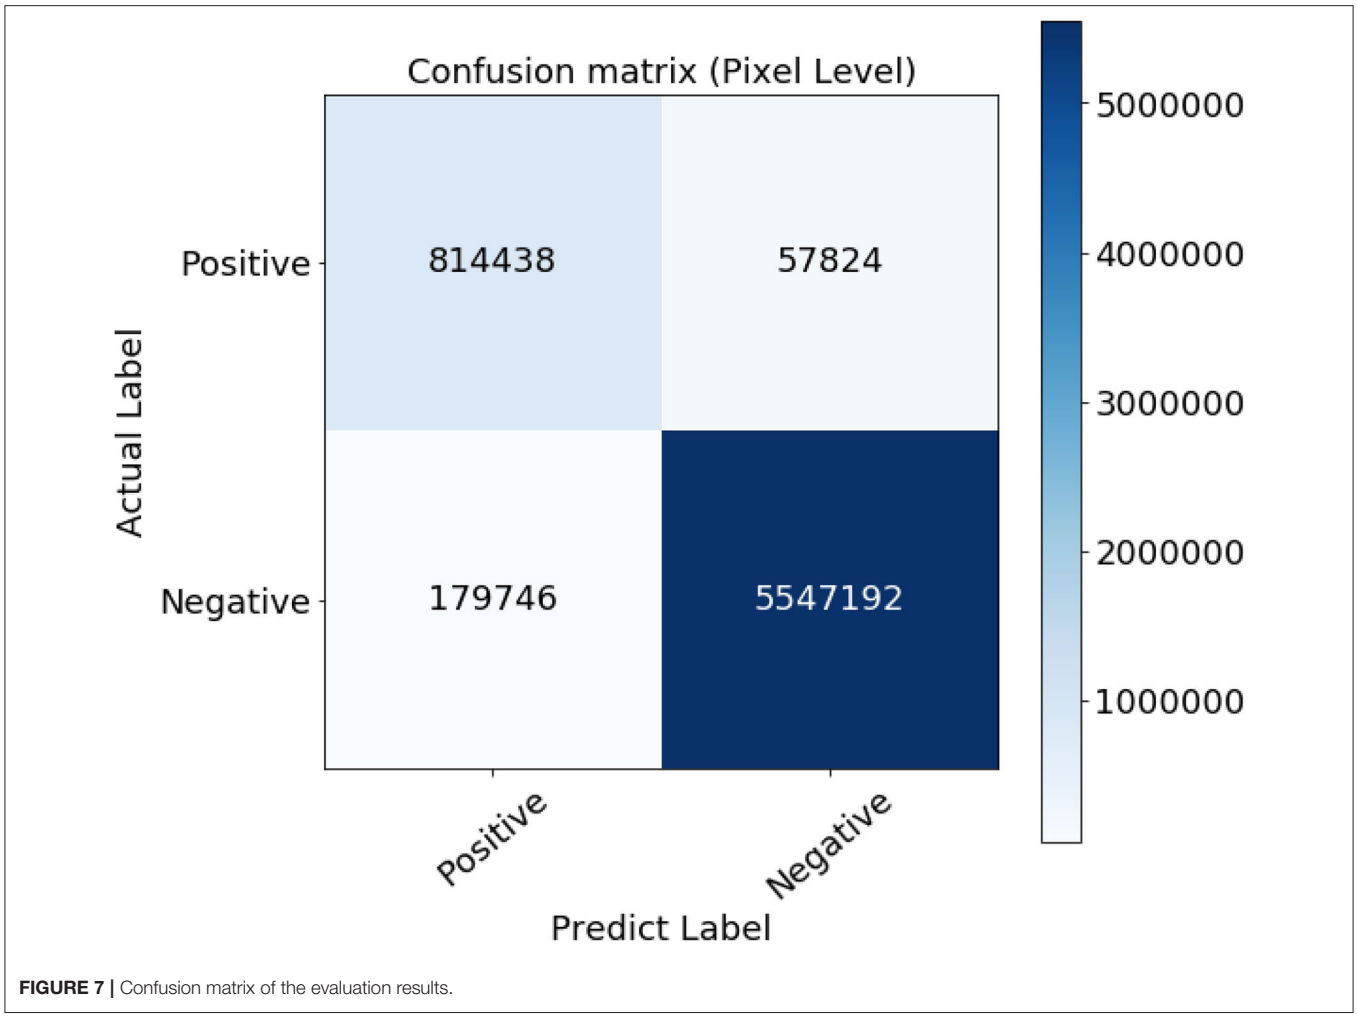

FIGURE 7 | Confusion matrix of the evaluation results.

standard approaches for evaluating binary results represented in (4–7).

$$Acc = \frac{T_P + T_N}{T_p + F_P + T_N + F_N} \tag{4}$$

$$Sen = \frac{T_P}{T_p + F_N} \tag{5}$$

$$Spc = \frac{T_N}{F_P + T_N} \tag{6}$$

$$Prs = \frac{T_P}{F_P + T_P} \tag{7}$$

In addition, the area under the Receiver Operating Characteristic curve (AUROC) for comparison with contemporary methods is obtained, as well.

The overall output of the proposed method is obtained via the receiver operating characteristic curve (ROC), which reflects the relationship between true positive and false positive rates concerning different thresholds when the network output is mapped into binary classes. For this purpose, global thresholding method with different threshold values was considered for the threshold-sensitive metrics by calculating sensitivity against the false-positive ratio ($FPR = \frac{F_P}{F_N + T_P}$) at various threshold values, and later plotting ROC curve per each FPR and thresholding rate pair. The same strategy is adopted for obtaining the average

TABLE 2 | Assessment of the obtained results with contemporary approaches.

precision obtained *via* (7) against the threshold at various threshold values.

Sensitivity Analysis of Global Threshold

To have robust evaluations for metrics that are sensitive to the employed global thresholding method (Acc, Sen, Spc, and Prc), a range of values has been studied threshold values sampled in $\tau_i \in \{0.01, \ldots, 0.99\}$. The study revealed that the changes in the metrics are slight around $\tau = 0.5$, which shows that this threshold value can be considered to be used for further evaluations.

Discussion and Comparison With Previous Approaches

Based on the obtained results, it can be discussed that the inclusion of an additional feature channel (the Cauchy matched filter response) improved the detection rate of vessels via enhancing vessel contrast against the background. In contrast, this strategy filtered the noisy red channel. Besides, vessels with various diameters were segmented by having a bank of filters at different scales for the matched filter. Vessels with multiple diameters were segmented, which assisted the DL method to improve the proposed classifier.

Concerning the subjective characteristic of manual labeling of the ground-truth data, a detailed visual comparison between the predicted vessel map (**Figure 6D**) and the ground-truth (**Figure 6C**) reveals that the proposed method can extract more vessels that had not been labeled before in ground truth images (**Figures 6A,B**).

However, since those new extracted vessels are not included in the subjective extracted ground truth images, total T_P and T_N pixels decreased while F_P and F_N increased, respectively. Such imbalance labeling has impressed the metrics to approach slightly toward a perfect detection. Hopefully, since the ground truth data is common for all the compared methodologies, they can be evaluated simultaneously. The confusion matrix presented in **Figure 7** certifies the details of the evaluation.

Additional visual comparison asserts that the proposed methods have detected thinner vessels in the central regions on the retina, where vessels are distributed in low density. It is due to the vessels' shape to fit better on the employed Cauchy curve.

Numerical comparison with other approaches (reported in **Table 2**) certifies the proposed model is ranked among most state-of-the-art methods, based on Sensitivity, Specificity, accuracy, and area under the ROC. However, some methods are ranked higher [such as the one presented in (44)], as they employed octave convolutions to extract multiple-spatial-frequency features aiming to capture retinal vasculatures with different thicknesses. This technique allowed them to improve the U-net structure and, at the same time, take benefit from features to enhance the detection rate significantly. **Figure 8** illustrates the AUROC of the proposed method, which shows a bigger area under the curve (0.9805) compared to the baseline model (0.9771) presented by Gao et al. (33).

Wang et al. Proposed a model that provides an accuracy rate of 0.9511 (39), while the model proposed by Saroj et al. Shows an accuracy rate of 0.9509 (46). Therefore, it can be concluded that the proposed model's accuracy in this paper is superior to existing models.

CONCLUSION AND FUTURE WORK

Targeting retinal vessel detection, this paper offers a novel approach that pools the response of a traditional matched filter with a fully connected U-net network. The uniqueness of the suggested method is to replace the noisy red channel of fundus images with a channel that can provide more vessel details. It is intended since the red blood vessel are barely visible distributed over the red retina tissue. The new pseudo-color image, called a multi-channel feature map, is processed by generating several patches for training via the U-net. The corresponding labels for the training patches are also provided using the ground truth data. This technique accelerates the training process and provides enough data to train the DL model. Evaluation of the results shows that vessel detection can be accomplished with an accuracy of 96.40% and sensitivity around 82%. This difference is seen since thin vessels have been discarded during the subjective annotation of ground truth images. The blue channel of retinal images can be replaced with a Gabor-filter response in future work. The bank of the used filters can be equipped with vessels presented in a variety of widths. Additional channels are also intended to be investigated to assist the DL model in associating the pixel values to the vessel or retinal tissue classes. Last but not least, and through comparison of this work to the other state-of-the-art methodologies, the proposed method shows a promising result highlighting the importance of combining feature maps to improve the detection of retinal vessels via U-net assisted DL approaches.

Gathering large quantities of fundus images is one of the most perplexing in creating strong deep-learning systems. Designing algorithms that can work from restricted data is one solution. Apart from limited images available in public datasets, there is still an opportunity for testing blood vessel segmentation approaches on noisy real-life pathological retinal pictures. The offered model has been tested only on the DRIVE dataset. Still, it can also be tested on the other available datasets to evaluate its accuracy and compare with other models. Also, the proposed model needs to be tested to real-time pathological retinal images.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

Internet of Things (IoT) involves a set of devices that aids in achieving a smart environment. Healthcare systems, which are IoT-oriented, provide monitoring services of patients' data and help take immediate steps in an emergency. Currently, machine learning-based techniques are adopted to ensure security and other non-functional requirements in smart health care systems. However, no attention is given to classifying the non-functional requirements from requirement documents. The manual process of classifying the non-functional requirements from documents is erroneous and laborious. Missing non-functional requirements in the Requirement Engineering (RE) phase results in IoT oriented healthcare system with compromised security and performance. In this research, an experiment is performed where non-functional requirements are classified from the IoT-oriented healthcare system's requirement document. The machine learning algorithms considered for classification are Logistic Regression (LR), Support Vector Machine (SVM), Multinomial Naive Bayes (MNB), K-Nearest Neighbors (KNN), ensemble, Random Forest (RF), and hybrid KNN rule-based machine learning (ML) algorithms. The results show that our novel hybrid KNN rule-based machine learning algorithm outperforms others by showing an average classification accuracy of 75.9% in classifying non-functional requirements from IoT-oriented healthcare requirement documents. This research is not only novel in its concept of using a machine learning approach for classification of non-functional requirements from IoT-oriented healthcare system requirement documents, but it also proposes a novel hybrid KNN-rule based machine learning algorithm for classification with better accuracy. A new dataset is also created for classification purposes, comprising requirements related to IoT-oriented healthcare systems. However, since this dataset is small and consists of only 104 requirements, this might affect the generalizability of the results of this research.

1. INTRODUCTION

One of the most important tasks of developing high-quality software is gathering the right requirements and ensuring no missing requirements. Often during the process of Requirement Engineering (RE), more attention is given to eliciting the functional requirements than non-functional requirements. This results in the poor quality end product and results in loss of

cost, effort, and even failure of the project. Non-functional requirements explain the important quality attributes (1, 2) and constraints (3) that must be implemented in the system. If these requirements are left ignored, the architecture is not designed properly (4). Thus, classifying the non-functional requirements becomes a mandatory task in the RE process for designing the architecture design and performing other related activities accordingly (4, 5). Traditionally, non-functional requirements are identified and extracted manually which is an erroneous process (5, 6) and laborious (7). The non-functional requirements are intertwined with the functional requirements in RE documents, not properly structured. Therefore, proper identification and categorization are required (8). Since the architect needs to know the types of non-functional requirements, non-functional requirements must be classified properly (9). Currently, the trend of using ML algorithms for classifying the non-functional requirements is gaining attention (8). However, there is still a need to classify the non-functional requirements accurately. By using automated techniques, the chance of missing the non-functional requirements is reduced, classification accuracy can be improved, and time and effort are also saved. IoT possesses a vital role in the health care systems of the present era. It includes a set of devices, which help store, process, and transfer data to achieve smart services (10–13). Healthcare systems, which are IoT-oriented, provide monitoring services of patients' data and help take immediate steps in an emergency (14–16). Thus, it is critical to ensure that these smart healthcare systems are extremely secure and perform reliably so that patients' sensitive data is not only kept protected from manipulation and attacks but also transferred entirely and safely in a timely fashion (17–19). In order to ensure that the IoT-oriented healthcare system possesses all these important non-functional requirements, it is necessary to extract all the non-functional requirements from the requirement document of the IoT-oriented healthcare system in the RE phase. Machine learning-based techniques are adopted to implement non-functional requirements in smart health care systems. However, attention needs to be given to the first classification of the non-functional requirements from the requirement document to ensure that non-functional requirements are not missed in the RE phase. By performing this classification task automatically, the chances of missing non-functional requirements will be reduced, and the probability of developing a high-performing and secure IoT-oriented healthcare system will increase (20).

In this research, the main focus is on finding machine learning algorithm and relevant features which helps in the classification of non-functional requirements with higher accuracy. For features extraction, Bag of Words (BOW) and Term Frequency-Inverse Document Frequency (TF-IDF) are adopted. The algorithms considered by this study are Logistic Regression (LR), Support Vector Machine (SVM), Multinomial Naïve Bayes (MNB), K-Nearest Neighbors (KNN), ensemble, Random Forest (RF), and hybrid KNN rule-based ML algorithms. The two main distinct additions here are the ensemble and hybrid classifiers.

The existing studies have limitations. Some studies have reported low performance (1, 6, 21). The types of non-functional requirements considered by some studies are very less (4, 22, 23). The dataset adopted by different studies has a limited number of non-functional requirements (2, 9, 21). Some studies adopted the manual process of validation which may have chances of error (21).

This article makes the following contributions.

- Creation of dataset, which includes requirements related to IoT-oriented healthcare system. The requirements included in this dataset belong to 8 categories: Accuracy, Reliability, Security and Privacy, Performance, Compatibility, Usability, Functional, and Maintainability. The numbers of requirements in this dataset are 104. IoT-oriented healthcare system requirement documents create this dataset (24, 25). Since there are no currently such dataset available that contains labeled requirements related to IoT-oriented healthcare systems, this will serve as an aid for future research purposes in automating the classification of non-functional requirements from IoT-oriented healthcare system requirement documents.
- Development of a novel hybrid KNN rule-based machine learning algorithm, which provides better classification accuracy than traditional machine learning algorithms like SVM, KNN, RF, MNB, LR, and ensemble. This novel hybrid machine learning algorithm helps classify non-functional requirements from IoT-oriented healthcare system requirement documents with an average classification accuracy of 75.9%.
- Provision of features relevant to non-functional requirements that the IoT-oriented healthcare system must possess. These features will help the researchers to create better classifiers by including them in machine learning-based techniques.

This research article is structured in the following manner. Section 2 describes the relevant work conducted earlier in the literature related to the classification of the non-functional requirements. Section 3 describes the research methodology which is adopted in this research. Section 4 shows the experiment portion. Section 5 presents the results and discussion. Section 6 provides the conclusion and highlights possible future directions.

2. LITERATURE REVIEW

In literature, many studies have highlighted the problem of ignored and missed non-functional requirements in the RE process (8, 21). Non-functional requirements are sometimes hidden and not clearly stated, due to which it becomes difficult to identify them, and chances of missing them increase. Initially, more importance is given to eliciting the functional requirements where non-functional requirements are discovered at late stages which results in issues related to architectural design (1–3, 5, 6), cost management (9, 22, 23), time management (4, 5, 7, 23), and risk (26) and quality management (5, 7, 27, 28). The problem extrapolates due to manual identification and classification of non-functional requirements (5). The manual classification is quite a time-consuming and laborious process (22, 29). Search function provided by tools is used by typing keywords and searching, which is an exhaustive process and

TABLE 1 | Non-functional requirements classification review.

Reference	Machine learning algorithm	Dataset	Limitations
Shreda and Hanani (30)	Convolutional Neural Network	PURE dataset sample	Only 5 non-functional requirement are considered, Probability of biased result due to 2 fold cross validation
Dias Canedo and Cordeiro Mendes (7)	Logistic Regression	PROMISE_exp	Classification error of 25% on average is reported which needs to be minimized
Younas et al. (32)	K Nearest Neighbor	PROMISE	Precision is found as 50.65%, Recall as 41.11% which indicates quite low classification performance.
Lu and Liang (29)	Bagging	21969 user review sentences	Only four non-functional requirement are considered
Kurtanovic and Maalej (33)	Support Vector Machines	PROMISE	Precision is found to be 78.25% which needs be further improved
Maiti (27)	K Nearest Neighbors	EU Procurement documents, NFRM data set, PROMISE	Datasets used for validation contains only 56 and 78 requirements which are very limited Validation is done only on EU procurement documents
Riaz et al. (31)	K Nearest Neighbors	CCHIT, ED, NU, OSCAR	Validation is done specifically on health care domain documents Only security related requirement are considered
Knauss and Ott (26)	Support Vector Machines	2,000 requirements in Mercedes-Benz specifications	Non-Functional requirement types are not mentioned Validation is done only on automotive industry domain document
Rashwan et al. (23)	Support Vector Machines	Corpus with 3064 annotated sentences	Only 5 non-functional requirement are considered Chances of biased results due to 6 cross fold validation
Slankas and Williams (9)	Support Vector Machines	CCHIT Ambulatory Requirements, iTrust, PROMISE	Performance is low in terms of precision and recall which are only 72.8 and 54.4%, respectively
Casamayor et al. (4)	Expectation Maximization with Naïve Bayes	PROMISE	Only accuracy of 75% is reported
Hussain et al. (22)	Decision Trees	PROMISE	Non-Functional requirement types are not stated
Cleland-Huang et al. (5)	Naïve Bayes	PROMISE, SIEMENS IET Datasets	Classification precision is 12.4% which is very low

may lead to missing the non-functional requirement (30). The concept of automating or semi-automating this task gained popularity (7, 27). However, this trend of automating the non-functional requirement classification is still young and requires further research for preprocessing, selecting optimum feature sets, acquiring relevant datasets, and using appropriate ML algorithms (8). Moreover, different studies have worked on different categories of non-functional requirements (8) and they considered different types of documents like Certification Commission for Healthcare Information Technology (CCHIT) Ambulatory requirement document (9), Emergency Department Information Systems Functional Document (31), Mercedes-Benz Specification Document (26), and European Union e-Procurement documents (27) from where the non-functional requirements are extracted. Due to different factors, the classification performance reported by different studies is different, and the comparison is not possible because of the element of biasness. Few studies have managed to report the full process of classifying the non-functional requirements from the requirement document (8). **Table 1** shows various techniques which are adopted by different studies for the classification of non-functional requirements.

2.1. Non-Functional Requirements Classification Using Naive Bayes

One of the techniques to classify the non-functional requirements from the requirement document is by Naive Bayes (5). In this technique, the probability is calculated to classify non-functional requirements. Nine non-functional requirements are focused on, and the PROMISE dataset is used. For evaluation, leave one out cross-validation is performed having 15 iterations. The classifier's performance is very poor precision, which is 12.4%. The classification error of the above classifier indicates that it needs improvement.

Similarly, in another study, the Naive Bayes algorithm is used to classify the non-functional requirement but with Expectation-Maximization (4). Non-functional requirements categories in which the data is classified are 9. The classifier's performance in terms of accuracy is reported to be about 75%.

2.2. Non-Functional Requirements Classification Using Decision Trees

Decision trees are also used to classify the non-functional requirements (22). PROMISE dataset is used, and 10-fold cross-validation is performed for evaluation. The accuracy of classification is 98.56%. The study above has not mentioned the types of non-functional requirements.

2.3. Non-Functional Requirements Classification Using Bagging

Research classifies the non-functional requirements from the requirement document by using machine learning ensemble meta-algorithm Bagging (29). The dataset consisted of 21,969 user reviews. The evaluation is performed using 10-fold cross-validation. The classifier's performance in terms of precision is found to be 71.4% and recall of 72.3%. The non-functional

requirements types that are considered by the study are 4. First of all, the types of non-functional requirements considered are only four. Furthermore, the performance of the classifier is relatively low.

2.4. Non-Functional Requirements Classification Using SVM

In one research, a SVM is used to extract the non-functional requirements from the requirement document (23). In the technique, the documents are first preprocessed. After preprocessing, SVM is applied. Cross-validation is applied for validation in which the dataset is divided into subsets, and validation is performed in iterations. One subset is used for validation in each iteration, and the remaining subsets are used for training. The performance of the classifier is evaluated using 6-fold cross-validation. The performance on the PROMISE corpus in terms of precision is 77%. The non-functional requirements types that are considered are 5. In terms of performance, there is still work that needs to be done to increase the precision. The Sequential Minimal Optimization (SMO) algorithm is used for classifying the non-functional requirements from the requirement document (9). First, preprocessing is done on text, then SMO is applied. The evaluation is performed using 10-fold cross-validation. The performance is found to be 72.8% in terms of precision. The precision of the classifier needs improvement.

Another study reported using the SVM algorithm to classify the non-functional requirements from the specification of Mercedes Benz (26). This approach is semi-supervised. Manual evaluation is performed. The performance of the classifier in terms of precision is >60%. The research is done using an automotive industry document; there is no surety about how the classifier performs in other industry specifications. SVM is used by one more study to extract the non-functional requirements (33). In this technique, the documents are first preprocessed, then applied SVM. The performance of the classifier is evaluated using 10-fold cross-validation. PROMISE dataset is used for classification. The non-functional requirements which are considered by the study are only 4. The performance in terms of precision is found to be 78.25%.

2.5. Non-Functional Requirements Classification Using KNNs

One of the studies focused on classifying security-related requirements (31, 34, 35). In the study, first preprocessing is done, then KNN is applied. The types of security requirements into which the sentences are classified are 7. The evaluation is performed using 10-fold cross-validation. The classifier's performance in terms of precision is found to be 82%. The above study focused on only security-related requirements, not other non-functional requirements.

In literature, another study used KNN to classify the non-functional requirements (27). In the article, first, the text is preprocessed, then KNN is applied. The classifier's performance is found to be 97.73% in terms of precision. The datasets used for evaluation contain requirement documents with 57 and 88 non-functional requirement sentences. The data set used for validation has a minimal number of non-functional requirements.

One of the research used the KNN algorithm concept to classify the non-functional requirements (32). The dataset used for classification is the PROMISE dataset. The classifier's performance is evaluated by iterating 14 times using different threshold values. The classifier's performance in terms of precision is found to be only 50.65%.

2.6. Non-Functional Requirements Classification Using LR

Logistic regression is used by research to classify non-functional requirements (7). This algorithm works based on the probability function. The data set used the PROMISE_exp dataset. The types of non-functional requirements considered for classification purposes are 11. The classifier's performance is calculated by performing 10-fold cross-validation, only 75% in terms of precision.

2.7. Non-Functional Requirements Classification Using Convolutional Neural Network (CNN)

One study proposed CNN for classifying the non-functional requirements from the requirement document (30). We focus on a total of 5 non-functional requirements. The text is first preprocessed in the study, then CNN is applied. A PURE dataset which consists of 1,247 requirement sentences, is used. The classifier's performance is calculated by performing 2-fold cross-validation, and it is found to be 92.2% in terms of precision.

Similarly, various techniques are proposed to ensure the security of IoT-oriented health care systems. One technique proposed is based on a machine-learning algorithm that uses a biometric framework for ensuring the security of sensitive data (36). In this technique, electrocardiogram (ECG) signals are used to extract the features used by a machine-learning algorithm. The proposed system is based on a multilayer perception model, where in order to secure the signal and protect it from possible interference, a secure communication channel is developed. The authentication process is carried out in the testing phase by considering unique generated EIs from the ECG and coefficients from polynomial approximation.

One study highlights the usage of the biometric cryptosystem (BCS) for ensuring security (37). The proposed approach considers Artificial Neural networks (ANN) to analyze the signal energy variations of implanted devices. The inertial measurement units (IMU) are fixed inside the implanted devices, which help detect signal energy changes. In this technique, ANN is trained so that the first sensor is placed on the chest, and then signals are processed by the algorithm. ANN in the proposed technique comprises three layers: an input layer, an output layer, and a hidden layer comprising 10 hidden nodes. The security is achieved by a 128-bit key generated by gait cycles. This key is difficult for hackers since it cannot be achieved by a modern attacking mechanism like dictionary attacks.

In research study, a novel machine learning-based security framework is proposed to detect malicious activities in healthcare systems (38). The proposed framework named Health Guard is developed by considering four machine learning algorithms: KNN, RF, Decision Trees, and ANN. The malicious activities are detected by observing the vital signals of the implanted devices and then correlating the vitals to identify the variations in the patient body. The classifiers are developed by training using nine databases of eight smart implantable devices and by considering activities, among which 7 are normal user activities, and five are disease-related. The validation process is conducted by testing through only three threats: denial of Service (DoS) attacks, tempered medical devices, and false data injection.

The literature review reflects the limitations of the current study. The performance of some techniques is quite average (1, 6, 26). The non-functional requirements classes considered by some studies are very few (4, 23, 31). The dataset contains limited non-functional requirement sentences for training and testing purposes (2, 3, 9). Studies have mostly considered classifiers, which are developed using single machine learning algorithms (8). Different combinations of hybrid and ensemble classifiers are barely considered.

3. RESEARCH METHODOLOGY

In order to find the relevant features and determine the ML algorithm that achieves better accuracy for the classification of non-functional requirements, the research answers the following research questions:

- **RQ.1.** Which features help to increase the accuracy of non-functional requirement classification?
- **RQ.2.** Which machine learning algorithm classifies non-functional requirements with better accuracy?

The research method used for the validation of the ML algorithm is experimentation (39). Experimentation is a systematic method that involves observation, manipulation, and control to generate accurate and reliable results. It is used to study the cause-effect relationship and prefers standardizing tools for maintaining control and achieving precision. It helps develop automatic techniques and evaluate the accuracy of classifying the non-functional requirements while controlling variables like data used for classification, number of non-functional requirements to be classified, and validation method adopted. Simulation, which is similar to experimentation, is not adopted because of the unavailability of its immense requirements to simulate the technique correctly and because of more chances of uncertainty in results due to its abstract nature (40).

PROMISE_exp dataset is used for classification (7). This dataset contains requirements from real projects, and it is the expanded form of the existing PROMISE dataset. The use of a large dataset also helps in generalizing the results (7). Eleven non-functional requirements are chosen for classification: Availability, Legal and Licensing, Look and Feel, Maintainability, Operability, Performance, Scalability, Security, Usability, Fault Tolerance, and Portability. These non-functional requirements are the common non-functional requirements in many projects and are also misclassified and ignored due to their ambiguous nature (41). The ambiguity level is reduced in this research by using features relevant to non-functional requirements. In addition to this, the PROMISE_exp dataset also supports learning on these types of non-functional requirements (7).

Bag of Words and TF-IDF are used separately to answer the first research question and find the relevant features. The reason for using these methods for finding relevant features is that they work well for classifying the non-functional requirements (7, 8). Moreover, both methods cover different weighing features, and experimenting with both methods helps find more relevant features. BoW ignores the sequence of words; however, in the case of non-functional requirement classification, some algorithms can work well irrespective of the order of the information. BoW method weighs the features according to their number of occurrences in all documents (29) while the TF-IDF method gives more weight to those features which have less overall frequency but more frequency in a specific document (4, 7). Some highly relevant features are also added to help rule-based learning, part of the hybrid KNN-rule based ML algorithm.

To answer the second research question and find the ML algorithm that helps classify non-functional requirements with better accuracy, LR, SVM, MNB, KNN, the ensemble made from these algorithms, RF and hybrid KNN-rule based ML algorithms are applied. The reason for choosing these ML algorithms for classifying the non-functional requirements is because these supervised ML algorithms perform better than unsupervised or semi-supervised ML algorithms (8). The algorithms are also selected while keeping in front the dataset, which is used to classify non-functional requirements. To evaluate the accuracy of these classifiers, 10-fold cross-validation is performed. The reason for choosing this method of evaluation is that it helps in producing more accurate and unbiased results (4, 23). Furthermore, many studies adopt 10-fold cross-validation method which helps in comparing the results without bias (4, 5, 7, 23). The steps to the classification of non-functional requirements are given in **Figure 1**.

Internet of Things plays a crucial role in the health care systems of the modern era. It provides a facility to monitor, control, and prevent diseases by collecting and processing health-related data through sensors (42). Since these health care systems are critical, it is important to ensure that they work efficiently, encompassing all the required non-functional requirements. Health care systems have compromised performance or security, resulting in the loss of critical health data and even threats and attacks by hackers, which may affect the life of patients (17). An IoT-oriented health care system generally has three layers, which are the perception layer, fog layer, and cloud layer (43–45). The layered architecture is shown in **Figure 2**. The perception layer includes actuators or devices that help collect sensory data. The fog layer processes the data to produce the required response quickly. The Cloud layer deals with storing the data and big data analytics (44).

3.1. Dataset Description

In this research, the PROMISE_exp dataset (46) is used for the classification of non-functional requirements. This dataset is the expanded form of the original PROMISE dataset, which comprised only a total of 625 labeled requirement sentences (21). The expanded form contains more labeled requirement sentences including 444 functional requirements and 525 non-functional requirements (7). The 11 types of non-functional requirements are distributed among the sentences in an unbalanced fashion. **Table 2** shows the formulation of this dataset.

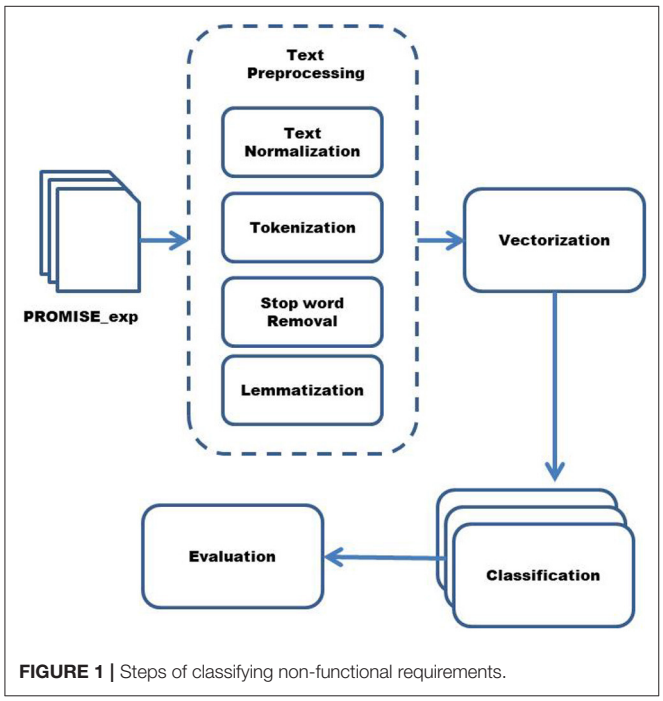

FIGURE 1 | Steps of classifying non-functional requirements.

TABLE 2 | Number of requirements per class.

Requirement type	Number of requirements
Functional requirement (FR)	444
Availability (A)	31
Security (SE)	125
Usability (US)	85
Look and Feel (LF)	49
Legal and licensing (L)	15
Maintainability (MN)	24
Operability (O)	77
Performance (PE)	67
Scalability (SC)	22
Fault Tolerance (FT)	18
Portability (PO)	12
Total	969

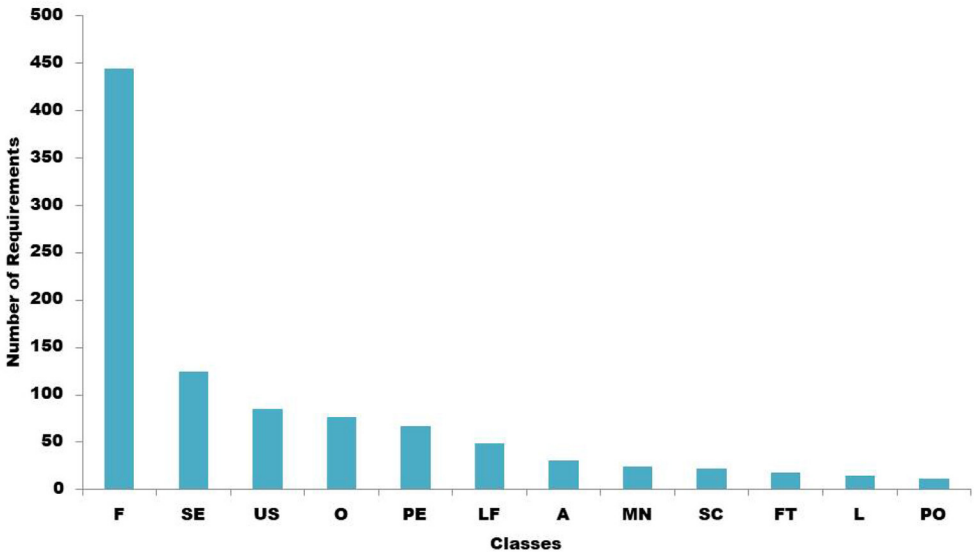

FIGURE 3 | Distribution of requirement classes.

The labeled requirements are distributed in the following manner: availability: 31, security: 125, usability: 85, look and feel: 49, legal and licensing: 15, maintainability: 24, operability: 77, performance: 67, scalability: 22, fault tolerance: 18, portability: 12, and functional requirements which are 444 in number. **Figure 3** below shows the distribution of the labeled requirement sentences.

3.2. Text Preprocessing

Text preprocessing is the first step in which the data is cleaned to remove redundant and less relevant features (8). In-text preprocessing, first, the data is normalized. During normalization, natural language text is first converted to lower case, then non-alphabetical characters, symbols, and punctuation are removed. Tokenization is performed after normalization, in which text is converted to tokens. Then in the next step, the stop words are removed, which are also less relevant features. Finally, words are lemmatized in which they are converted to their root form in order to remove extra features (7).

3.3. Feature Extraction

Feature extraction is the second step in which the preprocessed data is converted into vectors. To extract the features, BoW and TF-IDF are applied. The description of both techniques is given below.

3.3.1. Bag of Words

Bag of Words is a simple technique in which the words are converted into a numerical format based on their number of occurrences. Each feature gets its value equal to the number of times it appears in the requirement sentence. The vector of requirement sentence *'j'* is represented in Equation 1.

$$Xj = (x_{1,j} \ldots x_{i,j} \ldots xn, j) \tag{1}$$

In Equation 1, $x_{i,j}$ represents the weight of the feature which is calculated on the basis of the occurrence of *'i'* in the requirement *'j'*, whereas *'n'* represents the total number of words (7). When the vectors are created, they are given as an input to the ML algorithms in the next step.

3.3.2. Term Frequency-Inverse Document Frequency

In this technique of vectorization, two metrics play their role. The first metric is the Term Frequency (TF) which represents the number of times a particular word occurs in a requirement. The second metric is the Inverse Document Frequency which is achieved by dividing a total number of requirement sentences by the requirement occurrence number for each word and then applying a logarithmic function on the output (47). Below is the mathematical representation of TF-IDF.

$$TF - IDF(term_{i,j}) = tf_{i,j} \times idf_i \tag{2}$$

In Equation 2, $tf_{i,j}$ shows the frequency of the term i in the requirement j, where idf_i is the Inverse Document Frequency of *'i'* which is mathematically represented as Equation 3:

$$Idf_i = log \frac{total_requirements}{total_requirements_with_term_i} \tag{3}$$

3.4. Machine Learning Algorithms

The machine learning algorithms LR, SVM, MNB, KNN ensemble, RF, and hybrid KNN-rule based ML algorithms are applied to vectorized data. The classifiers are constructed not only by using the monolithic concept but also ensemble and hybrid are also considered since they yield better results according to literature (8).

3.5. Evaluation

The performance of the classifiers in terms of accuracy is evaluated using 10-fold cross-validation (7). In 10-fold cross-validation concept, the training set is divided into ten subsets of data which are of almost the exact sizes, and then testing takes place in 10 iterations, wherein each iteration, one fold which comprises 10% of the dataset is left for testing and other nine folds which comprises 90% of the dataset are used for training. In this way, each sample of the data is used once in both training and testing (30). The purpose of performing 10-fold cross-validation is to reduce the chance of biasness in results. In this research, the metric 'Accuracy' is considered to get an overall idea of the correct classification made by the classifier. Accuracy of the classifier is the measure of how many correct predictions are made by the classifier in contrast to a total number of predictions as shown in Equation 4.

$$Accuracy = \frac{(TP + TN)}{P + N} \tag{4}$$

Where TP represents the predictions correctly identified as positive, TN represents those correctly identified as negative.

4. EXPERIMENT

In order to implement the technique and perform the experiment, the Anaconda tool is used. PROMISE_exp dataset is obtained and converted into CSV format to process by the tool. The data is first preprocessed in order to remove useless features. In the first step of data preprocessing, the text is normalized. In the next step, the sentences are converted into tokens. Then in the next step, the stop words are removed. Then in the final step of text preprocessing, words are lemmatized and converted to their root form to remove extra features. After preprocessing, the data is vectorized using BoW and TF-IDF.

For classification of non-functional requirements, 7 ML algorithms are considered, which are LR, SVM, MNB, KNN, ensemble, RF, and hybrid KNN-rule based ML algorithms. The Hyperparameter of the classifiers is tested and set manually by checking their performance. The performance is evaluated in terms of accuracy by using 10-fold cross-validation.

The work in this research differs from the recent study (7) in the sense that this study considers more ML algorithms like RF, Ensemble, and hybrid KNN-rule based ML algorithm. Moreover, the relevant features are also added to increase the performance in terms of accuracy.

The non-functional requirements of an IoT oriented health care system generally include security (17, 42, 44) privacy interoperability, scalability, reliability (17, 44), accuracy, usability (17), performance (17, 44, 48), and maintainability (48). The system must possess these non-functional requirements since missing any critical non-functional requirement results in severe loss of healthcare data and other threats to patients' lives. Thus it is important to extract and classify all the non-functional requirements from the requirement document to be implemented accordingly in the IoT-oriented healthcare system. The manual process of extracting the non-functional requirements is erroneous and laborious. To avoid missing non-functional requirements, this research aims to adopt a machine learning-based approach to automatically classify the non-functional requirements from the IoT-oriented healthcare system's requirement document.

To implement the automatic technique, experimentation is performed. First dataset is created, comprising of functional and non-functional requirements of IoT-oriented health care systems (24, 25). This dataset contains requirements belonging to 8 classes: Accuracy, Reliability, Security and Privacy, Performance, Compatibility, Usability, Functional, and Maintainability. The dataset obtained is then preprocessed. IoT-oriented healthcare systems' requirement sentences are first normalized in the preprocessing stage. The text is converted to lower case in normalization, and punctuation marks and non-alphabetical characters are removed. In the second phase of preprocessing, the text is converted into tokens. In the third phase of preprocessing, stop words are removed. In the fourth phase, lemmatization converts the words into their lemma or dictionary format. After text preprocessing, vectorization is performed using TF-IDF. The features extracted by TF-IDF are then used to create classifiers by applying a machine learning algorithm. The machine learning algorithms adopted in this experiment are SVM, LR, KNN, MNB, RF, Ensemble, and hybrid KNN-rule based machine learning algorithm. For evaluation of classifiers performance, 10-fold cross-validation is performed.

5. RESULTS AND DISCUSSION

This section presents the experimentation results, which are conducted to find out the relevant features that increase the accuracy of classification of non-functional requirements (RQ1) and explore the ML algorithm, which performs better in terms of accuracy for classification of non-functional requirements (RQ2).

5.1. Relevant Features for Non-Functional Requirements Classification

In the experiment stage, two feature extraction techniques are adopted: BoW and TF-IDF. After preprocessing of text and extracting the features with the help of vectorization techniques, the top relevant features which are obtained from both the techniques are shown in **Table 3**. Furthermore, some coding is also performed to add more features.

In addition to these features obtained by the vectorization techniques, the features which are added according to the relevancy of the type of non-functional requirement are shown in **Table 4**. These added features helped achieve an accuracy as high as 85% on average, as can be seen, which is achieved by the hybrid KNN rule-based ML algorithm.

The performance of the ML algorithms when fed with the features is shown in **Figure 4**. **Figure 4** highlights the effect of BoW and TF-IDF on the classification accuracy of ML algorithms. In the hybrid KNN rule-based ML algorithm application, TF-IDF outperforms BoW to extract more relevant features and provide more accurate results. In the case of the ensemble, BoW provides more relevant features. BoW also outperforms TF-IDF in extracting more relevant features when

applied LR and MNB. In the case of SVM and KNN, the features extracted by TF-IDF proved to be more relevant. Both BoW and TF-IDF provide similar accuracy with RF.

5.2. Machine Learning Algorithm With Higher Accuracy

The second research question (RQ2) is about finding the ML algorithm that provides more accurate results than others classifying non-functional requirements. In **Figure 5**, the accuracy provided by all the 7 ML algorithms is illustrated in trend line fashion when BoW is used. There are a total of 10 iterations along which the accuracy is highlighted. The accuracy provided by the hybrid KNN rule-based ML algorithm is the highest overall. The accuracy of the ensemble drops at iteration 3, but overall, it provides almost average classification accuracy compared to the hybrid classifier. On the other hand, LR provides better accuracy than the ensemble overall but is still lower than the hybrid classifier's accuracy. SVM does not show

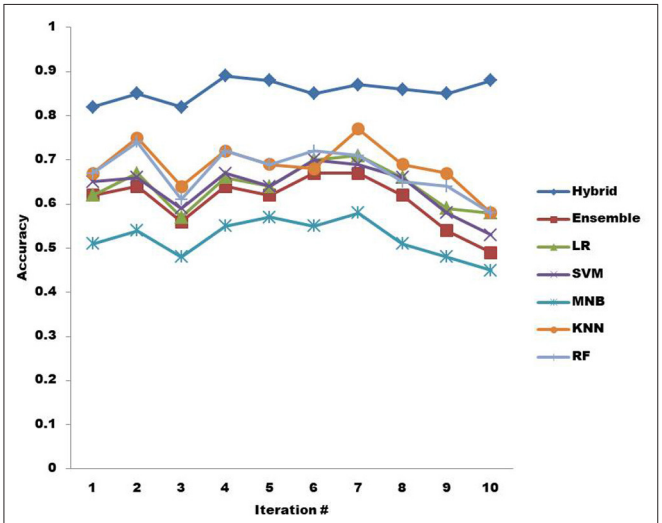

FIGURE 6 | Accuracy of machine learning algorithms with TF-IDF.

good classification accuracy and performs low overall compared to other ML algorithms except KNN. The classification accuracy provided by MNB is low compared to hybrid and LR overall but still better than other ML algorithms. KNN provides the least good accuracy compared to other ML algorithms overall. RF performs better in terms of accuracy overall than SVM and KNN.

In **Figure 6**, the classification accuracy of all ML algorithms is shown when TF-IDF is adopted. The hybrid KNN rule-based ML algorithm outperforms all other ML algorithms in providing better classification accuracy. Compared to other ML algorithms, ensemble only proved to perform better than MNB in providing better accuracy overall. LR provides better accuracy than MNB, SVM, and ensemble overall, while SVM provides better classification accuracy than just ensemble and MNB. The classification accuracy provided by MNB is low overall compared to all other ML algorithms. KNN, in this case, provides better accuracy than other ML algorithms except for hybrid. RF performs lower in accuracy than hybrid and KNN but provides better classification accuracy overall than other ML algorithms.

The classification results in terms of accuracy are shown in **Tables 5**, **6**. The result in **Table 5** clearly shows that hybrid KNN-rule based ML algorithm outperforms other ML algorithms by achieving an average accuracy of 0.778 with BoW. As a result of its nature, a hybrid classifier considers the usage of rules constructed with relevant features, which helps in the classification of non-functional requirements more accurately. Similarly, **Table 6** also shows that the highest classification accuracy among all the ML algorithms is achieved by the hybrid KNN-rule based ML algorithm, which is 0.857 accuracy on average. The results show that by using TF-IDF for feature extraction and hybrid KNN-rule based ML algorithm for classification, an average accuracy of 85.7% can be achieved, which is quite promising.

Table 5 shows the average classification accuracy of ML algorithms in 10 iterations when BoW is applied. The hybrid KNN-rule based ML algorithm achieves the highest average classification accuracy, which is 77.8%.

The results of experimentation using IoT-oriented healthcare requirement documents are shown in **Table 7**. **Table 6** shows the average classification accuracy of ML algorithms in 10 iterations when TF-IDF is applied. The hybrid KNN-rule based ML algorithm achieves the highest average classification accuracy, 85.7%.

The results show that the hybrid KNN-rule based machine learning algorithm outperforms others by showing average classification accuracy of 75.9%. In existing studies, many machine learning-based techniques are adopted to classify the non-functional requirements from the requirement document. However, to our knowledge, this is the first research that solely focuses on IoT-oriented healthcare system requirement documents to classify the non-functional requirements automatically. The automatic technique proposed in this research classifies the non-functional requirements with reasonable accuracy, enabling the development of an excellent IoT-oriented healthcare system.

Certain limitations are present in the approach presented by this research. First, the dataset adopted is minimal and contains only 104 requirements, which may affect the generalizability of the results of this research. Second, the non-functional requirements related to IoT-oriented healthcare systems covered by this research are only 7 in number. Third, the machine learning algorithms considered by this research for classification of non-functional requirements from IoT-oriented healthcare system requirement document are only 7, including only one ensemble and hybrid algorithm and five supervised machine learning algorithms. This research does not cover neural Networks, Semi-supervised or unsupervised machine algorithms.

6. THREATS TO VALIDITY

This section presents the possible threats which affect the validity of this research. The steps taken to mitigate the effect of threats are partially highlighted.

6.1. Construct Validity

Construct validity refers to the concept that defines the degree to which the variables measures accurately what they are supposed to measure (41). Many studies consider this measure for measuring the performance of classification, and it is believed to capture the aspect of performance required. In this research, the standard measure "Accuracy" is adopted to measure classifiers' performance.

6.2. Internal Validity

Internal validity is related to measuring the extent to which the experimental results are derived from the data and not any unconsidered variables (29). In this research, a threat is considered related to the over-fitting of test data on the machine learning algorithms. The effect of this threat is mitigated by using 10-fold cross-validation.

6.3. External Validity

External validity refers to the extent to which the results of this research apply to other settings (29). In this research, the domain and size of the dataset affect the external validity of this research. This threat is mitigated partially by selecting the PROMISE-exp dataset (46),

which contains requirement sentences from the software domain, and contains more requirements than the existing PROMISE dataset.

7. CONCLUSION AND FUTURE DIRECTIONS

Non-functional requirements are essential in the RE process since they play an essential role in driving the software architecture and determining the product quality. Since these requirements are written in natural language and often get twined up with the functional requirements, they are often missed or ignored. In order to overcome the difficulties caused due to human manual processes and inadequate tools, this research has focused on using ML algorithms for the automatic classification of non-functional requirements. Since this task of non-functional requirements classification has to be performed accurately, this study has focused on finding relevant features and ML algorithms that can perform this task with great accuracy. In this research, BoW and TF-IDF are used for feature extraction. Further, some features are also added for increasing the accuracy. The ML algorithms adopted in this research are LR, SVM, MNB, KNN, ensemble, RF, and hybrid KNN-rule based ML algorithms. The types of non-functional requirements considered are 11. The dataset used for classification is the PROMISE_exp dataset. In order to compare the accuracy of classifiers created by different ML algorithms and features, experimentation is considered. The experiment results show that by using TF-IDF for extracting the features and hybrid KNN-rule based ML algorithm for classification, an average accuracy of 85.7% can be achieved, which is a pretty excellent performance. It is noteworthy that the accuracy level achieved by this study is higher than the accuracy achieved by a recent study (7) on the PROMISE_exp dataset. Automatic classification of non-functional requirements using high-performing ML algorithms and relevant features helps the Requirement Engineers accurately classify the non-functional requirements. It saves their critical time by using fewer advanced tools and adopting human manual processes.

The research for using the machine learning approach for automatic classification of non-functional requirements with better performance is still in progress. The literature noted that the studies barely consider hybrids and ensembles to classify non-functional requirements. In the future, further study can be done to increase the size of the dataset and incorporate more types of non-functional requirements. Further attention can also be given to creating more custom classifiers by using different combinations of ML algorithms.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author/s.

Zhang L, Li Y, Bian L, Luo Q, Zhang X and Zhao B (2022) Analysis of Factors Affecting Cranial Nerve Function of Patients With Vascular Mild Cognitive Impairment Through Functional Magnetic Resonance Imaging Under Artificial Intelligence Environment. Front. Public Health 9:803659. doi: 10.3389/fpubh.2021.803659

The study aimed to explore the risk factors of effects of patients with vascular mild cognitive impairment (VaMCI) through functional magnetic resonance imaging (fMRI). In this study, 62 patients were selected from the department of neurology, admitted to Changzhi People's Hospital from October 1, 2018 to February 1, 2020. Patients with VaMCI were defined as the VaMCI group according to Clinical Dementia Rating (CDR), and subjects with normal cognitive function were defined as the normal control (NC) group. All patients underwent fMRI to identify the amplitude low-frequency fluctuation (ALFF) and regional homogeneity (ReHo) values, and to analyze their association with VaMCI. The results showed that the VaMCI group had lower scores for Mini-mental State Examination (MMSE), Montreal Cognitive Assessment (MoCA), and their subitems (visual space and execution, recall, attention and computation, and language ability) than NC group, with statistical differences ($P < 0.05$). In VaMCI group, the brain regions with increased ALFF values were the left temporal lobe, left parietal lobe, right temporal lobe, right parietal lobe, and posterior cingulate gyrus. Of them, the left parietal lobe and right temporal lobe were negatively correlated with the recall score on MMSE scale ($r = -0.216$, $r = -0.132$, $P < 0.01$). In VaMCI group, the brain regions with decreased ReHo values were the left temporal lobe, occipital lobe, and left middle temporal gyrus. Of them, the left temporal lobe and occipital lobe were positively correlated with MoCA score ($r = 0.473$, $r = 0.848$, $P < 0.01$). In conclusion, VaMCI patients have cognitive impairment and abnormally increased spontaneous brain activity, especially in the left parietal lobe and the right temporal lobe. At rest, VaMCI patients show decreased whole-brain ReHo in the left medial temporal lobe and occipital lobe. Hypertension is a high-risk factor for cognitive impairment in VaMCI patients. The study can provide a theoretical basis for early diagnosis of VaMCI.

Keywords: artificial intelligence, vascular mild cognitive impairment, computer functional magnetic resonance imaging, neuropsychological assessment, whole brain regional homogeneity

INTRODUCTION

Cerebrovascular diseases are a main factor causing vascular cognitive impairment (VCI) (1, 2). With the population aging, the incidence of VCI increases significantly, second only to Alzheimer's disease (3–5). Similar to other cognitive diseases, VCI is characterized by gait, emotion, behavior, and urination disorders (6, 7). Cognitive impairment in an early stage is often overlooked, while it is difficult to treat once it develops to the late stage, such as dementia (8). Vascular mild cognitive impairment (VaMCI), as a prodromal stage of VCI, is closely related to executive dysfunction (9, 10), so early detection of VaMCI is particularly important.

Currently, the clinical diagnosis of VaMCI mainly relies on neurological function evaluation and imaging examination. Of many diagnostic methods, artificial intelligence-based imaging is of great significance for early diagnosis of VaMCI (11–14). With the continuous improvement of modern medical technology, artificial intelligence (AI) technology is gradually introduced into fMRI and plays an important role. AI can mine effective imaging information from big data, providing convenience for doctors in the diagnosis and treatment of cerebrovascular diseases (15–18). The fMRI imaging technology is now widely used to explore the mechanism of cerebrovascular cognitive function by detecting the activity of brain neurons. When different activities occur, both vascular cognitive function and neuronal activity have corresponding changes (19). Artificial intelligence-based fMRI technology features non-invasiveness, repeatable and high spatial resolution. It is an important means to study the neural mechanism of VCI patients (20–23). However, there are few studies to use fMRI technology to diagnose VaMCI, and the related research is still in the exploratory stage at present.

In this study, case data and fMRI data of patients in the department of neurology and the department of physical examination, admitted to Changzhi People's Hospital from October 1, 2018 to February 1, 2020, were collected, to identify the ALFF and ReHo value, and to analyze their association with VaMCI, expected to provide a basis for the early diagnosis of cerebrovascular diseases.

MATERIALS AND METHODOLOGY

In this study, the subjects underwent fMRI to identify the ALFF and ReHo values, and to analyze their association with VaMCI, aiming to explore the risk factors of VaMCI by fMRI combined with neuropsychology under artificial intelligence.

Basic Information of Research Subjects

Case data and fMRI data of patients in the department of neurology and the department of physical examination, admitted to Changzhi People's Hospital from October 1, 2018 to February 1, 2020, were collected. Thirty two patients were in the VaMCI group according to the diagnostic criteria of CDR and the Guidelines for the Diagnosis and Treatment of Vascular Cognitive Impairment in China in 2019 (24). A total of 30 healthy patients without memory loss were in the NC group. The subjects in the NC group had no other related disorders that might affect cognitive function.

Inclusion criteria: 1. patients with complete case history and fMRI data; 2. acute cerebrovascular diseases did not occur within at least 1 year; 3. patients diagnosed with VCI as per the criteria of *the Guidelines for the Diagnosis and Treatment of Vascular Cognitive Disorders in China* in 2019; 4. there were cerebrovascular risk factors, and no evidence of cerebrovascular diseases such as hydrocephalus, intracerebral hemorrhage, lacunar cerebral infarction, and leukodystrophy from fMRI; and 5. other intracranial lesions were excluded, such as: tumor, trauma, infection or surgery.

Exclusion criteria: 1. Intracranial vascular color doppler ultrasound, head fMRI or head CT angiography showed intracranial vascular stenosis of more than 50%; 2. patients with abnormal neurological diseases such as Parkinson's disease, brain tumor, and encephalitis; 3. patients unable to complete the examination due to moderate aphasia, depression, or mental disorder; 4. patients with genetic microvascular diseases; and 5. patients with a history of major depression, drug, alcohol, or drug dependence.

Neurological Function Evaluation

The environment was quiet where the patient was tested. The test scales include MMSE, MoCA, Activities of Daily Living (ADL), and CDR (25), factoring into subitems such as memory, numeral symbol conversion, attention and computational power, visual space and executive function, recall power, orientation, language ability, and abstract ability. Neurological function evaluation was performed by neurologists with years of experience.

MRI Examination

MRI scanner used the Siemens verio 3.0T computer. The patient was in a supine position with his head in his hands. The patient should breath peacefully but not to think or fall asleep. For patients unable to cooperate in the MRI examination, chloral hydrate can be taken orally for sedation. The patient was scanned for conventional horizontal position, axial T2WI, vector T1WI, coronary T2, and fluid attenuated inversion recovery (FLAIR) images, and scanning parameters are set as follows:

I. Conventional scanning: scanning voltage of 120 kV, current of 150mA, with T1WI repetition time (TR) of 1800 ms, time of echo (TE) of 25 ms, T2WI (TR/TE = 2800/75 ms), FLAIR (TR/TE = 7500/120 ms), matrix 525 × 525, scanning layer thickness of 4 mm, and layer spacing of 5 mm.
II. fMRI scanning: TR/TE = 1800/30 ms, matrix 70 × 70, scanning layer thickness of 3 mm, layer distance of 1 mm. there are a total of 250 time points in 10 min.

Pretreatment and Analysis of fMRI Image Data

The MRI data are processed by Statistic parameter Mapping (SPM8) software of Matlab platform, and the specific steps are shown below (26).

I. Data conversion: SPM8 software converts the original data Dicom into NII format.

II. Time correction: all images are obtained at the same time to eliminate the influence of time difference on the data.
III. Head motion correction: during the scan, the patient's breathing and heartbeat will have certain influence on the head, so it is necessary to keep head motion within a maximum shift of 3 mm.
IV. Space standardization: due to brain morphology differences, space standardization is required. The volume size is set as 3 ×3 ×3 mm for resampling.
V. Spatial smoothing: spatial processing with 4 × 4 × 4 mm full width at half maximum (FWHM) is performed to suppress high frequency signal and image noise.
VI. De-linear drift and low frequency filtering: in order to eliminate baseline drift, it is necessary to remove linear drift, and the frequency band of 0.01∼ 0.09 hz is used for low-frequency filtering to remove high-frequency interference.
VII. Calculation of ALFF: the ALFF value indicates the activity of voxel in the brain, which is positively correlated with spontaneous brain activity. DPARSF software is used to calculate the average amplitude value between 0.01 and 0.09 Hz.

Calculation of ReHo

A high ReHo value indicates consistent local neuron signal activity and a low value indicates decreased consistency. The ReHo value of each voxel is obtained by computer analysis, and the ReHo values of all brain regions can form a complete ReHo diagram.

Statistical Analysis

SPSS13.0 statistical software is used to analyze and process all experimental data. The count experimental data are expressed as a percentage (%) and the measurement data are expressed as mean ± standard deviation (± s). The $\chi 2$ test is used for the gender and education background analyses of the patients. *T*-test is used for age comparison between the two groups. The fMRI data are processed by DPARSF and SPM8 software, and the differences in ALFF and ReHo are analyzed by *t*-test. SPSS Pearson software is employed to analyze the correlation between ALFF, ReHo with MMSE, MoCA. $P < 0.05$ indicates statistically significant differences.

RESULTS

Basic Information

Figure 1 showed the gender and age of patients in NC group and VaMCI group. In the NC group, there were 17 males (56.7%) and 13 females (43.3%). In the VaMCI group, there were 18 males (56.3%) and 14 females (43.7%). The χ^2-test results showed no significant differences in gender ($P > 0.05$). The subjects in NC group were aged between 45–85 years old and averaged 65.3 ± 9.38; the patients in VaMCI group were aged between 50–88 years old, and averaged 69.54 ± 7.23. There was no significant difference in age after *t*-test ($P > 0.05$). The basic information was comparable in gender and age ($P > 0.05$). In terms of the education background of the two groups, 5 cases of illiteracy in NC group accounted for 16.7%, 6 cases of primary school accounted for 20%, 13 cases of junior high school accounted for 43.3%, and 6 cases of higher education accounted for 20%. In VaMCI group, 3 cases of illiteracy accounted for 9.4%, 4 cases of primary school accounted for 12.5%, 15 cases of junior high school accounted for 46.9%, and 10 cases of higher education accounted for 31.2%. The χ^2-test showed no significant difference in educational background ($P > 0.05$).

The Medical History and Family History

Figure 2 showed the medical history and family history of patients in NC group and VaMCI group. In NC group (30 cases), 10 cases of hypertension accounted for 33.3%, 8 cases of diabetes accounted for 26.7%, 8 cases of heart disease accounted for 26.7%, 9 cases of hyperlipidemia accounted for 30%, and 3 cases with a family history of dementia accounted for 10%. In VaMCI group (32 cases), there were 17 cases with hypertension (53.1%), 15 patients with diabetes (46.9%), 15 patients with heart disease (46.9%), 7 patients with hyperlipidemia (21.9%), and 0 patients with a family history of dementia. The number of hypertension

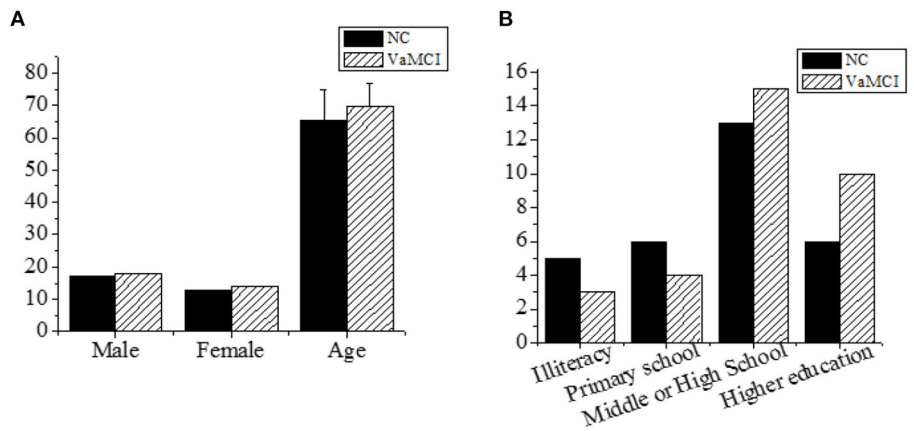

FIGURE 1 | The basic information. **(A)** The age and gender; **(B)** the education background.

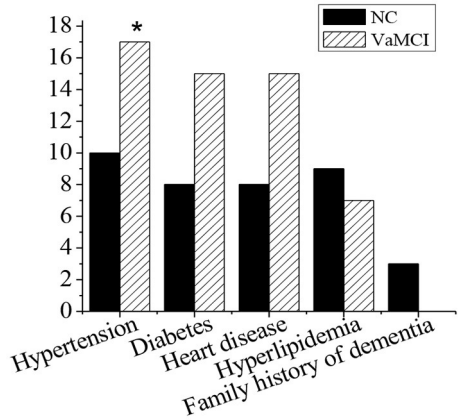

FIGURE 2 | Medical history and family history. There was a statistically significant difference in hypertension between the VaMCI group and the control group (*$P < 0.05$).

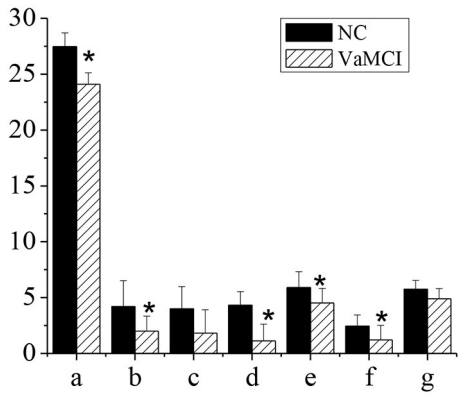

FIGURE 3 | MMSE and subitem scales. The comparison between the NC group and the VaMCI group was statistically significant, *$P < 0.05$. a-MMSE; b-visual space and execution; c-memory; d-recall power; e-attention and computation; f-language ability; g-orientation.

patients in VaMCI group was significantly higher than that in the control group (*$P < 0.05$).

MMSE and Subitem Scores

Figure 3 showed the MMSE and subitem acores of patients in NC group and VaMCI group. The total MMSE scores of VaMCI group were (24.11 ± 1.01), the subitem scores were (2.01 ± 1.34) for spatial and executive ability, (1.12 ± 1.5) for recall ability, (4.52 ± 1.3) for attention and computational ability, and (1.22 ± 1.3) for language ability, all of which were lower vs. the NC group, where the total MMSE score was (27.46 ± 1.23), and the subitem scores were (4.2 ± 2.33) for spatial and executive ability, (4.33 ± 1.21) for recall power, (5.89 ± 1.44) for attention and computational ability, and (2.45 ± 0.99) for language ability ($P < 0.05$). There was no statistically significant difference in memory and orientation between the NC group and the VaMCI group ($P > 0.05$).

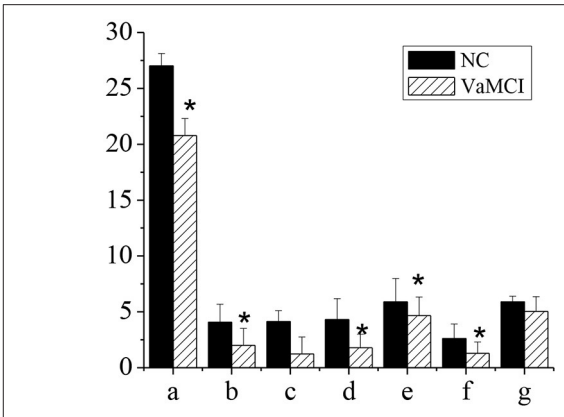

FIGURE 4 | MoCA and subitem scores. The comparison between the NC group and the VaMCI group was statistically significant *$P < 0.05$. a-MMSE; b-visual space and execution; c-memory; d-recall power; e-attention and computation; f-language ability; g-orientation.

TABLE 1 | Numerical analysis of ALFF in each brain region of VaMCI group.

Brain area	MINI coordinate			*T* value	Voxel
	x	y	z		
Left temporal lobe	−46	−15	29	−2.98	76
Left occipital lobe	58	21	42	−3.67	42
Left parietal lobe	−18	30	17	+2.54	52
Right temporal lobe	−62	−18	40	−4.28	61
Right occipital lobe	47	71	27	−3.17	30
Right parietal lobe	−8	−46	59	+3.26	51
Posterior cingulate	11	−51	25	+3.54	65

MNI, human brain region coordinates; T value, activation degree.

MoCA and Subitem Scores

Figure 4 showed the MoCA and subitem scores of patients in NC group and VaMCI group. The total MoCA score of VaMCI group was (20.78 ± 1.52), the subitem scores were (2.01 ± 1.51) for spatial and executive ability, (1.79 ± 1.22) for recall power, (4.66 ± 1.67) for attention and computational ability, and (1.29 ± 1.01) for language ability, all of which were lower vs. the NC group, where the total MoCA score was (27.01 ± 1.12), and the subitem scores were (4.08 ± 1.61) for spatial and executive ability, (4.3 ± 1.89) for recall power, (5.89 ± 2.1) for attention and computational ability, and (2.61 ± 1.3) for language ability ($P < 0.05$). There was no statistically significant difference in memory and orientation between the NC group and the VaMCI group ($P > 0.05$).

The fMRI Characteristics

Table 1 showed the ALFF value of each brain region in the VaMCI group. When the number of continuous volume pixel is greater than 50, the cluster is defined as a brain region, as shown in **Figure 5**. Compared with the NC group, there were 7 clusters with increased ALFF values in VaMCI group, which were located in the left temporal lobe, left parietal lobe, right temporal lobe,

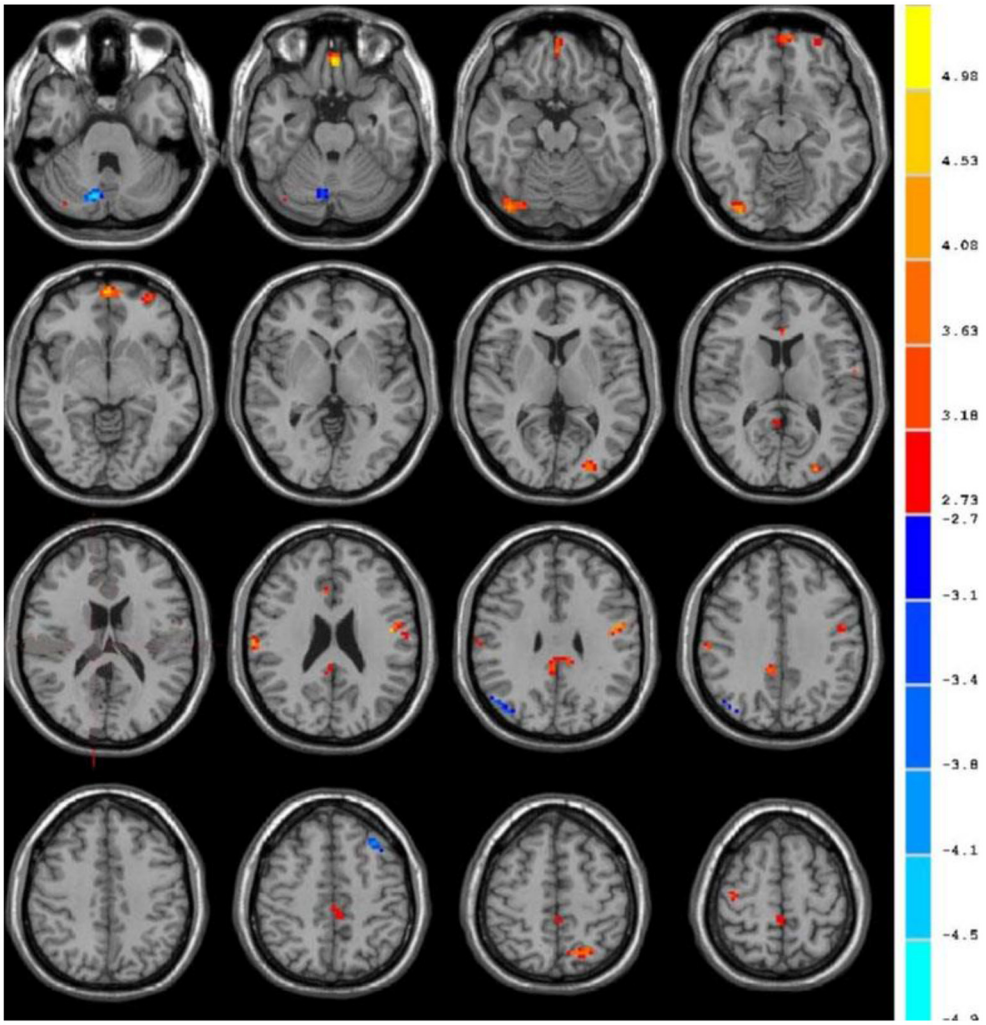

FIGURE 5 | fMRI images to show ALFF. The blue area represented the brain areas with increased ALFF in VaMCI group, the orange area represented the brain areas negatively correlated with the scale score, and the color bar represented the size of T value.

right parietal lobe, and posterior cingulate gyrus, with statistical significances ($P < 0.05$). No statistical differences were noted in brain areas of the left occipital lobe and the right occipital lobe ($P > 0.05$), and there was no brain area with abnormally decreased ALFF.

ReHo Values

Also, the cluster is defined as a brain region when the number of continuous voxels is greater than 50, as shown in **Figure 6**. **Table 2** showed the ReHo value of each brain area in VaMCI group. Compared with the NC group, there were 6 clusters with decreased ReHo values in VaMCI group, which were located in the left temporal lobe, occipital lobe, and left middle temporal gyrus, with statistical differences ($P < 0.05$). No statistical difference was noted in the left inferior temporal gyrus, left Para hippocampal gyrus, and insula ($P > 0.05$). There were 4 clusters with increased ReHo values, which were the left superior temporal gyrus, the right frontal lobe, the left frontal lobe, and the left inferior frontal gyrus ($P < 0.05$).

Spontaneous Brain Activity and Cognitive Impairment in VaMCI Group

The correlation between the ALFF value and MMSE score was analyzed. As shown in **Figure 7**, the right temporal lobe and the left parietal lobe were negatively correlated with the recall power of MMSE scale ($r = -0.216$, $r = -0.132$, $P < 0.01$), and the difference was statistically significant.

Correlation of ReHo With Cognitive Impairment

The correlation between the ReHo value and the MoCA score was analyzed. As shown in **Figure 8**, the ReHo in

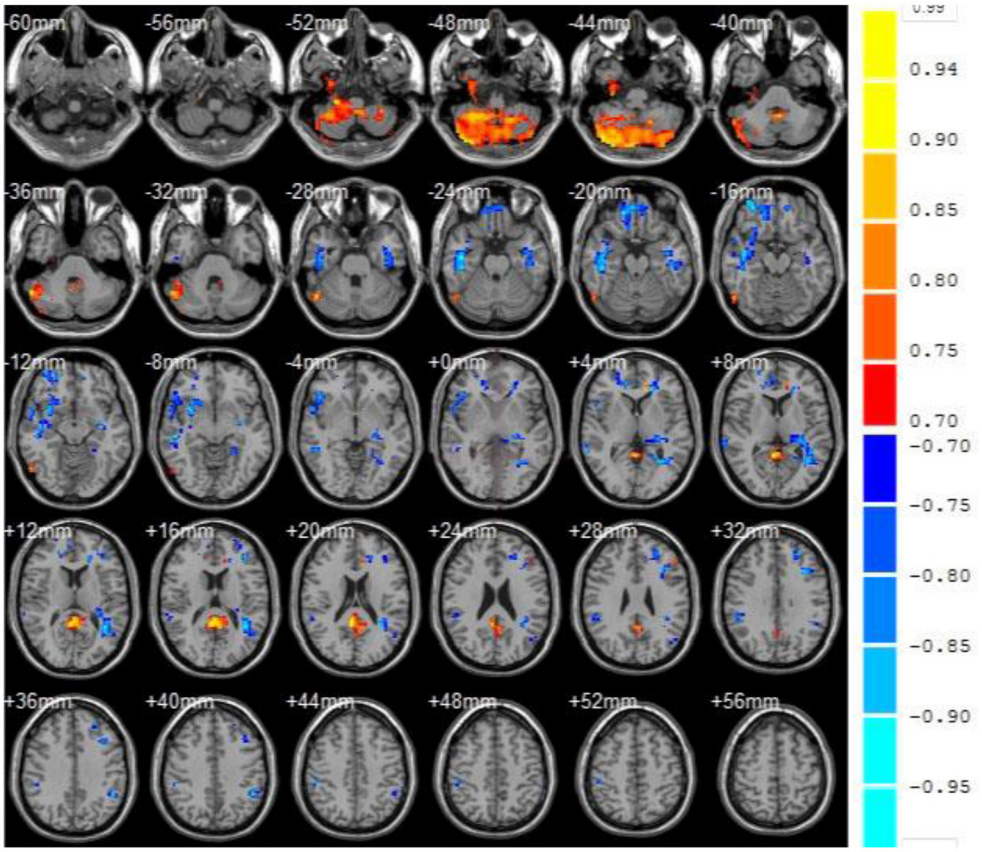

FIGURE 6 | fMRI images to show ReHo. Compared with the NC group, the blue area represented the brain areas with decreased ReHo value in VaMCI group, the orange area represented the brain areas negatively correlated with the score, and the color bar represented the size of T value.

TABLE 2 | Numerical analysis of ReHo in different brain regions of VaMCI group.

Brain region	MINI coordinate			*T* value	Voxel
	x	y	z		
Left temporal lobe	71	−59	−24	+2.98	74
Occipital lobe	−43	−64	−11	−3.67	53
Left inferior temporal gyrus	−46	−43	−10	+2.54	36
Left middle temporal gyrus	56	−35	−6	+4.28	84
Left Para hippocampal gyrus	47	47	21	−3.17	48
Insular lobe	26	8	5	+3.26	26
Left superior temporal gyrus	−44	5	−4	−2.89	58
Right frontal lobe	−14	16	43	+3.75	84
Left frontal lobe	−17	25	−7	−3.12	69
Left inferior frontal gyrus	−37	2	19	−2.91	52

MNI, human brain region coordinates; T value: activation degree.

the left temporal lobe and occipital lobe was positively correlated with the recall power of the MoCA scale ($r = 0.473$, $r = 0.848$, $P < 0.01$), and the difference was statistically significant.

DISCUSSION

VCI has a serious impact on human health and life. VCI at an early stage is often ignored thanks to mild symptoms. When it develops into dementia, it is already too late and difficult to treat. Therefore, early detection of VaMCI is particularly important (27). In this study, case data and fMRI data based on AI technology of patients in department of neurology and department of physical examination, admitted to Changzhi People's Hospital hospital from October 1, 2018 to February 1, 2020 were collected. The total MMSE score of VaMCI group was (24.11 ± 1.01), the subitem scores were (2.01 ± 1.34) for spatial and executive ability, (1.12 ± 1.5) for recall ability, (4.52 ± 1.3) for attention and computational ability, and (1.22 ± 1.3) for language ability, all of which were lower vs. the NC group, where the total MMSE score was (27.46 ± 1.23), and the subitem scores were (4.2 ± 2.33) for spatial and executive ability, (4.33 ± 1.21) for recall power, (5.89 ± 1.44) for attention and computational ability, and (2.45 ± 0.99) for language ability ($P < 0.05$). There was no statistically significant difference in memory and orientation between the NC group and the VaMCI group ($P > 0.05$). It indicated that VaMCI patients had cognitive impairment, consistent with previous research (28). The total MoCA score of

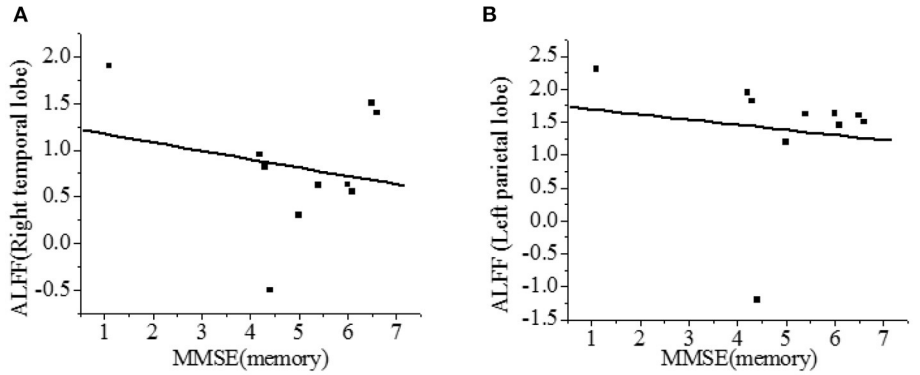

FIGURE 7 | Correlation of ALFF with recall power of MMSE scale [**(A)**-right temporal lobe; **(B)**-left parietal lobe]. There was a significant difference, $P < 0.01$.

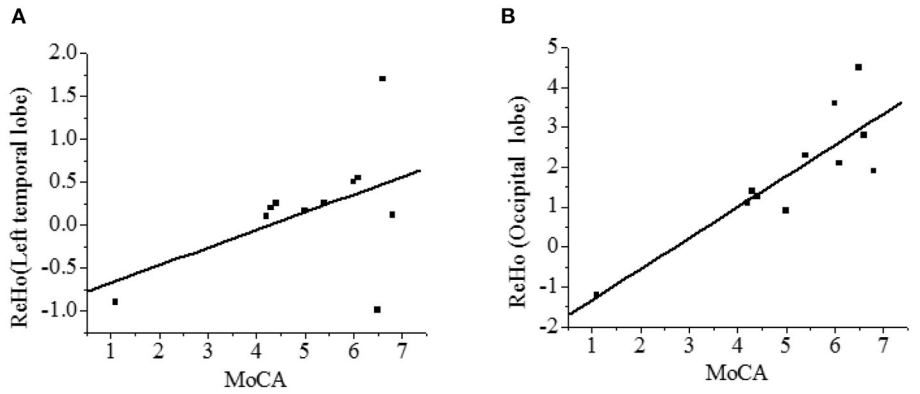

FIGURE 8 | Correlation analysis between ReHo and MoCA score [**(A)**-left temporal lobe; **(B)**-occipital lobe]. There was a statistical significance, $P < 0.01$.

VaMCI group was (20.78 ± 1.52), the subitem scores were (2.01 ± 1.51) for spatial and executive ability, (1.79 ± 1.22) for recall power, (4.66 ± 1.67) for attention and computational ability, and (1.29 ± 1.01) for language ability, all of which were lower vs. the NC group, where the total MoCA score was (27.01 ± 1.12), and the subitem scores were (4.08 ± 1.61) for spatial and executive ability, (4.3 ± 1.89) for recall power, (5.89 ± 2.1) for attention and computational ability, and (2.61 ± 1.3) for language ability ($P < 0.05$). There was no statistically significant difference in memory and orientation between the NC group and the VaMCI group ($P > 0.05$). It indicated that memory and orientation in VaMCI group were less impaired than other subitems. Studies have confirmed that the damage of subfrontal cortical neurons in the brain was the main cause of VaMCI (29).

In this study, the ALFF value of fMRI image was used to study the local spontaneous brain activity of patients in VaMCI group. Compared with the NC group, there were 7 clusters with increased ALFF values in VaMCI group, which were located in the left temporal lobe, left parietal lobe, right temporal lobe, right parietal lobe, and posterior cingulate gyrus, with statistical significances ($P < 0.05$). No statistical differences were noted in brain areas of the left occipital lobe and the right occipital lobe ($P > 0.05$), and there was no brain area with abnormally decreased ALFF. It showed that the spontaneous activity was increased in the left temporal lobe, the left parietal lobe, the right temporal lobe, the right parietal lobe, and the posterior cingulate gyrus in the rest state of patients in VaMCI group. The right temporal lobe and the left parietal lobe were negatively correlated with recall power on MMSE scale ($r = -0.216$, $r = -0.132$, $P < 0.01$). The parietal lobe played an important role in controlling visual movement, eye movement, and attention (30). The analysis of ALFF in VaMCI group showed that the temporal lobe and the Para hippocampal gyrus were closely related to memory, and that episodic memory was mainly impaired in early VaMCI period.

Compared with the NC group, there were 6 clusters with decreased ReHo values in VaMCI group, which were located in the left temporal lobe, occipital lobe, and left middle temporal gyrus, with statistical differences ($P < 0.05$). No statistical difference was noted in the left inferior temporal gyrus, left Para hippocampal gyrus, and insula ($P > 0.05$). There were 4 clusters with increased ReHo values, which were the left superior temporal gyrus, the right frontal lobe, the left frontal lobe, and the left inferior frontal gyrus ($P < 0.05$). Temporal lobe and occipital lobe are important brain areas involved in the subcortical circuits of the brain. The middle temporal gyrus is involved in cognitive and memory functions (31), and the

occipital lobe is responsible for processing of language, motion sensation, and abstract concepts (32). Chen et al. used fMRI to study the ReHo value of VaMCI patients in resting state. The findings were consistent with the conclusions in this study (33), indicating that the spontaneous brain activity was reduced in these areas mentioned above, reflecting the overall cognitive impairment of patients to a certain extent. In a word, VaMCI patients have cognitive impairment and abnormally increased spontaneous brain activity, especially in the left parietal lobe and the right temporal lobe. At rest, VaMCI patients show decreased whole-brain ReHo in the left medial temporal lobe and occipital lobe. Hypertension is a high-risk factor for cognitive impairment in VaMCI patients. The study can provide a theoretical basis for early diagnosis of VaMCI.

CONCLUSION

In the study, the fMRI was performed on subjects to identify the ALFF and Reho values and to analyze their association with VaMCI. It can be concluded that VaMCI patients have cognitive impairment and abnormally increased spontaneous brain activity, especially in the left parietal lobe and the right temporal lobe. At rest, VaMCI patients show decreased whole-brain ReHo in the left medial temporal lobe and occipital lobe. Hypertension is a high-risk factor for cognitive impairment in VaMCI patients. However, some limitations in the study should be noted. The sample size is small, which will reduce the power of the study. In the follow-up, an expanded sample size is necessary to strengthen the findings of the study. All in all, the study can provide a theoretical basis for early diagnosis of VaMCI.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author/s.

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Department of Neurology, Changzhi People's Hospital, Changzhi Medical College. The patients/participants provided their written informed consent to participate in this study. Written informed consent was obtained from the individual(s) for the publication of any potentially identifiable images or data included in this article.

A Study of Family Process Factors of Social Anxiety on the Internet Based on Big Data—Take Guangxi University Students as an Example

*Dexu Bi**

Department of Elementary Education, Guangxi Police College, Nanning, China

Background: Along with the popularization of the new medium of interpersonal communication, many researchers have found that the use of social media has brought about many mental health problems. For example, the virtual nature, vulnerability, and uncertainty of online communication lead to reduced online trust, causing interaction anxiety (IA). The data footprints left on the Internet are processed by malicious elements for big data, leading to the leakage of personal privacy data, bringing content sharing anxiety (SAC) and privacy concern anxiety (PAC), which are all typical forms of online social anxiety. In the face of this situation, analyzing the influence of online social networking on the social psychology of university students and guiding it has become an inevitable issue in the Internet era.

Methods: Learning from the classification of family environment, a self-administered family process factor questionnaire and the Social Anxiety Scale for Social Media Users (SAS-SMU) were used to investigate the online social anxiety of Guangxi University students. The study used SPSS26.0 and Stata for data analysis and descriptive statistics, ANOVA, *t*-test, and linear regression analysis were used to explore the relationship between family process factors and online social anxiety of the university students.

Results: The results showed that except for parental supervision ($p > 0.05$), the effects of interparental relationship, parent-child relationship, sibling relationship, and family atmosphere on university students' online social anxiety were statistically significant and showed positive correlations (F/t = 6.64, 3.53, 4.15, 5.94; $p < 0.05$). Multiple linear regression analysis showed that university students' total online social anxiety score = 36.914−4.09 × good parental relationship−4.16 × good family atmosphere−3.42 × good sibling relationship.

Conclusions: Based on the family systems theory, it is suggested that a comprehensive intervention should be conducted for the coupled system (parental relationship) and sibling system (non-only child's sibling relationship) in the family and focus on the protective factors of parental harmony, sibling relationship harmony, and relaxed family atmosphere. In the specific implementation method, the collaborative shared healthcare plan (CSHCP) can be used to strengthen remote family emotional interaction and avoid

INTRODUCTION

With the development of the Internet, there are at least two different forms of modern human interaction activities, namely, real face-to-face interaction in the traditional social presence space and non-face-to-face network interaction in the absence of field cyberspace. As a new form of social interaction, network interaction is changing the way people interact socially and has become an important way of interpersonal communication. The 2020 Digital Report, published by We Are Social, shows that more than 4.5 billion people use the Internet, and social media users have surpassed 3.8 billion (1). According to the 46th Statistical Report on the Development Status of the Internet in China released by the China Internet Network Information Center (CNNIC), Chinese Internet users reached 940 million by June 2020. The scale of instant messaging users reached 99.0% of the overall Internet users (2). It can be said that socializing through the Internet has become the most important form of human interaction.

Along with the popularization of the new medium of interpersonal communication, many researchers have found that the use of social media has brought about many mental health problems. For example, the virtual nature, vulnerability, and uncertainty of online communication lead to reduced online trust, causing interaction anxiety (IA). Social networking data is maliciously collected and leaked by people with the help of big data technology, resulting in content sharing anxiety (SAC) and privacy concern anxiety (PAC) among network users. Online social anxiety is a significant and persistent emotional response of worry, fear, and avoidance behavior to one or more interpersonal situations in the interpersonal exchange of information and emotions based on the Internet and mediated by computers (3). Basic performance behaviors are fear of interacting with others, fear of embarrassing oneself with the content shared, fear of chatting with others online, and fear of others making negative comments about oneself because of the content shared, etc.

As the main group of social media users, university students are troubled by "uncertainty," "social addiction," and privacy leakage while gaining access to various convenient services brought by the Internet, thus, giving rise to online social anxiety. In the face of this situation, it has become an inevitable problem to analyze the influencing factors of university students' online social networking and guide it. As a result, this article will select university students in Guangxi as the research object and take family process factors as the link to empirically analyze the family process factors of online social anxiety in university students in order to provide guidance for the treatment and behavioral improvement of online social anxiety.

Progress of Research on Social Anxiety in Adolescents Guided by Family Systems Theory

American scholar M. Bowen and his collaborator M.E. Kerr's family systems theory (4, 5) considers the family as a "grouped emotional body" that is the result of the interaction between the "father-mother-child" triangle in which individuality or separateness and togetherness or fusion are intertwined—individuality (or separateness) and togetherness (or fusion). Individuality and togetherness are two important balancing agents in the family system. The former seeks independence, while the latter seeks family belonging. Ideally, the family relationship is one in which these two forces are in balance. In this case, family members have their own independence and maintain close ties with each other. Suppose the family relationship is too close and the children are too emotionally involved with their families. In that case, the children will have low levels of Emotional Fusion and Differentiation and will be less independent. Conversely, if they are too distant, they have high levels of Emotional Fusion and Differentiation and are too independent. Both of these imbalance models produce dysregulation of the nuclear family emotional management system, where children need to pay constant attention to their parents' demands and emotional performance, are unable to think and act according to their own needs, are under high tension for long periods of time, have excessive emotional stress intensity and become increasingly attached to becoming independent, resulting in interpersonal difficulties within the family. Suppose individuals respond to the emotional needs of others by choosing to cluster or choosing Emotional Fusion and Differentiation in a fragmented way. In that case, they will develop anxiety and show anxious behavior.

Bowen's family systems theory has provided new research ideas for adolescent clinical psychology research. Based on this theory, many scholars have examined the mechanisms by which family systems interact with each other in the psychogenesis and development of adolescents, especially providing a new analytical framework for exploring the influence of parent-child relationship quality on the psychosocial adjustment of family members. Drawing on Bowen's family systems theory, Williams (6) further generalized the family environment into non-process and process factors based on the presence or absence of family members' interactions. The non-process factors refer to the members' own characteristics or inherent characteristics of the

family environment, which mainly include static factors, such as family structure, family socioeconomic status, primary provider, primary caregiver, and parents' own characteristics (7). Process factors refer to the interactions between members within the family system and the family climate formed by the interactions that mainly include the couple relationship, parenting, parent-child relationship, non-only child sibling relationship, and the family climate formed by them.

Chinese and foreign scholars have conducted a large number of studies on the effects of family non-process factors on social anxiety. They mainly involve the effects of gender (8, 9), family structure (10), grade level (11), and family economic and social status (12, 13) on social anxiety. The influence on family process factors involves parenting style (14, 15), family closeness (16), family function (17, 18), and parental conflict (19–22). Compared to the non-process factors that influence social anxiety, which are difficult to change, the process factors can be effectively guided and have more plastic value for the benign development of social anxiety. However, from the general status quo of research on family factors of social anxiety at this stage, family process factors are either done as single-factor research, which is in-depth but lacks systematicity, or put into family factors as grand unified research, which does not make specialized distinctions and lacks in-depth insight. Specifically, no directly relevant domestic and international literature has been retrieved on the empirical study of helping university students overcome online social anxiety through the improvement of family process factors.

MATERIALS AND METHODS

Study Participants

From September 2021 to October 2021, Guangxi Police College, Guangxi Foreign Language Institute, Nanning College, and Guangxi International Business Vocational and Technical College were selected. The anonymous questionnaire test was conducted with the informed consent of the subjects, and the information of the subjects was kept strictly confidential. A total of 2,400 questionnaires were distributed, and 2,373 valid questionnaires were returned, with a valid recovery rate of 94.6%. The age range was 18–22 years old, with 1,125 men (47.4%) and 1,248 women (52.6%). There were 995 people from rural areas, accounting for 41.9%, and 1,378 people from urban areas, accounting for 58.1%. As for the structure of majors, 1,350 students were studying literature, history, and finance, and 1,023 students were studying science and agriculture, accounting for 56.9 and 43.1%, respectively. In terms of grade structure, the numbers of freshmen, sophomores, juniors, and seniors were 503, 657, 797, and 416, accounting for 21.2, 27.7, 33.6, and 17.5%.

Research Method

The online social anxiety scale was adopted from the Social Anxiety Scale for Social Media Users (SAS-SMU) revised by Wang (23), which was validated and revised based on the online SAS-SMU established by Alkis et al. in Turkey. It consists of three dimensions with 15 entries, and the three dimensions are SAC, PAC, and IA. The 5-point Likert scale was used (not at all, rarely, sometimes, often, and completely), with higher scores indicating a more severe degree of online social anxiety (24). The Cronbach $\alpha = 0.928$ in this survey.

Family process factors include (1) parent-child relationships (poor, fair, and good), and problem behavior theory suggests that a good parent-child relationship will increase their regular behaviors with a corresponding decrease in problem behaviors. (2) Interparental relationships (poor, fair, and good), family dynamics theory suggests that if an individual is in a deteriorating family relationship, it will lead to poor socialization of the child (25). (3) Family climate (poor, fair, and good), research has shown that the more harmonious the family climate is perceived by adolescents, the less they engage in problem behaviors. (4) Parental supervision (rarely, occasionally, and often), according to Jessor's problem behavior theory, the higher the level of support and control (especially from parents) perceived by adolescents, the less likely they are to engage in problem behaviors (26). (5) Sibling relationship (poor, fair, and good).

Data Collection

The survey was conducted by the Public Foundation Department of Guangxi Police College and some students used the actual test. Before the survey, the investigators were trained in a unified manner. In the survey, arranged quality control personnel in the field are responsible for answering possible problems to the survey respondents in a timely manner. The surveyors are responsible for recovering and reviewing the completeness of the completed questionnaires (27). The study used SPSS 26.0 and Stata for data analysis; descriptive statistics, one-way ANOVA, *t*-test, and linear regression analysis were used to explore the relationship between family process factors and online social anxiety of university students. $P < 0.05$ indicates that the difference is statistically significant.

STATISTICAL ANALYSIS

Descriptive Analysis of Family Process Factors of Guangxi University Students

There were 322 (13.6%) only children and 2,051 (86.4%) non-only children among 2,373 university students. The numbers of non-only children's families with poor, fair, and good sibling relationships were 29 (1.41%), 317 (15.5%), and 1,720 (83.1%). The numbers of poor, moderate, and good parental relationships were 161 (6.78%), 640 (27%), and 1,572 (66.25%). The frequency of family supervision was rarely, occasionally, and often for 72 (3%), 1,520 (64.1%), and 781 (32.9%). Those with poor, average, and good parent-child relationships were 31 (1.3%), 692 (29.2%), and 1,650 (69.5%). Poor, fair, and good family atmospheres occurred in 531 (22.4%), 1,330 (56%), and 512 (21.6%).

Differential Analysis of Family Process Factors of Online Social Anxiety

Table 1 shows, except for parental supervision ($p > 0.05$), that the effects of interparental relationship, parent-child relationship, sibling relationship, and family atmosphere on online social anxiety in rural university students were statistically significant and showed positive correlations ($F/t = 6.64, 3.53, 4.15, 5.94$, $p < 0.05$).

TABLE 1 | Differential analysis of family process factors of online social anxiety ($n = 2,373$).

		N	$\bar{x} \pm s$	F/T	*P*
Only child	Yes	322	30.19 ± 10.95	−0.38	0.702
	No	2,051	30.93 ± 10.04		
Relationship with compatriots	Poor	29	42.67 ± 6.43	4.15	0.007
	Fair	317	35.13 ± 10.63		
	Good	1,705	29.72 ± 9.82		
Parent-child relationship	Poor	31	38 ± 17.35	3.53	0.031
	Fair	692	33.12 ± 8.85		
	Good	1,650	29.74 ± 10.38		
Family atmosphere	Poor	531	33.17 ± 10.54	5.94	0.003
	Fair	1,330	31.44 ± 9.13		
	Good	512	26.78 ± 11.27		
Parental supervision	Rarely	72	24.43 ± 10.72	2.58	0.078
	Occasionally	1,520	31.74 ± 9.37		
	Often	781	29.63 ± 11.31		
Inter-parental relations	Poor	161	35.13 ± 12.12	6.64	0.002
	Fair	640	33.83 ± 8.92		
	Good	1,572	29.17 ± 10.06		

Multiple Linear Regression Analysis of Online Social Anxiety

The total score of the online social anxiety scale of university students was used as the dependent variable. The five family process factors of parental relationship, parental supervision, parent-child relationship, sibling relationship, and family atmosphere were used as independent variables for multiple linear regression analysis. First, the covariance test was conducted, the VIF values were all <10, and there was no covariance between the variables. Total anxiety score = 36.914−4.09 × good parental relationship−4.16 × good family atmosphere−3.42 × good sibling relationship, i.e., the total anxiety score was on average 4.09 points lower when comparing good and poor parental relationships. The average total anxiety score was 4.16 points lower when comparing good and poor family atmospheres. The average total anxiety score was 3.42 points lower when comparing good and poor sibling relationships (refer to **Table 2**).

DISCUSSION AND SUGGESTIONS

Risk Factors and Protective Factors in Family Process Factors Affecting Online Social Anxiety of University Students

The results of the study showed that parental relationship, family atmosphere, and sibling relationship influenced Guangxi University students' online social anxiety, where parental friendship, sibling friendliness, and family harmony were protective factors for Guangxi University students. The opposite were risk factors. That is, the more parents punish and control when educating their children, the stronger the domestic violence environment, and the more family conflicts, the higher the incidence of university students' online social anxiety. On the contrary, good parental and sibling relationships and high intimacy in the family are protective factors to reduce the incidence of Guangxi University students' online social anxiety.

The risk factors among the family process factors that triggered or increased the online social anxiety of university students were poor parental relationships, poor sibling relationships in non-one-child families, and overall family climate disharmony. From the viewpoint of family systems theory, these risk factors occur in the coupled system (high conflict between spouses and strong violent environment) and sibling system (unfriendly sibling relationship), leading to children's overall perception of poor family climate playing a role in online social anxiety of university students' promoting effect. It is clear from this that the risky effects of negative family environments occurring in multiple family subsystems are significant, and it is evident that online social anxiety of university students is not the result of the action of a single system in the family but maybe the result of multiple risk systems acting together.

Suggestions From the Perspective of Family Systems Theory

According to stress-coping theory, one of the main reasons that adolescents face a variety of risk factors during their development and only a minority of them end up with problems is that these risk factors do not act on the same adolescent at the same time. Adolescents' own psychological abilities (e.g., mental toughness, high self-efficacy, etc.) counteract the negative consequences of negative factors, a principle that is also valid for online social anxiety. If an adolescent grows up with only one risk factor, such as poor parental relationship

TABLE 2 | Multiple linear regression analysis of online social anxiety ($n = 2,373$).

Dependent variable: Online social anxiety total score of Guangxi university students					
	Unstandardized coefficient		Standardization coefficient	t	Sig
	B	Standard error	Beta		
(Constant)	36.914	1.446		25.521	0
Good parental relationship	−4.094	1.347	−0.191	−3.04	0.003
Good family atmosphere	−4.158	1.548	−0.169	−2.686	0.008
Good sibling relationship	−3.417	1.413	−0.151	−2.418	0.016

or weak parental supervision, or sibling tension, the likelihood of online social anxiety in adolescents is low. However, when many risk factors, such as poor parental relationship, sibling disharmony, and family tension, act on adolescents at the same time, there is a high probability that online social anxiety will occur (28).

Developmental psychopathology suggests that the development of social adjustment problems in individuals is influenced by several factors that increase the risk of developing mental illness, while some factors protect individuals from physical and mental illness. Since the occurrence of online social anxiety is the result of a combination of risk factors, the more risk factors there are for online social anxiety interventions, the more protective factors there are to counteract the risk factors. The results of this empirical analysis of the factors influencing the online social anxiety of Guangxi University students showed that the total anxiety score of good parental relationships was on average 4.09 points lower than that of poor parental relationships. The average anxiety score of a good family atmosphere was 4.16 points lower than that of a poor family atmosphere. The average anxiety score of a good sibling relationship was 3.42 points lower than that of a poor sibling relationship, which were the protective factors of family process factors in reducing online social anxiety. A healthy developing adolescent has a positive support system, while a poorly developing adolescent has a negative support system behind him or her. In addition, there is a pattern of "good together and bad together" between the systems.

Although online social networking makes up for the deficiency of public real interpersonal communication to a certain extent. However, due to the virtuality, vulnerability, and uncertainty of the network, coupled with the proliferation of information, interpersonal overload, and privacy security of online social media, online social networking is mostly superficial and lacks depth, and personal emotional needs cannot be met, which promotes the emergence of online social anxiety and indulges it. As the most important place for emotional breeding and cultivation, the family should become a warm home to avoid and overcome the online social anxiety of university students. Based on the empirical analysis of this thesis, to intervene in the online social anxiety of university students, on the one hand, we need to intervene in the support system behind university students comprehensively. In terms of family process factors, we need to intervene in the coupled system, parent-child system, and sibling system in the family as a whole and improve the education and guidance mechanism of protective factors. On the other hand, when we intervene, we can also seize the key points and key links in the system. In the specific implementation method of correcting network anxiety through family, a generalized collaborative framework named collaborative shared healthcare plan (CSHCP) gives us a great idea to correct online social anxiety of university students (29). It is a CSHCP framework for daily life activity recognition and can be used for remote coordination and communication between family members to enhance emotion and avoid addiction to the network. This is more suitable for college students who leave their families to study. For college students with online social anxiety, their personal health records (PHRs) can be maintained using the Star File System (IPFS) (30), and they can access their records online and make targeted corrections at any time.

CONCLUSION

Family is not only an extremely important environment in the process of individual psychological development and even the formation of psychological quality but also the main influencing factor of individual personality characteristics and mental health. Based on this, the thesis makes some tentative enquiries into the relationship between family process factors and online social anxiety. Although the statistical value of the sample survey cannot infer the overall trend quantitatively, the survey results of the sample can explain some overall characteristics: that parental relationship, family atmosphere, and sibling relationship influenced online social anxiety of university students. To intervene in the online social anxiety of university students, on the one hand, we need to intervene in the coupled system, parent-child system, and sibling system in the family as a whole and improve the education and guidance mechanism of protective factors. On the other hand, we can also concentrate on the key points and key links in the family process system. Because this study is affected by the randomness of the sampling survey and the limitation of the number of questionnaires, and the understanding of online social anxiety will be more or less subjective, the conclusion of the study is not suitable for popularization and needs further verification. Finally, it is hoped that through the relevant elaboration of the family

factors of online social anxiety, the public can pay attention to family harmony.

Project. Front. Public Health 10:855680. doi: 10.3389/fpubh.2022.855680

Congenital syphilis (CS) remains a threat to public health worldwide, especially in developing countries. To mitigate the impacts of the CS epidemic, the Brazilian government has developed a national intervention project called "Syphilis No." Thus, among its range of actions is the production of thousands of writings featuring the experiences of research and intervention supporters (RIS) of the project, called field researchers. In addition, this large volume of base data was subjected to analysis through data mining, which may contribute to better strategies for combating syphilis. Natural language processing is a form of knowledge extraction. First, the database extracted from the "LUES Platform" with 4,874 documents between 2018 and 2020 was employed. This was followed by text preprocessing, selecting texts referring to the field researchers' reports for analysis. Finally, for analyzing the documents, N-grams extraction (N = 2,3,4) was performed. The combination of the TF-IDF metric with the BoW algorithm was applied to assess terms' importance and frequency and text clustering. In total, 1019 field activity reports were mined. Word extraction from the text mining method set out the following guiding axioms from the bigrams: "confronting syphilis in primary health care;" "investigation committee for congenital syphilis in the territory;" "municipal plan for monitoring and investigating syphilis cases through health surveillance;" "women's healthcare networks for syphilis in pregnant;" "diagnosis and treatment with a focus on rapid testing." Text mining may serve public health research subjects when used

in parallel with the conventional content analysis method. The computational method extracted intervention activities from field researchers, also providing inferences on how the strategies of the "Syphilis No" Project influenced the decrease in congenital syphilis cases in the territory.

Keywords: text mining, public health, congenital syphilis, content analysis, "no syphilis" project

1. INTRODUCTION

Syphilis is a sexually transmitted disease (STD) that surfaced in Europe in the late 15th-century (1, 2). While this condition is preventable, curable, and usually treatable with penicillin injections, it remains a global health security threat. In addition, syphilis is the second major cause of adverse pregnancy outcomes, including neonatal death (3–6). That fact raises the syphilis epidemic as a neglected problem that poses considerable challenges to many health systems.

Although there is an effective therapy to combat the infectious agent, Treponema pallidum, measures to control and prevent the disease require that health care systems integrate many levels of care. That includes planning and deploying preventive and therapeutic interventions for all stages and types of syphilis in different population groups. In sum, the infection is relatively simple to treat if diagnosed at an early stage but difficult to control among populations (3, 4).

In 2016, the World Health Organization (WHO) launched an initiative to eliminate congenital syphilis (CS). Its goal was that CS case counts would not exceed 50 cases per 100,000 live births in 80% of countries (7). However, the overall rate was 473 cases per 100,000 live births in this very period (8). In Brazil, rates of reported CS outnumber those of other nations, with 880 cases per 100,000 live births in 2017, thus representing an Average Annual Percent Change (AAPC) of 60.38% (8).

Confronted by the growing syphilis epidemic, the Ministry of Health (MoH) and governing bodies of Brazil's Unified Health System (SUS) developed a national project for implementing and integrating a syphilis response into healthcare networks (9). The "Syphilis No!" Project (SNP), as it was titled, represented the instrument with which the MoH implemented a public health response to reduce syphilis in pregnant women (SIP) and eliminate congenital syphilis in Brazil. It has been in progress since 2018 and is built on two cornerstones: (1) actions with a universal scope and (2) specific actions in priority areas. Specific actions were developed in 100 municipalities the Ministry of Health considered a priority due to the high burden of CS (9, 10).

A team of field researchers carried out the specific actions in line with the five thematic areas of the project (Surveillance, Management and Governance, Integral Care, Education, and Communication) to qualify the local response on syphilis. It seems clear that describing the work of RIS in the priority areas renders substantive material to support analyses on the impact of interventions and their associations as a tool to induce health policy responses to syphilis.

The "LUES Platform" was one of the resources of the project. It was developed and used to monitor field researchers' activities. In such a digital platform, the researchers entered reports or individual texts related to their activities in the territory. Nonetheless, well beyond the need to interpret data on the project's associations in the territory, it is clear that research approaches that interpret textual production (e.g., content or thematic analysis) pose challenges. This is closely related to the scarcity of consolidated methods for using and processing large volumes of text.

Theorists like Bardin (2011) have discussed computers' relevance and practicality to deepen content analysis techniques, as long as researchers prepare unambiguous instructions. From this standpoint, content analysis automation can occur in varying degrees (total or partial). That implies direct consequences on the analytic practice, such as increased speed, increased rigor in research setup, and the potential for complex data manipulation, and so on (11).

An additional challenge for research done with sheer volumes of text data is to objectively interpret structures that aid in understanding the impact of work included on reports available on digital platforms, or at least to attempt to do so. Thus, it would take years to analyze such types of data through conventional manual methods. To address this issue, there are software-related strategies for text analysis that are typically applied in the healthcare field (12).

However, the currently available software is insufficient for monitoring strategic intervention activities. This mostly happens because they produce limited information that does not consider textual modeling (13). Such software limits the ability of researchers to handle the results generated safely. In addition, there are several difficulties in interpreting the word processing in such programs (13).

As the use of Artificial Intelligence continues to expand across many healthcare fields, machine learning algorithms (MLA) for big data analysis and modeling started to emerge (14, 15). In this vein, the text mining technique has the potential to provide consistency in the interpretation of text monitoring strategies, as well as a reliable treatment for the rendering of word form n-grams (16). However, the strategy of using text mining techniques to identify the main intervention activities in large national projects, such as the "Syphilis No!" Project, has not been found within the current literature.

Incorporating text and data mining (TDM) and the content analysis method into research involving large volumes of data has the potential to support evaluative studies (17). Further, it can supplement indicators that assess the effectiveness of work processes and their performance, which will further assist public health strategies toward interventions dealing with challenges similar to congenital syphilis. Therefore, with the aid of a set of

algorithms – which make up a computational method applied to text mining – it is possible to identify which intervention activities developed by the RIS may have spurred public health policy strategies in the territory. In other words, strategies that point to a significant reduction in CS cases.

This article considers that the "Syphilis No!" Project has been contributing to syphilis cases reduction in Brazil. Our assumption is that field researchers' practices demonstrate the link between the goals of the project and the management of syphilis in the territory. Furthermore, their activities could have potentially influenced the indicators of syphilis in priority municipalities.

Hence, this article's scope is to analyze the connections amid the goals of the "Syphilis No!" Project and the content presented by the field researchers by using computational methods that apply text mining algorithms–in addition to discussing the role of such connections as health public policy drivers.

1.1. Related Works

We consider it adequate to briefly quote some studies that use computational methods, whether NLP methods or techniques based on Machine Learning (ML) to differentiate our use of Natural Language Processing. The analysis aimed to identify applications in several areas related to health. El Kah and colleagues studied a large volume of data produced through the implementation of an electronic patient record system (18). To efficiently handle these complex data, researchers employed NLP to extract patterns and elements of interest. By Valentim et al. (19) studied a similar Stochastic Petri Net Model describing the relationship between reported maternal and congenital syphilis cases in Brazilaspect; however, in a different field of application, i.e., the Virtual Learning Environment of the Brazilian Health System (AVASUS). In that example, the goal was to identify the writing style for authorship recognition using NLP methods. In (20), it was possible to find some methodological similarities regarding the work developed by Rocha et al. (21). Machine Learning methods enabled an optimized and more accurate analysis of text content and regular expressions. In our case, applying neural networks also proved to be a feasible way to work with NLP and TDM techniques.

Accordingly, the Clinical Record Interactive Search (CRIS) is another work applied in healthcare by means of content analysis. This work is developed within the context of large volumes of clinical data provided by the South London and Maudsley Trust. Its focus was to search for highly relevant elements in unstructured text, and for this purpose, NLP proved to be particularly important. Such practice prompted access to relevant results about the clinical status of patients.

Thus, it was observed that nearly 7,500 people affected by schizophrenia presented with a clinical picture of negative symptoms, which often leads to impaired cognitive ability, disordered thinking, and lack of concentration. Thus, NLP approaches were proposed, which enabled obtaining a more assertive context from the documents (22).

Regarding electronic patient records, the high volume of these records always stands out, especially when health information systems are centralized. Therefore, computational methods applied to content analysis can significantly contribute to this field, especially in patients' clinical histories studies.

Some studies focus on ubiquitous data acquisition, such as the work developed by Javed et al. (23). Such a study was underpinned by a generic, intelligent, autonomous, and collaborative Internet of Things (IoT) architecture. The proposed model is based on smartphones and machine learning. One of its most potent contributions is sharing health-related information, which can be used in comparative analysis. Furthermore, the ubiquitous model proposed in this study fosters the centralization and production of large volumes of data. Therefore, computational methods, especially regarding content analysis, can be of much value to measure, both quali- or quantitatively, the behavior of users of collaborative health settings, where the main objective is to evaluate the daily activities of these users.

These research efforts were applied in different contexts in the health field, yet they all used computational methods, whether NLP methods or techniques based on Machine Learning (ML). The studies in question approached aspects of patient care and were applied in clinical settings. However, computational methods were used in different contexts in all the studies, which indicates a fertile ground for scientific research and diverse applications. It is noteworthy that none of the studies listed used Natural Language Processing or Machine Learning to evaluate the impact of public health policies, which is one of the main contributions of this article.

2. MATERIALS AND METHODS

According to Bardin (11), content analysis is a set of methodological tools that, being continuously perfected, can be applied to varying types of text. These tools underscore the development of data categories and ratify how relevant it is to understand the significance of the context in which analyzed items have been applied (11).

The primary function of content analysis is to unravel the critic about a particular discourse (11). It can be done qualitatively or quantitatively. In the first approach, the analysis is performed both systematically and analytically. Hence, a researcher reviews themes or categories of analysis through conceptualization, data collection, analysis, and interpretation. In the second, the search is oriented for the quantification of content as to predetermined categories; and it is conducted in a systematic and replicable manner (11, 24).

In both approaches, the goal is to infer knowledge about the semantics of the prevailing discourse in the data or its message. In this study, we adopted a qualitative-quantitative approach. This stems from the fact that such an approach mixes TDM techniques and a conceptualization of the extracted discourse–with a theoretical basis that seeks to understand the intervention activities–from the perspective of public health in the territory. In this context, the theoretical basis that served as a contributing factor in determining this research's development steps was inspired by Bardin (11), and it is characterized into three main stages, namely: (i) pre-analysis; (ii) exploring the materials:

text mining; and (iii) analysis of Obtained Results: Inference and Interpretation, implemented in the Python programming language version 3.7.

These steps were essential to the development of this work. Given the volume of texts produced by the field researchers, the text mining method and subsequent content analysis were the most suitable approaches to study our research subject. Moreover, text mining was necessary to analyze the formation of the most relevant word statistically' and subsequently form logical semantic sentences based on content analysis.

2.1. Pre-analysis

Pre-analysis is the process in which the corpus is organized so it becomes operational and by which preliminary ideas are systematized. In this step, we carried out three tasks: (i) skimming, for an overall comprehension of the documents that would be collected; (ii) documents selection, which consisted in determining which ones would be analyzed; and (iii) formulating the hypotheses and objectives of the research to be developed (11).

In the pre-analysis, it was necessary to grasp (i) the central features that characterize the "Syphilis No!" Project in order to propose the subject of the present study; (ii) the ethical issues related to the research; and (iii) the features of the corpus (texts) for analysis in the next step—exploring the materials.

2.2. Features of the "Syphilis No!" Project

The SNP was developed by the Brazilian government through the Ministry of Health (MH). Over the last ten years, it has been the leading syphilis-related public health intervention in Brazil (8, 10, 25).

Within the breadth of strategies to combat syphilis, this study focuses on the institutional support network composed of field researchers who worked in priority municipalities in the regions of Brazil. Such a support network was assembled with the primary purpose of strengthening the "nexus between the Project and the health services managers in the territory," "to coordinate programmatic actions agreed upon within governance bodies of SUS with local plans" and to offer support for a "timely response to syphilis within the healthcare networks" (26).

The project relied upon 52 research and intervention supporters distributed across 72 of the 100 priority areas in all five Brazilian regions (26). RIS worked alongside health services managers to find the best strategies to confront syphilis. The following determinations guided them: evaluating the health plans and programs of local health departments; strengthening committees for investigating mother-to-child transmission (MTCT); strengthening strategic information systems for health surveillance and improving case reporting, laboratory follow-up, and closure of syphilis cases, as well as operationalizing the line of care for adult syphilis and congenitally exposed infants (10).

All activities developed by RIS were monitored by supervisors who used a digital management system, that is, the "LUES Platform." Through the platform, the researchers produced and submitted individual monthly reports in free text format (not systematized). Researchers produced and submitted individual monthly reports in free-form (not systematized) through the platform. These reports were based on the on-site experience and endeavors, as well as on the results of interactions between the project's actions and interventions in the public health agenda agreed upon in the inter-federative context of Brazil's SUS. It is particularly noteworthy that throughout the operationalization of the SNP, the Ministry of Health, responsible for implementing health policies in response to syphilis in Brazil, assigned the role of coordinating the syphilis policy and its set of actions at the local level to each RIS (8).

2.3. Research Ethics Issues

The database of texts related to the SNP interventions used in this article is in the public domain. In this manner, secondary data are used without any sensitive identification of the participants or public actors. Data were gathered after the extraction and anonymization of the documents released in the repository of the "LUES Platform." Of note, this data can be easily accessed by any researcher at the following link: http://vigilanciasaude.ufrn.br/files/anonymous_reports.csv.

2.4. Exploring the Materials

Each field researcher individually wrote the reports selected for content analysis. Texts could be written in a free format (not systematized), meaning that each supporter developed their own reports featuring an account of what was done and accomplished. Therefore, the project did not provide any template for RIS to follow. Of note, the MoH entrusted each field researcher with a set of actions to be carried out on a monthly basis during the SNP. Actions were aligned with the project's goals and the public health agenda.

Since reports featured free-form content and the health terms structures are identifiable—using the analytical method, by two, three, or more words—the TDM process was fully automated by text mining algorithms using N-grams (see "Words and data extraction" for detailed information). By applying the analytical method, we observed it was not enough to identify any intervention action taken by the field researchers that only one term. However, from two to five words, identification could be achieved.

Text mining may be defined as the automated discovery of hitherto unknown knowledge utilizing an unstructured database (14, 15). A keystone of this method is linking combined information to form new facts or new hypotheses to be explored.

The following actions were carried out for implementing the text mining technique in this research: (i) detailing the Database; (ii) pre-processing; (iii) Words and Data Extraction; and (iv) N-grams Extraction. Each of the activities is subsequently described in detail.

2.5. Detailing the Database

The database was extracted from the "LUES Platform." The texts collected refer to accounts about technical visits and meetings; and progress reports concerning work and research plans, thus totaling 4,874 text file documents–this sum corresponded to 3.86 Gigabytes of digitally stored files. Each document has nearly 740

TABLE 1 | Document Indexing Data.

Variable	Description
Identifier	Document identification number
Month	Month the document was created
Year	Year the document was created
State	Brazilian State where the document was created
Region	Brazilian Region where the document was created

words. The time frame for compiling the corpus was from May 2018 to December 2020.

In order to build the database, those documents underwent the process of anonymization and identification. Afterward, they were indexed according to the information provided in **Table 1**.

Each entry represents a document that has been collected. This document catalog has been saved in a comma-separated values (CSV) format, a text file separated by commas (27). The file is available for download at the following link: http://vigilanciasaude.ufrn.br/files/anonymous_reports.csv.

2.6. Pre-processing

Pre-processing consisted of 4 tasks: (i) Document Standardization; (ii) Text Normalization; (iii) Removal of Duplicate Documents; and (iv) Text Correction. The objective of the first task was to standardize the text database by saving the files separately. Then, each text document was processed and renamed according to the following structure: fileA_B.C, where:

- A = activity number of the Research and Intervention Supporter in the platform;
- B = identification number of the document, generated by the "LUES Platform;"
- C = file extension.

For instance, a file could be defined as: **file2923_22305.docx**.

The second task was text normalization. The purpose was to (a) standardize the text in lowercase; (b) delete extra spaces between characters; (c) remove any special characters, symbols, duplicate words in a row; and (d) remove accents and numbers. After that, a stop words dictionary was used to remove non-significant aspects of the language components. Since the text reports were written in Brazilian Portuguese, this was the language of the dictionary. Hence, it includes 204 unique words that are considered undesirable for meaningful analysis, such as: "de," "a," "o," "que," "e," "é," "do," "da," "em," "um," and so forth (28). An example of word processing is shown in **Figure 1**.

The third task consisted in removing the duplicate documents. Finally, the fourth one was to make the necessary text corrections, such as grammar error correction and adding missing spaces in some sentences.

2.7. Words and Data Extraction

For capturing words relevance within the text documents, it was necessary to highlight those sentences that came up often and were related to the topic in the texts. Therefore, not attaching any weight to those found in all files–sentences that were obvious in the portrayed context.

To obtain a representation of the topic addressed in the documents and to extract the sentences, the N-gram approach was applied, with $N = 2,3,4$ across the entire group of texts, as well as grouped n-grams using the content analysis method. Finally, the total number of field researchers and reports per region of Brazil was calculated.

2.8. N-grams Extraction: Bigrams, Trigrams, and Quadrigrams

In this step, automatic extractions of keywords formed by a sequence of two words were made. The algorithm also deduced it as automatically relevant in the text documents of Intervention Researchers, the bigrams (N-gram with $N = 2$) (29, 30).

The first step toward extracting the bigrams was to obtain a list of the ordered words from the text (tokens) through the bag-of-words (BoW) approach. Subsequently, the BoW model was converted into a two-word count matrix. Moreover, the Term Frequency—Inverse Document Frequency (TF-IDF) metric was applied (31, 32). Such a technique statistically measures the importance of a word within a text in relation to other pieces within the same database. The value of the word's importance increases proportionally as the total occurrence of that word in the text increases. Thus, the value is compensated by the frequency of that word in the database. That helps discriminate the occurrence of some words that are pretty common but unimportant within the text.

There are two steps to calculating the TF-IDF: (1) separately calculating the TF and then the IDF and (2) multiplying the two parts to find the final value. First, Equation (1) calculates the TF, which measures the probability of a word w occurring in a text *t*.

$$TF_{pt} = \frac{n_{pt}}{\sum_k n_{kt}} \tag{1}$$

Where n_{pt} is the number of times the word *w* occurs in the text *t*; in the denominator, it is the sum of the frequency of all the words in the text. Subsequently, Equation (2) calculates a word's overall relevance across all the texts in the database, IDF.

$$IDF_p = \log \frac{|T|}{\left|t_p : n_{pt} \neq 0\right|} \tag{2}$$

Where $|T|$ indicates the total number of texts in the database and the number of texts in which the word occurs at least a single time. The bigrams were also explored and clustered by region of Brazil. What is more, the same procedure was applied to other extracted n-grams.

When extracting the trigrams (N-gram with N =3), the keywords were formed by a sequence of three words. The same procedure was used for the bigram. However, with the counting matrix being obtained with the formation of three words.

For the extraction of the quadrigrams (N-gram with N=4), the keywords were obtained by a four-word sequence, using the same method as for the bigram, whereby the count matrix was attained by forming four words.

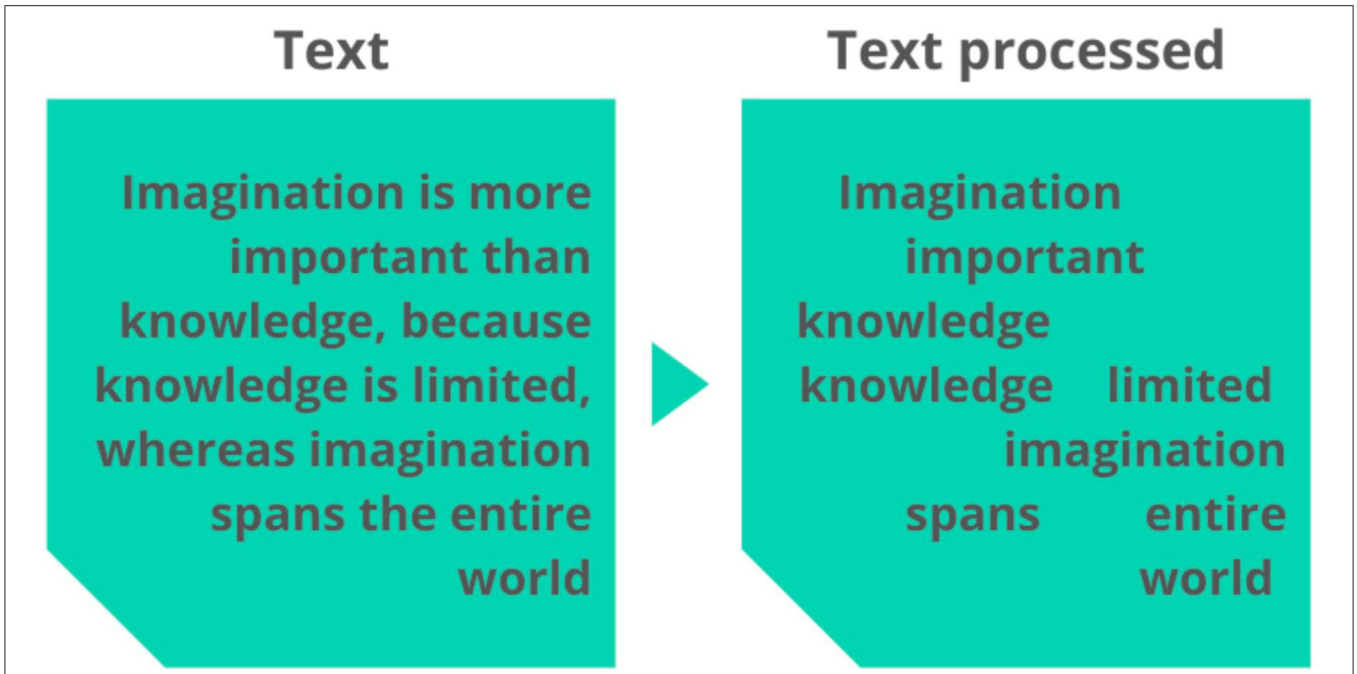

FIGURE 1 | Example of word processing.

N-grams were extracted and grouped by Brazilian region and year. We performed that step based on identifying the structures derived from the levels of health care, syphilis rapid response actions, and other predominant activities observed in reports. Then, the proportion of terms was calculated considering both groups (region and year), as follows:

$$Proportion_{termo} = \frac{\sum N - gram\ per\ report}{number\ of\ reports\ per\ region\ and\ year} \quad (3)$$

2.9. Analysis of Obtained Results: Inference and Interpretation

It is understood that the text production of the field researchers encompasses important content to emphasize the connections of the "Syphilis No" Project in the territory, especially when it comes to CS. In that case, it is about the healthcare field. More specifically, it is about the local response to syphilis and the data, or inputs, on the field researchers' observations and analyses during the project's operationalization. Moreover, in this study, "Syphilis No" is regarded as a public health intervention, based on the public health programs approach by Zulmira Hartz, who analyzes such interventions as actions that favor "adaptive behaviors across distinct human fields or activities" (33).

In the content analysis method, Bardin affirms, deductions are proposed from the significant results and according to the research goals (11). In this research, after the text mining with the formation of the most important bigrams, trigrams, and quadrigrams, a logical sequence was used for the conceptual clustering, depending on the different processes for actions for confronting syphilis that the field researchers have employed. In the conceptual clustering of the terms, the idea was to identify the structures of healthcare levels, programmatic actions in response to syphilis within healthcare networks, and the most prevalent stages identified in the reports produced.

3. RESULTS

Of the 4874 files inserted into the "LUES Platform" in the 2018–2020 period by field researchers, which after pre-processing, totaled 2164, the most are reports, thus totaling 1,019 files, as depicted in **Figure 2**. In addition, other kinds of textual productions were entered into the system, such as images (%), abstracts (%), technical reports (%), communications (%), events or meeting schedules (%), attendance lists (%), and more types of text files (articles, epidemiological bulletins, etc.).

The reports describe the field researchers' intervention activities in the municipalities. So, due to their importance, they were chosen as the basis, or corpus, for applying the content analysis method. It can be seen, from **Figure 3**, that in 2018, 430 reports were produced; in 2019, 355; and in the year 2020, 234 reports.

Figure 4 illustrates the map of Brazil with the geographical distribution of the field researchers. Besides, it describes the total number of reports produced during the three years the field researchers worked on the project and the population size by region. The Southeast of the country is the region with the most field researchers, totaling 22. According to the last census data, it is also where the higher number of reports (629) was created, being the largest region in terms of population size, with 80,364,410 people (34).

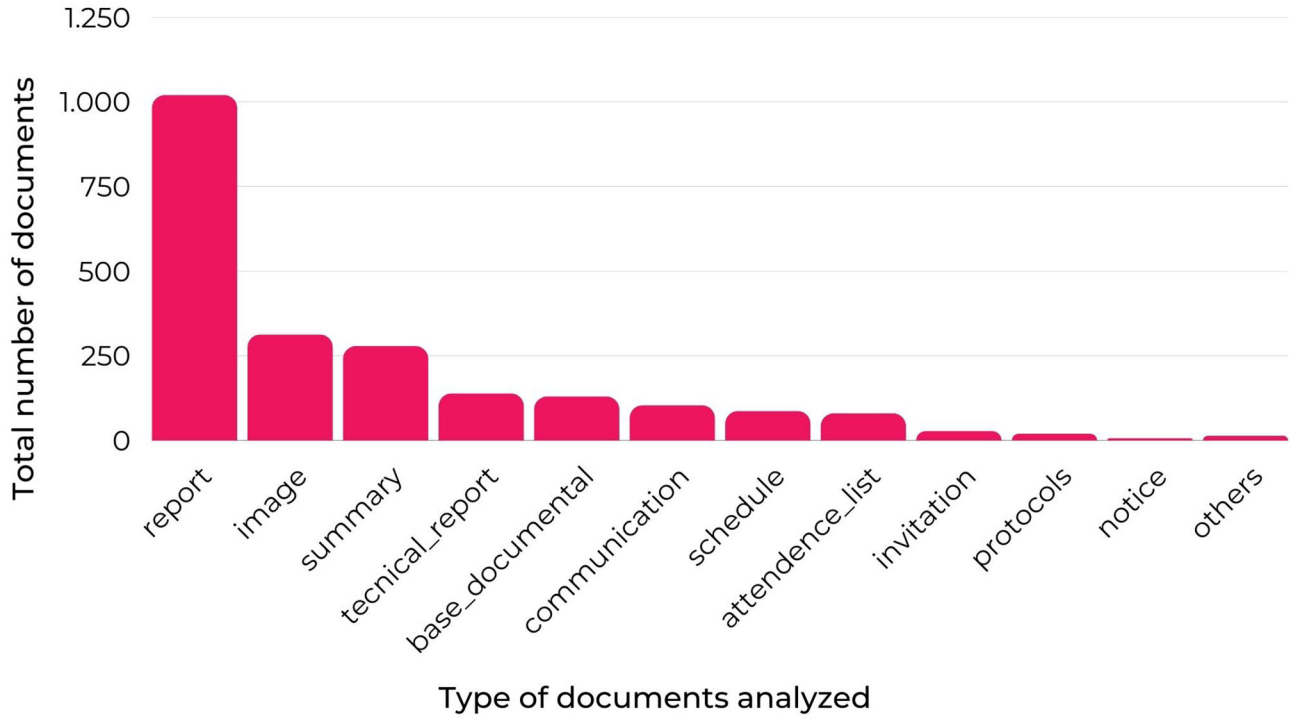

FIGURE 2 | Types of files in the "LUES Platform".

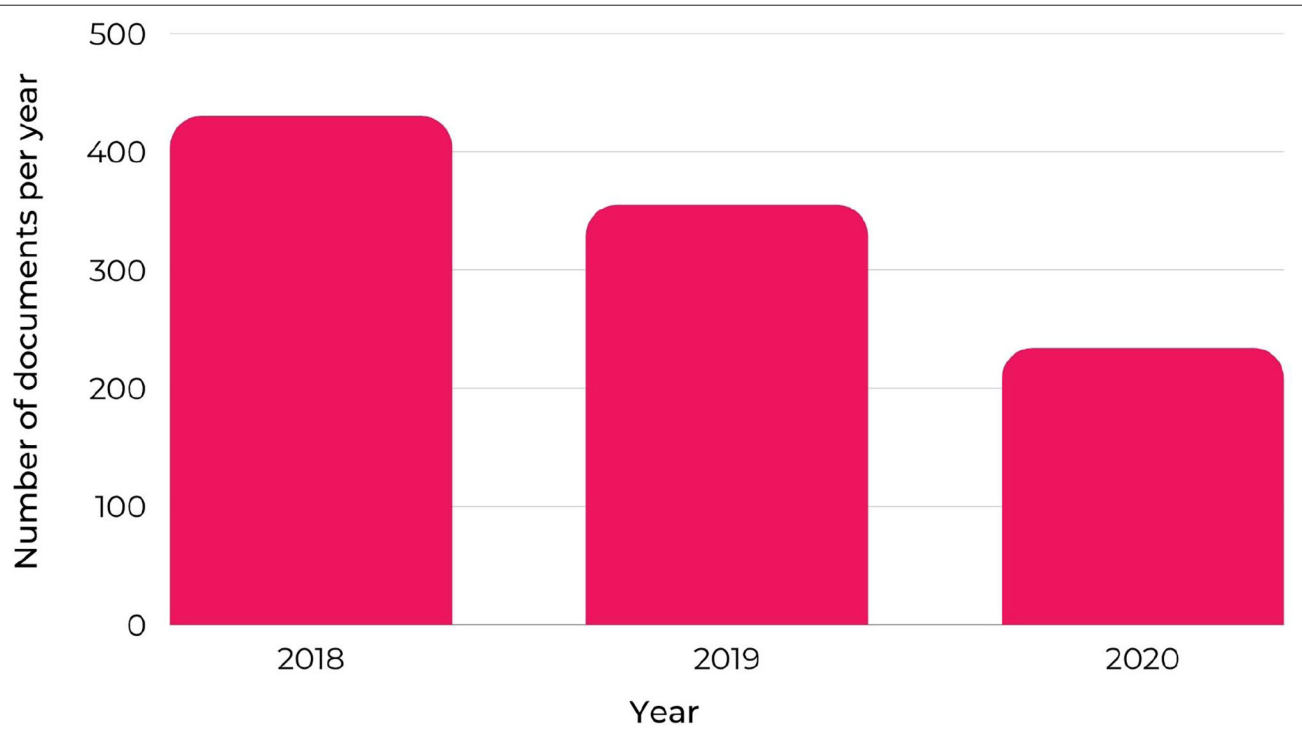

FIGURE 3 | Number of reports produced in Brazil per year.

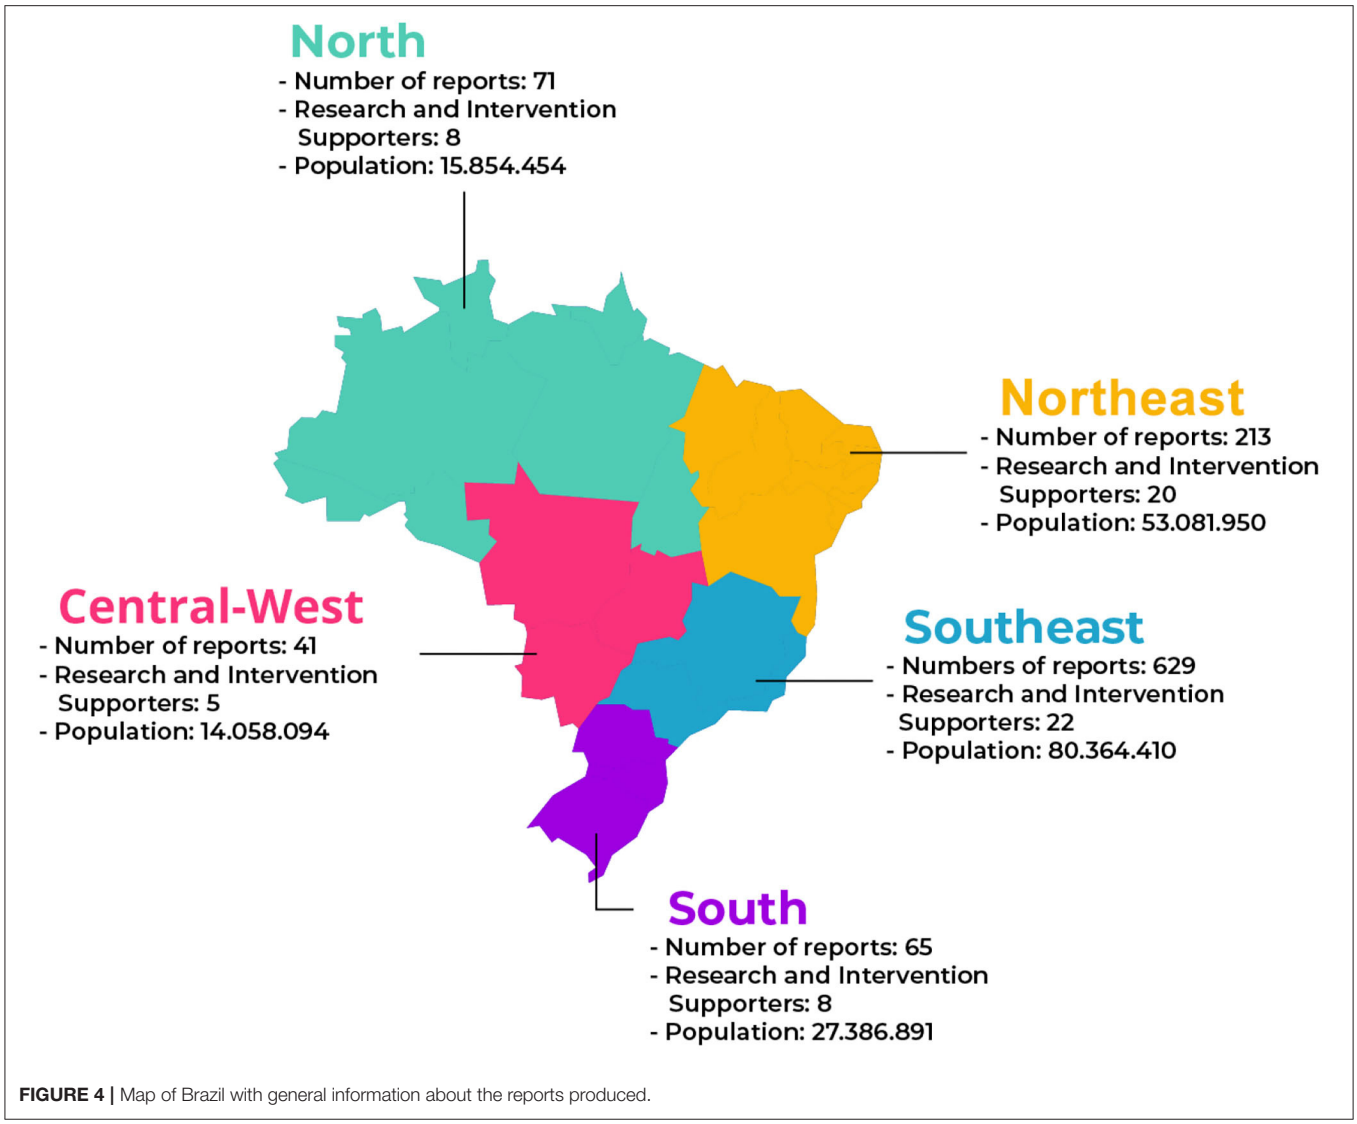

FIGURE 4 | Map of Brazil with general information about the reports produced.

The second region that most produced reports was the Northeast, with a total of 213. It is also the second-largest in relation to field researchers (20) and population size (53,081,950). The South region produced 65 reports, and the Central-West region, 41.

3.1. Analysis of Bigrams

The content analysis based on the bigrams has allowed the verification of which conceptual terms of "Syphilis No" present the most in the reports of the field researchers. The term "congenital syphilis" had the highest frequency. Hence, it signals that this ailment was the most important in the work reports, to the detriment of "syphilis in pregnant women," which had a much lower frequency. Likewise, "acquired syphilis" did not figure among the 20 most present bigrams in the reports (**Figure 5**).

The term "primary care" was the second most frequent. It indicates that this health system component was relevant the most for the supporters when it comes to "confronting syphilis" (third most frequent term). In this vein, "prenatal care" was the most relevant health service, "women's health" was the most significant programmatic area, and "pregnant women" was the most mentioned target audience. Among the other terms, "vertical transmission," "transmission investigation," "syphilis cases" suggest the relevance of epidemiological surveillance efforts in response to CS.

The analysis of the bigrams allowed them to be clustered into exploratory categories related to the response to congenital syphilis and the frequency of these terms in healthcare networks, referring to the original name of the "Syphilis No!" Project. **Figure 6** provides the distribution of the exploratory categories per year and region.

These are considered conceptual terms from the bigrams: "Confronting syphilis in prenatal care in primary health care" (**Figure 6A**); "investigation of transmission of congenital syphilis in the territory" (**Figure 6B**); "epidemiological surveillance within the municipal health plan" (**Figure 6C**); "syphilis in

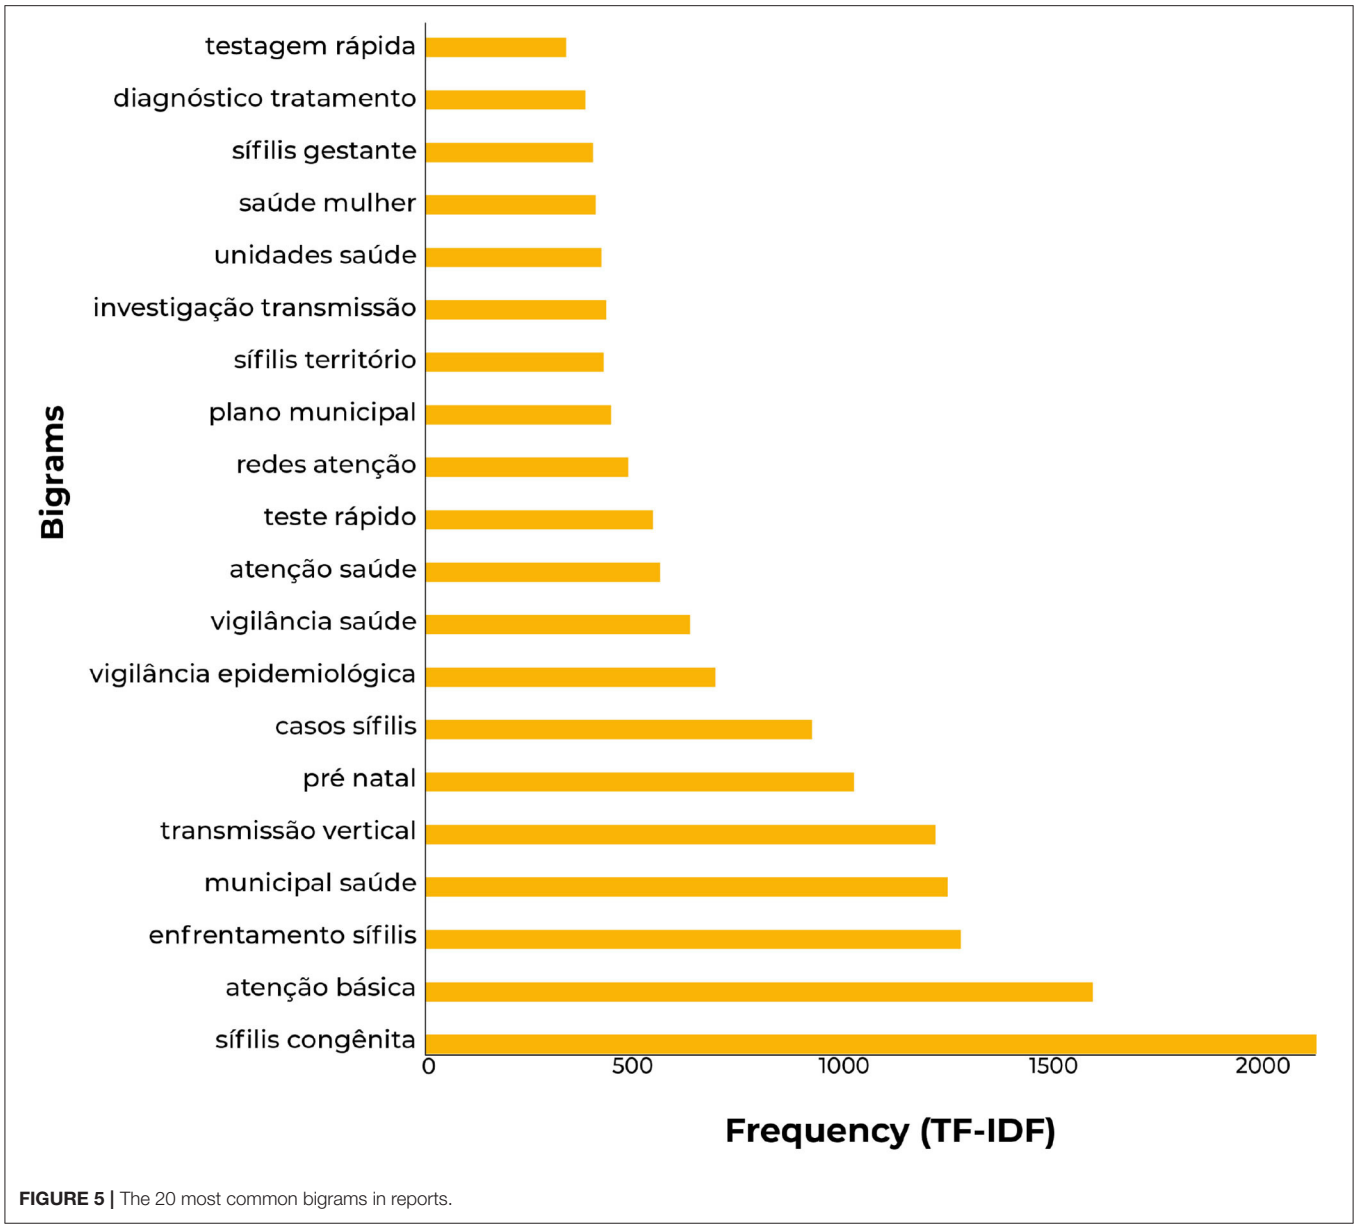

FIGURE 5 | The 20 most common bigrams in reports.

pregnant women in women's health care" (**Figure 6D**); "rapid testing, diagnosis, and treatment" (**Figure 6E**).

"Confronting syphilis in prenatal care in primary health care" (**Figure 6A**) shows that the top activities occurred in 2018 in most regions, except for the South and Southeast regions. For the "investigation of transmission of congenital syphilis in the territory" (**Figure 6B**), the Central-West and North regions indicated high proportions at the very beginning of the project. As for the "epidemiological surveillance within the municipal health plan" (**Figure 6C**), its best distribution was in 2018 in the Central-West and Southeast regions. For the "syphilis in pregnant women in women's health care" (**Figure 6D**), the South region exhibited the highest activity in 2019. Finally, the highest proportion of "rapid testing, diagnosis and treatment" (**Figure 6E**) was in 2019 in all regions, with the South region being prominent.

3.2. Analysis of Trigrams

The 20 most relevant trigrams extracted in the analysis have been pointed out in **Figure 7**, with greater relevance to "investigation vertical transmission," "congenital syphilis cases," "vertical transmission syphilis," and "syphilis healthcare networks." Such trigrams reveal that the response to MTCT (vertical transmission) of congenital syphilis–including the investigation of transmission within healthcare networks–was considered a priority in the reports.

These are considered conceptual terms from the trigrams: "Committee for investigation of MTCT of congenital syphilis"

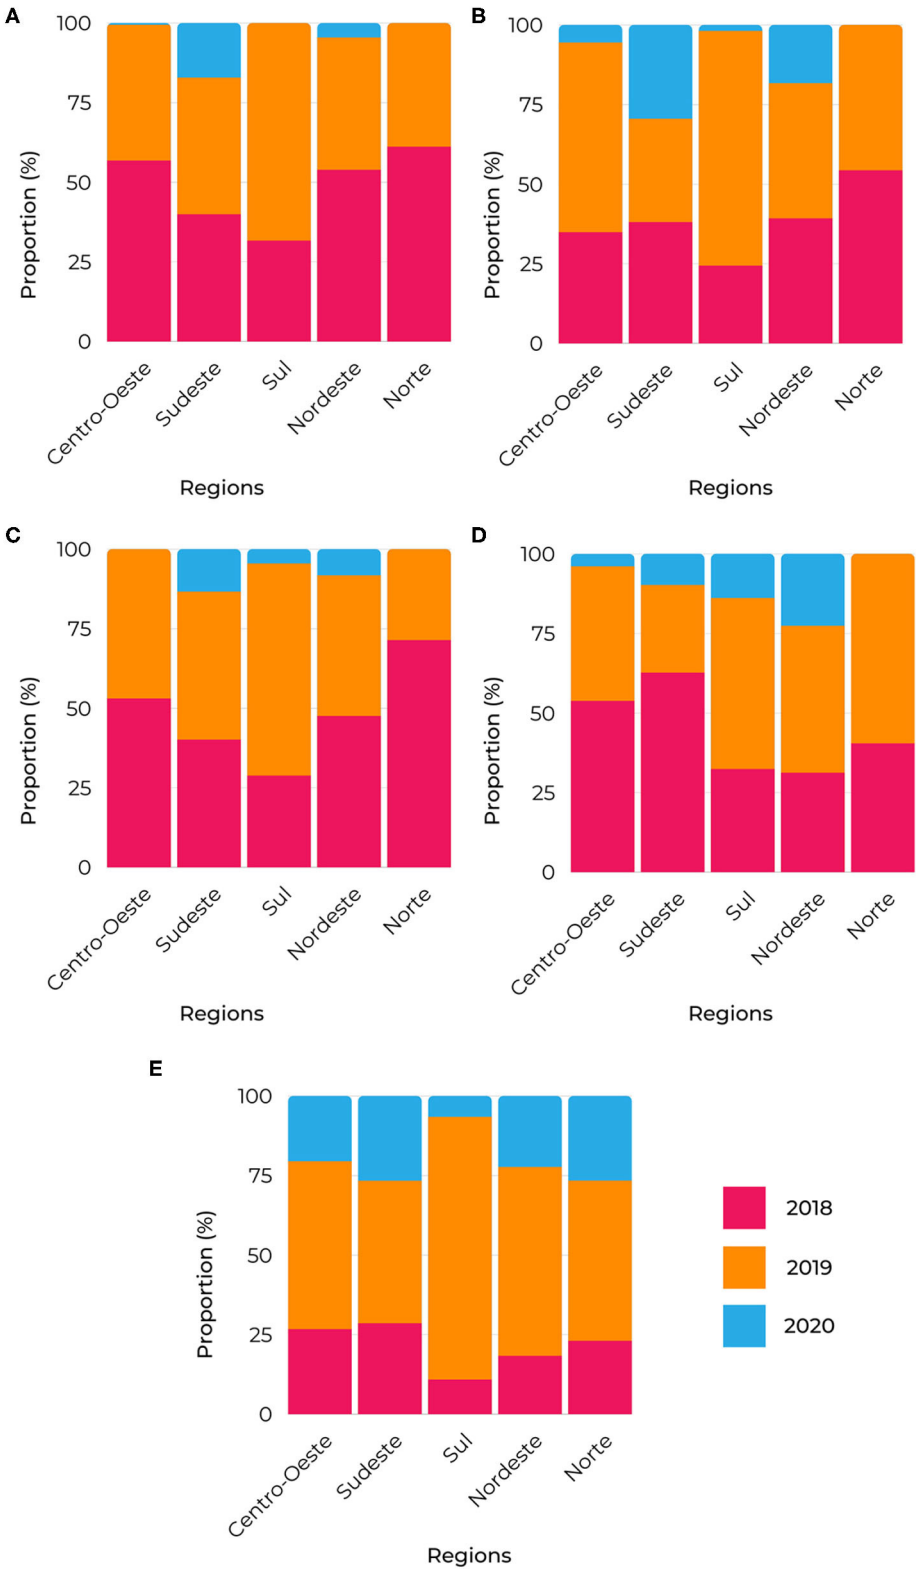

FIGURE 6 | Bigrams proportion of relevant terms segmented by region. **(A)** primary care, Confronting syphilis, syphilis cases and prenatal care; **(B)** care networks, health units, women's health and pregnant syphilis; **(C)** investigation transmission, syphilis territory, and congenital syphilis; **(D)** municipal plan, epidemiological surveillance, and health surveillance; **(E)** rapid testing and diagnosis treatment.

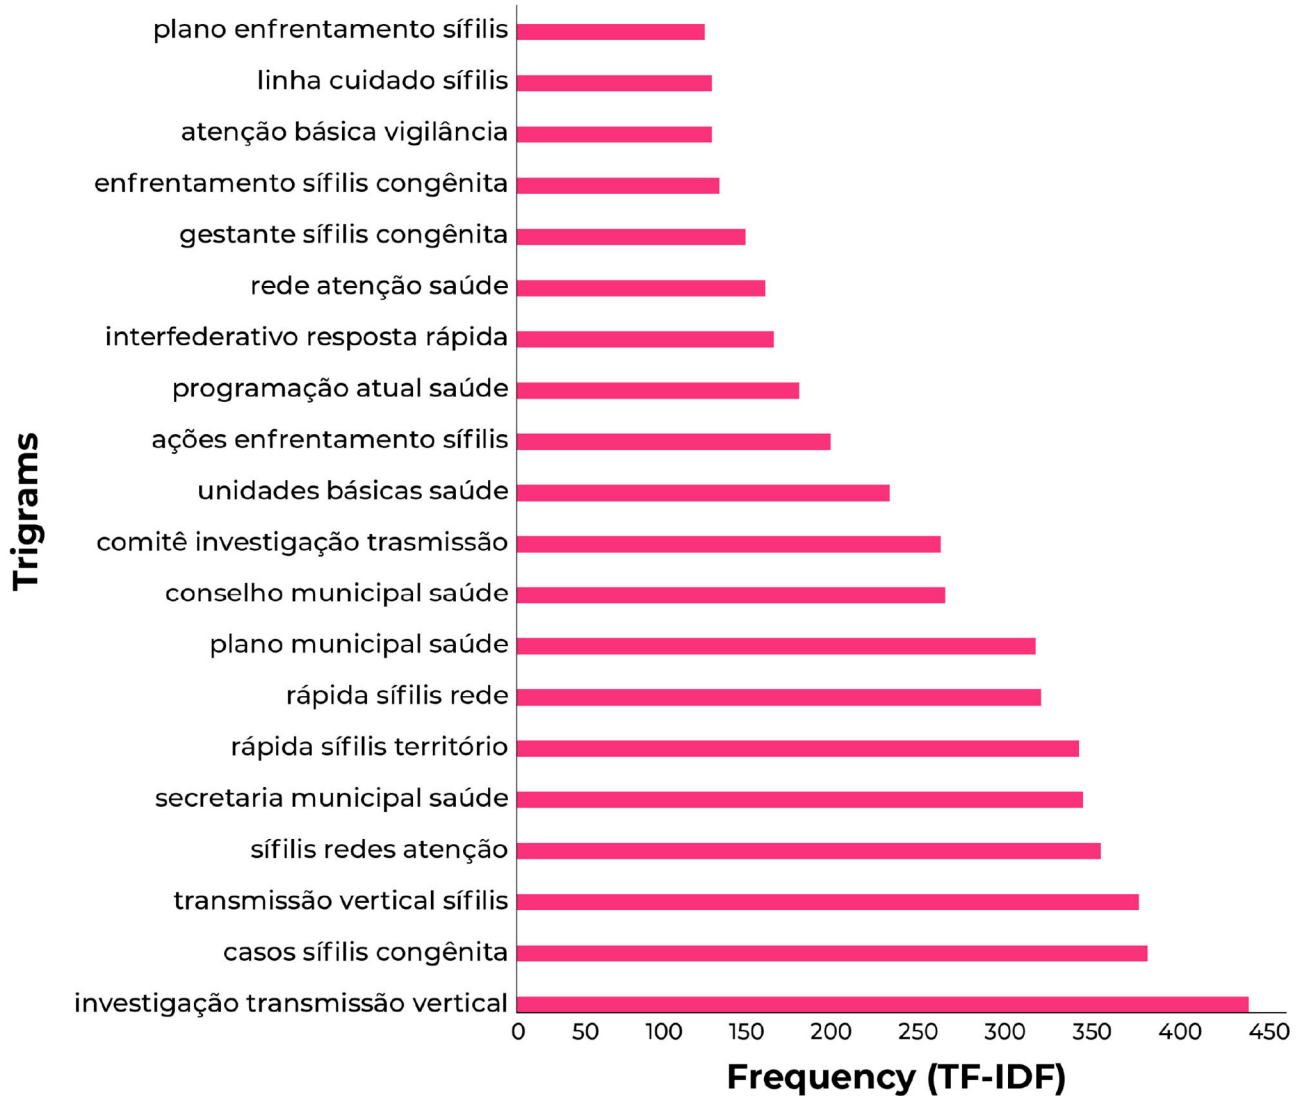

FIGURE 7 | The 20 most common trigrams in reports.

(**Figure 8A**), "congenital syphilis in municipalities' planning and yearly health programming" (**Figure 8B**), and "surveillance and attention in the lines of care for congenital syphilis and syphilis in pregnant women in primary centers of healthcare networks" (**Figure 8C**).

The analysis based on the trigram clusters corroborates the tendency of the work of the supporters within the scope of the "investigation of vertical transmission" of "congenital syphilis" (**Figures 8A–C**). Further, "pregnant women" remains as the most crucial target population (**Figure 8C**), and the "municipal health plan" emerges as a relevant instrument, adding to it the "yearly health programming" and the "municipal health councils."

Also, in **Figure 8**, the most significant activities for the "Committee for investigation of vertical transmission of congenital syphilis" (**Figure 8A**) and for "congenital syphilis in municipalities' planning and yearly health programming" (**Figure 8B**) occurred in 2018 for virtually all regions. Lastly, the topmost activity of the conceptual term "surveillance and attention in the lines of care for congenital syphilis and syphilis in pregnant women in primary centers of healthcare networks" (**Figure 8C**) was in 2019 across all the regions.

3.3. Analysis of Quadrigrams

The extracted quadrigrams can be seen in **Figure 9**. The highest frequency is for part of the full name of the "Syphilis No" project ("rapid response syphilis project").

The remaining quadrigrams confirm the field researchers' priority for investigating vertical transmission and the committee as a substantial means or service for response to CS in the territory. Besides, four conceptual terms were generated and distributed according to year and region (see **Figure 10**).

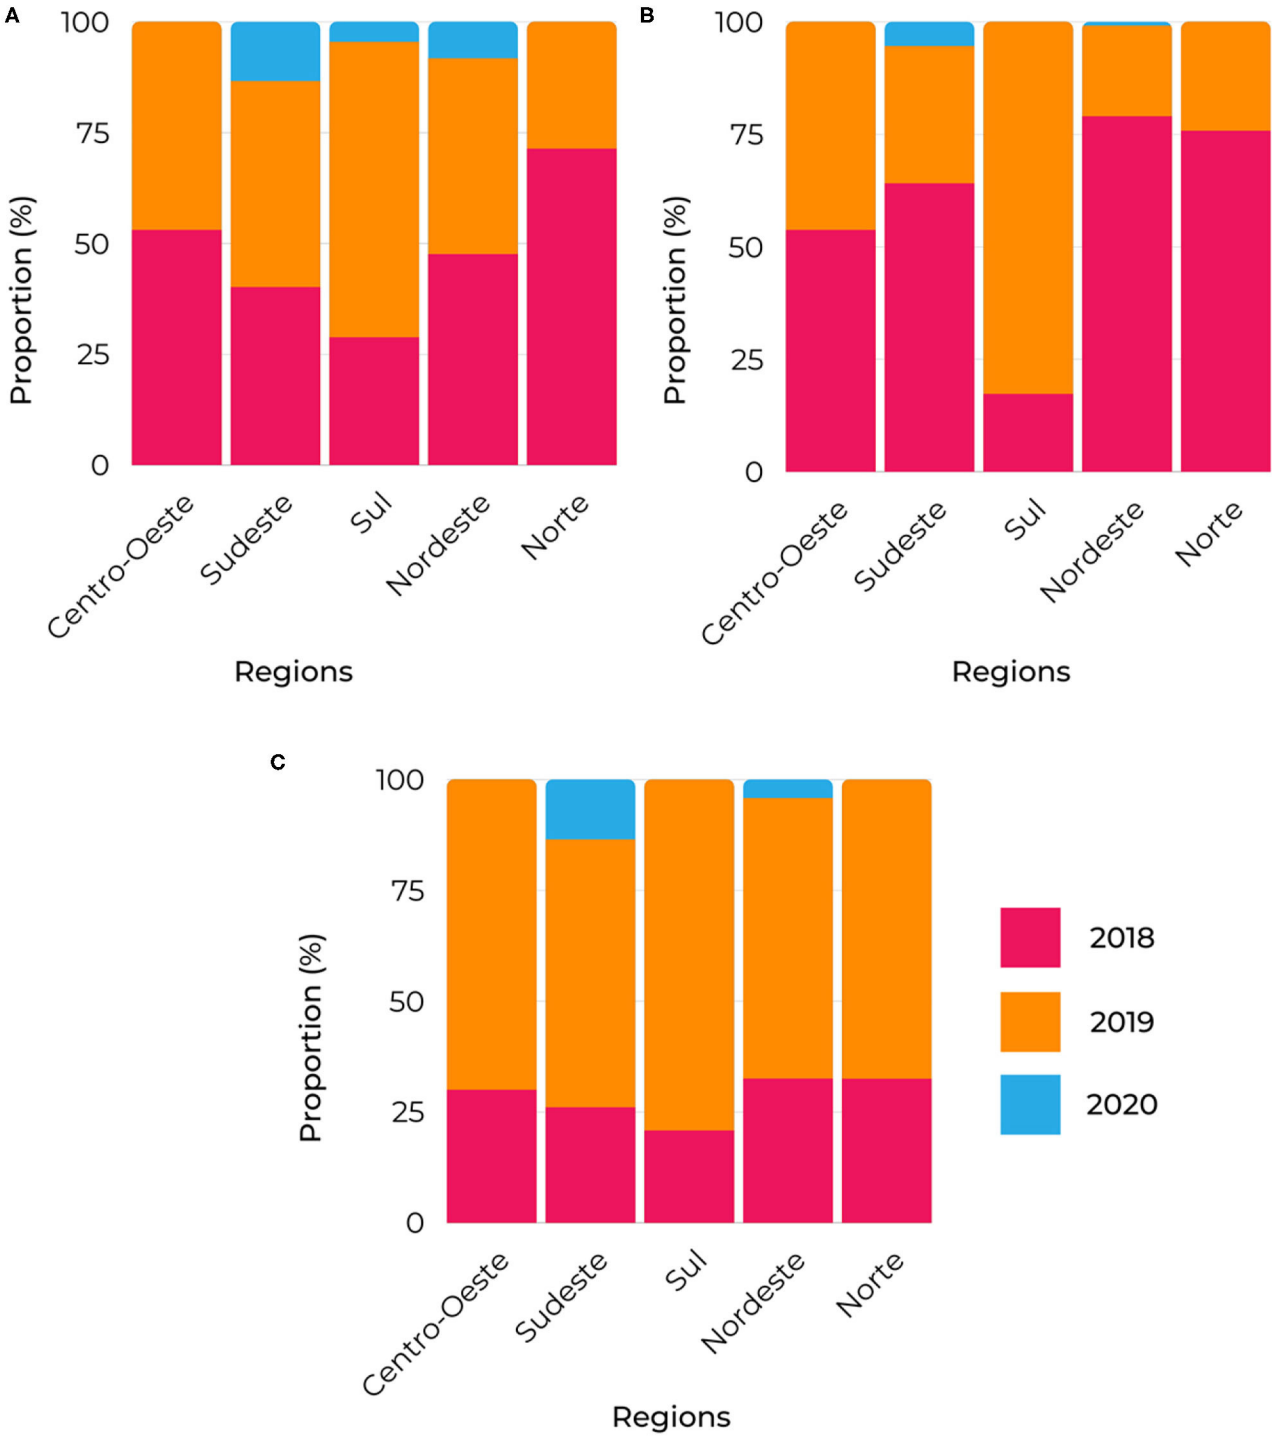

FIGURE 8 | Trigrams proportion of relevant terms segmented by region. **(A)** investigation vertical transmission, congenital syphilis cases, vertical transmission syphilis and investigation committee transmission; **(B)** municipal health plan, municipal health secretariat, municipal health council, annual health program and confrontation congenital syphilis; **(C)** primary health center, rapid syphilis network, rapid syphilis territory, congenital syphilis pregnant, health care network, primary care surveillance and line care syphilis.

In **Figure 10A**, the concept of "implementation of the rapid response project through strategic actions of the research and intervention supporter" has prevailed. As a result, this term attained its most outstanding distribution in all regions in 2019. The second conceptual term spawned was "rapid response to syphilis leads to advancements in healthcare networks regarding

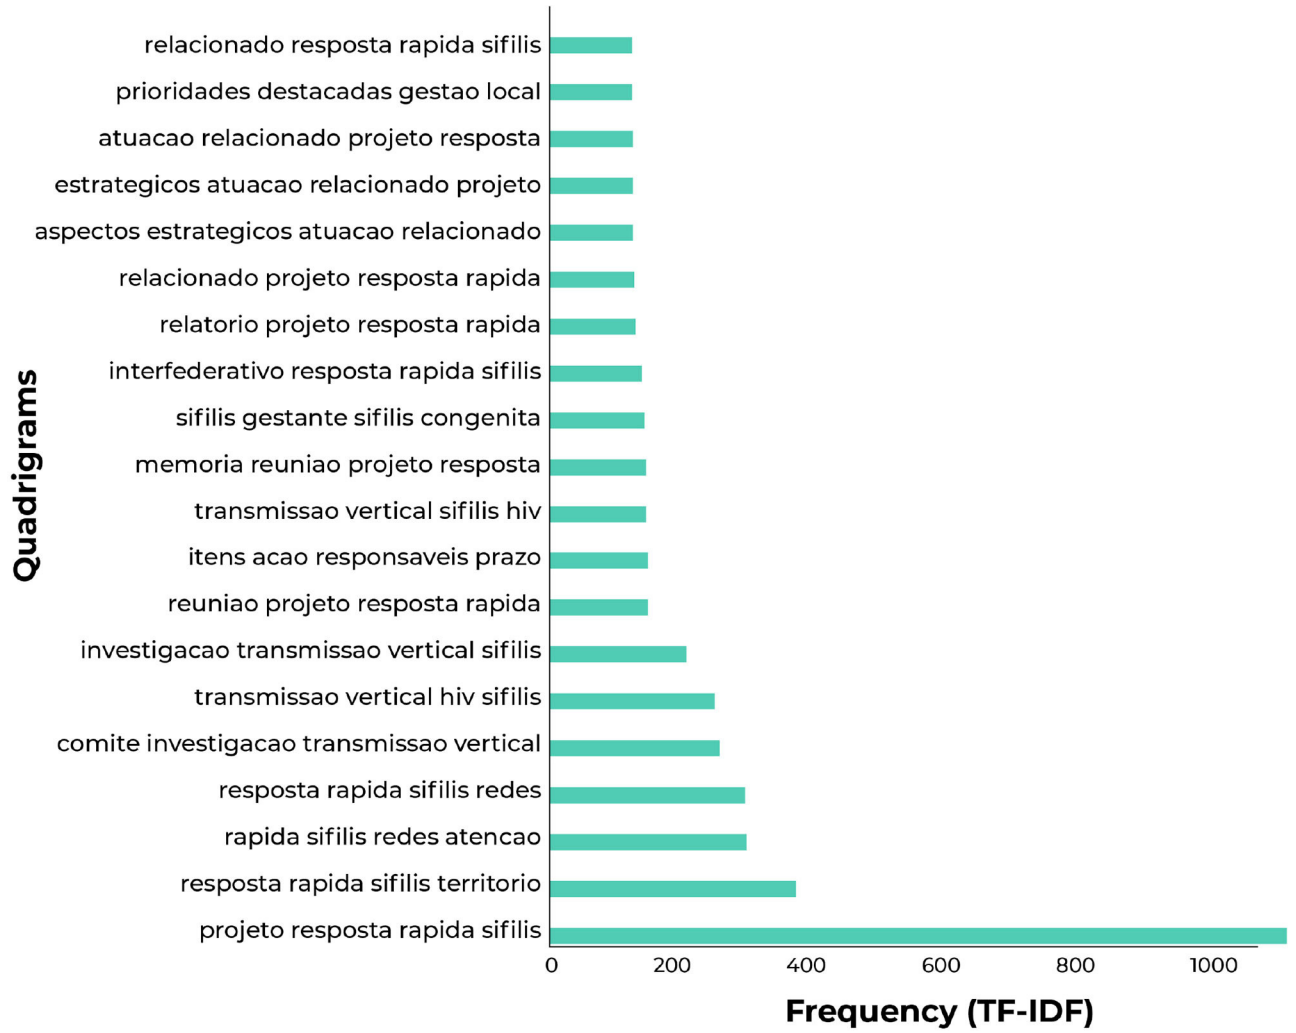

FIGURE 9 | The 20 most common quadrigrams in reports.

congenital syphilis," with predominant distribution in almost all regions at the project's onset (**Figure 10B**).

In **Figure 10C**, the conceptual term was "local management priorities for combating syphilis in pregnant women and congenital syphilis," with its almost total distribution in 2019 in virtually all regions. Last, the conceptual term "committee for the investigation of vertical transmission led by syphilis rapid response" had its highest distribution in almost all regions at the beginning of the project (**Figure 10D**).

It was noted that the quadrigrams have further underscored the possibilities for correlations between the activities of field researchers related to CS and the dimensions of Governance and Management, Surveillance and Comprehensive Care, of the SNP.

Figure 11 presents the interrelatedness between the conceptual terms formed in light of the objectives of the "Syphilis No" Project for the bigrams, trigrams, and quadrigrams. Still, the interpretation of these establishes at least five analytical categories that are considered representative of the associations between the research supporter's intervention work and the goals of the project:

1. Confronting syphilis during prenatal care in primary health care;
2. Committee for investigation of congenital syphilis in the territory;
3. Municipal plan for monitoring and investigating syphilis cases through health surveillance;
4. Women's health care networks for addressing syphilis in pregnant;
5. Diagnosis and treatment with a focus on rapid testing.

Thus, it can be inferred that the work of SNP field researchers was primarily that of intervention for confronting the response to congenital syphilis in the territory where they worked, following the line for eradication of CS by each municipality.

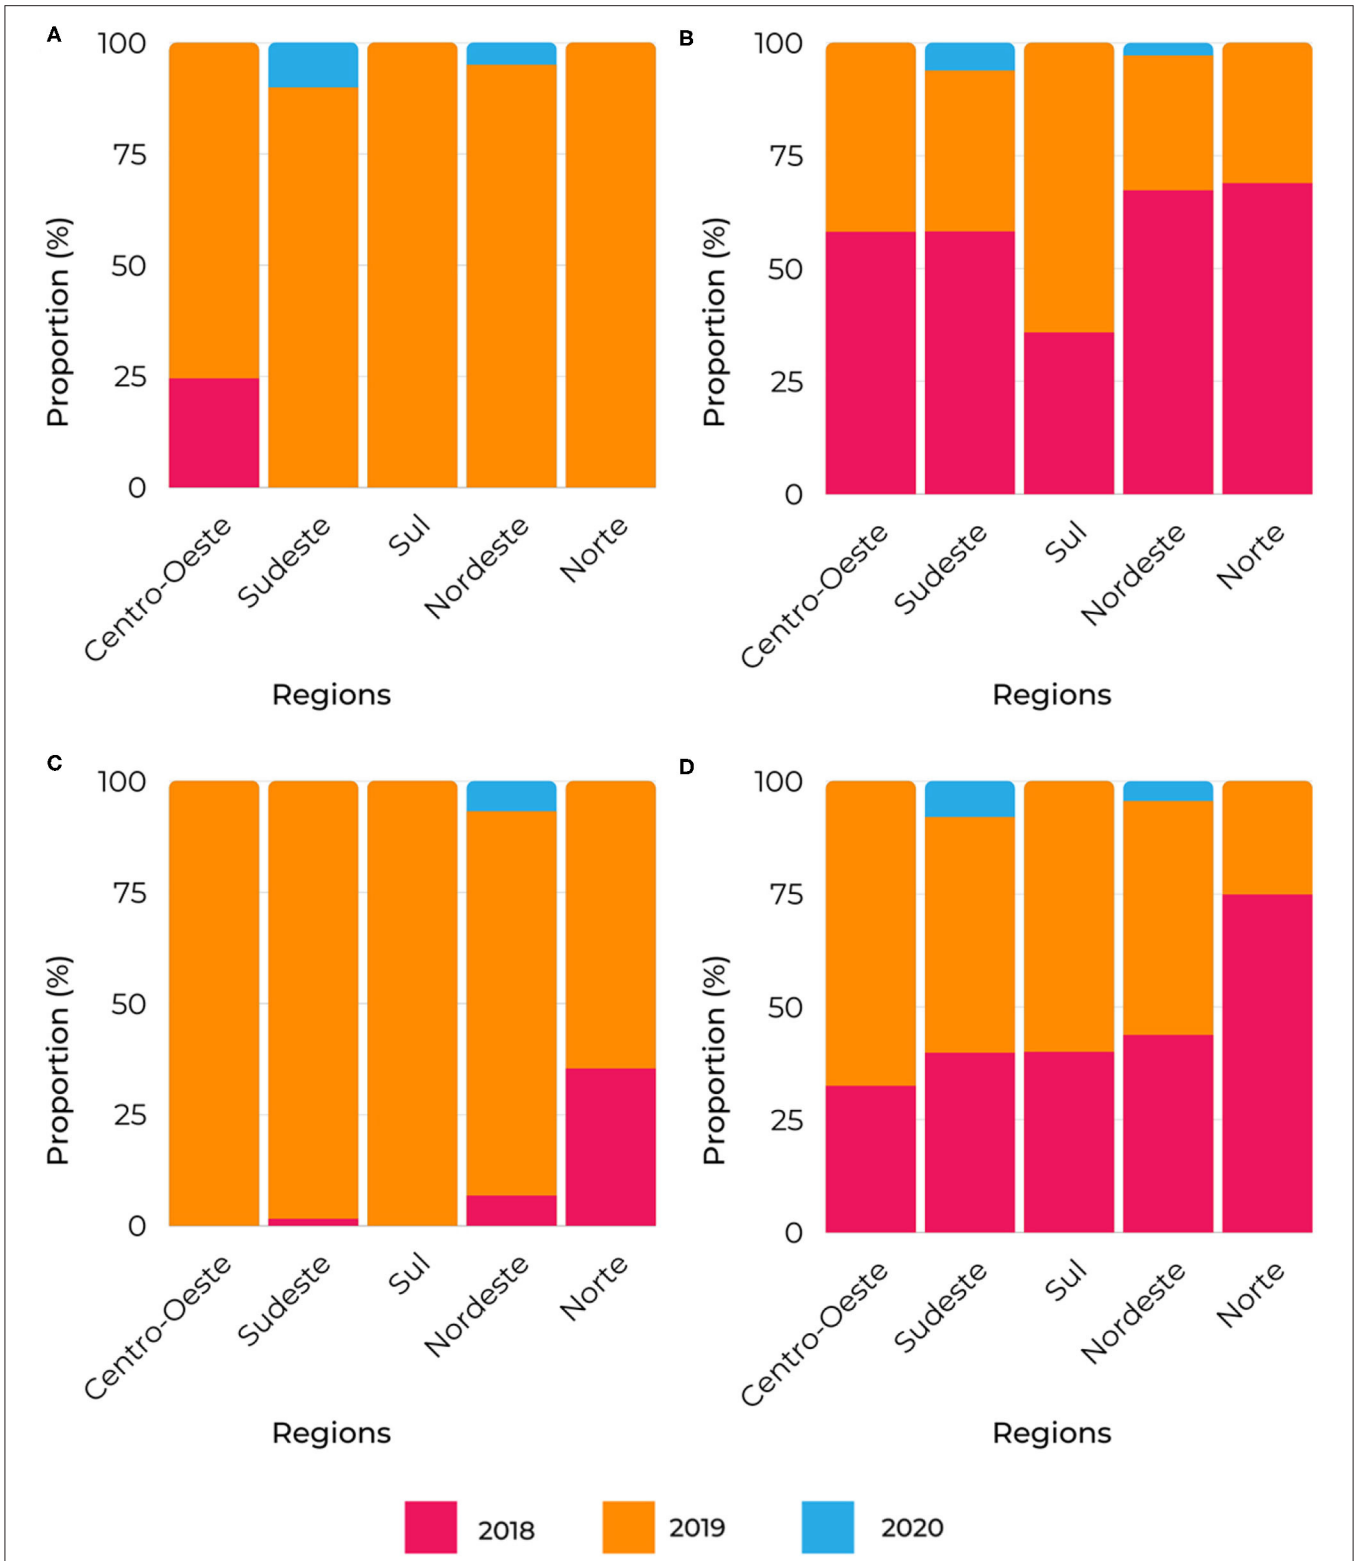

FIGURE 10 | Quadrigrams proportion of relevant terms segmented by region. **(A)** rapid response project implementation, supporter related response project, main activities developed territory, strategic aspects action supporter; **(B)** rapid syphilis care networks, congenital syphilis lower year, advances rapid response syphilis, related rapid response project; **(C)** highlighted priorities local management, highlighted local management related, syphilis pregnant congenital syphilis, national day against syphilis; **(D)** investigation vertical transmission committee, investigation vertical syphilis transmission, related rapid response syphilis.

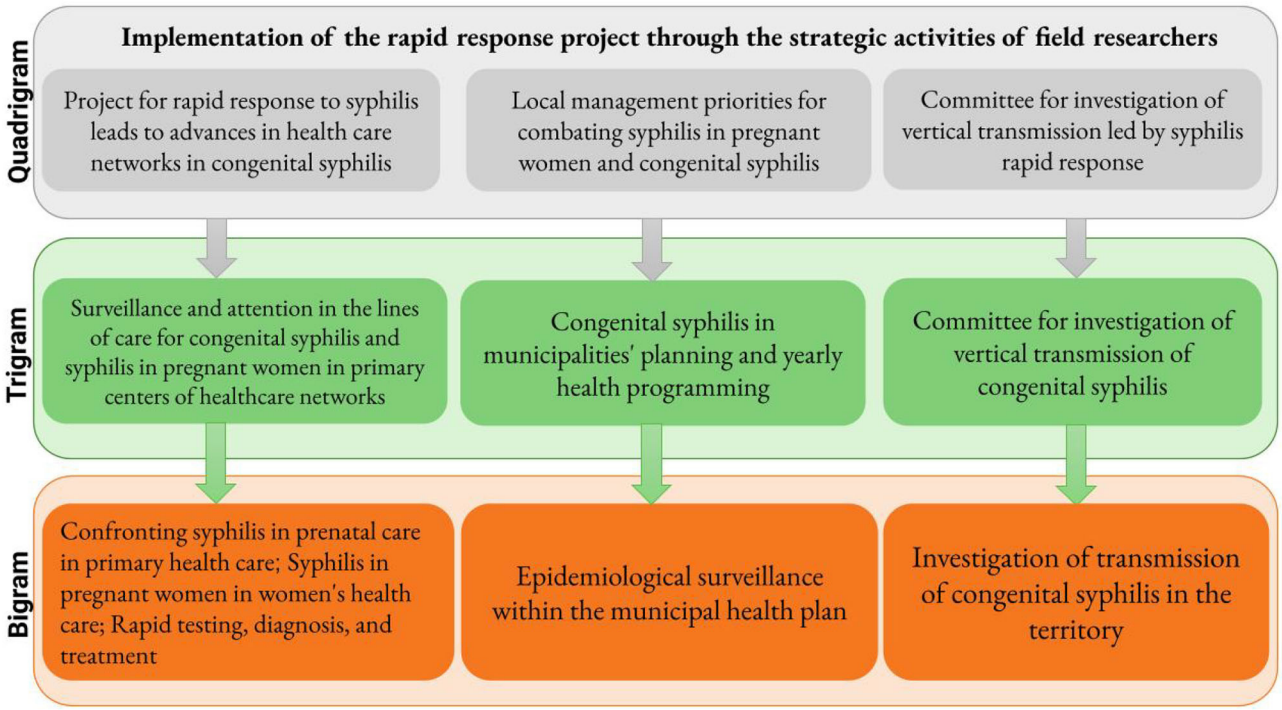

FIGURE 11 | Flow diagram of literature search.

4. DISCUSSION

The research has evidenced that using the text mining technique has enabled the identification of patterns related to the action or intervention of the field researchers' work regarding syphilis in the priority municipalities. Likewise, it has facilitated the measurement and comparison of the researchers' efforts by region of the country. Five analytical categories were determined. These demonstrate significant and representative associations between the articulation work of the Research and Intervention Supporter and the objectives of the "Syphilis No!" Project. Specifically, the categories were:

- Confronting syphilis during prenatal care in primary health care;
- Investigation committee for congenital syphilis in the territory;
- Municipal plan for monitoring and investigating syphilis cases through health surveillance;
- Women's healthcare networks for syphilis in pregnant;
- Diagnosis and treatment with a focus on rapid testing.

It is worth remarking that the field researchers' performance in the project has emerged to intervene and help the technical teams and local managers. So, one of the main actions was to reduce the high rates of congenital syphilis in priority municipalities (35). For instance, in Brazil, from 2010 to 2017, the rate of CS was from 2.0 cases per 1,000 live births to 8.8 per 1,000 live births, respectively. Thus, an increase of 338%. There was a significant upward trend in congenital syphilis in the same interval, with an AAPC of 15.75%, with no prospect of a change in the pattern (8).

In 2018, CS rates hit an all-time high, reaching the staggering incidence of 9 cases per 1,000 live births. Nevertheless, according to the most recent epidemiological bulletin, after the beginning of the SNP, the congenital syphilis rates have decreased to 8.2 cases per 1000 live births (36). As a result, there was a change in the growth trend. It went from 15.75% to a reduction of -8.8% in the annual incidence rate of CS, with a prospect for reduction over the next few years. It may reach the 90% reduction target established by PAHO in almost four years (37). In a short span, the nationwide decrease in congenital syphilis rates can be credited to the "Syphilis No" intervention model. In this manner, the epidemiological impact proved to be effective, especially from identifying the thematic areas of the intervention included in the reports of the RIS.

The research done by Pinto and colleagues assessed the impact of actions developed before and after the SNP in Brazilian municipalities based on interrupted time series analysis. These scholars have concluded that the intervention project model contributed significantly to CS rates decrease in priority areas. The conceptual terms built from the researchers' reports can point to the most significant actions that resulted in the reduced CS rates in the intervention territories.

Our findings made it possible to identify a tendency to terms clustering directed to the programmatic actions related to congenital syphilis in the priority municipalities. The trigrams and quadrigrams have solidified this trend observed in the

bigrams. In addition, they went beyond with information about the work of the supporters per axis of the project.

The Pan American Health Organization's (PAHO) Framework for Elimination of Mother-to-Child Transmission of STIs in the Americas has as one of the conceptual framework's dimensions to integrate policies targeted at women and children with the related health services. That includes the prevention stages that precede pregnancy and the health of women and children after perinatal care and childbirth (37). The results of this article have evidenced that the integration between surveillance and care is part of the field researchers' work. It is corroborated by the presence of the investigation committees of MTCT. Thus, showing that the response to syphilis in Brazil draws on a strategy not foreseen in PAHO's EMTCT Plus, and therefore is innovative. Furthermore, the data reveal that the principal intervention of the supporters was in the committees' efforts. It also indicates the strategic importance of such surveillance and comprehensive care policy to eliminate CS.

The Brazilian health system has its specific protocols for investigating and intervening in identified cases of CS. This work is conducted by the investigation committees of vertical transmission or multi-professional teams of specialists. These were formed to map the problems related to mother-to-child transmission and propose solutions based on a pre-established investigation protocol to mitigate CS. The committees are integrated into SUS as spaces for technical, confidential, non-coercive, and non-punitive activities and may be linked to municipal or state health management (38, 39).

Research findings also demonstrated that these research committees played a substantial role in the "Syphilis No!" Project, cited mainly in 2018, with prominence in the Northern region. In addition, the investigation of MTCT, shown in the bigram, had its different distribution, registering the highest proportions for the Northeast and Southeast regions, keeping these activities practically constant in the 2018-2020 time frame.

Such regional discrepancies can be attributed to the organizational complexity of Brazilian healthcare networks (40), whose implementation of committees for investigation of vertical transmission will depend on each local government in a decentralized approach. Therefore, the regions with weaker consolidation of the committees have probably required more in-depth attention from the field researchers at the beginning of the project, as observed in the Northern region (41). This fact may have influenced the effectiveness of the efforts to tackle CS in that region.

The process of mining the reports of field researchers' intervention activities has also highlighted the actions to confront syphilis in prenatal care, primary health care, and syphilis in pregnant women in women's health care. In Brazil, for example, among the experiences of the Ministry of Health considered specific to the prevention of mother-to-child transmission (PMTCT) that preceded the SNP' were the project "Nascer Maternidades" (2002) and the Operational Plan for Reducing HIV and Syphilis (2007).

The project "Nascer Maternidades" aim was to ensure the identification of the pregnant woman's serological status for HIV infection during labor (42). Moreover, the Operational Plan for the Reduction of HIV and Syphilis aimed at expanding the coverage of HIV and syphilis testing in prenatal care and guaranteeing actions agreed upon with the states and municipalities since the 1990s by the National HIV/Aids Program. Such actions were strongly related to improving HIV/AIDS indicators, having as primary strategies the acquisition and distribution of antiretroviral drug supplies; infant formula for breastfeeding HIV-exposed children; and determining the routine management of HIV during pregnancy, labor and delivery, and postpartum (43).

These policies were induced through purchasing the principal supplies and the accountability for their use by the three federative entities of SUS. Therefore, it can be concluded that these strategies, on the one hand, have contributed to PMTCT of HIV. However, on the other hand, they have not been able to curb the progression of the syphilis epidemic in Brazil, according to epidemiological indicators before the project's start (36).

Hence, the SNP is probably more advanced than previous projects because it introduced a proposal to induce public health policies in an integrated and cooperative way between surveillance and care as to syphilis in the territory—having RIS a pivotal role as articulating agents. Furthermore, the data suggest that these supporters have managed to align the activities and interventions of projects related to women's health that already existed in the intervention sites with the objectives of the "Syphilis No!" Project. Specifically, this research found that the most relevant interventions were observed for the target population of pregnant women in healthcare networks.

Regarding the distribution of the supporters' interventions by region, it stands out that prevention and assistance efforts were least reported in the South region at the beginning of the project. However, that distribution increased in 2019. It is worth pointing out that the same region has the highest growth trends of CS in Brazil (8). This fact may have contributed to more resistance from local managers at the beginning of the project's implementation. So, it can be inferred that the field researchers from the South have experienced more difficulty, when compared to the other regions, in their insertion in the territory.

Rapid testing for syphilis was another aspect of health care highlighted in the field researchers' production. For instance, a study developed by Santos and collaborators (44) to identify factors that influenced the fight against syphilis emphasized that rapid testing plays a crucial role in fighting syphilis in primary health care. Another study, developed by Roncalli and colleagues, showed that, from 2018 to 2019, there was the highest availability of rapid testing to confront congenital syphilis in history, independent of other confounding factors.

In this way, it can be surmised that the intervention activities of the field researchers contributed to the strengthening of Point-of-care rapid testing (45, 46) measures for CS prevention, which remained nearly constant throughout the production of the reports in most regions in the 2018-2020 period.

The intervention activities of the field researchers of "Syphilis No!" Project may have also contributed to the decrease in the number of congenital syphilis hospitalizations nationwide. Besides, hospitalizations rates for treatment of CS were verified to have significantly dropped from May 2018 to December 2019 (10). Such data corroborate this study's results, whose assistance and surveillance actions were featured

in the field reports' production and the formation of bigrams and trigrams.

Some limitations can be identified in this study. One example is that the formation of bigrams, trigrams, and quadrigrams was mined from an algorithm that highlighted the most substantial activities of the field researchers. Consequently, that may rule out activities that have been developed with the local health services management and had some significant impact on the changes in the work processes for syphilis prevention, such as words related to the education and communication axis of the project. Nevertheless, despite such a limitation, this research distinguished which efforts were most important in contributing to the current changes in the epidemiological indicators of syphilis in Brazil.

Although field researchers provided different types of data, e.g., images and videos, these were not explored as this study focused on the data mining method for written texts. As a result, such data were removed since they were out of scope and would require computer vision and digital image processing methods for information extraction. Future research could explore TDM applied to alternative types of data.

5. CONCLUSION

The study has found that when combined with the conventional content analysis method, text mining can address public health research subjects that comprise large volumes of data. This computational method made it possible to extract, from the SNP, the intervention activities of field researchers. Furthermore, it subsidized inferences on how the project's strategies may have led to a drop in CS cases in the priority municipalities.

This work offers contributions permeating several fields: (i) analysis of large sets of data through TDM techniques; (ii) strengthening the prospects for using TDM in conjunction with content analysis, broadly applied in health research involving text production to support the assessment of interventionist actions by field researchers in large-scale national projects; and (iii) evidence that efforts toward articulating and promoting public health policies in the territory have had positive effects in managing the response to congenital syphilis. In addition, the text mining of the reports pointed out there is an articulation among the actions of the field researchers regarding CS in three out of the four dimensions of the project aixes which are governance and management; surveillance and comprehensive care.

Another highlight was that the work of the field researchers revealed the links between the project's objectives and the confrontation of syphilis in the territory. Hence, it demonstrated through analytical categories how the field researchers' priority action was developed and their contribution to reducing indicators of CS in Brazil. Therefore, it is possible to infer that the field researchers' activities, highlighted in the reports, may have induced public health policies in the territory by supporting prevention and health promotion efforts to combat CS as a priority by local health services managers. Hopefully, further work will determine which field researchers' actions have positively influenced other essential indicators in the fight against syphilis. These steps are detailed in the following sessions.

Chronic diseases are increasing in prevalence and mortality worldwide. Early diagnosis has therefore become an important research area to enhance patient survival rates. Several research studies have reported classification approaches for specific disease prediction. In this paper, we propose a novel augmented artificial intelligence approach using an artificial neural network (ANN) with particle swarm optimization (PSO) to predict five prevalent chronic diseases including breast cancer, diabetes, heart attack, hepatitis, and kidney disease. Seven classification algorithms are compared to evaluate the proposed model's prediction performance. The ANN prediction model constructed with a PSO based feature extraction approach outperforms other state-of-the-art classification approaches when evaluated with accuracy. Our proposed approach gave the highest accuracy of 99.67%, with the PSO. However, the classification model's performance is found to depend on the attributes of data used for classification. Our results are compared with various chronic disease datasets and shown to outperform other benchmark approaches. In addition, our optimized ANN processing is shown to require less time compared to random forest (RF), deep learning and support vector machine (SVM) based methods. Our study could play a role for early diagnosis of chronic diseases in hospitals, including through development of online diagnosis systems.

Keywords: medical diagnosis, feature selection, chronic diseases, artificial neural network (ANN), prediction

INTRODUCTION

Hospitals and online medical systems are generating a large amount of data that is beneficial for researchers to apply Artificial Intelligence (AI) techniques in building advanced models. Disease diagnosis, disease stage prediction, medical wearable, hospital stay, and death prediction are the main research areas in medical computing. Early disease detection and risk identification can motivate people to change their lousy eating, lifestyle, and exercise habits. Early chronic disease risk identification is beneficial for patients to start treatment early (1). Artificial intelligence in the diagnosis of medical diseases is a trend research area. Artificial intelligence techniques and

algorithms help physicians in the decision-making process. A health specialist typically uses medical lab tests and experiments to decide whether a person is suffering from a specific disease or not. It is now easier to acquire information from previously available data using artificial intelligence techniques. In the present electronic era, massive amounts of data are generated from different health devices, namely sensors, clinical databases, social networks, and wearables (2). Except for laboratory tests and experimental results, age, gender, drug addiction, body mass index (BMI), blood pressure (BP), hypertension, lifestyle, diet, and exercise habits of patients are factors for the most common predictions of chronic diseases, including diabetes, heart attack, hepatitis, and kidney diseases (3). Artificial intelligence techniques are used to predict diseases based on available patient data. Medical diagnosis requires physicians and medical laboratories for testing, while artificial intelligence-based predictive systems are used for the early prediction of diseases.

Artificial intelligence is inspired by biological processes, especially input processing approaches used by the human brain. Artificial intelligence can learn, process inputs, identify patterns, predict, and make decisions (4). Artificial intelligence techniques are mainly divided into supervised and unsupervised learning. Supervised learning needs training on datasets available with required outputs. This training is used to build a model that is applied for future predictions (5). In unsupervised learning, similar data points are combined into groups called clusters. Each cluster consists of data points with similar characteristics (6). Supervised learning is further divided into two categories: Classification and Regression. Classification is used to predict the final class labels with positive and negative results. Classification algorithms are used to build a predictive model based on historical data and indicate classes of unlabeled data.

According to the World Health Organization (WHO) analysis, 41 million people die from chronic diseases, which is 71% of total deaths each year. Chronic diseases include heart attacks, cancer, diabetes, kidney disease, liver disease, etc. Diabetes killed 1.6 million people in 2016 (7). This rapid growth of diabetes patients requires an early detection system to treat their disease early. Diabetes mellitus occurs with an increase in blood glucose levels. There are mainly two types of diabetes: Type I diabetes occurs when the pancreas stops producing the required insulin. Type II diabetes occurs when a patient's body is not responding (8). Diabetes is a lifelong disease that affects different body organs, including the kidneys, heart, and eyes. Heart diseases are considered as another main reason for death in middle and old age. According to cardiovascular statistics provided by the World Health Organization (WHO), more than 17.9 million deaths occur due to heart stroke (9). Physicians refer to medical tests for heart disease diagnosis like electrocardiogram (ETC), echocardiogram (ECG), computerized tomography (CT scan), etc. In another way, early heart attack symptoms are used to predict disease so that the clinical burden can be reduced and physicians or patients themselves can diagnose their heart disease. Family history, blood pressure level, cholesterol, stress level, eating habits, age, weight, smoking, and alcohol consumption are the main factors that are examined to predict heart disease before occurrence.

Conventional methods of kidney disease diagnosis involve ultrasound, urine or blood tests, etc., which are followed by kidney dialysis, transplant, or simple medication. Almost one out of three diabetes patients suffer from kidney failure (10). Kidney diseases are predicted early by using automatic prediction systems. Early detection may reduce the mortality rate and cost associated with lab experiments. Kidney diseases are related to bad diet habits and unhealthy living; these attributes are easily used to build a predictive model. Hepatitis is an inflammation in the liver due to viral infections. It is another rapidly spreading chronic disease with more than 350 million patients (11). The reason behind death is hepatitis shows symptoms like viral infections, namely, fever, fatigue, and liver infections, etc.

Artificial intelligence makes it possible to diagnose Hepatitis C early without clinical expense (12). Breast cancer is overgrowing in European and Asian countries. It has become the most frequent type of cancer, causing the most incredible death rate among women that is 15% (13). Breast cancer diagnosis involves two steps: detection and screening. It is crucial to predict breast cancer early to provide necessary medical services and care. Many researchers contribute to the detection and prevention of breast cancer at an early stage. Breast cancer became the second leading cancer that causes the most deaths among women. It is necessary to propose a predictive analysis model for cancer diagnosis in its early stages. Early diagnosis of breast cancer will lead to early treatment and may reduce the risks of death. Web-based systems can also reduce the cost of lab experiments; therefore, they are beneficial to the patient and medical staff as well. Improvements in medical database systems help to generate a large amount of data that is unable to handle by a human. Artificial intelligence is used to extract patterns in huge datasets and to find the labels of data for patient disease diagnosis (14).

However, health-related data are more sensitive; therefore, they must be handled carefully to generate accurate results. Real-World data has many issues, including noisy data, class imbalance, missing values, and irrelevant entries (15). Different data pre-processing approaches have been applied in previous research to increase the performance of medical diagnosis systems (16). Data pre-processing plays a vital role in extracting valuable features in data. Data pre-processing consists of extraction, cleaning, and transformation steps (14). Chronic diseases are affected by hypertension, gender, obesity, age factors, smoking, unhealthy diet, and lifestyle; therefore, it is difficult to identify the disease from all functional aspects.

Furthermore, different hospitals or medical diagnostic laboratories have the attributes of other patients with the same strategies. A preferable method to handle other characteristics in the dataset is feature selection. Feature selection approaches make it possible to find weights of different factors so that only the most influencing factors are used for detection. Feature selection is used to select the most significant features and to eliminate irrelevant features from the dataset. Feature reduction techniques reduce processing time and increase classification performance that is affected by useless features in the data (17).

Some datasets are available online in different data repositories for research purposes. To find and evaluate the symptoms of other diseases, the researchers applied

various algorithms and built different effective prediction models. These models are applicable for the selected dataset to diagnose any specific disease early. In comparison, many research studies have proposed methods to predict various diseases, e.g., Diabetes, Cancer, Parkinson's, Heart Attack, Depression, Hypertension, etc. However, the medical diagnosis systems focus on a specific disease with limited attributes. Previous studies have shown that traditional methods for predicting chronic diseases are inadequate due to very limited feature selection techniques. Therefore, significant features identification and machine learning techniques are important to improve the performance of chronic diseases. The main contributions of this research paper are as follows.

- The significant features are chosen to eliminate redundant and inconsistent data through particle swarm optimization, which improves the efficiency of prediction model.
- An artificial neural network predicts five chronic diseases, diabetes, breast cancer, hepatitis, heart, and kidney.

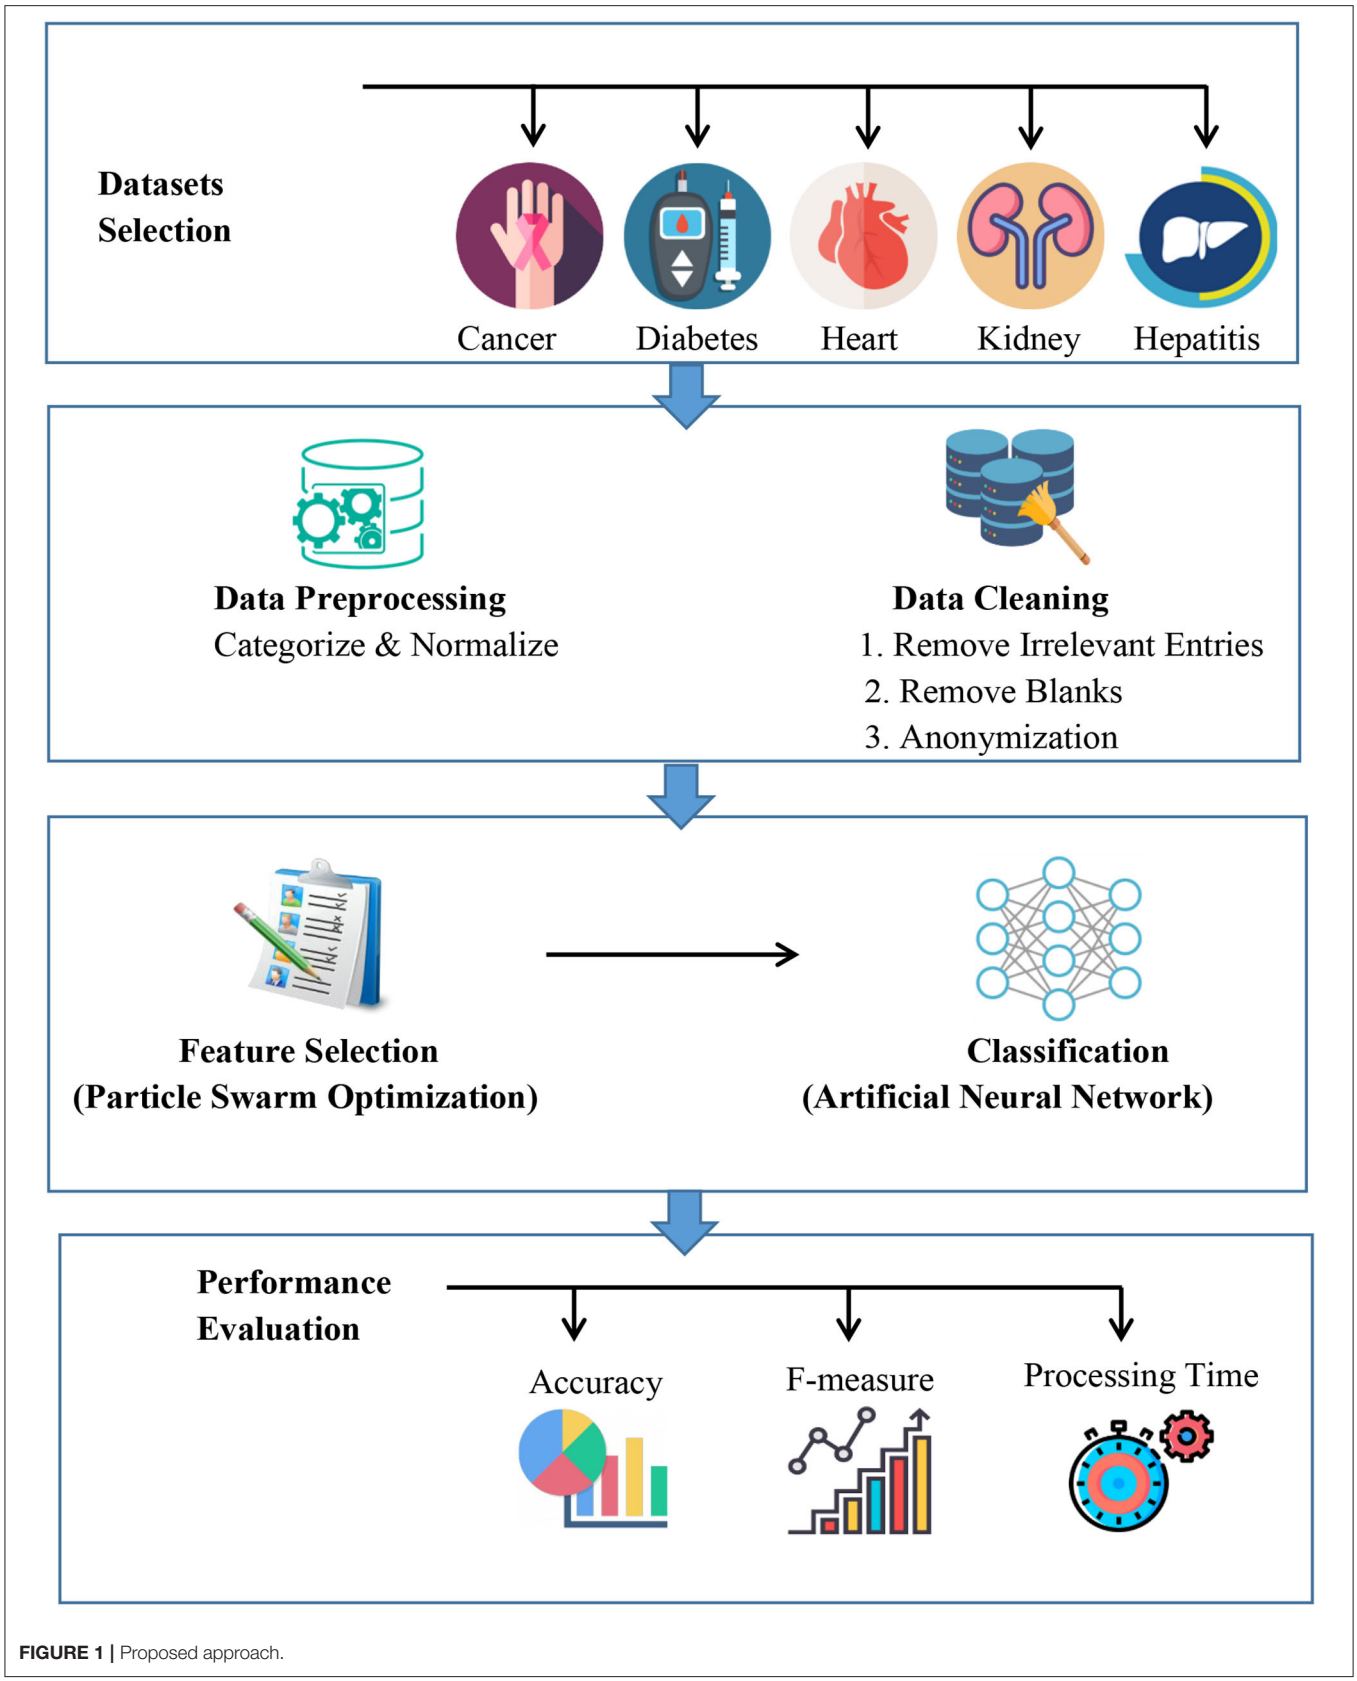

FIGURE 1 | Proposed approach.

- The k-fold cross-validation is used to train and test the proposed approach. Classification results are compared to a decision tree, random forest, deep learning, KNN, Naive Bayes, SVM, and logistic regression on chronic diseases datasets.
- The experimental results show that the proposed approach achieved a 99.76% accuracy and predicts chronic diseases more effectively and efficiently than other state-of-the-art models.

The rest of the study is arranged as follows: Section Literature Review represents a comprehensive review of studies in the previous literature. Section Materials & Methods discusses the materials and methods. Section Results and Discussions presents experimental results and comparative analysis. Finally, Section Conclusion concludes, and section Future Work and Limitations provides future directions and limitations for the research.

LITERATURE REVIEW

The literature review provides a clear view of previous approaches and potential areas. The latest literature reviews different disease detection methods using artificial intelligence approaches with or without other feature selection methods.

A research study proposed a machine learning-based predictive model to diagnose three primary chronic diseases, including Diabetes, Kidney, and heart diseases. The feature selection technique based on adaptive probabilistic divergence is used to select the most valuable features. The study concluded that the proposed approach gave the highest accuracy by optimizing the most significant features for disease detection (2). A feature selection-based machine learning algorithm is proposed to predict three chronic diseases, namely, diabetes, heart attack, and cancer. The incremental feature selection approach with Convolutional Neural Network (CNN) is applied to anticipate disease presence. The proposed method showed 93% classification accuracy in less computation time (18). Another study is conducted to explore the essential features of often chronic diseases. Feature selection approaches, including Information Gain, Gain Ratio, and correlation-based approaches, are applied. Several subsets of top-ranked features are then used in building the Random Forest prediction model. It showed that exploring the most significant features is significant for the medical diagnosis process (19). In another research study for chronic disease prediction (20), the Stacked Generalization approach is used to enhance the performance of classification algorithms. Five classification algorithms are compared: Decision Tree (DT), k-NN, SVM, Logistic Regression (LR), and Naive Bayes, to outperform five chronic disease prediction models. It is found that the Stacked Ensemble approach enhances the model performance and achieves the highest accuracy of 90%. Diabetes, Breast Cancer & Kidney diseases are predicting in (21), using classification algorithms. Rough K-means clustering is used to explore and eliminate ambiguous objects in datasets. It is observed that classification model applied with extracted features gave improved results compared to conventional models.

Early breast cancer prediction is an emerging research area in artificial intelligence. Many studies are conducted for breast cancer prediction at an early stage using online techniques and prediction models. The fuzzy rule-based classification is used for classification purposes, while fuzzy temporal rules are used to determine highly contributing factors for online breast cancer prediction. The results show that feature selection and fuzzy rule-based classification improve the accuracy of classifiers (22). Another study focused on feature filtering techniques to predict breast cancer early. Frequent item-set mining is used to select the essential features in patients' datasets. The decision tree, Naive Bayes (NB), k-Nearest Neighbors (k-NN), and Support Vector Machine (SVM) are compared, and it is found that SVM outperforms other models (23). A research paper focused on reducing erroneous prediction results that is false positive and false negative. Information gain with the Genetic Algorithm approach is utilized to rank highly significant features in the dataset. Classification of positive and negative results is done by SVM. This approach applied to

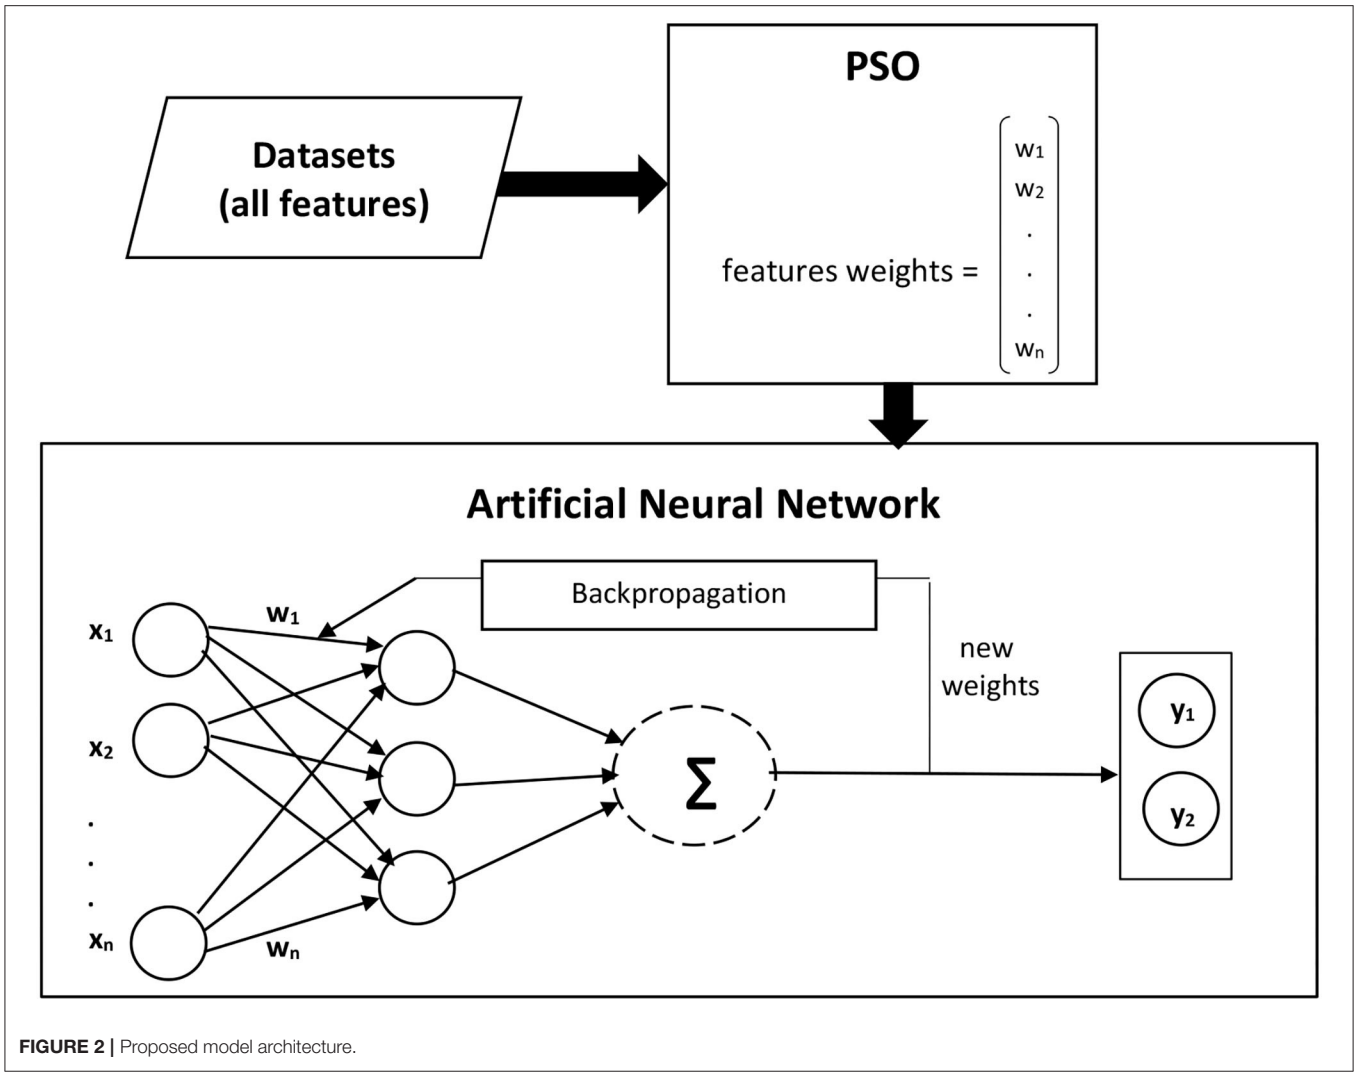

FIGURE 2 | Proposed model architecture.

two independent datasets increased the prediction accuracy and reduced prediction cost (24). In another research study (25), five classification models, namely SVM, K-NN, ANN, random forest, and logistic regression, are applied to predict early breast cancer. In this study, the Pearson correlation is applied to extract the most influencing features, and after feature selection, the ANN model obtained the highest accuracy of 98%. Two breast cancer datasets are used in (26), to differentiate cancer patients from healthy people. A genetic algorithm is used to select the most significant features in datasets.

Three classification algorithms, multilayer perceptron (MLP), probabilistic neural network (PNN) and radial based function (RBF) are used for the classification of breast cancer (27). MLP requires more processing time for the training model and assigning weights to its neurons than RBF and PNN. The highest accuracies of 97%, 98%, and 100% are achieved with MLP, RBF, and PNN. Another research study (28) applies SVM with multiple kernels to predict breast cancer. An energy-based shape histogram is used to extract the most significant features. The proposed model achieved the highest accuracy of 99%.

Diabetes prediction at an early stage can lead to saving patients' life. A research paper compares classification methods like Artificial Neural Network (ANN) and Random Forest with clustering technique k-means clustering. Principal Component Analysis (PCA) is used to select significant components. The study proved that PCA increases the accuracy of the prediction of diabetes, while body mass index (BMI) and glucose level strongly correlate with diabetes (28). Prolonged diabetes can cause vision loss, which is called diabetes retinopathy. A research study is conducted to predict the side effects of diabetes on eyesight. K-NN, Decision Tree, Multilayer Perceptron, and SVM are used to predict feature selection. The number of accurate predictions is compared before and after feature selection, demonstrating that feature selection approaches increased accuracy and sensitivity (29). Some techniques are used for diabetic retinopathy using PCA (30) and deep neural network (31). In (32), BMI is predicted from the images using the computer vison and

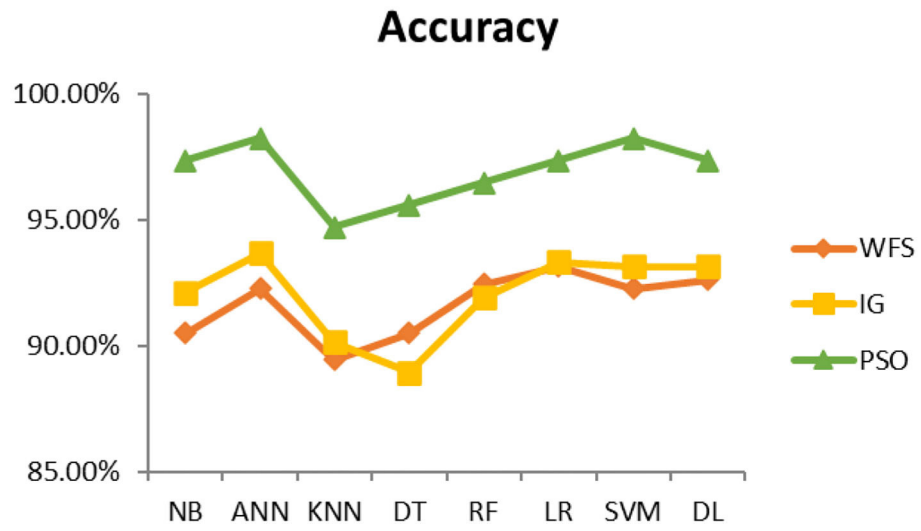

FIGURE 3 | Cancer diagnosis accuracy (dataset 1).

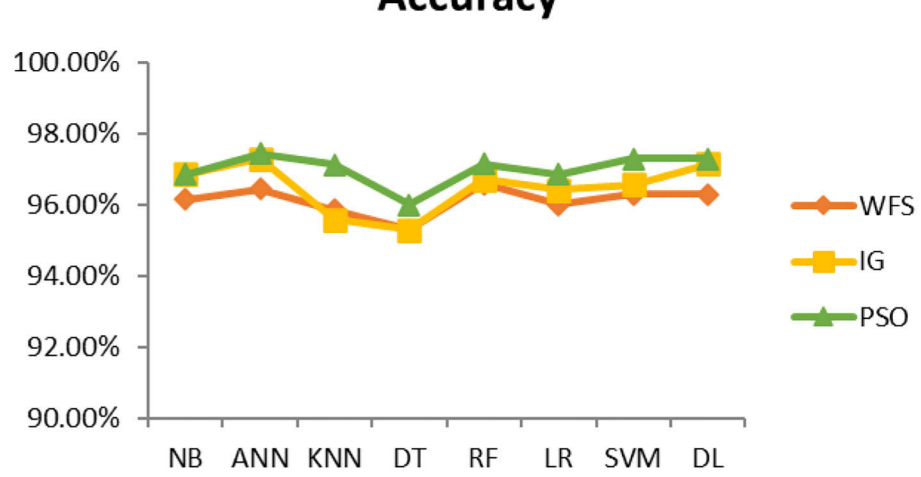

FIGURE 4 | Cancer diagnosis accuracy (dataset 2).

machine learning technique. Federated learning has a wide application in big data (33). The probabilistic procedure with sensors is used for censorious procedures (34). Some patients have diabetes with hypertension; therefore, a research study is conducted to predict diabetes type II and hypertension in both individuals. Synthetic minority oversampling is used to solve data distribution problems and the ensemble method is used to predict hypertension and type II diabetes. This study showed that pre-processing of data prior to model building enhances prediction accuracy (35). Machine learning methods are also used for the detection of some other medical diseases detection (36–38), text mining (39–42) and network security (43–47). Another analysis is conducted to predict the risks associated with diabetes. Logistic regression, Decision Tree, ID3, C4.5, k-NN, and Naive Bayes are used for classification. Irrelevant features are detected and reduced using PCA and PSO algorithms. A comparison of both feature selection techniques is performed in terms of improved accuracy and processing time. It shows that feature reduction is a powerful technique to enhance predictive model accuracy (48).

Iris-based and physiological features are used to predict diabetes type II, using decision trees and SVM. Some methods used the fuzzy for ergonomics-related disorders (49), Convolutional Neural Networks for Syndrome (50), object detection (51) and gender classification (52). Three ensemble techniques, AdaBoost, Bagging, and K-NN, are also used with Principal Component Analysis (PCA) to enhance classification performance. The highest accuracy of 95.81% is obtained

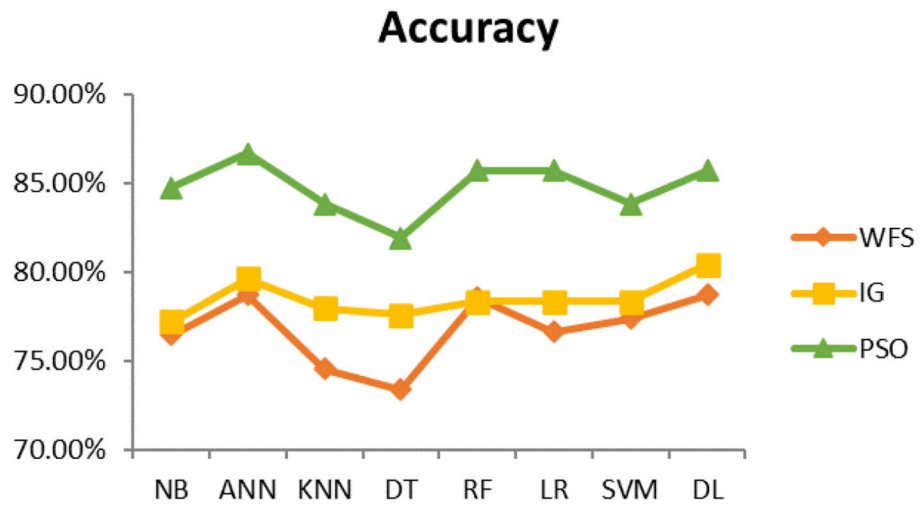

FIGURE 5 | Diabetes diagnosis accuracy (dataset 1).

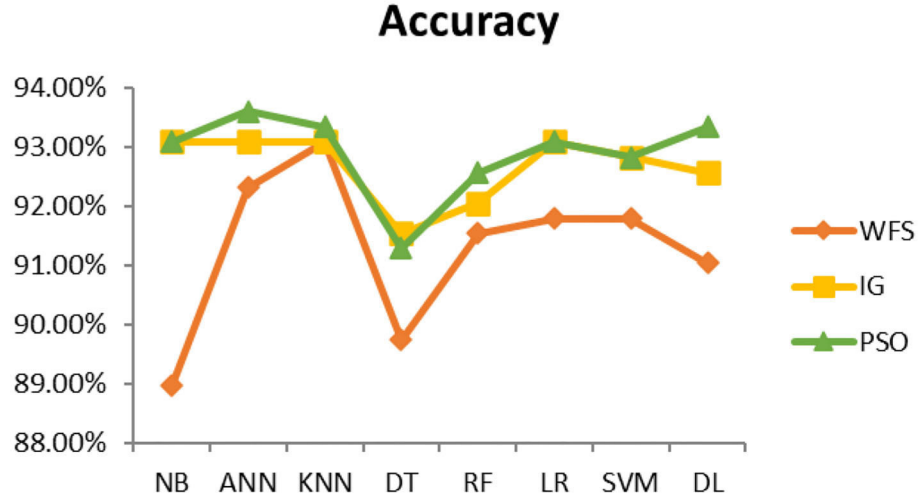

FIGURE 6 | Diabetes diagnosis accuracy (dataset 2).

with the most significant features (53). A convolution neural network (CNN) is a feed-forward and feature extractor Neural Network. In a study (54), early diagnosis of Diabetes Type II is performed by using CNN. A dataset of steel mill workers, including demographics, physical activities, and hypertension features, is used to implement CNN. The highest accuracy of 94.5% is obtained to diagnose diabetes patients from all workers' datasets. Diabetes patients are usually affected by some other chronic diseases. A research study (8) highlighted the features most common in heart and diabetes patients. Heart disease is found to be predicted early in diabetes patients by applying classification and regression techniques.

In recent decades, heart attacks have been one of the leading causes of death. Random forest is used in conjunction with a linear model to predict heart disease based on patient data in a study. The most significant features are classified using an a priori method, which showed an increase in accuracy. When compared to existing classification techniques, the suggested ensemble model produces the best results (55). Optimization techniques are used to deal with complex data by reducing irrelevant and functional data attributes. In a study, the Particle Swarm Optimization (PSO) and Ant Colony Optimization (ACO) algorithms are combined for redundant feature reduction. This approach is applied with different classification algorithms and is evaluated using F-measure, accuracy, precision, and recall. Feature optimization gave the highest accuracy of 99.65%, which is a remarkable achievement (56). Software quality (57–59) and semantic methods (60, 61) are also used in algorithm evaluations. A hybrid approach combines different AI techniques and evaluates them as a single algorithm. A research study

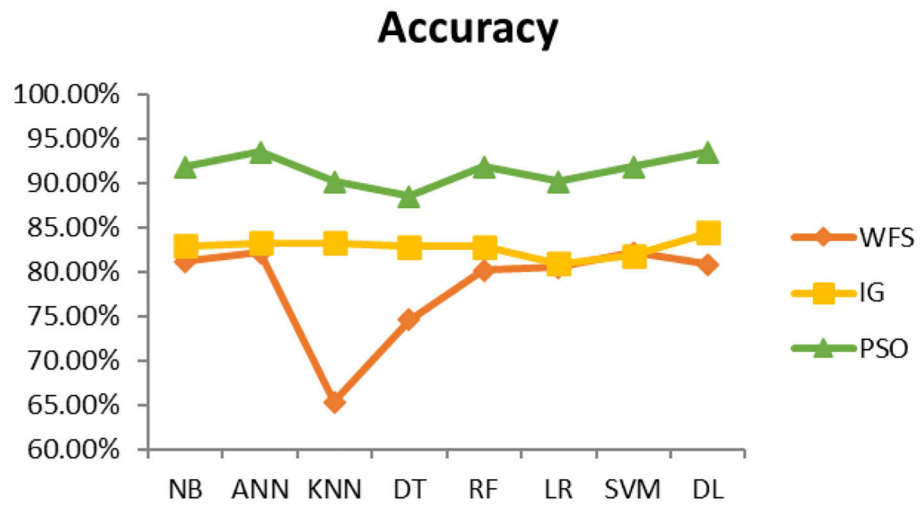

FIGURE 7 | Heart attack diagnosis accuracy (dataset 1).

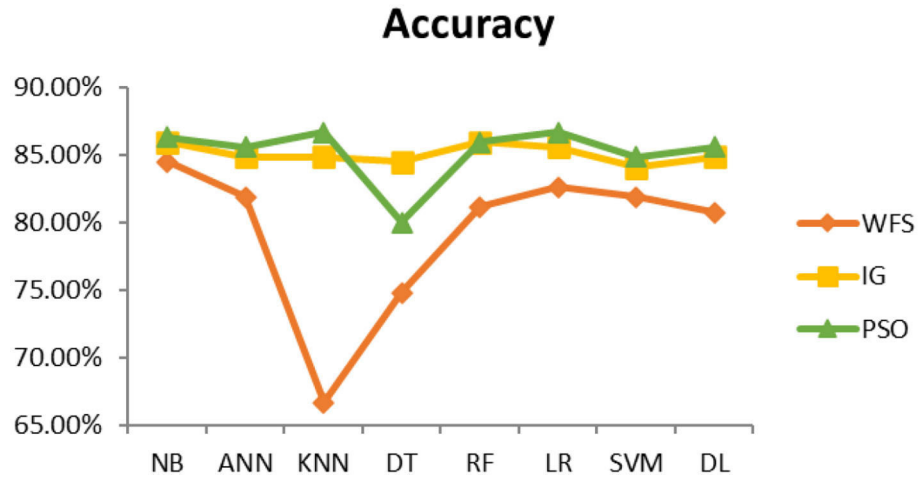

FIGURE 8 | Heart attack diagnosis accuracy (dataset 2).

applied various AI algorithms for heart disease prediction to find the best classifier. The best performing algorithms are then combined, and the results of the hybrid approach are compared with the results of individual techniques. The proposed hybrid algorithm gave more accurate results as all algorithms functions are combined to calculate a majority vote for a positive class. A drawback of using a hybrid approach is that more processing time is required (62). Another study applied a Fuzzy Rule-based classification model for heart attack risk prediction. Rough set theory identifies the most influencing features, and features that do not affect prediction results are eliminated. The Genetic Algorithm is used to reduce time complexity and optimize prediction results. Research proved that the proposed model is efficient with a large number of features (63, 64). A comparative analysis is presented in (65) for the diagnosis of cardiovascular disease. The experimental setup comprises classification algorithms, namely Logistic Regression, Decision Tree, and SVM. Different subsets of features are used to evaluate classification results. The highest accuracy of 82.97% is achieved by using a decision tree with forward and backward selection approaches.

A study is proposed to predict whether a patient would survive or die because of hepatitis. This study implemented SVM with multilayer perceptron for the binary classification of patients. Principal component analysis (PCA), a feature selection approach, is applied before prediction and three factors of zero correlation with the predictive class are eliminated. The proposed hybrid algorithm gave a higher accuracy than state-of-the-art classifiers (66). A combination of several prediction techniques results better than an individual model. Another study suggested a model for hepatitis diagnosis using ensemble learning techniques. A Neuro-fuzzy system

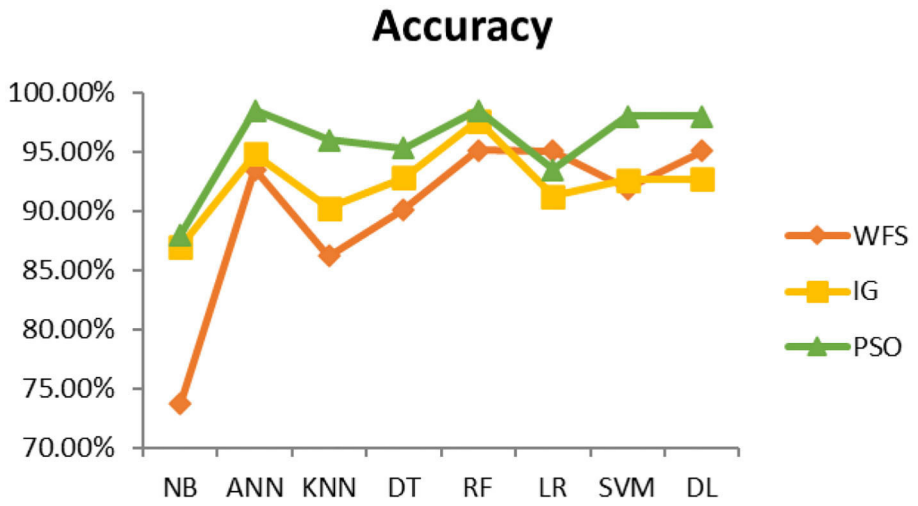

FIGURE 9 | Hepatitis diagnosis accuracy (dataset 1).

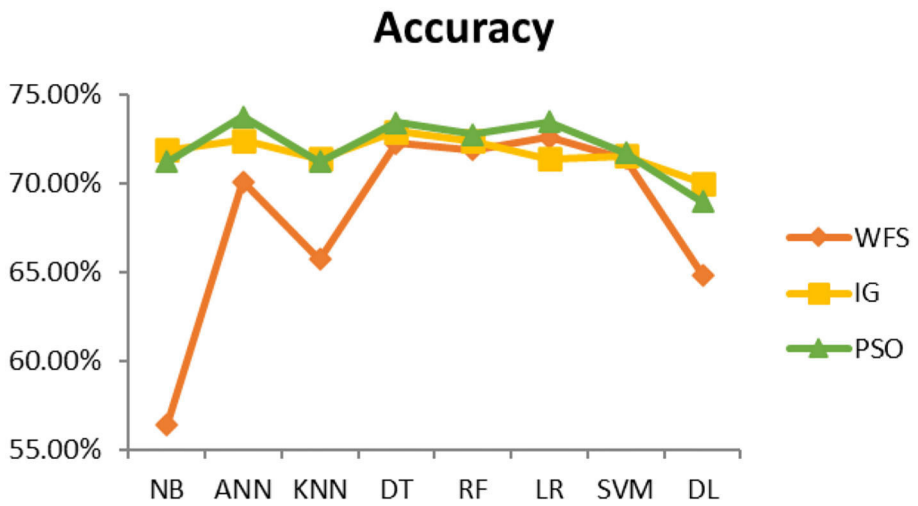

FIGURE 10 | Hepatitis diagnosis accuracy (dataset 2).

is used for patients' diagnosis with dimensionality reduction algorithms. The results demonstrate that the ensemble neuro-fuzzy model performed more accurately than ANN (67). A study is conducted to highlight risk prediction factors for hepatitis C using a random forest classifier. Chi-square and *P*-value statistical functions are used to estimate the importance of various risk determining factors. The importance of the factor is calculated several times and each important timeless factor is eliminated until the required predictive model has 98.3% accuracy. The research found that gender, drug addiction, frequent hospitalization, and migration from the area with a high HIV occurrence rate are the essential factors for hepatitis diagnosis (68). A two-step feature transformation method is proposed to increase the accuracy of the hepatitis prediction model. At first, the most valuable features are ranked based on their significance, and after feature reduction, the attribute space is expanded. This hybrid method manifested improved prediction results achieved in less computation time (11). Esophageal variants occur most commonly due to the side effects of hepatitis. The esophageal prediction model is proposed in a research study, with six feature selection approaches. Information Gain, PCA, and correlation are used to select the most significant features. The Greedy Approach, PSO, and Genetic Algorithm are applied to create subsets of the dataset by exploring the correlation between different features. This study concluded that Naive Bayes outperformed compared to ANN, Decision Tree, Random Forest, and SVM (12). Some other machine learning and soft computing methods are mainly used for the chronic disease detection (21, 69–71).

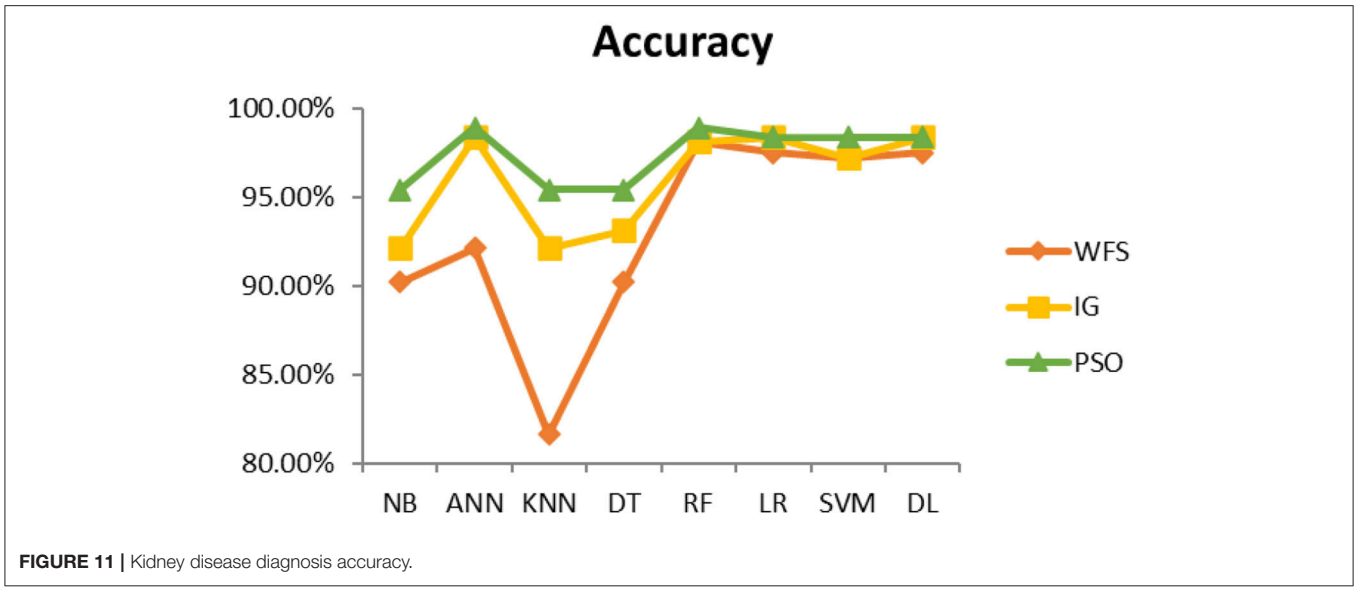

FIGURE 11 | Kidney disease diagnosis accuracy.

TABLE 3 | Highest accuracy achieved by proposed model.

Diseases	Highest results achieved by proposed model
Cancer	98.23%
Diabetes	93.59%
Heart	93.44%
Hepatitis	98.46%
Kidney	98.90%

Ant Colony Optimization is used for reducing irrelevant or least significant features. The study presented that ACO feature selection enhances the performance of supervised learning classifiers (17). Kidney disease stage identification is performed by applying artificial intelligence techniques to various patient attributes. The most influencing features in the prediction of kidney disease stage are serum creatinine, urine, and albumin. Probabilistic Neural Network beat other prediction models with 96.7% accuracy (72). Random Forest is applied to predict chronic kidney disease in patient data. Dataset is divided into demographics and clinical data, including patients' age, BMI, gender, diabetes history, hypertension, etc. Prediction results are estimated by R2 (73). Data are preprocessed by outlier detection, normalization, and irrelevant data features are reduced. The random subspace outperformed with 100% accurate results and proved that ensemble approaches are better to use than individual classifiers (74). Besides kidney disease presence prediction, kidney transplantation survival is another critical aspect of prediction. The study proposed a prediction model for patients' survival after kidney transplants. Information Gain and Naive Bayes are used for the most significant feature selection. When evaluated with Accuracy and F-measure, K-NN gave higher accuracy than other classifiers (75). Another study classifies kidney patient and healthy people data by applying correlation-based feature selection approaches. Three feature ranking approaches, namely ReliefF, information gain, and gain ratio, explore the most significant attributes (76). **Table 1** shows the summary of previous literature that presents their problem statements, diseases to be predicted, and proposed solutions.

MATERIALS AND METHODS

In this section dataset selection, data pre-processing, feature selection, proposed model architecture, classification methods, performance evaluation, experimental tools and setup and validation method are discussed. **Figure 1** describes the proposed automated artificial intelligence approach. The datasets are selected, and pre-processing is applied. The features are extracted with particle swarm optimization and then an artificial neural network is utilized.

Dataset Selection

Datasets for five chronic diseases, including Breast Cancer, Diabetes, Heart, Hepatitis, and kidney disease, are collected from multiple online sources e.g., Kaggle, Dataworld, Github & UCI machine learning repository. Four datasets are previously used in a research study (19), to predict different diseases, while other datasets are used in multiple research studies. Each dataset has information about numerous patients with various diseases; therefore, dataset features and instances vary. All datasets used in this research study have numeric and categorical data features based on patients' demographics and medical test results. Breast Cancer data attributes include the characteristics extracted from digital images of fine-needle aspirates of different breast tissues. Diabetes datasets are extracted from patients' demographic profiles and medical test results, including gender, age, glucose level, blood pressure, and body mass index, etc. Two datasets containing heart disease symptoms and patients' data are used to detect a person's heart disease or not. Heart disease dataset attributes used for detection include demographics, chest

pain, cholesterol level, glucose level, ECG results, maximum heart rate, depression, and exercise-induced angina. For the early prediction of hepatitis, demographics and medical lab test attributes are used. Dataset features used for diagnosis are categorical, including age, gender, antivirals, liver size, fatigue, discomfort, bilirubin, albumin, etc.

The kidney disease dataset is used to diagnose kidney disease presence, using features like sugar level, red and white blood cell count, glucose level, blood urea, diabetes presence, and hunger. All above datasets consist of multiple features; however, not all features are equally significant for disease diagnosis. This research study finds that feature selection approaches help to optimize classification results by considering useful features only. Therefore, for each disease, two publicly available datasets are used to verify the classification results. However, for kidney disease classification, only one dataset is found on multiple online platforms. **Table 2** describes the dataset attributes and their statistics.

Data Pre-processing

In predictive analytics, data quality is a significant factor, low quality of data leads to incorrect results. Due to their varied uses and sources, real-world medical data sets have many outliers, missing values, and irrelevant features. To make the artificial intelligence algorithm more productive, pre-processing is essential before using data for model training (87). Data pre-processing is a conventional artificial intelligence technique to convert raw data into useful information. Data pre-processing involves various steps needed to obtain relevant and valuable data from the original dataset. Data pre-processing steps involve data extraction, anonymization, integration, cleaning, outlier detection, and duplicate removal (15). Therefore, all the datasets are pre-processed before using data for prediction. In these datasets, it is observed that the patient's glucose level, BMI, skin thickness, insulin, blood pressure, and age have a minimum value of zero, which is impossible. Such outliers are replaced with average values. Some instances have blank entries, which are removed by using the replace missing values operator to make an accurate detection. **Table 2** presents the datasets and their values.

Feature Selection

Many datasets for all diseases are available in the hospital's database systems and online repositories. These datasets have different features for multiple usages; not all available features contribute to specific disease detection. Data pre-processing is an essential step before applying a model for the classification of data. The model trained on a dataset with wrong entries may lead to misleading results. Similarly, not all attributes in a dataset contribute to the detection process equally. Including irrelevant features increases the processing time of the model and it also decreases model performance. If all attributes are used for predictive analysis, classifier performance is affected negatively. For hospitals and medical labs, it is dependent on the physician's experience to diagnose a disease from different symptom input values. However, different feature selection approaches allow examining the contribution of various features on results. The main functionality of feature selection techniques is used to analyse that how each attribute takes part in output prediction. Feature selection is an essential approach to be used before model construction to redue data complexity by eliminating irrelevant and useless features from data. Feature selection approaches reduce the data size so that the model takes less time in the training and testing phases. Feature selection is beneficial as it reduces the data size so that processing time, space, and power consumption are also reduced (15). With a fewer number of features, the classification model becomes more interpretable and yields more effective results. Features with zero or very low contributions are eliminated by using feature selection. There are various feature selection methods. Information Gain (IG) is one of the most effective methods for feature selection. Information Gain is measured by entropy, which is the uncertainty of being selected. A low entropy value represents more chances of being selected as a final class label (16). Information Gain calculates the weight of each attribute to estimate its contribution to the last class selection. The highest weight represents the feature that has the most information about final class selection, therefore considered as the most influencing feature.

We present the significance of selecting the most significant features using Particle Swarm Optimization (PSO). PSO results are compared with Information Gain to evaluate its performance. Particle Swarm Optimization (PSO) is another feature ranking technique. PSO is introduced in 1995, inspired by groups of birds and fishes searching for food in a swarm group. Each species in the swarm searches for food, and the whole group follows that individual nearest to the food to travel in the right direction in minimum time. Similarly, the PSO technique is used to find an optimal solution for a problem consisting of various features (48). PSO is an evolutionary algorithm developed on the social behaviors and movements of species. PSO is applied to optimize classification results by assigning weights to the most significant features based on their previous results (88). Thus, only the significant features are used for the prediction process to decrease processing time and to enhance the efficiency of prediction model. The ANN classification model based on the most significant features obtained by PSO. Using PSO, all attributes are assigned weights according to their contribution to the classification process. In addition, a baseline information gain approach is also used to compare its results with the proposed model.

Proposed Model Architecture

The proposed model architecture is described in this section. Artificial intelligence algorithms are used to construct the chronic disease detection model. Artificial intelligence is an advanced machine learning approach to build detection models that can receive input data, train a model, and predict the output of future data. These model-building techniques are divided into two main categories: supervised learning and unsupervised learning. Supervised learning models are provided with a set of input data with desired output labels to construct a predictive technique for future datasets. Supervised learning algorithms include a set of tree-based, instance-based, probability-based, and ensemble algorithms (89). Classification is a supervised machine learning approach that works under supervised learning to predict the

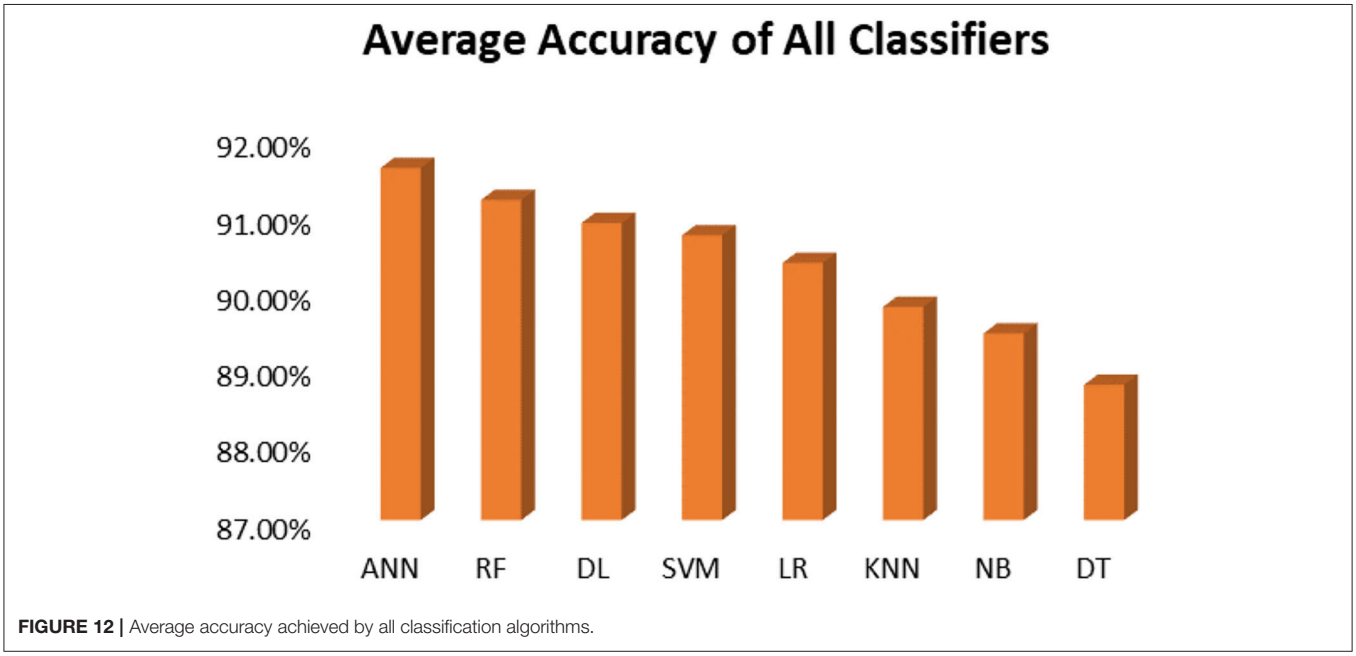

FIGURE 12 | Average accuracy achieved by all classification algorithms.

final class. In classification, the output variable is nominal such as patients' disease diagnosis that is positive or negative (5).

The forward and backpropagation are evaluated during the ANN learning phase, and it is observed that forward propagation gives higher accuracy. Therefore, an Artificial neural network with forwarding selection is used to predict disease presence. Dataset features with and without feature selection approaches are given as an input to the first layer. The processed output of the first layer is fed into the second layer as input until it reaches the output layer. Cross-validation with tens folds is used for the training and testing process. Each dataset is divided into 10 folds, and nine folds are used for training and one-fold for the testing process in such a way that each fold must be used for testing. The different number of training cycles is applied to get the best classification results, and finally, ANN with 200 training cycles is used to finalize the prediction results. ANN learning rate controls how fast Neural Network will learn a prediction problem. It is a configurable hyper-parameter tuned during the ANN training process. A learning rate of 0.01 is used, as a lower learning rate allows Neural Network to learn more optimally. For the breast cancer diagnosis, 31 input features are fed to the proposed model. After classification of the first breast cancer Wisconsin (diagnostic) dataset, the second breast cancer Wisconsin dataset with 10 features is provided as an input to the proposed model, and the results are recorded. Similarly, for the other four diseases detection, datasets with different features, as described in **Table 2**, are fed into the proposed model, and results for each disease diagnosis are recorded. For classification, at first, ANN is trained with all available features to classify patients and healthy people in each dataset. In the second step, features are assigned weights using Information Gain, and classification is made based on the weighted features. In the third step, PSO is applied to each dataset, and its results are compared with classification performance without feature selection and with Information Gain. **Figure 2** presents the architecture of the proposed model, where w stands for the weights assigned to the features, while x and y are used for input and output, respectively.

Classification Algorithms

The Artificial neural network classification algorithm is compared with seven state-of-the-art classification algorithms, namely, Naive Bayes, K-NN, Decision Tree, Random Forest,

Logistic Regression, SVM, and Deep Learning. There are various classification algorithms to find a correlation between patients' attributes and disease symptoms, but all algorithms have some limitations in input requirements, model construction function, and required computation time (15). ANN is used for five different chronic disease detection. It is inspired by biological neural networks that pass information from the human brain to other body parts by passing through neurons. ANN is a classification algorithm that learns from training examples and applies the trained model to future datasets to predict their output (16). ANN is a set of connected neurons comprising input, processing, and output layers. Each neuron is connected to its adjacent neurons (90), whereas each connection is assigned some weight. These weights are adjusted in the training phase to weaken or strengthen the relationship based on its contribution toward output prediction. Model training is done through backward or forward propagation (91). Naive Bayes is suitable for both numerical and nominal data with multiple dimensions. Naive Bayes is the Bayesian theorem-based classification algorithm, which works on conditional probability, the class with high probability is considered as the final output. Naive means each feature in the dataset is independent of other features and their presence does not affect others. Naive Bayes can be applied to large datasets as its feature independence makes classification faster than other classification algorithms (16).

KNN is the simplest and easiest algorithm used for classification. K is the nearest neighbor of a data sample whose class is being predicted (91). KNN, also referred to as lazy

learning (15), allocates weights to the contributing neighbors so that the nearest neighbor will have more influence on prediction. Most commonly, Euclidean distance is used to calculate the distance of all neighbors. KNN assumes that similar instances occur close to each other; hence, the nearest neighbors contribute to predicting the final class (75). KNN with a weighted vote is used for classification in this research study, with $k = 10$ which represents 10 nearest neighbors. A Decision Tree is the most straightforward classification algorithm, which follows a tree-like structure starting from the root node and reaches the output node (leaf) by evaluating some conditions. Each node is connected to its next node by a connection (branch); this connection represents a condition, if true, then reaches the next node. Since the decision tree works well with categorical data, it is most suitable for the dataset with fewer features (5). This paper uses decision trees with a maximum depth of 10 nodes for predictive analysis. Numerical data is changed to categorical data by using numerical with the nominal operator. Feature selection techniques are applied to select the most significant nodes so that the classification becomes more effective with a smaller number of features.

Random Forest is an ensemble learning technique used for prediction. Random Forest is a more effective algorithm than a decision tree as it combines a set of multiple decision trees by selecting random data samples and predicts the final class based on the majority vote. More trees mean more robust prediction, but implementing many trees requires more processing time (16). The primary aim of ensemble techniques is to strengthen weak algorithms to build a robust predictive model. In this paper, Random Forest with 100 trees is constructed. Logistic regression is a supervised learning classification technique used to output binary classes. It classifies the output by using probability function, results higher than 0.5 are classified as positive while <0.5 are predicted as negative. It operates numerical input data; therefore, categorical attributes are changed to numerical by using nominal to numerical operators (15). SVM is used to classify linear as well as multidimensional data. In SVM, a hyperplane is used to separate different classes of variables. Both sides of the hyperplane represent two other classes. The Euclidean function is used to calculate the distance between variables so that the hyperplane is drawn in its best place (12). SVM is used for both classification and regression problems. In this paper, SVM with the kernel (dot) is implemented to classify data into binary classes. Before the model, nominal building data is converted to numerical. Deep Learning (DL) is a machine learning approach (92), comprised of a Neural Network with multiple hidden layers. The label with the highest value is finalized as output class (93). Since more training gives more accurate results, but it also increases the processing time and makes the model more complex. Deep learning with epoch 10.0 is applied in this research study.

Performance Evaluation

After training and constructing a prediction model, its performance is tested on similar features with an unseen output class to evaluate how accurately the model performs. A confusion matrix is derived to check the similarity between the actual output and predictions of the designed model. In the confusion matrix, true positive (TP) indicates that positive output is predicted as positive, false positive (FP) indicates that negative class is predicted as a positive class, true negative (TN) represents the true prediction of negative class, and false negative (FN) shows that a negative class is falsely predicted as the positive class. These are the primary measures for any classification model. One of the most used performance measures is accuracy. It is the ratio of the correct number of predictions to the total number of instances. Equations 1, describe the accuracy formula.

$$\text{Accuracy} = \frac{\text{True Positive} + \text{True Negative}}{\text{All}} \tag{1}$$

Experimental Tool and Setup

In this research study, RapidMiner is used to implement classification algorithms. RapidMiner is a user-friendly platform for the implementation of artificial intelligence algorithms to solve data analysis and data mining problems. It is open-source software with multiple license types for user convenience. However, it is freely available for academic use. RapidMiner contains hundreds of classification, regression, clustering, and feature ranking operators that are used without coding skills (94). RapidMiner is designed for data mining, data pre-processing and visualization, statistical analysis, feature extraction, prediction, and classification. RapidMiner is easy to use as it has input, output, and processing operators that need drag and drop functions and connection building simply. RapidMiner is widely used for machine learning, text mining, sentiment analysis, future predictions, and statistical data analysis. Its Java-based graphical user interface allows business persons and researchers to use it for data preparation, processing, and business future predictions (95).

K-Fold Cross-Validation

K-fold cross-validation is a technique for dividing data into subsets for training and testing of the model. This technique is mainly used with prediction models to evaluate how the designed model will perform on new unseen data. In predictive analysis, a model is generally trained on a dataset available with the required class labels, and when the model is built, it is used for testing on a new dataset with unknown output labels, so that model performance is evaluated (15). There are two techniques for dataset splitting: split data and cross-validation. K-fold cross-validation has an advantage over the split data technique because it works efficiently when applied to a biased dataset. K represents the number of times the data is trained with k-1 subsets for training and 1 subset for testing. In cross-validation, each instance is checked for both training and testing both. The ten-fold cross-validation is used to train and test the classification models.

RESULTS AND DISCUSSIONS

This section presents the results achieved and then briefly describes these results. The ANN classification algorithm applied

to feature selection using PSO. The performance of the classifiers is presented using standard measure of accuracy. Seven classification algorithms are applied to each dataset to compare their prediction performance with the proposed model. The prediction performance of ANN is improved using the PSO feature selection approach. Results with and without feature selection are compared to explore the impact of the most influential features and to present how the proposed feature optimization method performs better than other techniques. **Figure 3** presents the accuracy of the first breast cancer dataset and shows that logistic regression without feature selection (WFS) gives the highest accuracy of 93.15%, while the information gain increased the performance of ANN and achieved the highest accuracy of 93.67%. Finally, PSO is applied and a 5% increase in accuracy is observed. Therefore, the proposed model obtains the highest accuracy of 98.23%. For the second breast cancer dataset, as shown in **Figure 4**, Random Forest without feature selection gave the highest accuracy of 96.57%, followed by ANN with an accuracy of 96.43%, which increases to 97.43% after the selection of features by PSO. For diabetes prediction, as shown in **Figure 5**, ANN and Deep Learning achieve the highest accuracy of 78.72%. After feature extraction with PSO, the accuracy of ANN increases to 86.67%, which is the highest compared to other classification algorithms. When the proposed model is applied to another dataset for diabetes prediction, as shown in **Figure 6**, the highest accuracy of 93.59% is observed in ANN applied to PSO. Therefore, for both diabetes patient datasets, the proposed model reveals the highest results. For heart attack prediction, as shown in **Figure 7**, ANN and Deep Learning provide the highest accuracy of 82.17 and 82.13%, respectively. The most significant features are extracted with PSO, which shows an accuracy of 93.44% obtained by the proposed model. The k-NN shows a remarkable increase with an accuracy of 68.88% without feature selection and 90.62% with PSO. The proposed model is applied to another dataset for heart attack prediction, as shown in **Figure 8**, and PSO is found to show a remarkable increase in accuracy. ANN gave an accuracy of 81.85%, which increases to 85.56% after selecting the most significant features with PSO. **Figure 9** presents a comparison of eight classification algorithms with the proposed model for prediction of hepatitis disease. Random Forest achieved the highest accuracy of 95.13%, while ANN gave an accuracy of 93.46%. After feature selection, the proposed model obtained an accuracy of 98.46%. Next, the proposed model evaluates another dataset for hepatitis prediction in order to examine the results more accurately. **Figure 10** shows that the proposed model achieved highest accuracy of 73.73%. **Figure 11** shows the accuracy of kidney disease prediction. It shows that after PSO optimization, ANN and Random Forest give 98.90% accurate results. Information Gain shows a prominent increase in accuracy, but PSO significantly gives the best results. Different datasets have different accuracy because of different types of features and the number of instances. Optimization techniques help classifiers reduce irrelevant and useless features, remove outliers, and convert complex data into a simple form. It is found that overall, ANN, Random Forest, and Deep Learning give the best results, but ANN outperformed all other techniques. **Table 3** presents the highest accuracy gained by the proposed model for all five selected diseases. **Table 4** and **Figure 12** present the overall accuracy of the eight prediction algorithms achieved with PSO feature selection. An average of the results obtained by each prediction algorithm is calculated and it is found that the proposed ANN model produces the most accurate results.

It is shown that the proposed model gives the highest results, that is, 91.61%, followed by Random Forest with an accuracy of 91.19%. However, the Random Forest required more processing time compared to ANN. Therefore, the processing time of different classification techniques is also evaluated. Only one dataset for each disease is evaluated for processing time comparison. Total processing time is calculated in milliseconds (ms). **Figure 13** presents the total training and testing processing time for cancer, diabetes, heart, hepatitis, and kidney. The cancer dataset shows that Random Forest takes the most time. The prediction time required for the diabetes dataset also indicates that Random Forest requires more time compared to other classification techniques. The processing time for a heart attack shows that Random Forest followed by the SVM algorithm takes additional time. Hepatitis data processing time shows that SVM followed by Random Forest requires more time for training and testing. Random Forest and SVM are shown to be the slowest prediction and data processing algorithms for kidney disease. Overall, **Figure 13** shows that Random Forest and SVM required the most time for processing. Random Forest is an ensemble technique; its processing time depends on the number of trees combined to construct a forest, while SVM processing time depends on the kernel type. However, Naive Bayes and Logistic Regression take minimal time to build classification models. Furthermore, the processing time is also dependent on the number of instances in the dataset. Large datasets require more time for training and testing processes for all classification techniques. In (19), 10 different datasets are used for disease prediction with multiple feature selection approaches Information Gain, Gain Ratio, and ReliefF. Their proposed model gives the highest results of 99% when used with various subsets of patient attributes. Another study (75), suggested a feature selection method using Information Gain with different numbers of k for cross-validation to early predict kidney disease and achieved an accuracy of 81%. A hybrid classification model is proposed in (2) to diagnose three chronic diseases, including kidney disease, diabetes, and Hepatitis. The probabilistic feature selection approach is applied to a Logistic Regression classifier, and 91.6% accuracy is achieved. In another study (18), a chronic disease prediction model is built with three datasets of Breast Cancer, Diabetes and Heart attack patients. Convolutional Neural Network is applied to correlation coefficient-based attributes ranking technique. Diseases are predicted in two steps, at first with all available features and secondly with features of high significance. **Table 5** gives a comparative analysis of previous research studies as compared to the proposed approach.

CONCLUSION

Early diagnosis of chronic diseases is a major research challenge. Various artificial intelligence techniques are used in literature for medical data classification and disease prediction. Such techniques are often applicable for selected datasets to diagnose

specific disease with a limited set of attributes. In this paper, chronic diseases are predicted using an augmented artificial neural network based approach. The accuracy of the proposed model is improved using the particle swarm optimization (PSO) feature selection algorithm. This is shown to eliminate irrelevant features and assign weights to the most contributing features. Our proposed approach performs predictions more effectively and efficiently than other state-of-the-art models. Five most widespread chronic diseases are selected for diagnosis, including breast cancer, diabetes, heart attack, hepatitis, and kidney disease. Nine publicly available benchmark datasets are used in this study. The proposed model comprising an ANN classifier applied with PSO based feature selection is compared with seven state-of-the-art artificial intelligence techniques: decision tree, random forest, deep learning, naive Bayes, SVM, KNN, and logistic regression. Comparative results show that our proposed model performs the best out of all eight classification algorithms, with the highest accuracy of 99.67%. Our model obtained 98.23, 93.59, 98.46, 93.44, and 98.90% prediction accuracy for breast cancer, diabetes, hepatitis, heart, and kidney diseases. Whilst our proposed model produced the best results; the classification performance is found to depend significantly on the data features used for outcome prediction. Therefore, up to two datasets for each chronic disease are further used to apply our proposed model on different attributes. Results showed that our proposed approach outperformed other models. A comparison of processing time of classifiers showed that our optimized ANN approaches required less time compared to random forest, deep learning, and SVM. Our study can play a vital role for predicting multiple diseases using optimized ANN based prediction models in hospitals and medical labs. Further optimizing essential features can be beneficial for medical purposes to reduce patients' data attributes.

FUTURE WORK AND LIMITATIONS

In future, we plan to predict more chronic diseases with our proposed model. In particular, ensemble feature selection approaches may result in better prediction of multiple chronic diseases. Developing a system that can diagnose various diseases in patients is an open research problem and there has been little research work reported in this area. The number of patients living with more than one chronic disease is growing globally. We plan to build a prediction model based on classification and feature selection approaches to diagnose two or more chronic diseases in a person. A limitation of this study is that all classification methods are applied to selected diseases, while a dataset with different patient diseases may lead to suboptimal predictions. Although our augmented artificial intelligence based prediction model has shown promising results, there are a number of open research problems. First, generalized and globally applicable systems for disease prediction are not available. Second, prediction performance in research does not scale to real-world clinical applications due to limited data availability and different sets of attributes used in research studies. Third, real-time implementation and clinical validation of prediction models is a major challenge. Other open research areas include continuously improving prediction results based on clinical validation and diagnosing previously unknown diseases.

DATA AVAILABILITY STATEMENT

The publicly available datasets are used in this study, whose details are included in the "Materials and Methods" section of this article. Please contact the corresponding author for further requests.

Diabetes is considered to be one of the leading causes of death globally. If diabetes is not treated and detected early, it can lead to a variety of complications. The aim of this study was to develop a model that can accurately predict the likelihood of developing diabetes in patients with the greatest amount of precision. Classification algorithms are widely used in the medical field to classify data into different categories based on some criteria that are relatively restrictive to the individual classifier, Therefore, four machine learning classification algorithms, namely supervised learning algorithms (Random forest, SVM and Naïve Bayes, Decision Tree DT) and unsupervised learning algorithm (k-means), have been a technique that was utilized in this investigation to identify diabetes in its early stages. The experiments are per-formed on two databases, one extracted from the Frankfurt Hospital in Germany and the other from the database. PIMA Indian Diabetes (PIDD) provided by the UCI machine learning repository. The results obtained from the database extracted from Frankfurt Hospital, Germany, showed that the random forest algorithm outperformed with the highest accuracy of 97.6%, and the results obtained from the Pima Indian database showed that the SVM algorithm outperformed with the highest accuracy of 83.1% compared to other algorithms. The validity of these results is confirmed by the process of separating the data set into two parts: a training set and a test set, which is described below. The training set is used to develop the model's capabilities. The test set is used to put the model through its paces and determine its correctness.

Keywords: decision tree, random forest, Support Vector Machine (SVM), Bayesian Naive, diabetes, AI, ML, classification

INTRODUCTION

Diabetes is a chronic disease also known as a silent disease. The World Health Organization (WHO) defines diabetes as a disease that prevents the body from properly using the energy provided by the food it consumes. In addition, the disease occurs when there are problems with the hormone insulin, which is naturally produced by the pancreas to help the body use sugar and fat and store some it (1).

More clearly, when we eat, food is broken down into glucose (sugar). This glucose provides energy for the body to function properly by drawing on its resources. During digestion, the blood carries the glucose throughout the body and supplies the cells. However, in order for the sugar in the blood to be delivered to the cells, the body needs insulin, a hormone secreted by the pancreas, which acts as a key to get the glucose from the blood into the cells of our body (2). There are three most common types of diabetes:

Type 1 diabetes: it is a condition in which the pancreas cannot produces enough insulin or does nor produces any insulin. It accounts for 5–10% of all diabetes cases, commonly affecting childhood and adolescence. Then, Type 2 diabetes–it is a condition in which the insulin produced does not effectively used to maintain the blood sugar level in the body. This type diabetes is common in people age 40 and above, but also appears in younger people. From all diagnosed diabetes cases worldwide, type 2 diabetes accounts for 90–95 percent. There is another type of diabetes called "gestational diabetes", caused by the lack response of the insulin receptors on the body tissues, even if the insulin levels are normal, which makes this condition different from the second type, and this case is very rare, account for 1–2% of all diabetes cased and it also increase the risk of developing type 2 diabetes later (3).

People with diabetes must be treated according to their type of diabetes. The goal of treatment is to keep the patient's blood sugar level within a normal range.

Kumari and Chitra	In the proposed work, SVM with radial basis function kernel is used for classification. The performance parameters such as the classification accuracy (78.2 %), sensitivity (80%), and specificity of the SVM and RBF have found to be high thus making it a good option for the classification process.	(4)
Ahmed	Accuracy of the proposed models has been compared. The random forest method provided an accuracy of 74.7%, ANN gave 75.7% and K-means clustering method has given 73.6% accuracy.	(5)
Shetty et al.	Used K-Nearest Neighbors (KNN) and the Naïve Bayes technique for diabetes prediction. This technique was implemented in the form of a software program, in which users provide data in terms of patient records and the finding that the patient is diabetic or not.	(6)
Bhoia et al.	In this paper. Various supervised learning algorithms have been used such as CT, SVM, k-NN, NB, RF, NN, AB, and LR, and generated the training dataset and testing dataset using k-fold cross-validation with k = 10. The results of accuracy = 76.80%	(7)
Kandhasamy and Balamurali	The authors in used data from the University of California, diabetes mellitus patients were classified using a machine learning data repository to compare the performance of four common classifiers (J48 DT, the K-Nearest Neighbors algorithm, the Random Forest algorithm, and the Support Vector Machines algorithm). They used a data sample from the UCI machine learning data repository. Preliminary results suggest that the J48 DT classifier outperforms the other three classifiers in terms of accuracy (73.82 percent) before data preparation, and that the KNN (k = 1) and Random Forest classifiers outperform the other three classifiers after data pre-processing.	(8)
Vijayan et al.	The KNN method and the ANFIS algorithm are comparable. According to the results of the experiment, the amalgam of KNN and ANFIS gives the highest classification accuracy of 80 % among the algorithms tested.	(9)
Soleh et al.	The data in this study divided into two, 75% for training data, and 25% for testing data. This study produces an evaluation with an accuracy 80%, which means it is better than the previous paper, which is 75, 97%.	(10)
Rajput et al.	The target of analysis made in the present research is to list the risks factors and correlation that exist among those risk factors. In this work, logistic regression, support vector machine, random forest, decision tree, Naive Bayes, K nearest neighbor classifiers are used for prediction, and their accuracy is compared to choose the better machine learning model. SVM provides higher accuracy (96.0) among the choosen algorithms.	(11)
Deepa et al.	This work aims to propose an artificial intelligence-based intelligent system for earlier prediction of the disease using Ridge-Adaline Stochastic Gradient Descent Classifier (RASGD. The results of the proposed scheme have been compared with state-of-the-art machine learning algorithms such as support vector machine and logistic regression methods. The RASGD intelligent system attains an accuracy of 92%, which is better than the other selected classifiers.	(12)

METHODOLOGY USED

Model Diagram and Study Explanation

The proposed process is presented in the form of a model diagram in **Figure 1** below. The following diagram depicts the flow of the research done in the process of building the model:

In this study, we split the data set into two parts: a training set and a test set. The training set is used to train the model. The test set is used to test the model and evaluate the accuracy.

In the second step we use a K-means algorithm for data correction in order to improve performance and control the classified model (By changing the number of clusters).

Next, we invite the learned algorithms to be tested using the test database. Finally model evaluation with other related work.

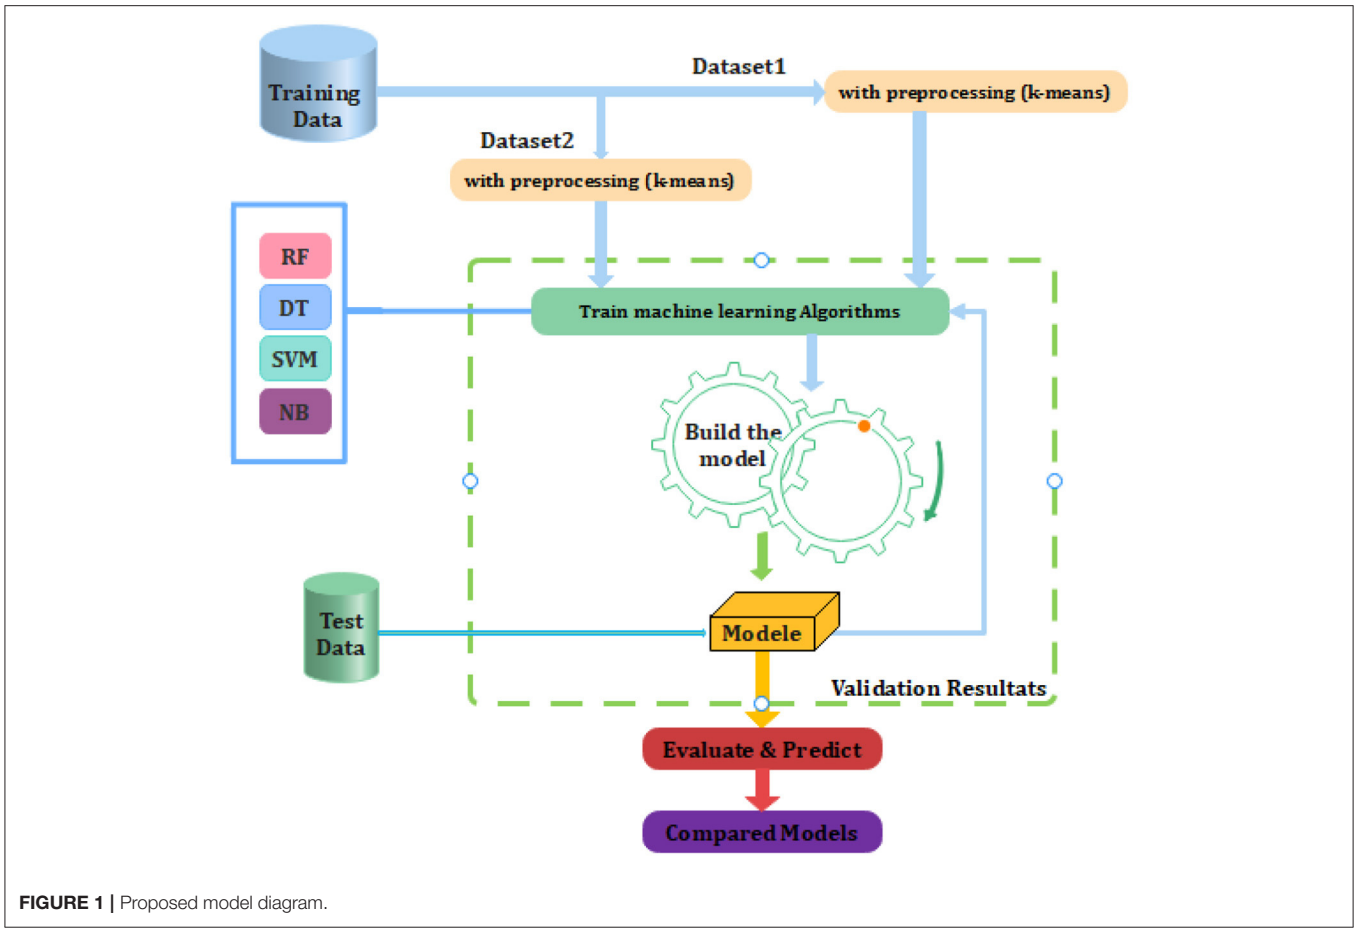

FIGURE 1 | Proposed model diagram.

Algorithms Used

Support Vector Machine

Support Vector Machine is based on statistical learning theory. SVMs were originally developed for binary classification, but can be effectively extended to multi-layer problems. SVM or Sequential Minimal Optimization (SMO) is a learning system that use a hypothesis space for linear functions in a high-dimensional space, and that has been trained using an optimization theory learning algorithm that employs a learning bias de-rived from statistical learning theory to achieve its results. SVM implements nonlinear class boundaries by translating nonlinear input vectors into a high-dimensional feature space using a linear model, which is implemented using the kernel of the SVM. Support vectors are training in-stances that are closer to the maximal hyper maximum level than the rest of the training examples. In order to define the binary layer boundaries support, all other training samples are rendered inapplicable.

As a result, the vectors are utilized to construct the ideal level hyper linear separation function (in the case of pattern recognition) or linear regression function (in the case of regression) in the feature space in question (13).

K-Means Clustering Algorithm

The k-means clustering algorithm is a machine learning algorithm that groups nearby points into clusters. In this algorithm, there is no learning model construction because we will locate the new point in any cluster based on its distance from all the clusters (mainly its distance from the cluster center or its arithmetic mean) and it is placed in the cluster that is closest. For example, imagine that you want to divide the points of a line into 3 groups. To Determine how close a point is to a particular group, we will use a measure of its distance from the group (for example, the distance between two points) (14).

Naive Bayes

NB is a classification approach in which the idea of independence and relatedness of all characteristics is defined as follows: Specifically, it specifies that the state of a given feature inside a class has no effect on the status of any other feature within the class. As a result of its foundation in conditional probability, it is regarded as a strong algorithm that may be utilized for classification applications. It performs effectively when dealing with data that has imbalance issues and missing values (15):

$$P(A \mid B) = \frac{P(B \mid A)\, P(A)}{P(B)} \quad (1)$$

- P(A|B): conditional probability that the response variable has a certain value given the input characteristics. Additionally, this is referred to as the posterior probability.

- P(A): The response variable's a priori probability.
- P(B): The likelihood that the training data or evidence is correct.
- P(B|A): This is referred to as the probability training data.

Decision Tree

DT learning is one of the predictive modeling techniques used in statistics, data mining, and machine learning. Use a decision tree (as a predictive model) to move from observations on an item (represented in the branches) to conclusions about the target value of the item (represented in the paper). They use a hierarchical representation the data structure in the form of a sequence decisions (tests) to predict an outcome or a category. Each individual (or observation), which must be allocated to a class, is represented by a collection of variables, which are tested in the nodes of the tree. In the internal nodes, testing is carried out, and choices are taken in the paper nodes (16). In graph theory, a tree is a linked graph that is undirected, acyclic, and has no edges. There are three categories of nodes:

- Root node: This is the base of the tree and the most sensitive element when the tree is created and before it is exploded.
- Internal node: refers to nodes that have offspring that are themselves nodes.
- Final nodes: that do not contain any branches.

There are many DT's algorithms, and we can cite: ID3, C4.5, CART, C5, CHAID, SLIQ, UFFT, VFDT... (16).

Random Forest

Random Forest algorithm (17) is for statistics and machines that employs several learning methods to improve prediction performance. The two-part algorithm A. Tree bagging b. Each tree is produced from tree bagging to random forest:

1. Sample N instances at random - but with replacement, from the original data if the number cases are N inside the training set. The training set for developing the tree will be this sample.
2. A random number of characteristics and the optimal division utilized for dividing the node are picked when there are M input variables. During the forest growth, the value M is kept constant.
3. Each tree is cultivated as much as possible.

Dataset Used

We used two different databases in this study; Pima Indian Diabetes provided by the UCI Machine Learning repository (18) and a database extracted from the hospital in Frankfurt, Germany (19). Database extracted from the hospital in Frankfurt the first data is 2000 Pima Indian has 768 patient data with 8 attributes/features and one out-put with the patient's label/outcome (0: Not diabetic, 1: Diabetic). Two databases together consist some distinct medical variables, such as:

1. Pregnancies: number of pregnancies.
2. BMI: Body Mass Index (weight in kg / (height in m) ^{2}).
3. Insulin: Dose of insulin (mu U/ ml).
4. Age: Age at least 21 years.
5. Glucose: Plasma glucose concentration.
6. Blood Pressure: Diastolic blood pressure (mm Hg).
7. Skin Thickness: Thickness of the triceps skin fold (mm).
8. Diabetes Pedigree Function: Diabetes pedigree function (heredity).

And two classes (1 and 0)

- If class =1 implies diabetic patient.
- If class =0 implies non-diabetic patient.

The choice of these two bases is justified by the following criteria:

- The size of the database.
- Number of attributes.
- Number of classes.

Data Correction

Data cleaning is the next step in machine learning. It is considered one of the main steps in the working stages, and it is either building the model or breaking it. There is a saying that "the best data beats the most complex algorithms" in machine learning. Several aspects of data cleansing must be considered:

1. Discordances and omissions
2. Data mislabeling, same category repeated.
3. Invalid or missing data.
4. Outliers.

Unexpected Outliers in Both Bases

The observation and analysis of the two databases are presented in **Table 1**.

Methods of Handling Invalid Data Values

The Existing Works

- Ignore/delete these cases: delete all the observations with zero values but in this method we get a significant loss of data (about 50% of the data set).
- Put the mean values: calculate the median value of a specific column and replace this value in that column where we have zero.
- Avoid using parameters: The model can avoid using parameters with too many incorrect values. This may help thicken skin, although it's hard to tell.

In This Study

- Use of a classification algorithm: use a classification algorithm to recover the missing data where we have zero and replace them with the value found.

In our case, we have to apply this method and we have chosen the k-means algorithm with a variable K number of cluster (group) and replacing each column needs cleaning by the representative of cluster.

Evaluation Method

Train/Test

The data set is split into two parts: training and testing. The training set teaches the model. The test set is used to evaluate the model's correctness.

TABLE 1 | The observation and analysis of the two databases.

Variable	Observation and data analysis	Total number where the value is 0 (Pima base)	Total number where the value is 0 (Frankfort base)
Blood pressure	The data shows that there are 0 number for blood pressure.	35	90
glucose	It is impossible for a person to have a glucose zero value even if they are fasting.	5	13
Skin thikness	For normal people, the thickness of the skin fold cannot be <10 mm.	227	573
BMI	It is impossible for a person to have a BMI 0 value.	11	28
Insulin	In a rare situation a person may have 0 insulin	374	956
Pregnancies	It is normal to have a zero value for this column so there is no need for cleaning.	111	301

TABLE 2 | Accuracy measures.

Measures	Definitions	Formula
Accuracy	Accuracy determines the accuracy of the algorithm in predicting instances	A = (TP + TN)/ (Nombre total d'échantillons)
Recall	Is the ability of a classification model to identify all relevant instances	R = TP/(TP + FN)
F1– Mesure	Is the weighted average of precision and recall	F = 2 * [(P * R)/(P + R)]
Precision	Classifiers correctness/accuracy is measured by Precision	P = TP/ (TP + FP)

TABLE 3 | Evaluation attributes results for different models (Frankfurt Germany).

Algorithm used	Clusters	Accuracy	Recall score	F1 score
Naïve bayes	C = 16	0.776	0.625	0.654
SVM	C = 20	0.783	0.566	0.638
Decision tree	C = 285	0.971	0.975	0.958
Random forest	C = 20	0.989	0.95	0.972

TABLE 4 | Evaluation attributes results for the different models (Pima Indian).

Algorithm used	Clusters	Accuracy	Recall score	F1 score
Naïve bayes	C = 55	0.785	0.6	0.62
SVM	C = 16	0.831	0.533	0.648
Decision tree	C = 55	0.707	0.622	0.554
Random forest	C = 20	0.805	0.711	0.68

TABLE 5 | Comparison of the proposed work with the existing works (Pima Indian).

Method	Accuracy	Reference
Logistic regression	76.80%	(7)
Decision table	79.81%	(13)
Naïve Bayes	76.3%	(20)
Logistic Regression (LR)	80%	(10)
SVM	83.1%	Our study

Pima Indian Database

"Test size = 0.2." That is, 20% for the test and the rest 80% for the training.

Hospital Frankfurt Database

"Test size = 0.3." That is, 30% for the test and the rest 70% for the training.

Accuracy Measures

This study uses Naive Bayes, Random Forest, SVM, and DT algorithms. Train/Test Split is used in experiments. This study uses Accuracy, F1-Measure, Recall, and Precision metrics to classify. See **Table 2** for accuracy measures (20).

- True positives (TP), False positives (FP)
- True negatives (TN), False negatives (FN).

Experimental Results

This is clear from **Table 3**, which compares the different performance measures (accuracy, recall, and F1 score) used to evaluate the investigated machine learning models. Random Forest (RF) demonstrated the best accuracy when used in the tuned configuration (97.6 percent). In addition to Random Forest (RF), additional algorithms such as Decision Tree (DT) have demonstrated sufficient accuracy (97.5 percent). We can see that DT, Gaussian Naive Bayes, Random Forest, SVM, performed better. From the basic level, we can observe that Random Forest and DT work better than other algorithms (**Table 4**).

Based on different performance measures such as accuracy, recall, and F1 score, it is clear that the examined ML models are comparable; this is seen in the **Table 5**, SVM (Support Vector Machine) demonstrated the best accuracy when used in its optimized form (83.1 percent). Other algorithms, such as the Random Forest (RF), have demonstrated sufficient accuracy in addition to the Support Vector Machine (SVM) (80.5 percent). We can see that DT, Gaussian Naive Bayes, Random Forest, SVM, performed better. From the basic level, we can observe that Support Vector Machine and Random Forest work well than other algorithms.

From the results of this experimentation, we observe that the accuracy values for this database with all measurements are satisfactory with a disturbance sometimes the rate increases and

TABLE 6 | Comparison of the proposed work with the existing works (Frankfort Allemagne).

Algorithmes used	Data correction methods	Train/test split size	Accuracy	Reference
Random forest	The median	Test size = 0.2	91%	(21)
Gaussian process	The mean	Test size = 0.2	98.25%	(22)
DeepNN	Linear interpolation	Test size = 0.1	99.5%	(23–26)
Randomforest	k-means	Test size = 0.2	100%	Our Study
Randomforest	k-means	Test size = 0.3	97.6%	Our Study

sometimes it decreases by a small difference when changing the number of cluster as well as the random initialization of cluster centers can influence the results.

Note: After running the model several times, different results can be obtained in the same cluster number. This depends on the step of random initialization of the cluster centers.

According to the above table, the SVM model obtained the best accuracy which is equal to 83.1%. That is, among 153 attributes that were chosen for testing this model are classified 127 patients correctly. We select the SVM model as the most optimal model that works best for our dataset because it's high accuracy.

According to the above table, the Random Forest model obtained the best accuracy which is equal to 97.6%. That is, among 600 attributes that were chosen for testing this model are classified 582 patients correctly. We select the SVM model as the most optimal model that works best for our dataset because it's high accuracy.

DISCUSSION

Based on the results given in **Tables 5**, **6**, the goal of the four algorithms is to better classify future observations while reducing classification errors. it can be concluded that the suggested models are more accurate than other type 2 diabetes prediction models that have been investigated in the research indicated in these tables. When comparing the above findings, it is obvious that the notion of utilizing the k-means algorithm was successful in our work; as a consequence, we infer that improving the quality of the data enhances the outcomes. This is consistent with other studies (26–35) which shows the predictive accuracy of machine learning algorithms.

CONCLUSION

In this study, we proposed a supportive diagnosis system based on the comparison four models of prediction algorithms to predict diabetes in two different databases. On the basis of several performance assessment methodologies like as accuracy and recall, as well as the F1 score, different machine learning algorithms are compared and assessed. Using the classification results obtained, it can be concluded that the random forest machine learning technique provides more accurate prediction and higher performance than the other methods described in this study. However, when compared to other research accessible in the current literature, some of the other approaches utilized in this study, such as naive Bayes, DT and SVM, Random Forest, and others, produce the most optimum outcomes.

The main objective of this study is to help diabetologist to establish an accurate treatment routine for their diabetic patients. Due to the high accuracy and diagnose the disease in a shorter time and the rapid treatment, this study could open a window in the development of an electronic health system for diabetic patients. There are also a few aspects in this study that could be improved or expanded in the future. In perspective term:

- Creation of diabetes database for Algerian patients
- Diabetes prediction with the deep learning approach.
- Developed a solution based on an Android application in order to help people predict if they have diabetes.

Zheng Y, Wu R, Wang X and Yin C (2022) Identification of a Four-Gene Metabolic Signature to Evaluate the Prognosis of Colon Adenocarcinoma Patients. Front. Public Health 10:860381. doi: 10.3389/fpubh.2022.860381

Background: Colon adenocarcinoma (COAD) is a highly heterogeneous disease, thus making prognostic predictions uniquely challenging. Metabolic reprogramming is emerging as a novel cancer hallmark that may serve as the basis for more effective prognosis strategies.

Methods: The mRNA expression profiles and relevant clinical information of COAD patients were downloaded from public resources. The least absolute shrinkage and selection operator (LASSO) Cox regression model was exploited to establish a prognostic model, which was performed to gain risk scores for multiple genes in The Cancer Genome Atlas (TCGA) COAD patients and validated in GSE39582 cohort. A forest plot and nomogram were constructed to visualize the data. The clinical nomogram was calibrated using a calibration curve coupled with decision curve analysis (DCA). The association between the model genes' expression and six types of infiltrating immunocytes was evaluated. Apoptosis, cell cycle assays and cell transfection experiments were performed.

Results: Univariate Cox regression analysis results indicated that ten differentially expressed genes (DEGs) were related with disease-free survival (DFS) (P-value$<$ 0.01). A four-gene signature was developed to classify patients into high- and low-risk groups. And patients with high-risk exhibited obviously lower DFS in the training and validation cohorts (P $<$ 0.05). The risk score was an independent parameter of the multivariate Cox regression analyses of DFS in the training cohort (HR $>$ 1, P-value$<$ 0.001). The same findings for overall survival (OS) were obtained GO enrichment analysis revealed several metabolic pathways with significant DEGs enrichment, G1/S transition of mitotic cell cycle, CD8+ T-cells and B-cells may be significantly associated with COAD in DFS and OS. These findings demonstrate that si-FUT1 inhibited cell migration and facilitated apoptosis in COAD.

Conclusion: This research reveals that a novel metabolic gene signature could be used to evaluate the prognosis of COAD, and targeting metabolic pathways may serve as a therapeutic alternative.

Keywords: COAD, metabolic, LASSO, Cox, signature, prognostic prediction

INTRODUCTION

Metabolic reprogramming has been recognized as one of the distinguishing feature of tumor cells recently (1). Cancer metabolism is a major contributor to tumor initiation, growth, and metastasis in colorectal cancer (2).

Colon adenocarcinoma (COAD) is a primary intestinal aggressive malignancy (3). It is the third most prevalent cancer (10.0%) and is ranked second (9.4%) in cancer-related mortality worldwide (4). Further, this disease is genetically heterogeneous whose prognosis is uniquely challenging. China, with the most population in the world, is also ranked first in terms of new cases of cancer and cancer-related deaths in the world (5, 6). In China, more than 555,000 new colon and rectum cancer cases are projected to be discovered annually (4, 6). The world's cancer burden including COAD continues to increase and malignancy is quickly becoming the foremost cause of human death in this century (7). Therefore, predicting the prognosis of COAD patients and identifying new therapeutic strategies for COAD are critical.

According to previous reports, metabolism serves a vital role in the progress of COAD and some key genes such as OMA1 mediate metabolism reprogramming under hypoxia, thus facilitating colorectal cancer development by promoting the Warburg effect (8). And LINRIS stabilizes IGF2BP2 and facilitates aerobic glycolysis in COAD (9). However, the link between metabolic-related genes and the prognosis of COAD patients remains largely uncharacterized. Metabolism and expression of specific genes affect the occurrence of metabolism, making it a therapeutic potential target for the management of malignant tumor (10). Thus, it is important to gain further understanding of the underlying metabolic mechanisms of COAD tumorigenesis and progression. Further, it is needed urgently to identify new prognostic-related markers which could become therapeutic potential targets in COAD (11, 12).

First, we acquired expression profiles of mRNA and the relevant clinical features of COAD patients from open data resources in our research. We then established a multigene prognostic characteristic of COAD by metabolic-related differentially expressed genes (DEGs) in a Gene Expression Omnibus (GEO) cohort. Finally, functional enrichment analysis was performed to explain the potential mechanisms involved, after which a prognostic model was developed based on several metabolic-related genes. We consider that this prognostic model with the strong predictive power of COAD will improve prognosis risk assessment of patients with COAD and help to develop a more accurate evaluation of their clinical management.

MATERIALS AND METHODS

Publicly Available mRNA Data and Metastasis Gene Sets

An RNA-sequencing (RNA-seq) dataset and relevant clinical data of COAD patients were acquired from The Cancer Genome Atlas colon adenocarcinoma dataset (TCGA-COAD) and GEO website (GSE25071) to compare human colorectal tumors and normal colorectal tissues. The normalization of gene expression profiles was performed by the scale method provided in the "limma" package in R. We then identified DEGs though the comparison of patients with COAD with recurrent and normal humans in the GEO cohort (GSE21510 and GSE32323). A total of 566 COAD patients from the training set of the TCGA-COAD cohort and 573 COAD patients from the GSE39582 cohort used for the validation set were eventually enrolled. A list of metabolic-related genes was then gathered from the Gene Set Enrichment Analysis (GSEA, v3.0, http://software.broadinstitute.org/gsea/index.jsp) website (13) and is exhibited in **Supplementary Table 1**.

Building and Verification of a Prognostic Model of Metabolic-Related Genes

DEGs with log (|fold change|) >1 and a false discovery rate (FDR) < 0.05 between tumor tissues and adjacent non-cancerous tissues in the TCGA-COAD and GSE25071 datasets were identified by the "limma" package in R. Differences between the recurrence and normal human GEO cohorts (GSE21510 and GSE32323, respectively) were also evaluated. Univariate Cox analysis of disease-free survival (DFS) and overall survival (OS) in DEGs were carried out to identify the metabolic-related genes with prognostic significance. We utilized the log-rank test to adjust the *p*-value.

To reduce the number of genes, we used the least absolute shrinkage and selection operator (LASSO) Cox regression analysis to screen genes for DFS and OS, respectively. The input of the LASSO Cox regression analysis were the above-mentioned screened genes. The most vital value in the LASSO Cox regression analysis was λ. Using different λ values, LASSO Cox regression analysis can be utilized to screen for different genes. We used cross-validation to select the optimal λ for DFS and OS. With these λ values, the genes associated with DFS and OS were identified via LASSO Cox regression analysis, respectively. These genes were then subjected to multivariate Cox regression analysis to determine their coefficients for the prognostic models of DFS and OS, respectively. The prognostic models were represented as a risk score, which was expressed as follows:

$$\textit{Risk Score} = \sum_{i=1}^{N} \textit{Expi} \times \textit{Coefi}$$

A total of 222 patients obtained from the TCGA-COAD cohort with a DFS survival status and survival time were classified into low- and high-risk groups by the best cut-off point determined by the surv_cutpoint function in the "Survminer" package in R. We then plotted the survival curves for the risk score via the "survfit" function with the "survival" R package. We did the same for the 214 patients included in the TCGA-COAD data set who had the stages (stages I, II, and III) information of all those 222 patients, 51 patients for stage I, 147 patients for stage I and II, and 67 patients for stage III. To appraise the predictive power of the risk score, we plotted the receiver operating characteristic (ROC) and displayed the 1-, 3- and 5-year projections as function of survival ROC in the "survivalROC" R package.

Validation of the Prognostic Model as an Independent Clinical Factor

To explore the correlation of the established prognostic model with the clinical information, we carried out univariate cox regression analyses to generate risk scores and consider other clinical features including stage, sex, and age in 214 DFS patients included in the TCGA-COAD data set. Risk scores and other clinical factors were deemed statistically relevant at a *p*-value threshold of <0.05. Association between risk score levels and other clinical factors with DFS and OS were investigated by multivariate Cox proportional hazard models. The results of the multivariate Cox regression model were visualized in a combined forest plot and the same procedure was also performed in TCGA OS patients and the validation data set.

Verification of the Nomogram

A nomogram was created to forecast the DFS of patients at 1-, 3-, and 5-year survival probabilities to help doctors understand and apply the model. Then, we performed ROC analysis to gain the area under the curve (AUC) and verify the predictive effect of the model. The same procedure was performed in TCGA OS patients and the validation data set. The calibration curve of the nomogram was drawn to validate the nomogram's predictive value. The calibration curve was produced by using the calibration function in the "rms" package in R.

The decision curve analysis (DCA) results were plotted to quantify and assess the clinical value of the nomogram (14). DCA can be performed to obtain the clinical net benefit of the nomogram compared with all or none of the strategies (15).

Functional Enrichment Analysis and Cell Immune Infiltration

A comprehensive knowledge-base update to the sixth version of the original web-based programs is provided by the Database for Annotation, Visualization and Integrated Discovery (DAVID, v6.8, https://david.ncifcrf.gov/). With the comprehensive set of function annotation tools provided by DAVID, researchers can examine the biological meanings of a large set of genes. The Gene Ontology resource (GO; http://geneontology.org) provides structured, computable knowledge regarding the functions of genes and gene products (16). The knowledge of GO resource is both human-readable and machine-readable, and is a foundation for computational analysis of large-scale molecular biology and genetics experiments in biomedical research. DAVID was used to conduct GO analysis based on genes in a univariate Cox analysis of OS and DFS.

Tumor Immune Estimation Resource (TIMER; https://cistrome.shinyapps.io/timer/) is a web interactive platform and is used to analyse tumor-infiltrating immunocytes systematically. We utilized TIMER to study the correlation of genes in the risk score model and the signatures of tumor-infiltrating immunocytes in COAD. The "Gene" module was carried out to investigate the relevance between the risk score model expression and immunocyte infiltration levels specific to each gene (B-cells, neutrophils, macrophages, dendritic cells, CD4+ and CD8+ T-cells) with the TCGA database. We applied TIMER to explore the relationship between the gene expression in the risk score model and the marker gene sets of different immunocytes with the "Correlation" module. The relationship between the gene expression in the risk score model and the tumor-infiltrating immune cells were assessed by purity-correlated partial Spearman's correlation and statistical significance (17).

External Validation Using Online Databases

Hub genes in LASSO Cox were surveyed from the following online databases: (1) Oncomine database analysis. Oncomine database (https://www.oncomine.org/resource/main.html) is a tumor microarray database and online data analysis tool that collects many "multi-arrays" (18). This tool was used to determine gene expression signatures. Gene expression levels in various types of cancers were identified using the Oncomine database at a *p*-value threshold of 0.001 and a fold change threshold of 2 using gene ranking. The following conditions were used to acquire the mRNA expression level in tumor tissue compared with normal tissues: $P < 1E\text{-}4$, fold change > 2, and top gene rank 10% (19). (2) cBioPortal analysis. The cBioPortal for Cancer Genomics (http://cbioportal.org) was constructed specifically to decrease the difficulty of obtaining complex data sets and promote the translation of genomic data into novel biological knowledge, treatments, and clinical trials (20). This platform encourages the study of multidimensional tumor genomics data by supporting visualization and estimating across genes, samples, and data types. The resource allows researchers to visualize the patterns of gene alterations across samples in one tumor research, to compare the frequencies of gene alterations across multiple tumor researches, and to aggregate alterations of all related genomes in an single cancer sample. cBioPortal encompasses multiple genomic data types such as somatic mutations, DNA copy number alterations (CNAs), mRNA and microRNA (miRNA) expression, DNA methylation, protein abundance, and phosphoprotein abundance (21). (3) PrognoScan database Analysis. The PrognoScan database (http://www.abren.net/PrognoScan/) was utilized to explore the association between gene expression and survival across various types of cancers. PrognoScan was utilized to dissect the correlations between gene expression and prognosis indicators (e.g., OS and DFS) across a large number of open tumor microarray datasets. The threshold of Cox *p*-value was adjusted to <0.05 (22). (4) GEPIA database Analysis. The Gene Expression Profiling Interactive Analysis (GEPIA, http://gepia.cancer-pku.cn/) database is a developed interactive web server for analyzing the RNA sequencing expression data of tumor and normal samples from the TCGA and the GTEx projects, using a standard processing pipeline. GEPIA provides customizable functions such as tumor/normal differential expression analysis, profiling according to cancer types or pathological stages, patient survival analysis, similar gene detection, correlation analysis and dimensionality reduction analysis (23).

Apoptosis and Cycle Assay

The analysis of the previous sections indicated that FUT1 was an aberrantly expressed gene in COAD tumors and therefore high FUT1 expression could be used as a predictor of adverse

TABLE 1 | Clinical characteristics of colorectal patients.

Characteristics	TCGA (*N* = 566)	GSE39582 (*N* = 573)

IV	81 (14%)	59 (10%)

outcomes. So we examined the function of FUT1 in cell apoptosis and cell cycle and performed a flow cytometry assay. We cultured HCT-116 cells for 24 h with FUT1 and then harvested the cells. Next, Annexin V and propidium iodide (PI) were used in accordance with the manufacturer's recommendation (Beijing Solarbio, China). The apoptotic rate and cell cycle were detected using a NovoCyte flow cytometer (ACEA, Biosciences, USA) and analyzed using the NovoExpress software (ACEA, Biosciences, USA).

Cell Transfection

Cell transfection was also performed to further verify the effect of FUT1. HCT-116 cells were gained from the American Type Culture Collection. The cells were kept in Dulbecco's modified Eagle's medium (DMEM) (Gibco, USA), supplemented with 10% fetal bovine serum (FBS) (Gibco, USA), 100 μg/mL streptomycin (Gibco, USA) and 100 U/mL penicillin (Gibco, USA) in a humidified incubator with 37°C and 5% CO_2. FUT1 was silenced in HCT-116 cells by transfection with FUT1 short interfering RNA (si-FUT1). si-FUT1 and the siRNA negative control (si-NC) were purchased from Tsingke Biotech (Beijing, China). Lipofectamine 3000 (Invitrogen, Carlsbad, CA, USA) was used to carried out the transfection trials according to the manufacturer's instructions.

RESULTS

Patient Selection

A total of 566 COAD patients were selected as the training set from TCGA and 573 COAD patients were selected from the GSE39582 cohort as the validation set. The specific clinical features of the patients were listed in **Table 1**. A flow chart of our research was illustrated in **Supplementary Figure 1**.

Identifying of Prognostic Metabolic-Related DEGs in the TCGA Cohort

A total of 153 overlapping DEGs were identified between (1) tumor tissues and non-tumor adjacent tissues in TCGA and GSE20571, and (2) recurrent and normal human tissues in the GEO cohort (GSE21510 and GSE32323). A total of 62 genes were identified by matching 153 DEGs with metabolic-related genes, 21 of which were correlated with OS and 10 were correlated with DFS in the univariate Cox regression analysis ($P < 0.01$) in the training set (**Tables 2**, **3**).

Establishment of a Prognostic Model in the TCGA Cohort

We used LASSO Cox regression analysis to both the 10 DFS genes and 21 OS genes to develop prognostic models with the expression profile of the above-mentioned genes. LASSO Cox

regression analysis was used to screen four genes (CCND1, EDAR, FUT1, and PPAT) in DFS and eight genes (CCNB1, CDC6, FUT1, GPD1L, MAD2L1, MMP1, SPP1, and TKT) in OS, which acted as the input for multivariate Cox regression analysis. We obtained the coefficients of the prognostic models of both DFS and OS using multivariate Cox regression analysis (**Figures 1A,B,D,E**). Finally, prognostic models were displayed in the form of a risk score as follows:

$$\begin{aligned} \textit{Risk score of DFS} &= \mathbf{0.411228099154717} \times \textit{CCND1} \\ &+ \mathbf{0.547206032433896} \times \textit{EDAR} \\ &+ \mathbf{0.302185127495718} \times \textit{FUT1} \\ &- \mathbf{0.583673054198275} \times \textit{PPAT} \\ \textit{Risk score of OS} &= -\mathbf{0.0985300797882395} \times \textit{CCNB1} \\ &- \mathbf{0.0566241392969015} \times \textit{CDC6} \\ &+ \mathbf{0.111288163590287} \times \textit{FUT1} \\ &- \mathbf{0.144434028275748} \times \textit{GPD1L} \\ &- \mathbf{0.21174022083491} \times \textit{MAD2L1} \\ &- \mathbf{0.231299794085908} \times \textit{MMP1} \\ &+ \mathbf{0.129051446614179} \times \textit{SPP1} \\ &- \mathbf{0.140224178453846} \times \textit{TKT} \end{aligned}$$

GO term analyses were carried out to investigate the potential biological meanings of the 21 identified DFS genes and 10 OS genes. As depicted in **Figures 1C,F**, GO annotation revealed top categories that were positively correlated with metabolism in DFS such as chemokine-mediated signaling pathway, G1/S transition of mitotic cell cycle, and re-entry into mitotic cell cycle, among others. Other pathways were identified for OS including G1/S transition of mitotic cell cycle, cell division, and inflammatory response. These results indicate that GO enrichment is critically important in COAD patients and is strongly associated with metabolism, especially in the G1/S transition of the mitotic cell cycle.

The relevance between the gene expression in the risk score DFS model and six types of infiltrating immunocytes (B-cells, neutrophils, macrophages, and dendritic cells, CD4+ and CD8+ T-cells) was examined further. The DFS analysis indicated that 3/4 of the expression levels in the risk score model were obviously related with the infiltrating of B-cells, CD8+ T-cells, and macrophages (**Supplementary Figure 2**). The EDAR coefficient in the risk score of DFS was positive and EDAR expression was positively associated with the levels of B-cell and CD8+ T-cell infiltrating in COAD (**Supplementary Figure 2B**). Our analysis indicates that CD8+ T-cells and B-cells may be obviously associated with COAD.

We also investigated the correlation between the gene expression in the risk score OS model expression and 6 types of infiltrating immunocytes. The OS analysis indicated that the genes in the risk score OS model were associated with CD8+ T and B-cell infiltrating. The coefficients of FUT1 and SPP1 in the risk score of OS were positive, and FUT1 expression was critically correlated with the levels of B cell infiltrating in COAD (**Supplementary Figure 3C**). SPP1 expression was critically associated with the infiltrating degrees of CD8+ T-cells in COAD (**Supplementary Figure 3F**). Above all, we considered that CD8+ T-cells and B-cells may be obviously correlated with COAD in both DFS and OS.

Independent Prognostic Role of the Prognostic Model

Kaplan-Meier (KM) survival analysis was conducted for the risk score. The optimal risk score cut-off point in 222 DFS patients with DFS status and time records was 0.18 as illustrated in **Figure 2A**. Based on this best cut-off point, we divided the 222 DFS patients into high- and low-risk groups, the distribution of which was illustrated in **Figure 2A**. The survival curves of the 222 DFS patients under the optimal cut-off point were depicted in **Figure 2B** ($P < 0.0001$). The optimal cut-off point for the risk score in all 214 patients with stages I, II, and III was 0.13, as illustrated in **Figure 2C**. Based on this optimal cut-off point, we separated all 214 DFS patients into high- and low-risk groups, the distribution of which was depicted in **Figure 2C**. The survival curves of the 214 patients are shown in **Figure 2D** ($P < 0.0001$). The survival curves of the patients with stage I, I + II, and III are depicted in **Figures 2E–G** with $P = 0.015$, $P < 0.0001$, and $P = 0.00038$, respectively. All survival curves indicated that the risk score was an independent prognostic parameter, and the low-risk group had a favorable prognosis. As an independent prognostic parameter, the predictive performance of the risk score was represented by the ROC in **Figure 2H**. The AUCs of 1-, 3-, and 5-year predicted by the risk score were 0.779, 0.798, and 0.845, respectively. The OS results for TCGA are included in **Supplementary Figure 4**. The survival curves of DFS and OS for the validation data set are also included in the **Supplementary Figures 5**, **6**.

The Prognostic Model as an Independent Clinical Parameter

Univariate Cox regression analysis of the 214 DFS patients included in the TCGA-COAD data set indicated that sex and our prognostic model were significantly correlated. Multivariate Cox regression analysis revealed that this prognostic model was an independent prognostic parameter of DFS (**Figure 3A**). Among the 554 OS patients included in the TCGA-COAD data set, the prognostic model was also shown to be an independent prognostic parameter of OS (**Figure 3C**), which was consistent with the results from the TCGA-COAD DFS cohort. To make the proposed approach more practical for clinicians, nomograms for both DFS and OS were developed to predict survival probability (**Figures 3B,D**). The C-indices of DFS and OS were 0.786 and 0.748, separately. The results for the validation data set are included in the **Supplementary Figure 7**.

Validation of the Nomogram

The calibration curve for TCGA-COAD was plotted to validate the predictive performance of the nomogram, which was presented in **Figure 4**. The calibration curves illustrated in **Figures 4A–C** represent the 1-, 3-, and 5-year survival of DFS patients in TCGA. The x-axis suggests the nomogram prediction probabilities and the y-axis indicates the observed

shown in **Figures 5D–F**. Additionally, the DCA for the validation dataset of GSE39582 is shown in **Supplementary Figure 9**.

External Validation Using the Online Database

In the cBioportal for Cancer Genomics website, FUT1 exhibited the most frequent genetic alterations (2.9%) among the four genes of the prognostic model, with missense mutation being the most common alteration (**Figure 6A**). Consistent with our results, CCND1, FUT1, and PPAT were found to be significantly overexpressed in tumors, whereas EDAR was not significantly expressed in COAD in Oncomine (**Figure 6B**). FUT1 was also found to be significantly overexpressed in COAD tumors compared to normal tissues in the GEPIA database (23) (**Figure 6C**). Survival analyses were carried out by the GEPIA database. Patients with high FUT1 expression displayed remarkably shorter DFS and OS in GEPIA (**Figures 6D,E**); however, CCND1, EDAR, and PPAT showed no significant differences in DFS and OS (**Supplementary Figure 10**). Further, FUT1 was found to be consistent with the DFS and OS results of GSE17536 in PrognoScan (**Figures 6F,G**). Taken together, our findings indicated that FUT1 was an aberrantly expressed gene and high FUT1 expression could be used as a predictor of adverse outcomes.

si-FUT1 Inhibited Cell Migration and Induced Apoptosis in Colon Cancer Cells

A flow cytometry assay was performed to examine the effect of FUT1 on cell apoptosis and the cell cycle. Transfection with si-FUT1 significantly raised the apoptotic rate of HCT-116 cells compared with that of NC cells (**Figures 7A,B**), and significantly reduced the number of cells in the G2 phase (**Figures 7C,D**). Next, cell migration was detected using the streak method. Transfection with si-FUT1 significantly inhibited the cell migration rate of HCT-116 cells compared to that of NC cells (**Figures 7E,F**).

DISCUSSION

Metabolic reprogramming is considered as a new critical feature of malignancy (1). Some potential molecules regulating abnormal metabolism have been tested in preclinical or clinical investigations (24). The interactions between bile acids, cholesterol metabolites, and colonic epithelial cells may be relevant in colon carcinogenesis (25). Meanwhile, big data analysis is an important tool for Prediction task (26–30), and disease forecasting is a vital part of the medical research (31, 32). However, the role and mechanisms of metabolic-related genes in COAD remain unclear. The present study was thus conducted to further explore the association of metabolic genes with prognosis in patients with COAD.

Big data and machine learning algorithms have been widely used in basic and clinical medicine research, such as antlion re-sampling based deep neural network model for classification of imbalanced multimodal stroke dataset, and deep neural networks to predict diabetic retinopathy (32, 33). High-throughput multimodal massive medical data is just right for research with big data and machine learning algorithms. The blockchain-enabled internet of medical things (IoMT) can provide strong trust establishment and ensure the traceability of data sharing in the IoMT networks (34). Due to the emergence of heterogeneous IoMT, large volumes of patient data are dispatched to central cloud servers for disease analysis and diagnosis (29). Many publicly available data resources and analytical tools are available for research. Analysis methods including survival analysis, nomogram and data visualization have also been developed with corresponding R packages for researchers to use. Our work used LASSO machine learning algorithms as survival analysis and

prediction tool. Multiple data sources and analytical tools in a way that leverages data from previous studies and yields valuable results even when clinical trials are not yet readily available. As more data resources and analysis tools are developed, we believe that big data and machine learning algorithms will be more widely used in medical research.

In our research, we comprehensively probed the expression of 62 metabolic genes in COAD tumor tissues and the relationships between recurrent patients and DFS and OS. A new prognostic model including four metabolic genes associated with DFS was first established based on the TCGA dataset and validated using the GSE39582 dataset. The validity of the novel signature was shown in the training, validating, and stage subgroups. The signature exhibited a robust prognostic capacity, especially for the short-term survival of patients with COAD. Besides, the OS of patients with high-risk was shorter than that of patients with low-risk in the TNM stage. Multivariate Cox regression analysis indicated that our prognostic model was an independent prognostic parameter for DFS and OS (HR $>$ 1, $P < 0.001$). ROC curve analysis verified the predictive power of the features. Additionally, the forest plot suggested that the risk score was an independent parameter in the multivariate Cox regression analyses. Moreover, a nomogram was built to predict 1-, 3-, and 5-year DFS rates. The efficacy of the nomogram was verified in validation cohorts, and the calibration plots and DCA showed that the precision of the nomogram was good. Therefore, our nomogram may provide simple and accurate prognostic predictions for COAD.

In the cBioportal for Cancer Genomics website, FUT1 possessed the most frequent genetic alterations (2.9%) among the four genes of the prognostic model. FUT1 was also found to be obviously overexpressed at the mRNA level in COAD tumors compared to normal tissues in the GEPIA database (**Figure 6C**). Patients with high FUT1 expression displayed remarkably shorter DFS and OS in the GEPIA to low FUT1 expression (**Figures 6D,E**). Moreover, the FUT1 results were consistent with the DFS and OS results in GSE17536 in PrognoScan (**Figures 6F,G**). Taken together, our findings indicated that FUT1 was an aberrantly expressed gene and therefore high FUT1 expression could be used as a predictor of adverse outcomes.

FUT1 encodes a Golgi stack membrane protein that participates in the synthesis of a precursor of the H antigen. Gene expression profiling analysis unexpectedly showed a significant number of up- and down-regulated metabolism-associated FUT1 genes in nasopharyngeal carcinoma (35). Additionally, FUT1 plays an important role in a regulatory mechanism involving fucosylation through which glucose restriction promotes cancer stemness to drive tumor recurrence and drug resistance. FUT1 overexpression is a poor prognostic indicator of hepatocellular carcinoma (36). We also examined the function of FUT1 in cell apoptosis and cell cycle and performed a flow cytometry assay. Transfection with si-FUT1 significantly raised the apoptotic rate of HCT-116 cells and obviously reduced the number of cells in the G2 phase while also significantly inhibiting the cell migration rate of HCT-116 cells compared to that of NC cells. Therefore, si-FUT1 inhibited cell migration and induced apoptosis in colon cancer cells. FUT1 overexpression may thus be a new prognostic marker and therapeutic target of COAD tumors.

Functional analyses also revealed enriched metabolism-related pathways. The top categories were critically important in COAD patients and strongly associated with metabolism, particularly the G1/S transition of the mitotic cell cycle. Correlation analysis between the genes in the risk score DFS model expression and six types of infiltrating immunocytes suggested that CD8+ T-cells and B-cells may be significantly related with COAD in both DFS and OS.

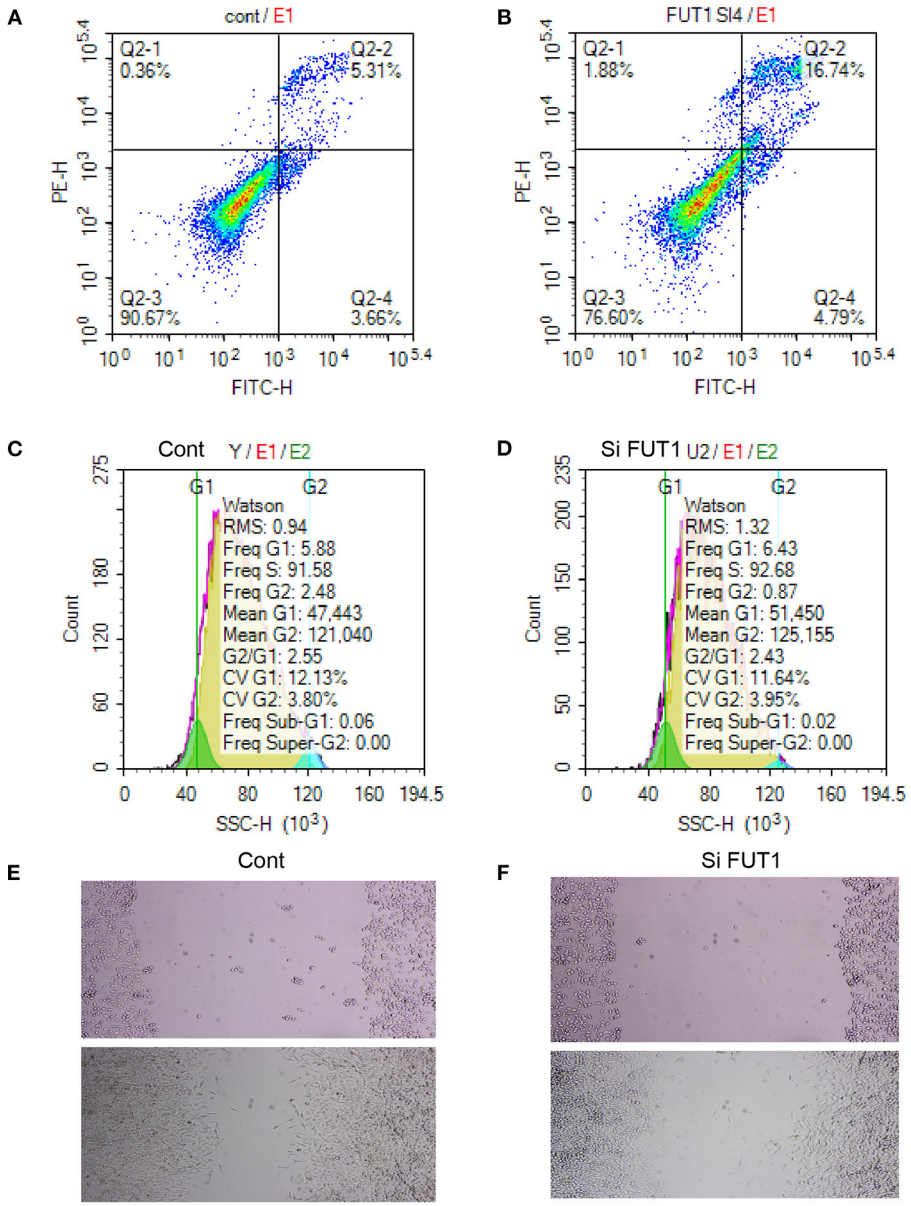

FIGURE 7 | Apoptosis and cycle assay and cell transfection experiment. **(A)** Flow cytometry assay in NC cells. **(B)** Flow cytometry assay in HCT-116 cells. **(C)** Cell cycle in NC cells. **(D)** Cell cycle in HCT-116 cells. **(E)** Cell migration in NC cells. **(F)** Cell migration in HCT-116 cells.

Immunocytes are essential ingredients of the tumor microenvironment. These immunocytes differentiate into subsets with distinct effects, and metabolic reprogramming participates in this process (37). These immunocytes in the tumor microenvironment have metabolic characteristics that differ from those in non-tumor tissues (38). OS was dramatically worse in patients with low levels of CD8+ T-cell infiltrating than those with high levels of CD8+ T-cell infiltrating. The survival rate in patients with high CD8+ T cell infiltrating was 100%. Peritumoral CD8+ T-cell infiltration has an anti-tumor effect in patients with colorectal cancer (39). CD8+ T cell expansion and function rely on glycolysis; however, the mechanisms underlying CD8+ T cell metabolism remain unclear (40). We previously demonstrated that increasing B-cell a infiltrating, clonal expansion, and mutational frequency from the cecum to the sigmoid colon were linked to an increasing number of reactive bacterial species (41). Numerous B-cell clones distribute into two broad networks: one includes the blood, bone marrow, spleen, and lung, whereas the other is distributed to digestive tract, including colorectal tissues (42). B-cell clonal lineages is a basis for investigations on tissue-based immunity, including infection, vaccine response, autoimmunity, and tumor (42). Metabolic reprogramming of tumor cells and the tumor microenvironment are up-and-coming as essential characteristics affecting tumor development, metastasis, and response to treatments (43). A better understanding of

metabolic communications among tumor cells, intestinal flora, and immunocyte populations will open new ways for identifying strategies to boost anti-tumoral immune responses in COAD patients.

Although our work has yielded many meaningful results through bioinformatics methods, these results still need to be further validated by preclinical studies and clinical trials. The use of numerous data sources and analytical tools also makes it more difficult to understand the research process and results. The interpretation of the results of big data studies is also an area prone to controversy. Therefore, there is still work to be done in predicting the prognosis of patients with COAD. For example, more patients and clinical characteristics of patients should be included in further studies.

CONCLUSIONS

In summary, we identified a novel signature comprised of four metabolic genes that could precisely predict the prognosis of patients with COAD. Metabolic-related signatures may have a potential role in the anti-tumor process and serve as therapeutic targets for COAD.

DATA AVAILABILITY STATEMENT

Agricultural is an indispensably public healthcare industry for human beings at any time and smart management of it is of great significance. Since substantial technical advance relies on long-term efforts and continuous progress, reasonably scheduling the distribution of agricultural products acts as a key aspect of smart public healthcare. The most intuitive factor affecting the distribution of agricultural products is its dynamic price. Forecasting price fluctuations in advance can optimize the distribution of agricultural products and pave the way to smart public healthcare. Most researchers study the prices of various agricultural products separately, without considering the interaction of different agricultural products in the time dimension. This study introduces a typical deep learning model named graph neural network (GNN) for this purpose and proposes deep data analysis-based agricultural products management for smart public healthcare (named GNN-APM for short). The highlight of GNN-APM is to take latent correlations among multiple types of agricultural products into consideration when modeling evolving rules of price sequences. A case study is set up with the use of real-world data of the agricultural products market. Simulative results reveal that the designed GNN-APM functions well.

1. INTRODUCTION

Since ancient times, agriculture has been a life industry for human survival, which is closely related to the most basic life guarantee of human beings. At present, food shortage is one of the most important problems faced by many regions in the world (1). This phenomenon is generally reflected in two aspects (2). For one thing, there is still room for improvement in current agricultural technology, which makes grain yield fail to meet the expectations (3). For another, due to the lack of scientific management and scheduling strategy, the production of agricultural products is not reasonable (4). The exploration of advanced agricultural technology has lasted for at least a 100 years, and some technological breakthroughs have been made in some key fields (5, 6). However, this process exerts an imperceptible influence as we all know, which needs to be accumulated over a long period of time to make progress (7). The use of advanced computing technology to manage the agricultural products market can improve the distribution and dispatch efficiency of global agricultural products to a certain extent (8), and then alleviate the problem of food shortage (9). The key to improving management efficiency is to forecast the market conditions of several major types

of agricultural products (10). To realize such a goal, data-driven methods are the most intuitive ways (11, 12).

Rationalizing the distribution of agricultural products is an important aspect of smart public healthcare. Predicting price fluctuations in advance can optimize the layout of agricultural products and pave the way for smart public healthcare. Many scholars have studied the agricultural products market in recent years (13–32). For example, Fan et al. (14) analyzed the value-added mechanism of agricultural products circulation value chain and put forward three optimization methods of agricultural products organization mode. These existing researches are mainly realized through the research methods of social sciences. Their analyses focus on the mechanism of social development and evolution but have to deal with large-scale computational tasks in a manual way. Without the assistance of intelligent computing, these methods are always faced with certain limitations. There are also some scholars who use intelligent computing methods to solve this problem. They regard the forecasting problem of the future agricultural products market as a time series forecasting problem based on historical data. However, most of them just treat different agricultural products as independent categories and then build time series prediction models separately. In this way, potential relationships between categories are ignored, so that the precision of the modeling process is reduced.

In order to solve the above challenges, a graph neural network (GNN) can be used to model this time series prediction problem (33). Different from the traditional model that deals with grid-structured data, GNN deals with the data of topological structure. GNN is based on deep learning (34) and is widely used in various fields due to its good performance and interpretability (35). It can deeply perceive the relationship between entities in the process of modeling by graph-structured data. Vertexes and edges connecting vertexes together constitute graph structure. The vertexes are object entities, and the edges are the specific relationship between the entities. Specifically, several common agricultural products can be regarded as entities, and the correlation between them can be regarded as edges, which together constitute a kind of graph network. By introducing a neural computing structure, a GNN model for time series prediction can be constructed. Therefore, this study designs a graph neural network-based smart management for the agricultural products market (GNN-APM). The main highlights of this article can be summed up as follows:

- The internal complexity of agricultural products systems is investigated for further management.
- The GNN is employed to construct a time-series price prediction method for agricultural products systems.
- A case study is carried out to evaluate the performance of the proposed method on real-world scenes.

2. SYSTEM MODEL

The left part of **Figure 1** illustrates the learning and training process inside GNN-APM. First, the feature space of different types of agricultural products is coded into vectorized representations. Then a prediction model is obtained by learning the data samples. As a necessity in our life, agricultural products have a strong correlation among various categories, and these correlations are very meaningful and worth exploring further. The complex interrelation between different categories affects their demand to a great extent. The introduction of the GNN model deeply excavates the correlation between different categories of agricultural products and builds a graph structure with agricultural products as the entity. Through analysis, the market conditions of agricultural products can be predicted and further intelligent management of public health can be realized.

Generalized to the problem scenario in this study, there are several types of agricultural products whose market conditions need to be forecasted. The learning algorithm of GNN-APM is shown in **Algorithm 1**. Types of agricultural products are viewed as the set of nodes, and their internal relations are regarded as the set of edges. Market conditions of agricultural products refer to the average market price in this research and will be updated temporally. Each time that the market condition is updated, is defined as a timestamp t which ranges from 1 to M. During each timestamp, market conditions of all the agricultural types are denoted as $V_i^{(t)}$, where i is the index number of agricultural products types. Inputting market conditions data of M timestamps, the main goal is to predict unknown market conditions data of following timestamps. Obviously, internal relations among nodes are likely to influence the tendency of market conditions. Thus, a relationship-aware sequential forecasting problem is formulated, and the GNN model is adopted to deal with such a problem.

3. METHODOLOGY

Graph convolution network (GCN), a typical GNN model, is utilized here to model correlated sample space. The GCN extends the convolution operation to non-Euclidean data with graph

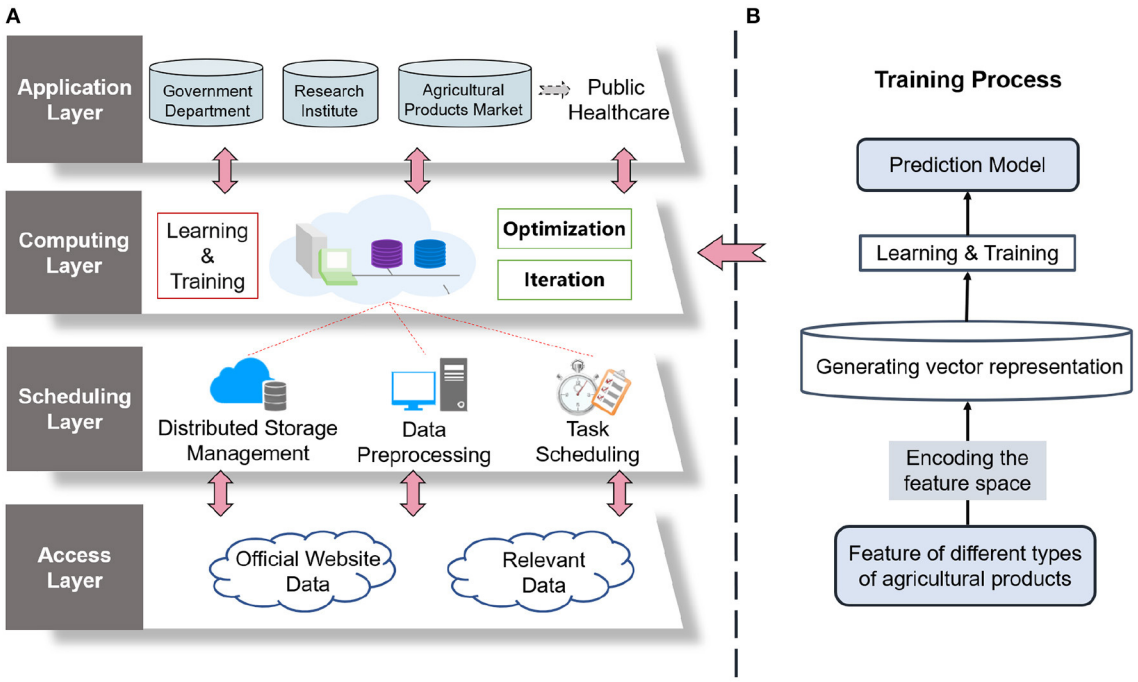

FIGURE 1 | System model and overview of the designed graph neural network-based smart management for agricultural products market (GNN-APM). **(A)** architecture and **(B)** training process in computing layer.

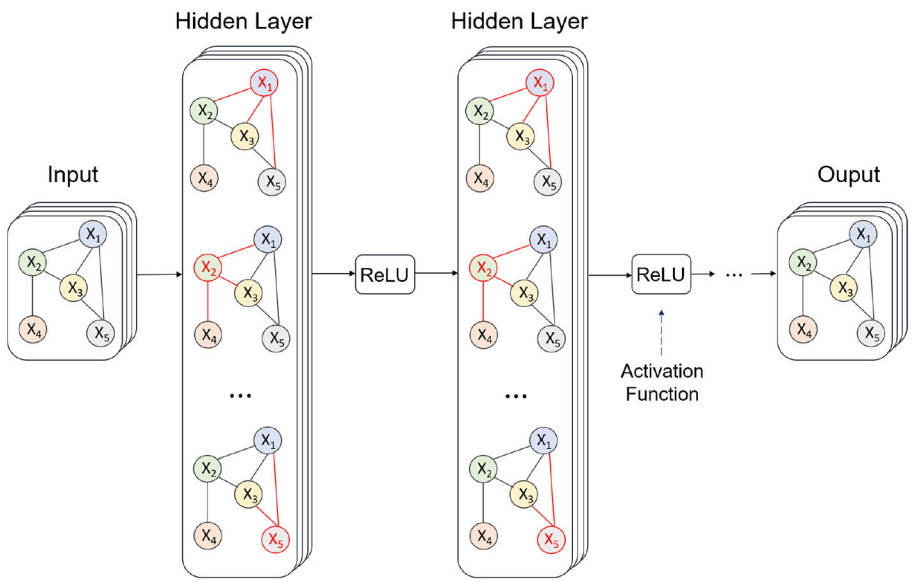

FIGURE 2 | Workflow of the graph convolutional network employed for prediction.

structure. It is a deep learning method for graph structured data. Graph data can naturally represent data structures in real life, such as traffic networks, communication networks, and social networks. In other words, it is the way to represent this kind of data format. Unlike image and text data, graph data has different local structures for each node. This is because the nodes in the graph represent the different entities in the network, and the edges that connect the nodes represent the relationships between the entities.

As is shown in **Figure 2**, taking graph structure as input, GCN obtains new node representation through graph convolution operation on neighbor nodes of each node in the graph. Then,

all nodes are pooled to obtain the representation of the whole graph. In particular, an undirected graph with nodes is defined as $G(V, E)$, where V is the number of nodes and E is the edge between two nodes. Enumerating i from 1 to N, v_i constitutes the node set V. Let j denote the index number of nodes different from node i, edge e_{ij} constitutes all the edges between pairs of nodes. Additionally, all the edge states inside graph G are able to make up an adjacency matrix A.

There are two kinds of GCN methods: spectral method and spatial method. Spectral CNN is the first method to construct a convolutional neural network on the graph. This method uses the convolution theorem on the graph to define graph convolution from the spectral domain. Specifically, it uses the convolution theorem to define the graph convolution operator in each layer. Under the guidance of the loss function, it learns the convolution kernel by gradient backpropagation and builds neural networks by stacking multiple layers. The spectral method is more general in most time-series prediction problems and is selected as the main technique of this study.

The spectral GCN method derives from the Fourier transform (FT) theory which can transform signals of the time domain into signals of the frequency domain. After such transformation, complicated convolution operations of the time domain can be approximated as multiplication operations of the frequency domain. The FT and inverse Fourier transform (IFT) are defined as follows:

$$\hat{x} = FT(x) = U^T x \tag{1}$$

$$x = IFT(x) = U\hat{x} \tag{2}$$

where U is the eigenvector that approximates the FT to matrix computation. Thus, the graph convolution operation is defined as follows:

$$x \otimes_G g = U\left(U^T x \odot U^T g\right) \tag{3}$$

where x is the input, $\otimes_G$ is the graph convolution operator, g is the core, and $\odot$ is the harmand product operator. Introducing Laplacian eigenvector as a basis function, the input signal can be expanded as:

$$x\begin{bmatrix} x(1) \\ x(2) \\ \vdots \\ x(\gamma) \end{bmatrix} = \left(u_1, u_2, \cdots, u_\gamma\right)\begin{bmatrix} \hat{x}(1) \\ \hat{x}(2) \\ \vdots \\ \hat{x}(\gamma) \end{bmatrix} \tag{4}$$

Expanding g with matrix forms and then substituting Equation (4) into Equation (3), the following formula can be deduced:

$$x \otimes_G g = U\begin{bmatrix} \hat{g}(\lambda_1) & & \\ & \ddots & \\ & & \hat{g}\left(\lambda_\gamma\right) \end{bmatrix} \tag{5}$$

Letting $Chev(\lambda_1)$ denote first-order Chebyshev polynomials of λ_1, the convolution operator g can be approximated as:

$$g_\theta = U\begin{bmatrix} Chev(\lambda_1) & & \\ & \ddots & \\ & & Chev\left(\lambda_\gamma\right) \end{bmatrix} \tag{6}$$

Among, the $Chev\left(\lambda_\gamma\right)$ can be represented as:

$$Chev\left(\lambda_\gamma\right) = \xi_0 \Gamma_0\left(\lambda_\gamma\right) + \xi_1 \Gamma_1\left(\lambda_\gamma\right) \tag{7}$$

Hence, Equation (5) can be rewritten as the following formula:

$$x \otimes_G g = \left[\alpha_0 - \alpha_1\left(E^{-\frac{1}{2}} \cdot A \cdot E^{-\frac{1}{2}}\right)\right]x \tag{8}$$

where E is the degree matrix, and α_0 and α_1 are parameters to be learned. For simplicity, it is supposed to set $\alpha_0 = \alpha_1 = -\theta$. Therefore, the above equation can be rewritten as:

$$x \otimes_G g = \left[\theta\left(E^{-\frac{1}{2}} \cdot A \cdot E^{-\frac{1}{2}} + D_\eta\right)\right] \tag{9}$$

In order to facilitate searching for optimum, renormalization operation is conducted on the above formula:

$$E^{-\frac{1}{2}} \cdot A \cdot E^{-\frac{1}{2}} + D_\eta \approx E^{-\frac{1}{2}} \cdot \tilde{A} \cdot E^{-\frac{1}{2}} \tag{10}$$

$$\tilde{A} \approx A + D_\eta \tag{11}$$

$$\tilde{E}_{ij} \approx \sum_i \tilde{A}_{ij} \tag{12}$$

where $\tilde{E}_{ij}$ is the degree matrix of the i-th node, and $\sum_i \tilde{A}_{ij}$ is the number of edges between the i-th node and other nodes. The final expression of graph convolution operation can be represented as:

$$x \otimes_G g = \theta\left(E^{-\frac{1}{2}} \cdot \tilde{A} \cdot E^{-\frac{1}{2}}\right)x \tag{13}$$

At the t-th timestamp, the main input is related to the outputs of the previous several timestamps and the relation status among nodes. For the i-th node, its information state at the t-th timestamp can be represented as the following formula:

$$S_i^{(t)} = \beta \cdot O_i^{(t)} \cdot W_{S1} + (1 - \beta) \cdot a_i \cdot W_{S2} \tag{14}$$

where $O_i^{(t)}$ is a vector that records output values at previous several timestamps, a_i is a vector that records relation status between the i-th node and other nodes, β is a tuning parameter that adjusts the weight of two parts in Equation (14), and W_{S1} and W_{S2} are parameters to be learned. It is widely known that the internal of GCN is the information propagation process, as GCN emphasizes modeling of various dynamic or static relations. Accordingly, the representative vectors for node status can be also

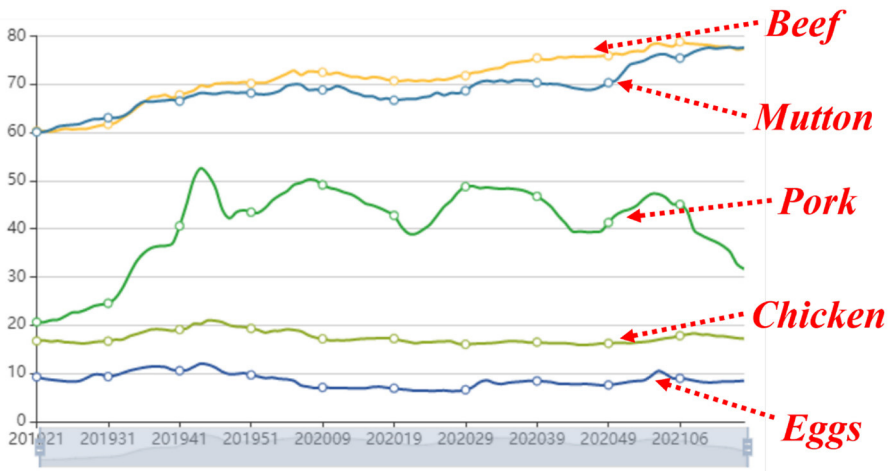

FIGURE 3 | The total tendency of market conditions concerning five types of agricultural products.

propagated to the following timestamps, which can be expressed as the following formula:

$$S_i^{(t+1)} = \sigma_1\left[\tilde{E}^{-\frac{1}{2}} \cdot S_i^{(t)} \cdot \tilde{E}^{-\frac{1}{2}} \cdot W_{S3} + b_{S1}\right] \tag{15}$$

where W_{S3} and b_{S1} are parameters, and $\sigma_1(\cdot)$ is the Reluctant Unit activation function represented as follows:

$$\sigma_1(x) = \begin{cases} 0, & x \leq 0 \\ x, & x > 0 \end{cases} \tag{16}$$

Hence, the prediction result at the t-th timestamp can be calculated as the following formula:

$$V_i^{(t)} = \sigma_1\left[S_i^{(t)} \cdot W_{S4} + b_{S2}\right] \tag{17}$$

where W_{S4} and b_{S2} are parameters. As for training, the following optimization objective can be formulated to search for the optimal parameters:

$$\min \sum_{i=1}^{N}\sum_{t=1}^{M}\left[\left\|V^{(t)} - \hat{V}^{(t)}\right\| + p \cdot \|\Theta\|_F^2\right] \tag{18}$$

where $V^{(t)}$ is the predicted result at the t-th timestamp, $\hat{V}^{(t)}$ is the real result at the t-th timestamp, Θ is the parameter set, p is the penalty parameter, and $\|\cdot\|_F^2$ is the Frobenius norm. Finally, the Adam optimization algorithm can be utilized to search optimal solution for Equation 18.

4. SETTING OF CASE STUDY

To evaluate the GNN-APM designed in this study, real-world data is used here to set a simulative analysis situation. The real-world data was crawled from the official website of the Ministry of agriculture of China [1], including the market data of several key agricultural products from April 2019 to March 2021. The data demonstrates the average market price of agricultural products wholesale and contains five types of agricultural products. Market condition data for these agricultural products are updated once a week, and there are totally 96 weeks of data concerning the five types of agricultural products. Of all the five types of agricultural products, there are 10 kinds of node combinations, indicating 10 kinds of edges among these nodes. In other words, the adjacency matrix in this situation is a matrix with five columns and five lines, representing relation status between every two combinations of nodes.

During each round of simulations, these 10 groups of relations are randomly generated according to a Gaussian distribution whose mean is set to 0.5 and variance is set to 0.05. As for the ratio between training data and testing data, it is majorly set to 7:3 and 6:4. To quantify the error between prediction results and real results, two typical metrics are selected. They are mean absolute error (MAE) and root mean squared error (RMSE). In addition, two general prediction models are employed as baseline methods for comparison. Different from the designed GNN-APM in this study, the two baseline methods never take internal correlations among nodes into consideration. The two methods are the long short-term memory (LSTM) model and the multi-layer perceptron (MLP) model.

5. RESULTS AND ANALYSIS

In this study, the whole simulative experiments are composed of three parts. First, the fluctuation tendency of the involved five agricultural product types is visualized using a curve diagram. Second, the prediction efficiency of the GNN-APM on five objects is compared with two baseline methods. Third, the

The bold values correspond to results of the proposed GNN-APM method.

robustness of the GNN-APM is tested by changing several parameter combinations.

5.1. Data Pre-processing

Figure 3 visualizes the total tendency of market conditions for five types of agricultural products. It can be observed from the figure that five curves from the bottom to the top correspond to eggs, chicken, pork, mutton, and beef. During a long period about nearly 2 years, eggs and chicken remain relatively stable, mutton and beef show an ascending tendency, and the pork fluctuates frequently. These five types of agricultural products possess their own fluctuation tendencies and satisfy the assumption of diversity. And it can be also seen that the fluctuation tendency of pork has some effect on the other four types of agricultural products. Thus, the assumption that correlations exist among these types of agricultural products is reasonable.

5.2. Performance Assessment

Tables 1, **2**, respectively give MAE results and RMSE results of these experimental methods when the proportion of training data ranges from 50 to 70% and the learning rate ranges from 0.001 to 0.002. Each of them has five lines and seven rows. The first two lines list the experimental setting, and the other lines present the experimental results of three methods. The first row lists three experimental methods, the second to the fourth rows present results under a learning rate of 0.001, the fifth to the seventh rows present results under a learning rate of 0.002. It can be observed from the two tables that MAE results and RMSE results of GNN-APM are below two other baseline methods, regardless of the proportion of training data and learning rate. This demonstrates that the performance of the GNN-APM is better than baseline methods.

Figures 4, **5** illustrates prediction efficiency with respect to using two metrics: MAE and RMSE. As there are totally five types of agricultural products involved, the MAE results and RMSE results are obtained as the mean value of prediction results on the five types. This figure has two subfigures, corresponding to MAE results and RMSE results. Among them, **Figure 4** is the curve diagram and **Figure 5** is the bar diagram. For the former, the X-axis demonstrates three kinds of training sizes and the Y-axis demonstrates values of MAE results. For the latter, only the two most typical training sizes are utilized for evaluation. Thus, it has two clusters of bars, corresponding to RMSE results under two training sizes. It is clearly observed that the GNN-APM is always endowed with better prediction efficiency compared with baseline methods. To sum up, this group of simulative experiments well demonstrates the good performance of the designed GNN-APM.

In order to visualize the tendency of MAE results and RMSE results under different experimental settings, some of the results are illustrated with the use of curve diagrams or bar diagrams. **Figure 4** illustrates the MAE results of three methods under two different learning rate values: 0.001 and 0.002. It has two subfigures that correspond to results about two learning rate values. In each subfigure, the X-axis denotes the proportion of training data ranging from 50 to 70%, and the Y-axis denotes values of MAE results. **Figure 5** illustrates RMSE results of three methods when the training data size is set to 60 and 70%. This is because it can be seen from previous experiments that result under the two training data sizes are relatively better. It has two subfigures that correspond to two learning rate values. In each subfigure, the X-axis denotes two training sizes, and the Y-axis denotes values of RMSE results. It can be observed from these figures that values of GNN-APM are obviously below the other two methods and that values show descending tendency when the proportion of training data increases. Such results demonstrate the improvement process of methods with being trained more sufficiently. These figures show a better performance tendency of GNN-APM compared with two other baseline methods.

5.3. Parameter Sensitivity

Besides, it is also expected to explore parameter sensitivity of the GNN-APM, and relevant simulative results are illustrated in **Figure 6**. During this group of experiments, the GNN-APM is not compared with baseline methods and just performance of itself is explored. **Figure 6** has two subfigures, corresponding to sensitivity results using two different metrics: MAE and RMSE. Inside each subfigure, the X-axis denotes the change of learning rate, and the Y-axis denotes the change of training size. In the middle square area, the color depth indicates the different values of evaluation metrics. As the two subfigures are heatmaps, the color depth degree inside figures is able to indicate values of metrics. Each subfigure includes a squared area, gentle color change inside it indicates that the performance of GNN-APM fluctuates not heavily. It can be objectively found that color fluctuation in both two subfigures seems quite gentle, revealing that the GNN-APM is not susceptible to parameter change. In other words, the GNN-APM is always able to remain stable, no matter how the key parameters change. This group of simulative results well prove that the GNN-APM possesses proper robustness.

6. CONCLUSION

Agriculture has been viewed as the most fundamental industry since ancient times. Nowadays, E-commerce is an important sales channel of agricultural products. To better manage and schedule the supply of agricultural products, dynamic price prediction for agricultural products in the E-commerce market is of great significance. To overcome the shortcomings of

existing research studies, this article proposes a deep learning-based price prediction model for agricultural products in the E-commerce market. In particular, the most typical GCN is utilized to establish a time-series prediction model for the dynamic price of agricultural products. In addition, the whole simulative experiments are composed of three parts. First, the fluctuation tendency of the involved five agricultural product types is visualized using a curve diagram. Second, the prediction efficiency of the GNN-APM on five objects is compared with two baseline methods. Third, the robustness of the GNN-APM is tested by changing several parameter combinations.

Nowadays, data mining and data management for many industries are gradually approaching the application of the Internet of Things (IoT), yielding such as mobile IoT (36, 37), financial IoT, medical IoT (38), cloud-assisted IoT (39), vehicular IoT (40), and industrial IoT (41, 42). As is known to all, the IoT is a kind of effective tool or platform to integrate multi-domain data and schedule business flows. To realize more effective scheduling management of the agricultural product market, designing an integrated microservice IoT platform that is embedded with robust artificial intelligence algorithms (43), is in urgent demand to deal with many disturbing issues in various industries. Thus, for future outlook, the authors plan to deeply investigate optimal scheduling and management schemes for the agricultural product market with the use of novel IoT-related technologies.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found at: http://www.moa.gov.cn/.

To avoid the problems of relative overlap and low signal-to-noise ratio (SNR) of segmented three-dimensional (3D) multimodal medical images, which limit the effect of medical image diagnosis, a 3D multimodal medical image segmentation algorithm using reinforcement learning and big data analytics is proposed. Bayesian maximum a posteriori estimation method and improved wavelet threshold function are used to design wavelet shrinkage algorithm to remove high-frequency signal component noise in wavelet domain. The low-frequency signal component is processed by bilateral filtering and the inverse wavelet transform is used to denoise the 3D multimodal medical image. An end-to-end DRD U-Net model based on deep reinforcement learning is constructed. The feature extraction capacity of denoised image segmentation is increased by changing the convolution layer in the traditional reinforcement learning model to the residual module and introducing the multiscale context feature extraction module. The 3D multimodal medical image segmentation is done using the reward and punishment mechanism in the deep learning reinforcement algorithm. In order to verify the effectiveness of 3D multimodal medical image segmentation algorithm, the LIDC-IDRI data set, the SCR data set, and the DeepLesion data set are selected as the experimental data set of this article. The results demonstrate that the algorithm's segmentation effect is effective. When the number of iterations is increased to 250, the structural similarity reaches 98%, the SNR is always maintained between 55 and 60 dB, the training loss is modest, relative overlap and accuracy all exceed 95%, and the overall segmentation performance is superior. Readers will understand how deep reinforcement learning and big data analytics test the effectiveness of 3D multimodal medical image segmentation algorithm.

INTRODUCTION

In current medical practice, medical images such as MRI image, CT image, and ultrasonic imaging are important diagnostic basis for diagnosing patients' physical conditions. Doctors or researchers analyze the tissues and organs in the human body through the medical image, obtain the relevant information of the tissues and organs in the human body according to the medical image, and carry out treatment planning in combination with medical knowledge. Therefore, medical image has become an indispensable part of disease diagnosis and treatment and quality. Medical image segmentation is not only a prerequisite for computer-aided diagnosis and many medical image applications, but also an important stage of medical image visual analysis (1, 2). Image segmentation of medical image can help to directly obtain the contour of the target by identifying the target of interest. In diagnosis, it is convenient for doctors to obtain the patient's condition information (3). With the development of medicine, medical images have been continuously optimized to gradually form three-dimensional (3D) multimodal medical images, which make medical images clearer and have higher resolution (4, 5). In order to effectively distinguish the pathological region from the normal region in medical image and enable doctors to diagnose and treat more intuitively, the segmentation of 3D multimodal medical image has become the focus of current research. However, in practical application, the factors such as image device, organ position, and shape still hinder the high-precision segmentation of medical image. The traditional image segmentation algorithm is difficult to overcome the influence of many factors and the effect of segmented medical image is poor.

At present, with the continuous improvement of science and technology, deep reinforcement learning technology has been applied in a large number of fields because this technology has high feature extraction ability. Compared with the traditional segmentation algorithm, it has obvious advantages and is widely used in the process of image segmentation (6). Therefore, a 3D multimodal medical image segmentation algorithm using deep reinforcement learning is proposed in this article. The image segmentation is performed by constructing a deep reinforcement learning model. The main contributions of this article are as follows: (1) We combine wavelet denoising with bilateral filtering to realize 3D multimodal medical image denoising. According to the traditional wavelet denoising method, Bayesian maximum a posteriori estimation method is used to realize wavelet shrinkage and combined with bilateral filter to improve the denoising performance of image; (2) The extended convolution is added and two-dimensional convolution is introduced to improve the receptive field and ensure that comprehensive context information can be obtained during segmentation; and (3) In deep reinforcement learning, the residual network is introduced to make the segmentation results more accurate and improve the training speed of deep reinforcement learning. Using the introduced residual structure, the feature extraction performance of the network can be improved.

RELATED WORKS

Many scholars have studied the related problems of medical image segmentation. Literature (7) studied medical image segmentation based on spatial constraints and fuzzy spatial segmentation. By analyzing the image edge position, the realization of spatial constraints and complete medical image segmentation were determined. However, the algorithm is only suitable for fuzzy and uncertain medical image processing. When it is used for 3D multimodal medical image, the segmentation performance of the algorithm is poor. Literature (8) studied the weakly supervised retinal vascular segmentation algorithm and used the hierarchical clustering algorithm to classify the vascular and non-vascular pixels. Moreover, the classification results based on the driving database were used as the basic facts to train the neural network. By calculating and comparing the image feature differences between the target domain data and the source domain data extracted from the network, the data required for training were extended based on semi-supervised clustering to realize retinal vessel segmentation. The algorithm can make pixels highly reliable, but the algorithm can improve the segmentation accuracy of retinal vessels, but its segmentation effect is poor. Literature (9) studied the automatic segmentation of lung tumors in CT images based on multiresolution residual connected feature flow. Incremental and dense multiresolution residual connected networks were used to detect and segment lung tumors by combining the features of multiple image resolutions and feature levels. The algorithm can effectively improve the image dimension in the segmentation process, but the segmentation operation can only be realized according to the feature flow, so the segmentation quality factor is poor. Literature (10) studied image segmentation combining image weighting and transfer learning and used kernel learning as a method to reduce the difference between training and test data, so as to enhance the performance of image segmentation through continuous learning and training. However, the algorithm does not consider the multimodality of 3D image in the segmentation process, so the definition is poor. Literature (11) studied Pulse Coupled Neural Networks (PCNN) medical image segmentation based on multifeature gray wolf optimized bionic algorithm and used image multifeatures to realize segmentation. However, the algorithm has poor structural similarity between training and actual segmentation, cannot completely realize segmentation, and the signal-to-noise ratio (SNR) is low, resulting in more noise points in the image. Literature (12) studied medical image segmentation based on dice score and the Jaccard index and the relationship within the measurement sensitive loss function group from a theoretical point of view. Moreover, the existence of the optimal weighting scheme of weighted cross entropy was questioned to optimize the dice score and the Jaccard index during the test and realize medical image segmentation through dice score and the Jaccard index. This method optimized medical image segmentation to some extent, but it did not denoise the image, so the effect of medical image segmentation is poor. Literature (13) studied medical image segmentation based on context feedback loop and expressed the segmentation

problem as a recursive framework by using two systems. The first is the forward system of encoder-decoder convolutional neural network, which predicts the segmentation results from the input image. The predicted forward system probability output is encoded by a context feedback system based on a complete convolution network. Then, the coding feature space of the complete convolution network is integrated back into the feedforward learning process of the forward system. This method uses the context feedback loop based on complete convolution network and the forward system can learn and extract more advanced image features. Moreover, it fixes the previous errors and improves the segmentation accuracy over time. This method can effectively improve the segmentation accuracy, but it does not denoise the collected medical image, so that the segmentation quality factor is low.

In the process of image segmentation by the above methods, the analysis of influencing factors in the process of image segmentation is not comprehensive, resulting in low relative overlap and signal-to-noise ratio of image segmentation 3D multimodal medical image. Therefore, this article studies the 3D multimodal medical image segmentation algorithm based on deep reinforcement learning and uses wavelet algorithm and bilateral filter to denoise the image to make the image clearer. Then, a deep reinforcement learning model is constructed to realize multimodal medical image segmentation by combining residual structure and dilated residual and deeply supervised U-Net (DRD U-Net) convolution model. The performance of the proposed algorithm is verified by experiments.

METHODOLOGY

Medical Image Denoising of Three-Dimensional Multimodal Based on Wavelet and Bilateral Filtering

Combined with wavelet denoising and bilateral filtering, 3D multimodal medical image denoising is realized. According to the traditional wavelet denoising method, Bayesian maximum a posteriori estimation method is used to realize wavelet shrinkage and combined with bilateral filter to improve the denoising performance of image.

Setting of Wavelet Threshold Function

In order to realize the accurate segmentation of medical image segmentation, it is necessary to denoise the image. In this article, the wavelet threshold function is set to provide the prerequisite for image denoising. The calculation formula of wavelet shrinkage threshold function is constructed $T = \sigma_N\sqrt{2\log M}$ for analysis.

where M refers to the total number of wavelet coefficients in the corresponding wavelet domain. Because the calculation effect of the general threshold function is not perfect, the general threshold function is redesigned in an improved form, as shown in Equation (1).

$$T_j = a_j\sigma_N\sqrt{2\log M} \tag{1}$$

where after decomposition, the number of layers with wavelet coefficients is described by $j = (1, 2, ..., J)$. The maximum number of decomposition layers is J, a_j is the adaptive parameter, and the adaptive parameter corresponding to layer j is 2^{J-j+1}.

Design of Wavelet Shrinkage Algorithm

In order to obtain the threshold function of wavelet shrinkage, according to the constructed wavelet shrinkage threshold function, the wavelet coefficients of noiseless signal are analyzed by generalized Laplace distribution. Moreover, the Bayesian maximum a posteriori estimation method is used to calculate the a posteriori probability and complete the design of wavelet shrinkage algorithm.

Wavelet coefficients of noiseless signals can be analyzed by generalized Laplace distribution $G^j_{l,k}$ and calculate its probability distribution through Equation (2).

$$p_G(g) = \frac{v}{2s\Gamma\left(\frac{1}{v}\right)}\exp\left(-\left|\frac{g}{s}\right|^v\right), s, v > 0 \tag{2}$$

where $p_G(g)$ refers to the probability distribution of the coefficient, g refers to noise-free signal, subscript (l, k) is coordinates in wavelet domain, the gamma function is $\Gamma(a) = \int_0^\infty x^{a-1}\exp(-x)\,dx$, and the scale parameter is s. If shape parameter $v = 1$, Equation (2) can be changed to Laplace distribution, as shown in Equation (3).

$$p_G(g) = \frac{1}{2s}\exp\left(-\left|\frac{g}{s}\right|\right), s > 0 \tag{3}$$

The speckle noise $N^j_{l,k}$ in the wavelet domain can be calculated by Gaussian distribution, as shown in Equation (4).

$$p_N(n) = \frac{1}{\sqrt{2\pi}\sigma_N}\exp\left(-\frac{n^2}{2\sigma_N^2}\right) \tag{4}$$

where $p_N(n)$ refers to the probability distribution of the speckle noise and the noise SD in wavelet domain is described by σ_N. In order to obtain the signal estimation in the domain, the Bayesian maximum a posteriori estimation method is used to calculate the a posteriori probability. It is obtained by Equation (5).

$$\begin{aligned} &p_{G|F}(g|f) = \frac{1}{p_F(f)}p_{F|G}(f|g)\,p_G(g) = \\ &\frac{1}{p_F(f)}p_N(f-g)\,p_G(g) \end{aligned} \tag{5}$$

where f refers to the medical image network signal obtained in the initial state and Equation (3) and Equation (4) are introduced into Equation (5) to obtain Equation (6).

$$\begin{aligned} &p_{G|F}(g|f) = \frac{1}{p_F(f)}\cdot\frac{1}{2\sqrt{2\pi}s\sigma_N}\times \\ &\exp\left(\frac{2\sigma_n^2|g| - s(f-g)^2}{2s\sigma_N^2}\right) \end{aligned} \tag{6}$$

To calculate the maximum a posteriori probability, set the result of derivation calculation from $\ln\left(p_{G|F}(g|f)\right)$ to g is 0. It is obtained by Equation (7).

$$\hat{g} = \mathrm{sgn}(f)\max\left(|f| - \frac{\sigma_N^2}{s}, 0\right) \tag{7}$$

where g is estimated to be $\hat{g}$ and set f and g are of the same number. The threshold function of wavelet shrinkage is obtained through the Equation (7) calculation. Therefore, the wavelet shrinkage algorithm is expressed by Equation (8).

$$\hat{g} = \begin{cases} 0 & f \le T_j \\ \operatorname{sgn}(f) \max\left(|f| - \frac{\sigma_N^2}{s}, 0\right) & f > T_j \end{cases} \tag{8}$$

Combination With Bilateral Filter

The traditional wavelet denoising methods retain the unchanged wavelet coefficients in the low-frequency domain and only deal with the threshold of wavelet coefficients in the high-frequency domain, so the denoising effect is not obvious (14, 15). In order to remove the noise spots in the low-frequency domain, this article combines the bilateral filter to filter the wavelet coefficients in the low-frequency domain. The structure of the bilateral filter is represented by Equation (9).

$$h(x) = k^{-1}(x) \times \int_{\xi \in \Omega(x)} f(\xi)\, c(\xi, x)\, s\left(f(\xi), f(x)\right) d\xi \tag{9}$$

where the normalization factor is described by $k(x) = \int_{\xi \in \Omega(x)} c(\xi, x)\, s\left(f(\xi), f(x)\right) d\xi$ and the window region with the pixel x as the center is $\Omega(x)$. A bilateral filter is formed by combining two filter cores (16, 17), i.e., the regional kernel $c(\xi, x)$ and range kernel $s\left(f(\xi), f(x)\right)$. In the above formula, the distance function from the edge pixel ξ in region $\Omega(x)$ and the pixel of the central region x is $c(\xi, x)$. Meanwhile, in the $\Omega(x)$ region, the similarity function between the pixel value cc of the edge pixel point ξ and the pixel value $f(\xi)$ of the pixel point $f(x)$ in the center region is described by $s\left(f(\xi), f(x)\right)$. After bifiltering by $f(x)$, the calculation result is shown by $h(x)$.

Steps of Medical Image Denoising

In order to obtain the denoised medical image, the ultrasonic network signal collected by the ultrasonic imaging system needs to be processed by logarithmic transformation.

(1) Log transforms the ultrasonic network signal collected by the ultrasonic imaging system. If 3D multimodal medical image is directly collected, this step is not required.

(2) Through the image obtained in wavelet decomposition processing step (1), four frequency domains are obtained, which are LL^1, LH^1, HL^1, and HH^1. Continue wavelet decomposition of LL^1 in low-frequency domain and obtain four frequency domains again (18, 19), in order: LL^2, LL^2, HL^2, and HH^2. Perform wavelet decomposition repeatedly until the maximum number of layers is decomposed J.

(3) The bottom low-frequency region LL^J is processed by bilateral filtering of Equation (9).

(4) The wavelet coefficients in the high-frequency region (LH^j, HL^j, HH^j, $j = 1, 2, ..., J$) of each layer are shrunk by Equation (8) and the SD of noise, image, and noise-free signal in each frequency domain is calculated, respectively.

(5) The inverse wavelet transform is performed on the above parameters to obtain the denoised medical image and complete the denoising.

DRD U-Net Model Using Deep Reinforcement Learning

This article selects the end-to-end DRD U-Net model to segment the 3D multimodal medical image after denoising. The convolution part of the traditional reinforcement learning model is adjusted to the residual module (8, 20) and multiscale context feature extraction atrous spatial pyramid pooling (ASPP) is introduced into the model, so that images of different sizes can be segmented.

Multiscale Context Feature Extraction Module

In order not to increase the parameters rapidly, this article adds extended convolution and introduces two-dimensional convolution to improve the receptive field.

By expanding convolution, the receptive field can be increased when the parameters remain unchanged, so as to ensure that comprehensive context information can be obtained during segmentation (21). It is assumed that ASPP consists of four parallel extended convolutions. At the same time, set the module input as $x \in R^{4c \times h \times w}$, the expansion rate is set as [3, 5, 7, 9]. Then, Equation (10) can be used to calculate the output of the module.

$$m = concatenate\,(m_1, m_2, m_3, m_4) \tag{10}$$

where $m_i \in R^{c \times h \times w}$, according to the expansion convolution with different expansion rates, a large number of context features are obtained and then a variety of features are spliced to comprehensively extract image multiscale features.

Medical Image Segmentation Algorithm of DRD U-Net Model

The model introduces residual network in deep reinforcement learning to make the segmentation result more accurate and improve the training speed of deep reinforcement learning.

Residual Structure

The residual module can improve the optimization performance of neural network, make the training process easier, and slow down the degradation speed of deep network. In this article, batch normalization (BN) operation is combined in the residual module and ReLu is selected as the excitation function. At the same time, in order to improve the problem of channel number mismatch during input and output, 1×1 convolution is used to speed up the channel number transformation and a large number of parameters are not added to the convolution.

The residual structure of the module actually refers to the introduction of a bypass, so that the input and output data can be added to obtain the deep reinforcement learning model. The introduced bypass is usually called shortcut. Using the residual structure, the convergence speed of learning can be increased. Suppose b_1 is network input, then the output of a residual network unit can be represented by Equation (11).

$$m_1 = h\left(b_1\right) + I\left(b_1, w_1\right) \tag{11}$$

where the function to be fitted in the network is described by $h(\cdot)$, the convolution calculation is described by $I\left(b_1, w_1\right)$, the weight parameter in the network is w_1, and the first layer network output

is m_1. If $h(\cdot)$ belongs to identity mapping, $h(b_1) = b_1$. Therefore, the network output m_1 of the first floor residual structure can be calculated by Equation (12).

$$m_1 = b_1 + 1 = b_1 + I(b_1, w_1) \tag{12}$$

After the initial data of the input image and the output data after convolution calculation are linearly added, it is all the outputs of the residual unit. Therefore, one addition algorithm can be used to describe all the network outputs. If there are N residual structure network modules in the whole network, the overall network output can be calculated by Equation (13).

$$b_N = b_n + \sum_{i=n}^{N-1} F(b_i, W_i) \tag{13}$$

Medical Image Segmentation of Joint Residual Structure and DRD U-Net Convolution

For 3D multimodal medical image, the edge of medical image has high complexity, so it is usually difficult to effectively segment the lesion area from the normal area. Therefore, by adding the residual structure, the initial output characteristics of the image are retained to prevent the edge data around the tissue from being damaged during segmentation. At the same time, the local data in multimodal medical image can be fully combined during training.

In this article, the convolution layer in the residual module is set as 3D convolution form, a multiscale context feature extraction module is added, and the BN layer is adjusted to GN layer. According to the convolution kernel size, construct the convolution layer of $3 \times 3 \times 3$. Then, it is introduced into the GN layer to improve the convergence ability of the network and then input to the non-linear activation function layer. Next, it is input to a $3 \times 3 \times 3$ convolution kernel again. In order to accurately extract context features, two 3D convolution layers are used to increase the depth of the network. On this basis, the computational complexity can be effectively improved. Using the introduced residual structure, the feature extraction performance of the network can be improved.

Medical Image Segmentation Algorithm for Three-Dimensional Multimodal

With its powerful feature representation ability, deep reinforcement learning can accurately segment multidimensional and multimodal medical images. The 3D multimodal medical image segmentation algorithm based on deep reinforcement learning is as follows:

$$W = \frac{B}{H} \times \frac{u \cap v}{u \cup v} \tag{14}$$

where B refers to obtain the pixel value of the target of interest in the medical image, H refers to the total pixel value in the medical image obtained, v refers to the region where interested target locates, and v refers to the region where interested denoised target locates.

Negative rewards often occur in the process of deep reinforcement learning. In order to solve these problems, the reward method from the starting point of intermediate difficulty is used to calculate from the intermediate process. The reward calculation of medical image segmentation is as follows:

$$f(l_t, m_t) = sign(W(s_{t+1}, n) - W(s_t, n)) \tag{15}$$

where after the best segmentation m_t, get the next monitoring region s_{t+1}, and predict the reward according to the segmented W. If the image segmentation at time $t+1$ is greater than the image segmentation at time t, a reward is given. Otherwise, a penalty is given. Through the reward and penalty mechanism, the incorrect segmentation of medical images is minimized. The image segmentation at time t can be expressed by the following Equation:

$$Q = \sum_{t=1}^{t_{\max}} \kappa^{t-1} f_t \tag{16}$$

where $\kappa \in [0, 1]$ represents the discount factor. The greater its value, the greater the total reward.

To prevent local minima, use χ to mean the accurate qualitative strategy, χ begins from 0.9 and decreases by 0.1 each time till χ remains at 0.1.

$$m_t = \begin{cases} \text{Re-segmentation}, & \text{Under } \chi \text{ probability} \\ P(l_t, m_t), & \textit{Others} \end{cases} \tag{17}$$

Through the above calculation process, the 3D multimodal medical image segmentation is realized and the calculation process is shown in **Figure 1**.

EXPERIMENTAL RESULTS AND ANALYSIS

Data Set

In the experiment, PyTorch is used to build the structural framework of deep reinforcement learning and python language is used to complete the programming of medical image segmentation algorithm.

In order to verify the effectiveness of 3D multimodal medical image segmentation algorithm based on deep reinforcement learning, the algorithm is verified by experiments. The LIDC-IDRI data set, the Segmentation in Chest Radiographs (SCR) data set, and the DeepLesion data set are selected as the experimental data set of this article. The LIDC-IDRI data set: This dataset includes diagnostic and screening chest CT scans for lung cancer. A total of 1,018 study examples are included in the data set, with annotated lesions indicated. The SCR data set: This data set is a public database containing 247 chest images with segmentation of each image. The DeepLesion data set: This data set is an open dataset of CT images, including 32,735 CT images and lesion information from 4,427 patients, of which brain images and lung images are selected for this experiment. From the above three datasets, 5,000 medical images were selected for experimental analysis. The image sizes in the medical data were adjusted to 84×84 and the resolution of the images was $0.84 \times 0.84 \times 3$ mm. These experimental data were randomly sorted and 4,000 images were selected as the training data set and 1,000 images were selected as the test data set for the experiments in this article.

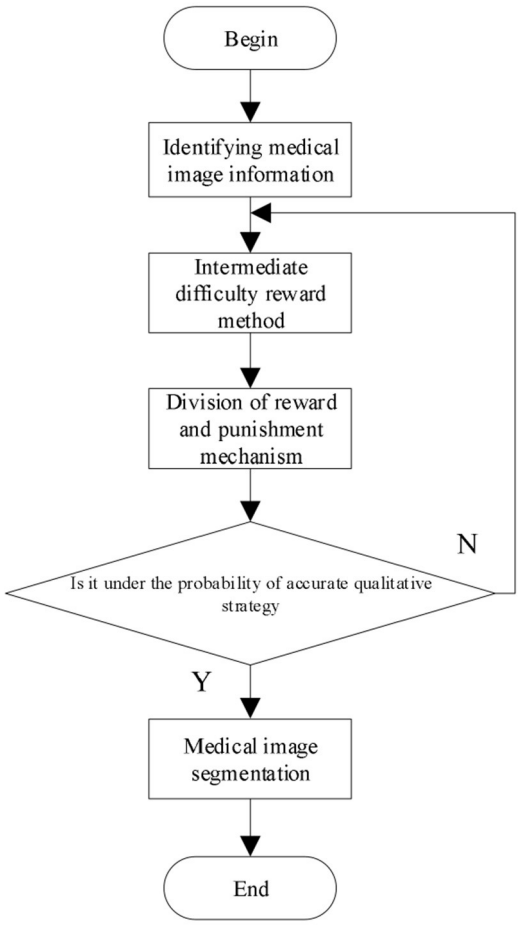

FIGURE 1 | Process of three-dimensional (3D) multimodal medical image segmentation.

Evaluation Criteria

1 Structural similarity: Medical image has a good structure and the pixels of image have many important correlations. The calculation procedure is shown in Equation (18).

$$SSIM\,(X,Y) = \left[l\,(X,Y)\right]^{\alpha}\left[c\,(X,Y)\right]^{\beta}\left[s\,(X,Y)\right]^{\gamma} \tag{18}$$

where brightness comparison is described by $l(X,Y)$, contrast comparison is described by $c(X,Y)$, image structure comparison is described by $s(X,Y)$, through parameters α, β, and γ, adjust the relative importance of the above three components. The greater the structural similarity, the better the segmentation effect.

2 Signal-to-noise ratio: The ratio between image information and noise is the SNR. Through the analysis of SNR, we can get the noise situation after image segmentation. When the SNR is higher, it means that the segmentation effect is better.

3 Training loss: The loss is a numerical value indicating the accuracy of image segmentation. If the segmented image is the same as the actual image, the loss is zero.

4 Relative overlap: The segmentation performance verification criteria is defined by the Equation (19) and the relative overlap is shown in Equation (19).

$$R_overlap = \frac{A\,(T \cap S)}{A\,(T \cup S)} \tag{19}$$

where the overall target area is described by $A\,(T)$, the size of the segmented target area is described by $A\,(S)$, and the higher the *R_overlap*, the more accurate the segmentation.

5 Accuracy: Accuracy analysis is performed on the test data set, when the greater the accuracy, the more accurate the segmented image is, using the Equation (20) to calculate the accuracy.

$$P = \frac{A\,(T \cap S)}{A\,(S)} \tag{20}$$

RESULTS AND DISCUSSION

In order to verify the effectiveness of the 3D multimodal medical image segmentation algorithm based on deep reinforcement learning, the proposed algorithm is validated by simulation experiments.

The proposed algorithm is used to segment the 3D multimodal medical images in the test set. Five brain images in the DeepLesion data set and three lung images in the SCR data set are selected for this study and the comparison of the effect pre- and postsegmentation is shown in **Figures 2**, **3**.

According to **Figures 2**, **3**, the application of the segmentation proposed algorithm can effectively achieve medical image segmentation. The image edge is clear for postsegmentation, the noise points can be effectively removed, and the definition is high.

In order to further verify the performance of the segmentation algorithm, the structural similarity, SNR, training loss, relative overlap, and accuracy are selected to verify the actual performance of the algorithm.

The training data set was trained with different iterations to analyze the structural similarity of the different algorithms after training and the analysis results are shown in **Figure 4**.

According to **Figure 4**, with the increase of the number of iterations, the structural similarity of different algorithms increases, which shows that the training of each algorithm can optimize the algorithm. Among them, the structural similarity of the algorithm in literature (11) remains the lowest in the last iteration. Therefore, the segmentation performance of the algorithm is poor, while the structural similarity of the algorithm in literature (8) increases rapidly during the iteration and finally reaches 96%. This shows that the algorithm can effectively ensure the structural similarity of the image during segmentation, but the algorithm is still lower than the proposed algorithm. When the number of training iterations is 250, the structural similarity reaches 98% and each iteration has the highest structural similarity. Therefore, compared with other algorithms, the segmentation training effect of proposed algorithm is better. The proposed algorithm combined with bilateral filter to filter the low-frequency wavelet coefficients and uses deep reinforcement

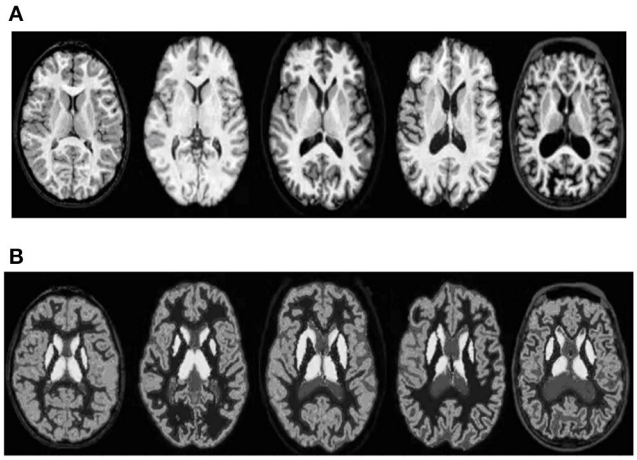

FIGURE 2 | Comparison of the effect of brain image segmentation before and after. **(A)** Presegmentation brain images. **(B)** Brain images postsegmentation by proposed algorithm.

learning to segment the medical image, which can enhance the structural similarity of image.

The ratio between image information and noise is the SNR. Through the analysis of SNR, the noise content after image segmentation can be obtained. The higher the SNR, the better the segmentation effect, so as to analyze the changes of the SNR of different algorithms after training. The results of the analysis are shown in **Figure 5**.

It is seen from **Figure 5** that when the number of iterations increases gradually, the SNR increases postsegmentation by different algorithms. Among them, the SNR of the algorithm in literature (8) increases greatly, gradually from 24 to 47 dB, but the SNR of the algorithm is still lower than that in literature (11) and the proposed algorithm. The SNR of the algorithm in literature (10) remains the lowest during iteration and there is no significant increase and the maximum SNR is only 33 dB, which shows that the algorithm has low noise reduction ability during training. The proposed algorithm always has a high SNR during training and is very stable. Under different iterations, the

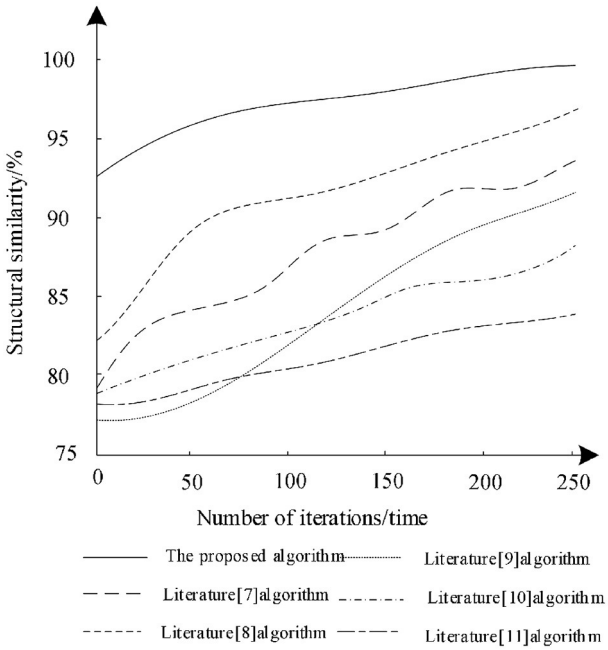

FIGURE 4 | Comparison of structural similarity of different algorithms.

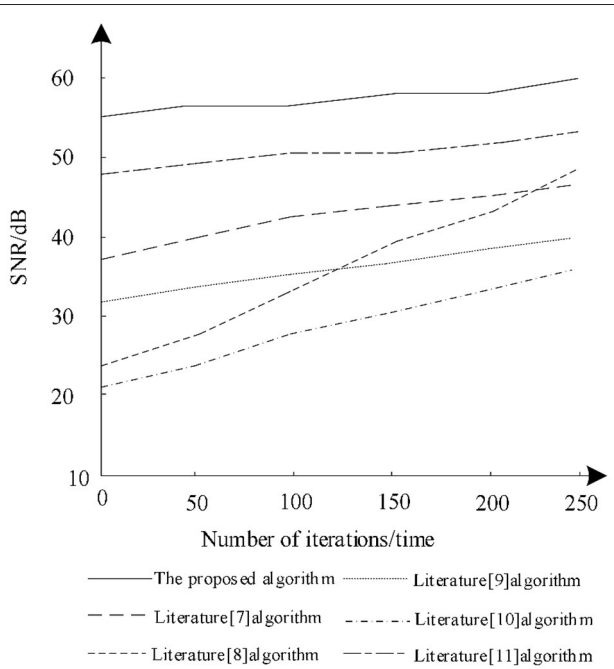

FIGURE 5 | Comparison of the signal-to-noise ratio (SNR) variation of different algorithms.

SNR is always maintained between 55 and 60 dB. Therefore, using proposed algorithm for segmentation can effectively reduce image noise.

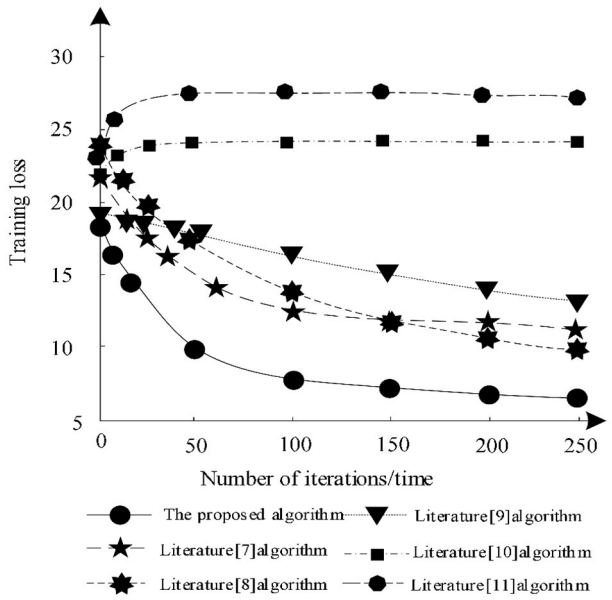

FIGURE 6 | Training loss of different algorithms.

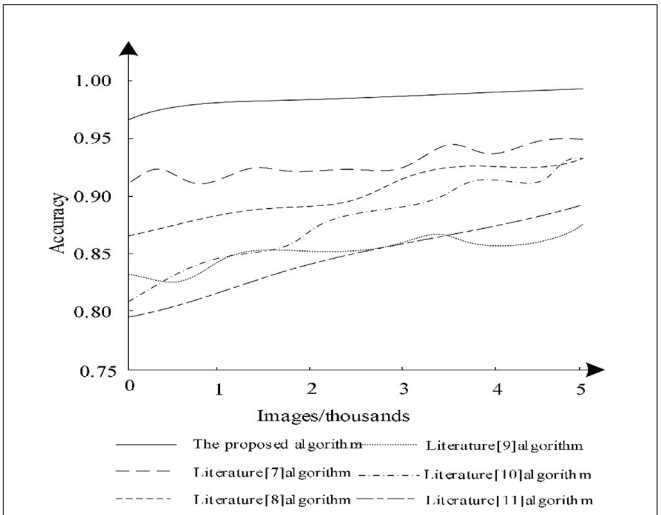

FIGURE 7 | Comparison of segmentation accuracy of different algorithms.

TABLE 1 | Comparison of the relative overlap of different algorithms.

Algorithms	Relative overlap		
	LIDC-IDRI	SCR	DeepLesion
The proposed	0.95	0.96	0.95
Literature (7)	0.89	0.80	0.84
Literature (8)	0.85	0.81	0.85
Literature (9)	0.87	0.81	0.81
Literature (10)	0.83	0.80	0.80
Literature (11)	0.85	0.84	0.87

The training loss of each algorithm segmentation under different training times is analyzed and the analysis results are shown in **Figure 6**.

According to **Figure 6**, when the number of iterations increases, the training losses of algorithm in literature (7), algorithm in literature (8), algorithm in literature (9), and algorithm in this article gradually decrease, while the training losses of algorithm in literature (10) and algorithm in literature (11) show an upward trend. Among them, the training loss of the algorithm in literature (11) is always the highest, indicating that the algorithm always has a large loss during segmentation training and cannot guarantee the integrity of the image. The training loss of the proposed algorithm decreases gradually in the iterative process, which shows that after training, the proposed algorithm can make the image segmentation more complete and ensure the effectiveness of segmentation. Because proposed algorithm uses DRD U-Net model, the model introduces residual network in deep reinforcement learning, which makes the segmentation result more accurate and the training loss less.

The relative overlap analysis is performed on the test image data set by comparing the proposed algorithm with those of literature (7), literature (8), literature (9), literature (10), and literature (11). The experimental results are shown in **Table 1**.

As can be seen from **Table 1**, the relative overlap of each algorithm reaches more than 80%. Among them, there are small differences in the relative overlap of the algorithms under the three data set tests of the LIDC-IDRI, the SCR, and the DeepLesion, but in terms of numerical size comparison, the proposed algorithm always maintains a high relative overlap of up to 95%, which is much higher than other algorithms in the literature, indicating that the proposed algorithm can achieve a more complete segmentation. Because the proposed algorithm uses deep reinforcement learning methods, with its powerful feature representation capability, it can accurately segment multidimensional multimodal medical images through its reward and punishment mechanism, thus improving the relative overlap of segmentation results.

The accuracy analysis was performed on the test dataset, when the larger the accuracy value, the better the image segmentation effect. The test images were analyzed using Equation (20) and the segmentation accuracy capabilities of different algorithms were compared and the analysis results are shown in **Figure 7**.

According to **Figure 7**, it can be seen that when the number of images increases, the segmentation accuracy of different algorithms changes. Among them, the algorithm of literature (11) has a large increase, but its segmentation accuracy always remains low and the segmentation accuracy of literature (7) is higher compared to other algorithms in literature, but the highest does not exceed 95%, whereas the proposed algorithm always maintains the highest accuracy and is 95% when performing segmentation. Therefore, it is clear that the proposed algorithm can effectively guarantee the accuracy of image segmentation. Because the proposed algorithm uses deep reinforcement learning method, proposed algorithm used the framework of

deep learning and reinforcement learning thinking, which can segment medical images accurately.

CONCLUSION

This article proposed the 3D multimodal medical image segmentation algorithm based on deep reinforcement learning, so as to realize the segmentation of 3D multimodal medical image through deep reinforcement learning training and verify the actual performance of the algorithm by experiments. Experiments show that the algorithm in this article has high relative overlap, structural similarity, and quality factors and has strong image segmentation ability and high definition. It can effectively reduce image noise and has high application effect. In the future studies, we can continue to optimize according to the existing research theory, continuously strengthen the segmentation ability of medical images, and realize the effective segmentation of various types of medical images.

Background and Objective: Viral hepatitis is a major public health concern on a global scale. It predominantly affects the world's least developed countries. The most endemic regions are resource constrained, with a low human development index. Chronic hepatitis can lead to cirrhosis, liver failure, cancer and eventually death. Early diagnosis and treatment of hepatitis infection can help to reduce disease burden and transmission to those at risk of infection or reinfection. Screening is critical for meeting the WHO's 2030 targets. Consequently, automated systems for the reliable prediction of hepatitis illness. When applied to the prediction of hepatitis using imbalanced datasets from testing, machine learning (ML) classifiers and known methodologies for encoding categorical data have demonstrated a wide range of unexpected results. Early research also made use of an artificial neural network to identify features without first gaining a thorough understanding of the sequence data.

Methods: To help in accurate binary classification of diagnosis (survivability or mortality) in patients with severe hepatitis, this paper suggests a deep learning-based decision support system (DSS) that makes use of bidirectional long/short-term memory (BiLSTM). Balanced data was utilized to predict hepatitis using the BiLSTM model.

Results: In contrast to previous investigations, the trial results of this suggested model were encouraging: 95.08% accuracy, 94% precision, 93% recall, and a 93% F1-score.

Conclusions: In the field of hepatitis detection, the use of a BiLSTM model for classification is better than current methods by a significant margin in terms of improved accuracy.

Keywords: disease diagnosis, deep learning, hepatitis diagnostics, decision support system, bidirectional LSTM

INTRODUCTION

Data mining is becoming more common in a variety of industries, including business, education, and healthcare, as a result of the rise of AI. Many researchers are interested in healthcare decision support systems because they make it possible to glean valuable information from vast amounts of medical records. Decision support systems may be able to speed up the diagnosis process for human health care providers (1). Data mining techniques known as "deep learning" (DL) employ a variety of feature-encoding algorithms to learn from past data and deliver accurate predictions (2). Sentiment categorization (3), smart agriculture (4), and other applications are among them. In the last several years, neural network models have shown a stunning capacity to predict and classify information. Deep learning algorithms, as demonstrated by Shickel et al. (5) and Miotto et al. (6), have appeared notably in healthcare for knowledge discovery and illness diagnosis, such as heart diseases, mental disorders, and hepatitis disorders, utilizing health data.

A Need for Hepatitis Disease Prediction

Viral hepatitis is a major public health concern around the world. Hepatitis A and E viruses (HAV and HEV) are endemic in many low-income countries. They usually cause self-limiting hepatitis, but in case of compromised liver status, they can cause fulminant liver failure and chronic infection. Hepatitis B and C viruses (HBV and HCV) both cause acute liver injury and are more frequently associated with progressive liver fibrosis, cirrhosis, and a higher likelihood of liver cancer (hepatocellular carcinoma or HCC). Hepatitis D virus (HDV) is often transmitted by co-infection with HBV. Because of the severity of complications, co-infection is considered the most serious type of viral hepatitis. Hepatitis viruses are 100 times more infectious than HIV/AIDS and are the leading cause of liver cancer, which is the world's second-leading cause of cancer-related deaths. Abnormalities in liver function tests such as aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, gamma-glutamyl transferase, lactate dehydrogenase, bilirubin, and albumin can indicate the liver injury and are the integral part of the biochemical investigations in hepatitis patients. Hepatitis is one of the leading causes of liver cancer, which underscores the critical importance of early detection and diagnosis for an effective antiviral treatment (7–10).

Aims of the Project

Computational techniques like machine learning (ML) have been researched by a majority of researchers (8, 9) in recent years in order to predict the prevalence of hepatitis. Detecting hepatitis before symptoms manifested was the primary focus of their scientific work, and they were successful in this aim. Conventional encoders couldn't handle the illness dataset's predictors' relationships well. For the sake of this investigation, the suggested BiLSTM-based framework properly identifies (survivability or death) in patients with severe hepatitis. The goal of this research is to develop a prediction model that will assist physicians in determining the prognosis and survival of hepatitis patients based on medical conditions provided by the patients themselves. As a result, patients who receive early care are less likely to die.

Baselines

Akbar et al. (9) created an ML-based hepatitis disease prediction method. ML was used to better predict hepatitis using random forest (RF), support vector machine (SVM), and other classifiers. There are intrinsic links between the predictors, but this is not taken into consideration by ML classifiers. Because of this, current ML models fail to accurately forecast hepatitis patients' long-term survival using medical information. BiLSTM is an updated DL model that has previously been applied effectively in several areas, such as DDoS attack prediction (10), behavior identification (2), and others (3). To better understand hepatitis, we created a BiLSTM model. The steps are as follows: an oversampling method and a BiLSTM model were used to balance the dataset for hepatitis. Using our recommended technique, we can anticipate hepatitis patient survival from patient health data by using both data balance and the BiLSTM layer.

Problem Statement

It is challenging to reliably predict hepatitis from patient data when standard feature sets are used in conjunction with a machine learning classifier (8, 9). Aside from that, the absence of important information makes DL models for the prediction of hepatitis sickness less successful than they could be. To deal with the aforementioned challenges, the prediction of hepatitis from patient data is considered a binary-label prediction problem. The presence of hepatitis is predicted based on the disease dataset provided. The dataset contains two types of class labels: D1 (Hepatitis_patient_ survivability = yes) and D2 (Hepatitis_patient_ survivability = no). In order to predict whether or not someone has hepatitis, the neural network makes use of these two sets of information: we intend to use a deep neural network to construct an automated system that can learn from training data and predict the survivability of hepatitis patient based on contextual information.

Research Questions

The following are the research questions we hope to achieve in our study so that we can accurately diagnose hepatitis.

RO1: Using patient sickness data, the BiLSTM deep learning model will be used to create predictions regarding hepatitis infection.
RO2: BiLSTM model's comparison with traditional machine learning and deep learning models for hepatitis prediction.
RO3: The efficiency of the suggested technique in predicting hepatitis patients is compared to previous studies.

Research Contributions

The following are some of the most significant outcomes of this research work:

1. The development of a deep learning (BiLSTM) system for hepatitis disease diagnosis.
2. The proposed deep learning hepatitis detection approach outperforms existing machine learning techniques.

3. The effectiveness of the model in predicting hepatitis has been significantly improved as a result of the recommended strategy.

The following is the sequence in which the remaining sections of the study are organized: Section Related Work provides a review of the existing literature, and section Proposed Methodology outlines the approach that has been proposed by the authors. section Experimental Results and Discussion presents the findings and discussion, and Section Conclusion and Future Work discusses the application of the suggested strategy in the future.

RELATED WORK

This section summarizes previous research on hepatitis illness prediction.

Chicco and Jurman (7) used a RF classifier model to examine the EHRs of 540 control subjects and approximately 80 patients who had been diagnosed with hepatitis C. We use the best classifier (Random Forests) to find the most important variables for hepatitis C. The work of Kashif et al. (8) focuses on predicting LOLA therapy responses in hepatitis c patients. They employed K Nearest Neighbor, kStar, Bayesian Network, Randomized Forest, Radial Basis, PART, Logistic Regression, OneR, Svms, and Multi-Layer Perceptron to estimate therapeutic efficacy. For the purpose of evaluating the effectiveness of machine learning algorithms, several performance metrics are employed. It was shown that CDSS may be used to predict and diagnose Hepatitis-B infection in studies by Panigrahi et al. (11). The expert system's knowledge base has 59 rules. ES-builder, a web-based Expert System Shell, is used to implement the envisioned system (ESS). Querying the suggested system has been extensively tested to verify its efficacy. The goal of the study conducted by Wicaskno and Mudiono (12) is to use artificial intelligence to help diagnose hepatitis effectively. In this study, the certainty factor was used to diagnose the kind of hepatitis early on. Based on the data provided by the patients, this study's findings will aid in the early diagnosis of hepatitis types with precision. In order to forecast HBV integration sites, Wu et al. (13) created the DeepHBV model. DeepHBV was taught and evaluated using HBV inclusion data files from the dsVIS database by autonomously learning localized genomics features. By combining machine learning and artificial neural networks, Butt et al. (14) created an Intelligent Hepatitis C Stage Diagnosis System (IHSDS) (ANN). Only 19 of 29 attributes from the Uci repository were chosen for the study; 70% of this dataset was used for training and 30% for validation. Orooji and Kermani (15) employed machine learning to handle unbalanced data in hepatitis diagnostics. They used data preparation, data analysis, examination, and software implementation as phases. Data balance strategies were used in data preprocessing. When it comes to predicting the diagnosis of individuals with persistent hepatitis, Parisi and RaviChandran (16) have developed an innovative variable selection (FS) technique that merges neighborhood component analysis and ReliefF by taking the average of their findings, paired with a Lagrangian SVM Classifier (LSVM), which is utilized as an ML-based classification model for decision-making. Wu et al. (17) published the results of a comprehensive review and meta-analysis of the available literature, followed by validation and attention in an external cross-section of 986 cases. The area under the curve method (AUROC) and the calibrating indices were used to evaluate the model's potential to anticipate HCC within three, five, seven, and ten years. **Table 1** presents a review of selected studies.

TABLE 1 | A review of selected studies.

Study	Technique(s)	Results	Limitations
Chicco and Jurman (7)	RF classifier model	The [−1, +1] interval of MCC has increased by 8.25%	The validation cohort dataset lacked some of the attributes of the discovery cohort dataset.
Kashif et al. (8)	K Nearest Neighbor, kStar, Bayesian Network, Randomized Forest, Radial Basis, PART, Logistic Regression, OneR, Svms, and Multi-Layer Perceptron	Acc: 87%	Lack of data balancing techniques
Panigrahi et al. (11)	Web-based Expert System Shell	Knowledge base consists of 59 rules to design the expert system	Procedural knowledge can be enhanced for more effective diagnosis
Wicaksno and Mudiono (12)	certainty factor was used for early diagnosis of hepatitis	CF = 97%	Limited rule base
Wu et al. (13)	DeepHBV model	AUROC = 0.6363 AUPR = 0.5471	Lack of appropriate hidden layer selection
Butt et al. (14)	Intelligent Hepatitis C Stage Diagnosis System	Precision (94%)	Lack of external validation
Orooji and Kermani (15)	machine learning to handle unbalanced data in hepatitis diagnostics	More than 90%	Skewed dataset
Parisi and RaviChandran (16)	Merges neighborhood component analysis and ReliefF Lagrangian SVM Classifier (LSVM)	F1-score = 94%	Expanding its applicability to additional hematological diseases in order to improve patient outcomes more comprehensively.

PROPOSED METHODOLOGY

For this complex problem of decision-making, it is critical to use deep learning techniques to combine existing data and experience into a DSS. Our DSS (see **Figure 1**) incorporates data, experience,

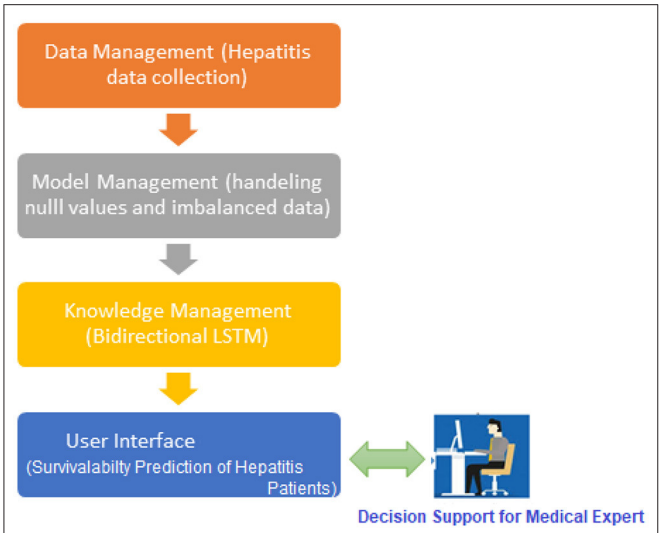

FIGURE 1 | A preview of the proposed hepatitis disease prediction system.

and models so that hepatitis clinicians may use this knowledge to form diagnostic decisions. As recommended by Turban et al., we spoke with medical experts at every phase of the design process, in order to include the users even more deeply. We followed Turban et al. (1) in building the DSS because of the DSS's nature and the sophistication of the decision topic. There are four major components of the DSS: data management, model management, knowledge-based management, and user interface.

Data Management System

A decision support system (DSS) makes use of databases and/or datasets in order to give relevant data to the decision support system. In addition to local, public, and customized sources (1), DSS data may be obtained from organizational and official sources (1). The dataset utilized in this study is the Hepatitis dataset from the University of California, Irvine repository (18). If we look at the dataset (see **Figure 2**), there are 155 instances with 20 attributes. The dataset contains 19 attributes and a single class (outcome), which may be divided into the following five groups (19).

How to Make Use of the Data

The spreadsheets are transformed into CSV format. The "csv" command line option is specified via the "pd.read" command—line interface option. This is an important Panda utility. We divided the training/testing sets through using sklearn train (80%) and test (20%) partitioning tool (2) to get the desired results.

Train Set

Approximately 80% of the data from the training set was used throughout the training process (3). Both outcome descriptors (response variables) and input parameters are included in the training phase (predictor variables).

Validation Set

Overfitting and underfitting may be handled by using validation data in the system. The model is evaluated using data from a 10% validation subset (2). When working with Keras, you have the option of changing parameters manually or automatically. Automated validation in this study will allow for a more objective evaluation of the suggested strategy.

Test Set

The test set offers unique cases to assess the algorithm's effectiveness. This process is used after considerable training and testing. Evaluation of the model is possible through the use of a test set (10). 10% of the testing data was employed, with no relation to the training instances. It is utilized once the model has already been adequately trained. It is then validated against actual data. Scikit-train-test divides the data into 90/10 ratios, with 10% of the data used for testing and the other 90% used for learning. Using a validation set, we adjusted the model's settings and analyzed the outcomes.

Treatment of Data

A 10-fold cross-validation test is used to verify the model. Ten copies of the training instance are collected and stored at each level. In this instance, we looked at one more "holdout" model. The variant with the greatest F1 score was selected for the holdout sample.

Model Management System

It performs the function of a data management system. Incorporated into DSS is a modelbase of statistical and other algorithms that allow for the provision of complex analytics. An MMS transforms data from a DMS into information by applying models to it. For the purpose of developing a viable prediction model, it is necessary to adequately pretreat the available health data. Null value substitution and imbalanced datasets are both taken care of by the data management system.

Management of Unbalanced Data Sets

There is a considerable imbalance in the underlying dataset, which treats both groups unequally. Patients who die make up 26% of the class, whereas 74% of those who live make up the remaining 26% of the class. It might be difficult to get accurate predictions from predictive algorithms when the data is imbalanced.

When a model learns from data that is skewed and unequally classified, the output generally favors the main class while neglecting the smaller categories during the classification step (20). This is seen as a class imbalance issue. Oversampling, a data processing sampling technique, is used to equalize all instances of a class. Small classes can be expanded by oversampling. Increasing the imbalance percentage is all that random up sampling accomplishes. The categorization results were much improved with the addition of small group replication. In both the T1:415 and T2:414 classes, random oversampling is applied to the balanced dataset in the same way. The total number of instances is 829.

Category	Attribute	Type	Description

FIGURE 2 | Hepatitis dataset breakup.

How to Deal With Missing Data

Reliable data should be entered into the model to patch in any empty attributes (20). Filling the spaces can be done by averaging the values of the items in the previous levels, picking a random element, or switching back and using the previous level's number. Following our decision to go with the third alternative, we proceeded to update all of the missing data. In the dataset, there are just a few missing values. The PROTIME

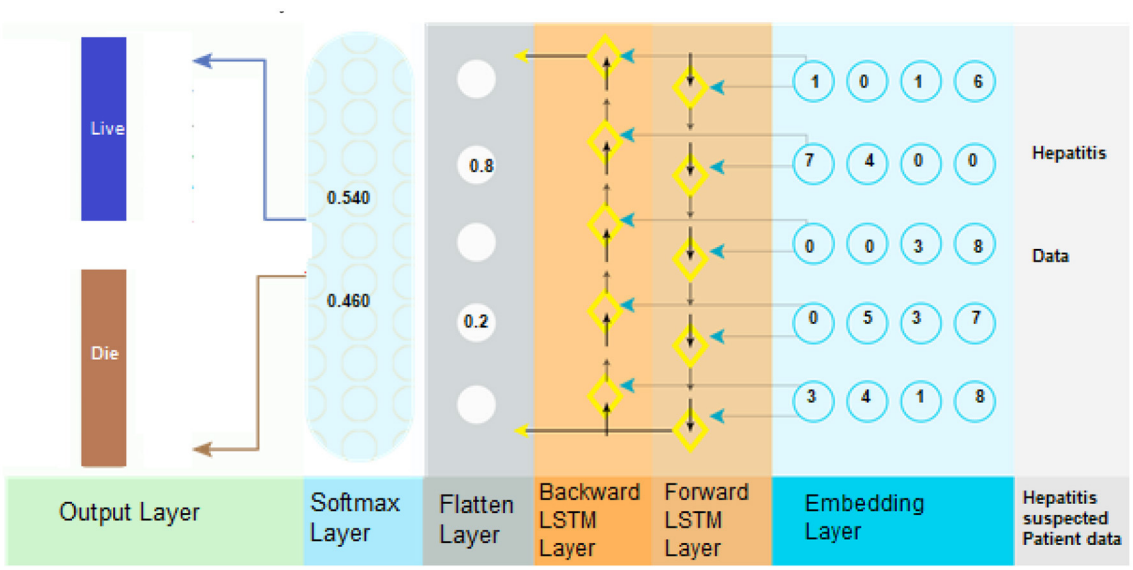

FIGURE 3 | BiLSTM is used for the hepatitis prediction system.

attribute has 67 missing values (43%), accounting for <10% of the total dataset.

The Knowledge Management System

Combined with other DSS modules, this component may be able to offer the most current information to help fix the issue. It is necessary to change information into knowledge when it has been discovered, acquired, and organized in some way. Analyzing and categorizing data is an essential part of the research process. To summarize, the suggested model consists of three main parts: embedding layer data structure, storing forward as well as backward contextual information, and softmax layer-based categorization. The second module can encapsulate features using numeric representation (21). Using Bi-LSTM to encode data contexts inside a sequence when it comes time for the final module, softmax activation is used to classify the data (see **Figure 3**). Here's a breakdown of each component:

Embedding Layer

Using embedding, it is possible to convert items (categories) into a continuous numeric array of a certain size (vectors). In neural networks, elements represent discrete variables as low-dimensional vector embeddings, which are then represented as a function of the input data. There are a number of advantages to utilizing neural embeddings in categorical data reduction and in identifying categories in the resultant space over other methods of data reduction and description. Keras facilitates the usage of embeddings by making them more accessible. Embedding vectors with attribute-level representations were employed to represent the data in the hepatitis dataset, with an embedding dimension that was equal to or greater than the dimension of the input data (22). The data embedding vector was constructed using a Keras embedding layer with 32 layers. Within the embedding layer, a two-dimensional embedding matrix (feature matrix) was built in which "represents the length of the input data" and "denotes the dimension of a word embedding" were used as input parameters. Once the embedding matrix had been produced, it was moved to the next tier in the hierarchy.

The Bi-Directional LSTM Layer

When predicting hepatitis sickness, the suggested technique makes use of a deep neural network, especially a bidirectional long-short time memory (BiLSTM), which can distinguish between D1 (Hepatitis_patient_ survivability = yes) and D2 (Hepatitis_patient_ survivability = no). Long-term dependencies are discovered through the use of the Bi-LSTM layer. As a result, it aids in the preservation of the two preceding and subsequent contexts of encoded data (23). In place of storing information from earlier contexts, a single unidirectional LSTM simply retains the information that has already been stored. As a result, Bi-LSTM is capable of analyzing encoded patient data in considerably more depth. Bi-LSTM employs both forward and backward LSTM to learn the context of data in the past and future (2). This is accomplished by the use of the following mathematical formulas (Equations 1–12).

The formulas for Forward LSTM:

$$f_t = \sigma\left(W_f x_t + U_f h_{t-1} + b_f\right) \quad (1)$$

$$i_t = \sigma\left(W_i x_t + U_i h_{t-1} + b_i\right) \quad (2)$$

$$o_t = \sigma\left(W_o x_t + U_o h_{t-1} + b_o\right) \quad (3)$$

$$c \sim t = \tau\left(W_c x_t + U_c h_{t-1} + b_c\right) \quad (4)$$

$$c_t = f_t \bigodot c_{t-1} + i_t \bigodot c \sim_t \quad (5)$$

$$h_t = o_t \bigodot \tau\left(c_t\right) \quad (6)$$

The formulas for Backward LSTM:

$$f_t = \sigma\left(W_f x_t + U_f h_{t+1} + b_f\right) \quad (7)$$

$$i_t = \sigma\left(W_i x_t + U_i h_{t+1} + b_i\right) \quad (8)$$

$$o_t = \sigma\left(W_o x_t + U_o h_{t+1} + b_o\right) \quad (9)$$

$$c \sim t = \tau\left(W_c x_t + U_c h_{t+1} + b_c\right) \quad (10)$$

$$c_t = f_t \bigodot c_{t+1} + i_t \bigodot c \sim_t \quad (11)$$

$$h_t = o_t \bigodot \tau\left(c_t\right) \quad (12)$$

Prediction Based on the SoftMax Algorithm

After that, SoftMax is utilized to determine the probability of forecasting target labels (i.e., the hepatitis disease). Using the formula (Equation 13), it is possible to calculate the net value of the input.

$$d_i = \sum w_i l_i + b \quad (13)$$

The input vector is denoted by "l," whereas the weight vector is denoted by "w." Bias is represented by "b." By putting it into Equation (14), one can calculate the SoftMax.

$$softmax\ \left(d_i\right) = \frac{expd^{d_i}}{\sum_{n=1}^{m} \exp^{d_n}} \quad (14)$$

Applicable Case

Based on the available illness data, we ran a number of computations to predict the presence of hepatitis. Every level of the BiLSTM model is described in depth.

Preparing the Data

For each patient occurrence in the disease dataset, our model predicts whether the patient has hepatitis D1: hepatitis Yes or "D2: hepatitis No.". Data on disease is first obtained for the DL model by using the attribute selection module. A Keras parser was used to turn the input into a matrix of indexes, which was then sent to the embedding layer of the DL model for assessment. Using the embedding layer, each illness indication is transformed into a vector of streaming values. [0.6 0.4 0.3 0.7] is an example of a vector embedding, which contains information about disease in the form of the index [1]. It ended out like this in terms of the wrapping of the matrices: [0.66, 0.53, 0.75, 0.14], [0.62, 0.71, 0.41], [0.81, 0.42, 0.74, 67], [0.54, 0.28, 0.41].

Retrieval of Contextual Data

A corrected feature map created from the previous deep network serves as input for this layer's neural network. The most important components in BiLSTM layer computations are the potential candidate value ($c \sim_t$), output gate (o_t), forget gate (f_t), and input gate (i_t).

1st Hidden Layer

(i_t) and (h_{t-1}) are the LSTM's present and previous states, respectively. To perform the calculations, we need Equations (1–6). Finally, the "$\overrightarrow{h}$" hidden state is computed (see **Figure 4**) by the first hidden layer (forward pass LSTM).

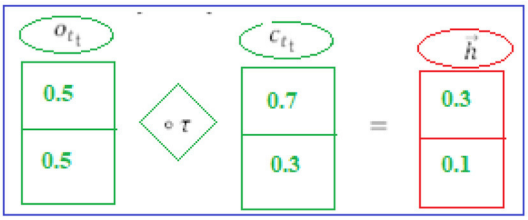

FIGURE 4 | 1st hidden layer.

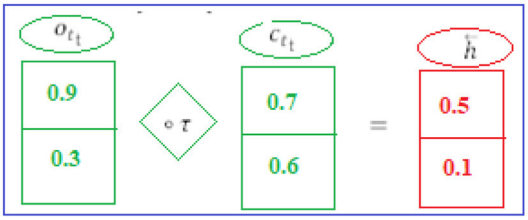

FIGURE 5 | 2nd hidden layer.

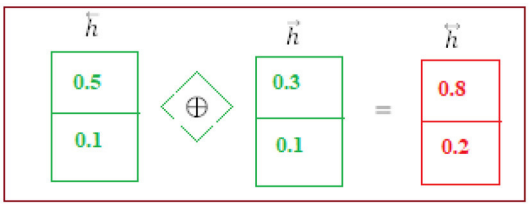

FIGURE 6 | BiSLTM outcome.

2nd Hidden Layer

The backward phase LSTM is composed (see **Figure 5**) of the current input (i_t) and the future state (h_{t+1}). The Equations (7–12) are used to do the computations. The final step is to employ the following layer to generate the hidden state $\overleftarrow{h}$ (backward phase LSTM).

BISLTM Outcome

Combining forward "$\overrightarrow{h}$" and backward "$\overleftarrow{h}$" from the neural network (see **Figure 6**), we arrive at the "$\overleftrightarrow{h}$" that make up BISLTM's final state (5).

Prediction of Hepatitis Patient Survivability

In order to find out how probable each of the tags "D1" and "D2" is, we used the SoftMax technique. The following is an example of how the overall input was calculated using Equation (13).

For Hepatitis_patient_ survivability = yes, *the class label for decision attribute 1 is "D1."*

$$d_1 = l_1 \times w_2 + l_2 \times w_2 + b$$

$$d1 = 0.6 \text{ x } 0.8 + 0.7 \text{ x } 0.2 + 0.5$$

$$d_1 = 0.48 + 0.14 + 0.5 = 1.12$$

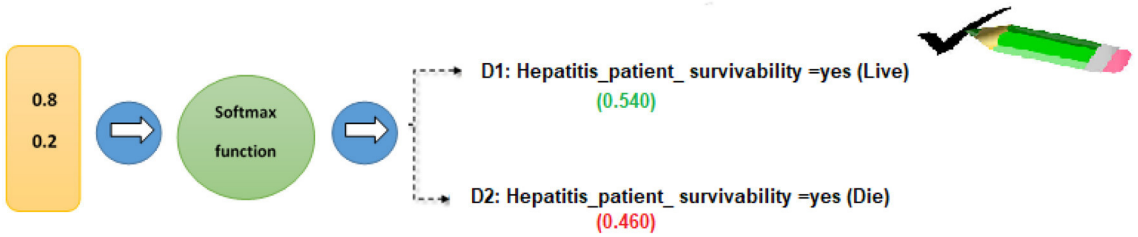

FIGURE 7 | Hepatitis patient survivability classification using the softmax function.

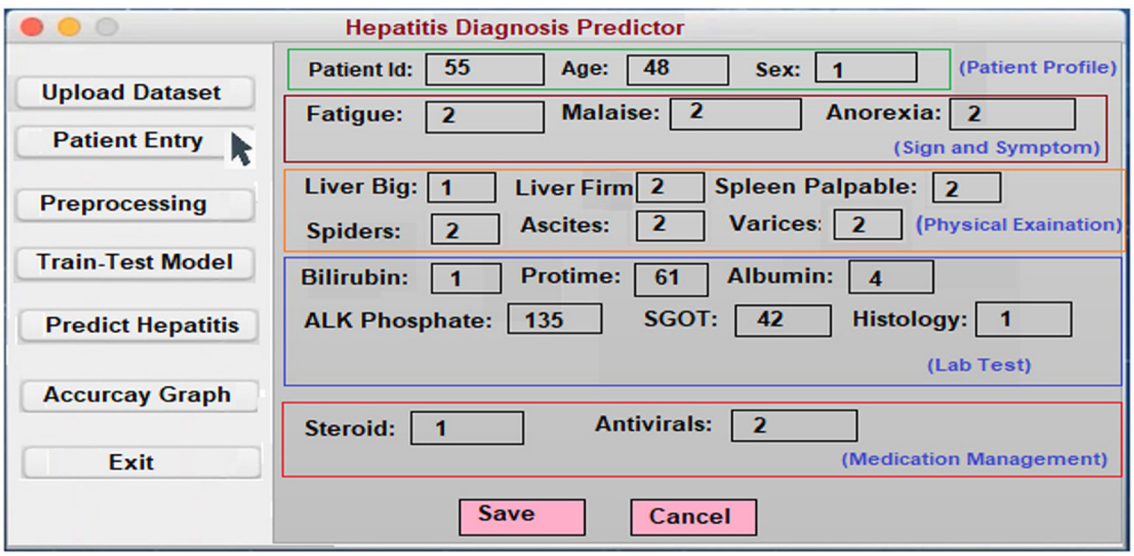

FIGURE 8 | Patient entry form.

For Hepatitis_patient_ survivability = no, *the class label for decision attribute 2 is "D2."*

$$
\begin{aligned}
d_2 &= l_1 \times w_2 + l_2 \times w_2 + b \\
d2 &= 0.5 \text{ x } 0.8 + 0.3 \text{ x } 0.2 + 0.5 \\
d2 &= 0.4 + 0.06 + 0.5 = 0.96
\end{aligned}
$$

Each target class (D1 and D2) is assigned a probability of success using the SoftMax algorithm (14).

$$
\begin{aligned}
softmax\ (d_1) &= \frac{\exp^{d_1}}{\sum_{i=1}^{n} \exp(d_1)} \\
softmax\ (d_1) &= \frac{\exp^{1.12}}{\exp^{1.12} + \exp^{0.96}} \\
softmax\ (d_1) &= \frac{3.065}{3.065 + 2.612} = \frac{3.065}{5.677} = 0.540
\end{aligned}
$$

Similarly, the SoftMax function was developed for the second class of hepatitis patient survival predictions.

$$
\begin{aligned}
softmax\ (d_2) &= \frac{\exp^{d_2}}{\sum_{i=1}^{n} \exp(d_2)} \\
softmax\ (d_2) &= \frac{\exp^{0.96}}{\exp^{1.12} + \exp^{0.96}} \\
softmax\ (d_2) &= \frac{2.612}{4.305 + 2.013} = \frac{2.612}{5.677} = 0.460
\end{aligned}
$$

Class D1: Hepatitis patient survivability = yes (live) had the highest likelihood in our calculations (0.681). Based on these data, we may estimate the patient's likelihood of survival as "D1" (live) (**Figure 7**).

User Interface

In order to assist in the prediction of hepatitis, the Keras package (3) incorporates a Python user interface. Specialists and other practitioners can use hepatitis prognosis software to better diagnose hepatitis. In order to make the content more accessible and easier to understand, it has been broken down into smaller chunks. In the software's body, there are three main parts: data acquisition, categorization, and hepatitis detection.

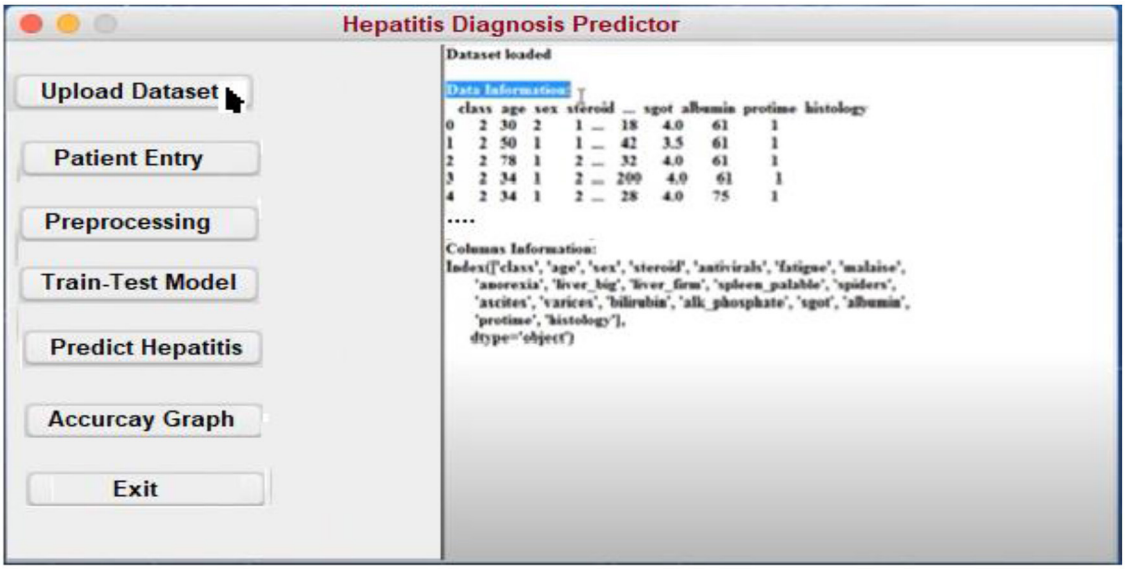

FIGURE 9 | Hepatitis prediction data input form.

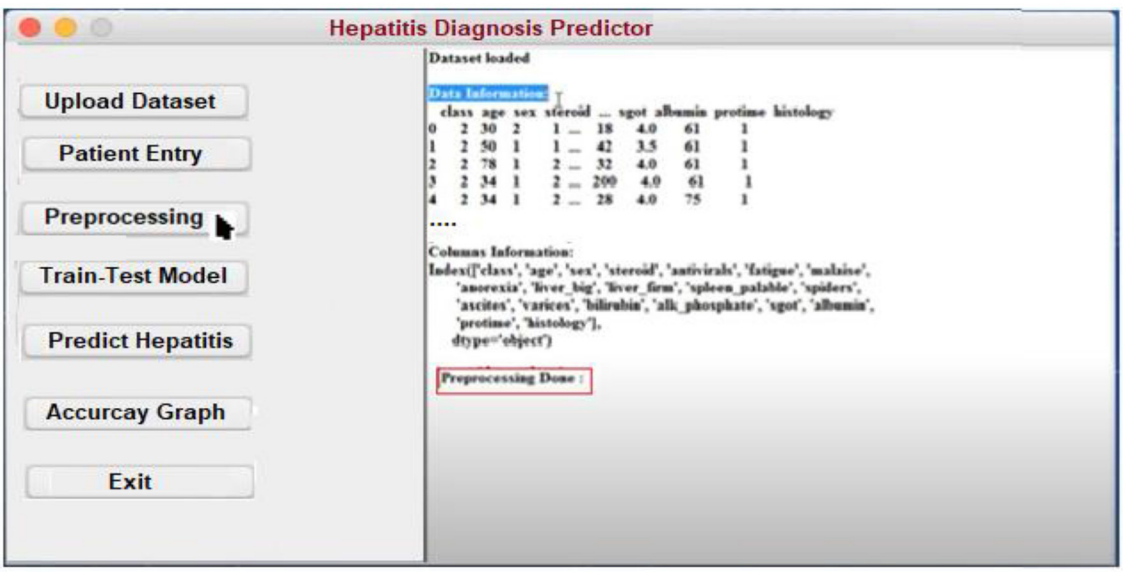

FIGURE 10 | Preprocessing form for Hepatitis prediction.

- **Patient Entry:** A patient's medical history is required for this section. Each patient in the database has a new case patient identifier created from the improved and more recent information. The hepatitis prediction system utilizes a patient's medical history to generate educated guesses about their condition. As soon as the necessary information is entered into the software, a patient specific identity is generated. Using this identifier, each patient's specific condition may be diagnosed and followed. A patient case entry is shown in **Figure 8** on the interface that has been used to gather and evaluate the data. Previous assertions are applied to the data when it is handled on the system's server. It is because of this that we have a design that can be tailored to the needs of every unique patient.
- **Uploading the Dataset:** It is possible to train classifiers and develop models using a hepatitis dataset, as shown in **Figure 9**.
- **Preprocessing:** Data preprocessing yields a classifier and a model that can predict the outcome of hepatitis. On the backend, the data is preprocessed (**Figure 10**).
- **Model Training and Testing:** The screen below shows what happens when a patient clicks on the "Model Training" option.

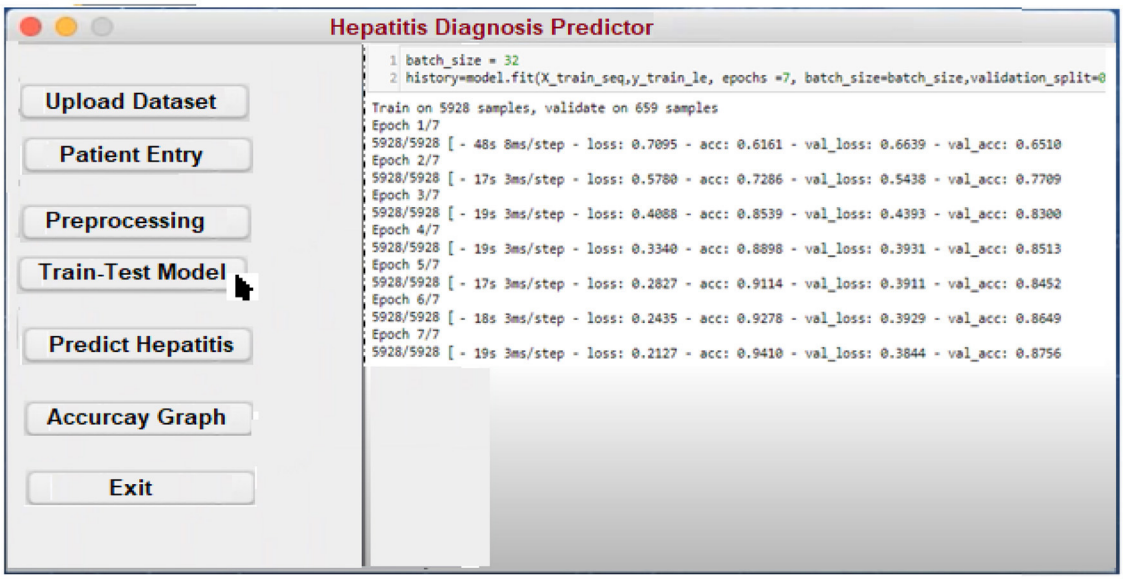

FIGURE 11 | Model training interface.

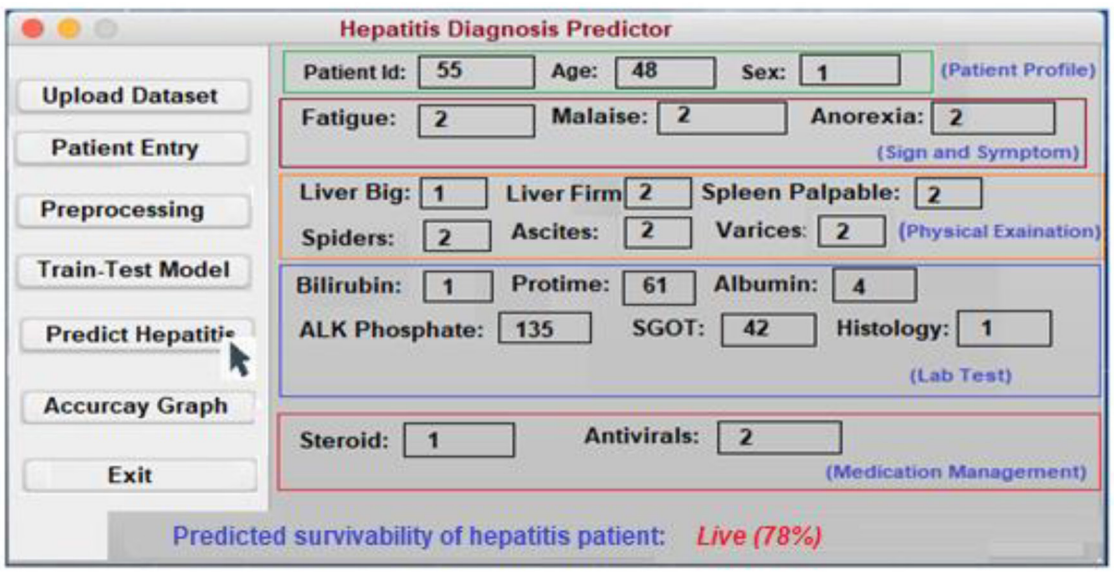

FIGURE 12 | The interface for predicting hepatitis.

It serves as a training aid by displaying the loaded data. Model training is activated by clicking on the "train-test model" (**Figure 11**).

- **Predicting survivability of Hepatitis Patient:** To predict hepatitis, all you need to do is enter the necessary patient information and click the "Predict hepatitis" option on the site. The "Update Training Set" button activates an updated training set. After inputting the patient's disease details and clicking on the "predict hepatitis" button, the findings are shown as "Hepatitis_patient_ survivability = yes," "D2: Hepatitis_patient_ survivability = no," and a predicted degree of confidence for each option. "Hepatitis_patient_ survivability = yes (Live)" is the possible outcome of the hepatitis illness prediction for the given list of criteria, as shown in **Figure 12**.

EXPERIMENTAL RESULTS AND DISCUSSION

This section presents the results of a series of experiments aiming to address the questions raised in section Introduction.

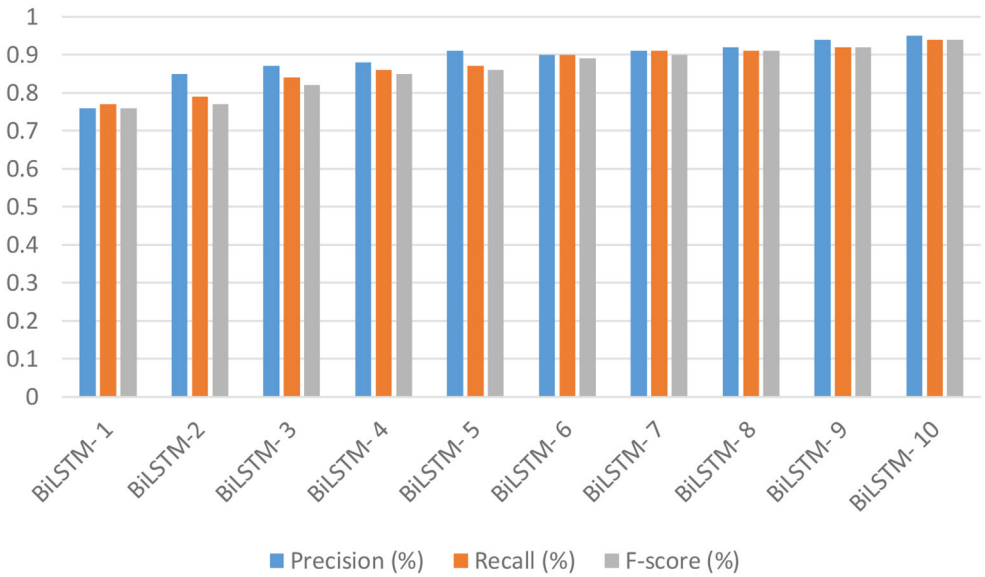

FIGURE 13 | The accuracy, recall, and f1-score of the BiLSTM deep learning models.

TABLE 2 | Accuracy, test loss, and training time of the BiLSTM models.

Model	Test accuracy	Test loss	Train time (s)
BilLSTM-1	84%	0.86	20 s
BiLSTM-2	85%	0.83	7 s
BilLSTM-3	86%	1.06	18 s
BiLSTM-4	87%	1.15	16 s
BiLSTM-5	88%	0.88	7 s
BiLSTM-6	90%	0.85	15 s
BiLSTM-7	91%	1.23	12 s
BiLSTM-8	91%	0.78	14 s
BiLSTM-9	92%	0.87	17 s
BiLSTM-10	95%	0.80	12 s

Experiment#1

Based on patient sickness data, we applied the BiLSTM deep learning model to generate hepatitis predictions.

Research question # 1 was answered by altering the parameters of one of the most commonly used models for survivability prediction of hepatitis patients, the BiLSTM algorithm. Various additional epochs and filtering techniques were employed as well. Several batch sizes and epochs are included in the algorithm's three hidden layers. As a result of using the SoftMax activation function, there were 62 vocabulary vectors, and the embedding dimension was 128 (8, 16, and 32). A selection of BiLSTM models' accuracy, recall, and F-scores are shown in **Figure 13**. This filter has an accuracy of 93% when used with the following parameters: filer size of 280, unit size 2, "f1 score" of 94%, recall of 94%, and precision of 94%. Filter number 8 has an accuracy of 95.08%.

The results of 10 BiLSTM experiments with varying parameter values are presented in **Table 2**. We compared the accuracy of each model against one another. Because it included eight filter sizes, sixteen filters, and ten LSTM units, it had the highest accuracy of all the models tested.

Experiment#2 With Datasets That Are Balanced and Unbalanced

As stated in section 2.0, an imbalanced data classification, randomized training division, and testing set created an uneven class result. It is unbalanced since there are 71 surviving patients and 22 deceased. To equalize the dataset, we used random oversampling. As shown in **Figure 14**, when data balancing is used instead of not using data balancing, efficiency is significantly increased. By analyzing the empirical values, it is possible that the proposed model may be utilized to properly predict the survivability of hepatitis patients in real-world situations.

Experiment#3

This experiment is carried out to compare of the BiLSTM model for predicting hepatitis survival with traditional machine learning and deep learning. Conventional machine learning algorithms and deep neural networks were compared to see how the BiLSTM findings for diabetic illness prediction stacked up.

- **ML vs. recommended system (BiLSTM):** Patients' data was used to compare the proposed method (BiLSTM) to other commonly used machine learning methods. Machine learning makes use of feature extraction approaches like TF-IDF and CountVectorizer. **Table 3** displays the outcomes of the assessments. A brief summary of the findings is provided in the following paragraphs.
- **BiLSTM vs. SVM:** We utilized the SVM algorithm to compare the proposed BiLSTM model to various machine learning approaches. **Table 3** summarizes the findings.

FIGURE 14 | Confusion matrix.

- **BiLSTM vs. KNN:** In this experiment, we compared a typical machine learning classifier with a BiLSTM model. A closer look at **Table 3** indicates that KNN classifiers have worse precision, recall, F1-score (0.78), and accuracy (0.77) compared to other classifiers.
- **BiLSTM vs. NB:** In this experiment, the BiLSTM classifier was competing against the Nave Bayes (NB) classification. **Table 3** shows that the F1-score (0.74%), recall (0.73%), and precision (0.73%) are all lower than in the previous Table (0.73%).
- **Deep learning vs. suggested method (BiLSTM):** The proposed method is compared to existing deep learning techniques, such as long/short-term memory (LSTM), convolutional neural networks (CNN), and recurrent neural networks (RNN), in order to properly forecast hepatitis based on patient data. **Table 4** sums up the findings of the study.
- **LSTM vs. Proposed BiLSTM:** In this study, we evaluated the performance of the BILSMTM model against that of the LSTM model. **Table 4** shows that the LSTM model had the lowest precision, recall, F1-score, and accuracy of the four models tested.
- **CNN vs. Proposed BiLSTM:** Our goal was to compare the performance of the BiLSTM approach to that of the CNN model in this particular experiment. For accuracy, precision,

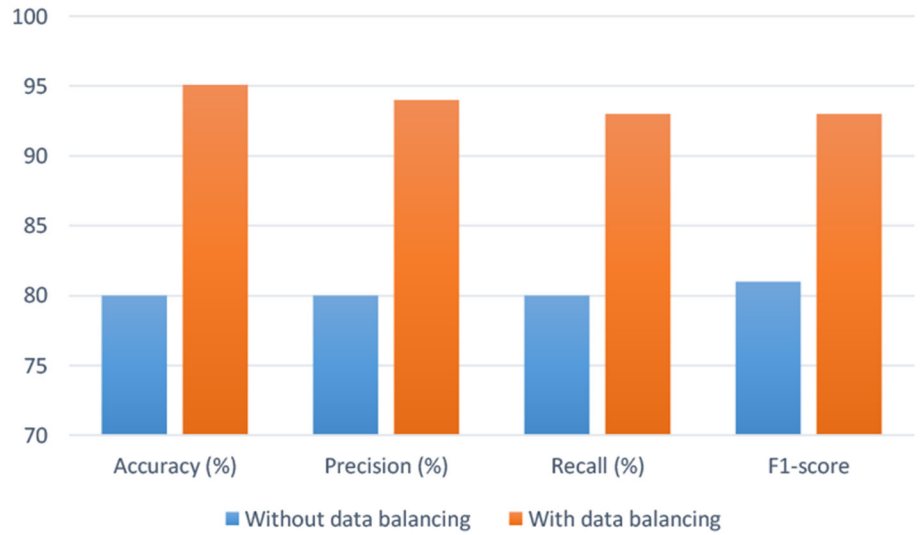

FIGURE 15 | Proposed model's performance with and without balancing data.

recall, F1, and precision, the CNN model behaved poorly in **Table 4**.

- **RNN vs. Proposed BiLSTM:** We ran this test to see which approach worked best. On the basis of the results in **Table 4**, it can be concluded that the RNN model's performance on these four metrics is less than ideal.

Experiment#4

In this experiment, the suggested method's efficacy in predicting hepatitis patients is compared to baseline research. In the third research question, we evaluated the suggested BiLSTM model's effectiveness in similar research. To determine how effective the proposed system is, it is contrasted with a variety of other comparing methodologies. According to this study (**Figure 15**), BiLSTM surpasses a baseline study when compared to the latter. For a variety of reasons, it is difficult to conduct a comprehensive assessment of published methodologies. These approaches were hard to compare because of the variety of datasets.

Kashif et al. (8)'s work: Kashif et al. (8) created an ML-based hepatitis disease prediction method. ML was used to better predict hepatitis using random forest (RF), support vector machine (SVM), and other classifiers

Akbar et al. (9)'s work: Prediction of hepatitis using ML has been proposed. Hepatitis data sets were analyzed using a variety of machine learning methodologies. The performance of a DL model can be improved by using a more effective data balancing method.

Proposed work (our model): The DL-based hepatitis prediction approach uses a deep neural network. **Figure 16** shows that the predictor variables (**Figure 16**) selected have a considerable influence on the anticipated (target) parameter. The combination of data balance and the BiLSTM neural learning model is the most important factor in our achievement in predicting hepatitis illnesses. By using the BiLSTM layer, contextual information can be retained.

TABLE 3 | Classifiers based on machine learning vs. suggested model (BiLSTM).

ML modal	Accuracy (%)	Precision (%)	Recall (%)	F-score (%)

Analyzing Results

A comparison is made between experts' predictions and the prognosis supplied by the suggested strategy, and the performance of the proposed method is evaluated. The processes for the first 12 patients are depicted in **Table 5**.

CONCLUSION AND FUTURE WORK

Because of the tremendous expansion in healthcare content, it has become more important to gather and analyze healthcare data in order to discover hepatitis illness in patients. A successful DSS model based on DL was created and put into practice in order to accomplish this. A deep neural network (BiLSTM) is used to predict hepatitis based on data gathering, preprocessing,

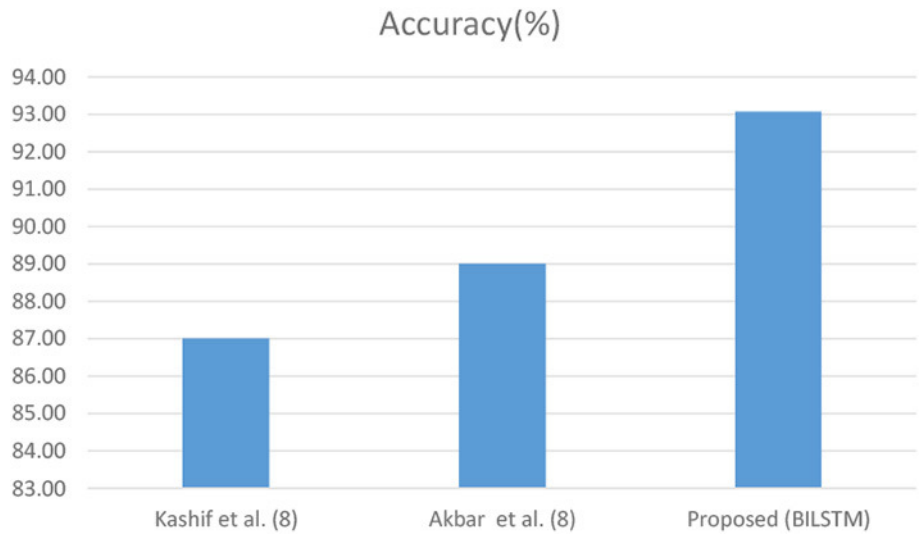

FIGURE 16 | Comparison of other research and the BiLSTM model.

7	Hepatitis_patient_ survivability = yes	Hepatitis_patient_ survivability = yes
8	Hepatitis_patient_ survivability = no	Hepatitis_patient_ survivability = no
9	Hepatitis_patient_ survivability = yes	Hepatitis_patient_ survivability = yes
10	Hepatitis_patient_ survivability = no	Hepatitis_patient_ survivability = no
11	Hepatitis_patient_ survivability = yes	Hepatitis_patient_ survivability = yes
12	Hepatitis_patient_ survivability = yes	Hepatitis_patient_ survivability = yes

and validation. Additional experiments were conducted using both balanced and unbalanced data sets. A BiLSTM model was also utilized to predict the chance of having hepatitis in the future. The results are encouraging when compared to prior attempts. The suggested strategy's dependence on embedding rather than on a pre-trained model is an obvious limitation. In the future, the use of pre-trained algorithms like word2vec or Fasttext with hepatitis data sets from different fields (e.g., patient data from different fields) may be looked into.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Percentage mammographic breast density (MBD) is one of the most notable biomarkers. It is assessed visually with the support of radiologists with the four qualitative Breast Imaging Reporting and Data System (BIRADS) categories. It is demanding for radiologists to differentiate between the two variably allocated BIRADS classes, namely, "BIRADS C and BIRADS D." Recently, convolution neural networks have been found superior in classification tasks due to their ability to extract local features with shared weight architecture and space invariance characteristics. The proposed study intends to examine an artificial intelligence (AI)-based MBD classifier toward developing a latent computer-assisted tool for radiologists to distinguish the BIRADS class in modern clinical progress. This article proposes a multichannel DenseNet architecture for MBD classification. The proposed architecture consists of four-channel DenseNet transfer learning architecture to extract significant features from a single patient's two a mediolateral oblique (MLO) and two craniocaudal (CC) views of digital mammograms. The performance of the proposed classifier is evaluated using 200 cases consisting of 800 digital mammograms of the different BIRADS density classes with validated density ground truth. The classifier's performance is assessed with quantitative metrics such as precision, responsiveness, specificity, and the area under the curve (AUC). The concluding preliminary outcomes reveal that this intended multichannel model has delivered good performance with an accuracy of 96.67% during training and 90.06% during testing and an average AUC of 0.9625. Obtained results are also validated qualitatively with the help of a radiologist expert in the field of MBD. Proposed architecture achieved state-of-the-art results with a fewer number of images and with less computation power.

Keywords: breast cancer, BIRADS Density Classification, DenseNet, deep learning, multichannel architecture, mammographic breast density

INTRODUCTION

Breast cancer has its reputation as a deadly disease and it is the second most frequent event of departure for the women community in society. It is frequently diagnosed in women with 12.3% compared to the average population (1–4). The incidence of breast cancer is associated with many biomarkers such as calcifications, masses, mammographic breast density (MBD), and architectural distortion. Advanced apprehension and proactive strategy are the unique alternatives to protect the lives of breast cancer cases and regress their subconscious shock (5–8). MBD is an essential biomarker in interpreting digital mammograms and preparing a systematic mammography screening program. According to epidemiological investigations, females with highly dense breast tissue risk developing breast malignancy (9, 10). MBD is a radiographically visible density on the mammogram, consisting of lobular elements, ducts, and fibrous connective tissue compared to the lucent fatty tissue in the breast (11). The reports are prepared during the digital mammography screening program as per the American College of Radiology Breast Imaging Reporting and Data System (ACR BIRADS) catalog. This catalog was last modified in November 2015 (12, 13). As per the BIRADS, MBD gets classified into the four significant groups of mammographic breast density as class A, class B, class C, and class D, which reduces the sensitivity of digital mammography (14). **Figure 1** depicts all the MBD BIRADS classes.

Different scientific studies have revealed that digital mammograms' sensitivity strongly depends on the density class of the breast tissue. In dense breasts, the sensitivity of mammograms is as low as 63%, while in the low-density breast, there is an exponential rise of 87%. Hence, patients with high-density breasts have to go for additional imaging such as tomosynthesis, ultrasound, or breast MR to enhance cancer detection chances (15). Researchers have proposed many semiautomatic and automatic approaches for measuring breast density from the last two decades. However, the assessment of mammographic breast density (MBD) is subjective, which expert radiologists do (16). Despite this labeling, due to poor interreader and intrareader reproducibility, MBD classification has many limitations (17).

For an automatic objective assessment of MBD classification, many study efforts have been in progress from the last few decades. The initial study focuses on image processing techniques such as area-based thresholding, region growing, and clustering algorithms. A significant step formulated was the emergence of the machine learning (ML) algorithms based on different extracted image topographies from the histogram, texture intensities, patterns, and image acquisition parameters. Nowadays, deep learning algorithms provide yet another leap forward in MBD classification. Deep learning algorithms can go substantially deeper and discover all the significant features from the image. Due to system architecture and hardware improvements, it is possible to train deep learning architecture intensely. This improvement makes deep learning architecture an excellent tool for medical image analysis. Many deep learning architectures such as LeNet, (visual geometry group) VGG19, highway networks, residual networks, and DenseNet are recorded in literature.

Nevertheless, before every deep learning network lets more intelligence, a new study intricacy happens, the "vanishing gradient problem." DenseNet (dense convolutional network) provides unique insight to secure the best data flow between layers to solve the connectivity problem. This interface immediately combines all the layers, agreeing on characteristic map dimensions in feed-forward type; hence, the individual layer receives input from all the previous layers also transfers its distinct map to all the farther layers. Thus, the DenseNet concatenate feature map passes through all the subsequent layers instead of summarizing features such as ResNet. This concept includes L (L+1)/2 connections instead of L connections, identifying a dense connectivity pattern (18). The consequence of this connectivity guide, i.e., DenseNet architecture, provides the following advantages:

1. Effective solution for gradient vanishing.
2. Consolidation in characteristic distribution.
3. Provision of feature recycle.
4. Significant reduction in training parameters.
5. Easy to train and offers better parameter efficiency.

Due to these advantages, it is helpful to use this model without pretraining for medical image analysis.

The elemental aspiration behind this study is to investigate the use of multichannel DenseNet architecture for MBD classification and analyze the proposed architecture compared with different existing methods. **Figure 2** depicts the proposed multichannel architecture for MBD classification.

The key feature of this architecture is classifier performance that is evaluated with 800 digital mammograms among the diverse BIRADS density categories. Results are confirmed exclusively by expert radiologists and objectively with classification accuracy and the area under the curve (AUC). Various sections described in this article are as below. Related study section covers unique existing deep learning algorithms for MBD classification, Study dataset section presents the aspects of the source dataset, Proposed methodology section represents the proposed architecture, and Analysis of experiment and outcomes section introduces the empirical outcomes. Finally Discussion section discusses the future scope and Segment 7 concludes this study.

RELATED STUDY

Mammographic breast density classification is a long-lasting study area due to more thought-provoking and challenging image preprocessing, segmentation, and classification tasks. Successful deep learning classifiers such as ResNet, VGGNet, and GoogLeNet give brand-new pathological imaging and investigation prospects. This section describes the remarkable of such existing methods used for MBD classification. In summation, these classifiers offer better results on different imaging modalities for image classification. Intrinsically, high interreader fluctuations are the prime problem in MBD

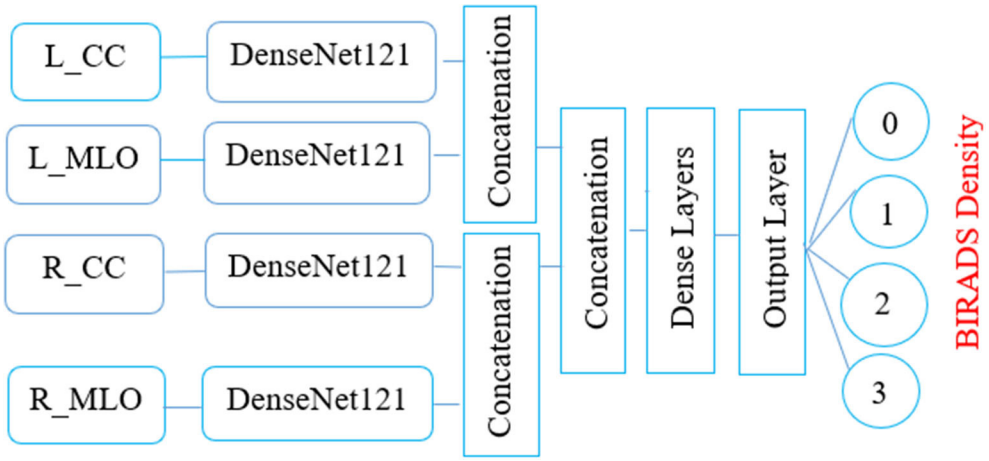

FIGURE 1 | The proposed multichannel architecture for mammographic breast density classification.

assessment. To overwhelm this problem, Ciritsis et al. (19) suggested deep learning architecture with 11 convolutional layers, three fully connected layers, and an output SoftMax layer to distinguish breast density into two classes and four classes. Two expert radiologists marked density ground truth during this classification task. A combination of mediolateral oblique (MLO) and craniocaudal (CC) (left or right) views (20,578) digital mammograms were used to train the proposed model. During the training, to enhance the model's performance and desist overfitting, the convolutional layers are zero-padded and used a dropout rate of 50%. Batch size and the highest number of epochs used during training are 40 and 120, respectively. Input data segmented as 70% for training and 30% for validation. This model is validated independently on CC and MLO views for two-class classification and achieved an overall classification accuracy of 89.9 and 86.6%.

Predominantly, fat appears darker than fibroglandular tissue in MBD assessment. Hence, the pixel intensity of the histogram acts as an essential feature for classifier training. Wu et al. (20) suggested this technique for MBD classification. In this method, the SoftMax regression classifier is used to learn pixel intensity histograms. Four regular views [left CC (LCC), right CC (RCC), left MLO (LMLO), and right MLO (RMLO)] of 2,00,000 screening images were given individually to train the prototype. The proposed architecture is deep and consists of 100 hidden units between input and output layers. All the hidden layers use Rectified Linear Unit (ReLU) as an activation unit. This model is tested for two- and four-class classification and achieved 81.1 and 82.5% classification accuracy. Thus, this model provides moderate classification accuracy despite an extensive dataset. Lizzi et al. (21) suggested a residual convolutional network for MBD classification. The recommended design consists of 41

TABLE 1 | Input dataset used for testing and validation of proposed algorithm.

convolutional layers formed in residual blocks with 2 million parameters. The first block of this architecture consists of a convolutional layer, a batch normalization layer, a leaky ReLU as an activation function, and a two-dimensional (2D) max pooling. A series of four sections consisting of three residual modules uses the output features of the input block. Leaky ReLU with $\alpha = 0.2$ activation functions was used to train the architecture. Categorical cross-entropy as a loss function validates the performance of the model. Maximum accuracy with four-class classification is 78% and the two-class accuracy is 89.4%.

In a comparative study for evaluating the performance of deep learning and transfer learning on a similar dataset, Lee et al. (17) proposed both the approaches on 22,000 mammographic images. In this approach, expert radiologists marked density ground truth for the input images. Initially, the model's training starts with 500 images with the AUC of 0.942 and the final value of the AUC is 0.9882 reported on the whole dataset. Then, the proposed model is cross-validated with the transfer learning (ImageNet) application and obtained the overall AUC of 0.9857. Thus, this study shows that both the deep learning and transfer learning applications provide almost identical results on the equivalent dataset. The requirement of a larger dataset for training is an essential need of deep learning architecture. Shi et al. (22) proposed optimized lightweight deep learning architecture to optimize deep learning performance on smaller datasets. This architecture combines three convolutional neural networks (CNNs), one dense layer, and an output layer with the SoftMax function. Data augmentation is done with additional image processing to increase the numbers in the dataset. This architecture was trained and tested on the 322 mini-Mammographic Image Analysis Society (MIAS) dataset. This architecture provides overall accuracy of 83.6% on four-class classification. The main limitation of lightweight architecture on smaller datasets is the low stability of the network, which may occasionally cause large and significant variations in the accuracy. Data augmentation can enlarge the dataset in this method, but it is still challenging to get well-trained convolutional layers due to little diversity between the original and generated datasets. In the literature, there are two ways that are recorded to enhance the model performance with a smaller dataset, which are generative adversarial network (GAN) and another is transfer learning (23).

Recently, different researchers proposed the concept of transfer learning on a smaller dataset. For example, Kaiser et al. (24) proposed new architecture that can take all the four views of single patients to classify MBD into two-class classification (dense and nondense). For this purpose, the author proposed four-channel VGGNet architecture to extract all the features with average global pooling from input mammograms. Before the classification layer, to concatenate all the input layer features, two dense layers are used. Then, the proposed model is trained with 5-fold cross-validation and recorded 88% classification accuracy with the AUC of 0.954. Finally, subjective assessment is done with a panel of 32 radiologists to compare interobserver variability. In this approach, interobserver variability for breast density assessment is observed even high in two-class classification. Thus, the automated processes for MBD can help to minimize interobserver variability. Despite different automated approaches, MBD assessment is subjective and consists of intra- and interobserver variations. Objective evaluation of other commercially viable methods consists of mixed evaluation results. Another fundamental limitation is that most of existing deep learning methods need a higher dataset and validated density ground truth; hence, data acquisition becomes difficult for researchers. In addition, mammographic images are vendor specific, making deep learning more robust; training the deep learning model through different vendor-specific samples is required, another bottleneck in MBD classification. All the limitations mentioned above result in moderate objective MBD classification accuracy.

The primary motivation behind this study is to investigate the transfer learning application of DenseNet architecture toward enhancing the classification accuracy of MBD. A significant contribution is the design and development of multichannel architecture to utilize four mammographic views of a single patient.

STUDY DATASET

The intended study utilizes the openly available dataset from digital database for screening mammography (DDSM) (25), consisting of 2,620 samples of various classes labeled as benign, normal, and malignant with confirmed pathogeny data. The aimed algorithm uses 200 Right-MLO, 200 Left_MLO, 200 R_CC, and 200 L_CC views. A total of 800 mammograms are used for training and testing purposes. The ground truth of each class is labeled with the help of specialist radiologists team into four classes as 0, 1, 2, and 3 as a four MBD classes. All the density groups consist of 200 cases of different images (MLO, LMO, R_CC, and L_CC). **Table 1** presents the details of the ground truth input dataset used in this proposed study.

PROPOSED METHODOLOGY

This segment explains the proposed MBD classification technique and divided into three subsections as presented subsequently.

Segmentation of Pectoral Muscle

Instead of using raw images for models' training, the proposed method preprocesses both the LMO and MLO views. Input mammographic images consist of high-intensity marks of artifacts and tags and pectoral muscle. Those fields in the breast region can reduce the MBD classification accuracy (26, 27). The proposed method uses the depth-first search algorithm, our previous study (28), to remove pectoral muscle, artifacts, and tags from all the MLO and LMO views. This preprocessing study helps the model to classify all the BIRADS classes correctly with less input images. Depth-first search (DFS) algorithm identify all the unwanted high-intensity areas (artifacts and pectoral muscle) of MLO and CC views and removes them, which further help the model to make the correct decision. **Figures 3**, **4** depict the input and output images after preprocessing.

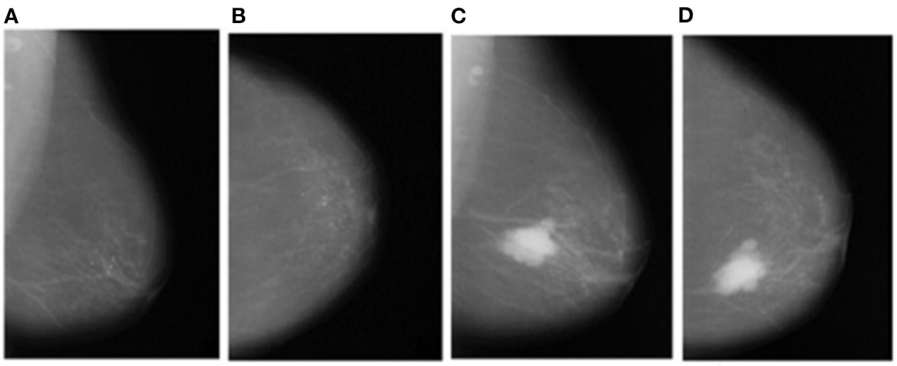

FIGURE 3 | Input raw images- **(A)** Left_MLO **(B)** Left_CC **(C)** Right_MLO **(D)** Right_CC.

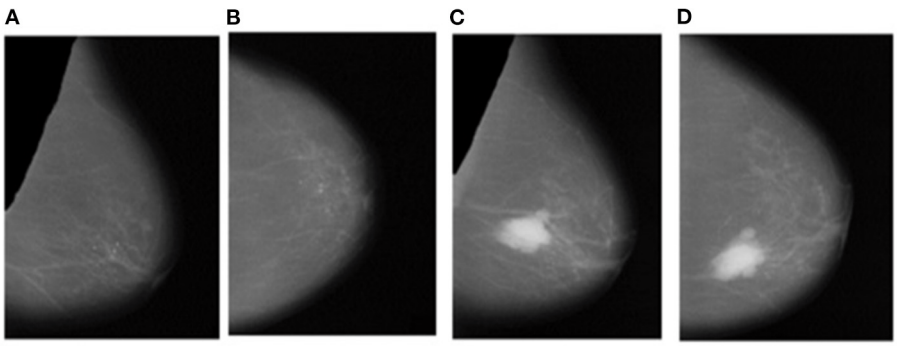

FIGURE 4 | Output Images after segmentation and cropping - **(A)** Left_MLO **(B)** Left_CC **(C)** Right_MLO **(D)** Right_CC.

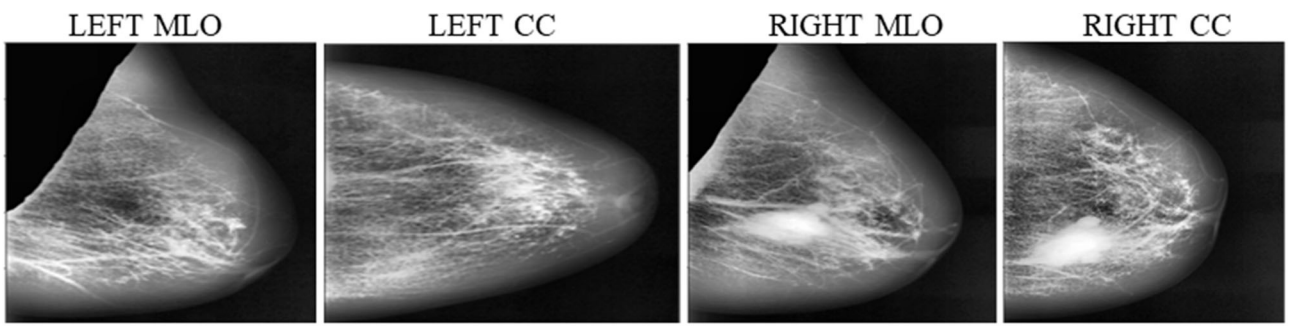

FIGURE 5 | Contrast enhancement of input images.

Contrast Enhancement

Mammographic breast density classification is a function of the density of fibroglandular tissues inside the breast. Contrast enhancement helps to improve the visibility of fibroglandular tissues. Subsequently, it helps to improve the classification accuracy of deep learning models. In literature, many contrast enhancement methods are recorded to enhance the quality of medical images. These methods are "histogram equalization (HE)," "adaptive histogram equalization (AHE)," and "wavelet transform (WT) coefficients" (29–31). But, these documented practices take ample processing time and are less effective in noise reduction. Another recorded method is the "unsharp masking (USM) method," which enhances the local contrast inside the image by limiting the global contrast. Still, this technique creates artifacts in the image. Due to this, the image looks artificial; therefore, it is not fitting for the enrichment of the medical images (32–34).

In contrast to gain agreement for the high-frequency element of the image, which is the basic principle behind "adaptive contrast enhancement (ACE)," it consists of limitation in terms of

high processing time (32–38). In MBD classification, local details are more important than global features and reduce processing time; the proposed architecture uses the contrast limited adaptive histogram equalization (CLAHE) algorithm for limited contrast enrichment of fibroglandular tissues (39–41). The first merit of this method helps to minimize the edge shadowing effect and noise produced in homogeneous input digital mammograms. Second, small images known as tiles are used instead of the entire image to perform the CLAHE operation. Hence, contrast enhancement of each tile histogram matches with exponential distribution or Rayleigh distribution. Moreover, to overcome artificial-induced borders, neighboring tiles are connected by bilinear insertion. This advanced CLAHE technique is outlined under:

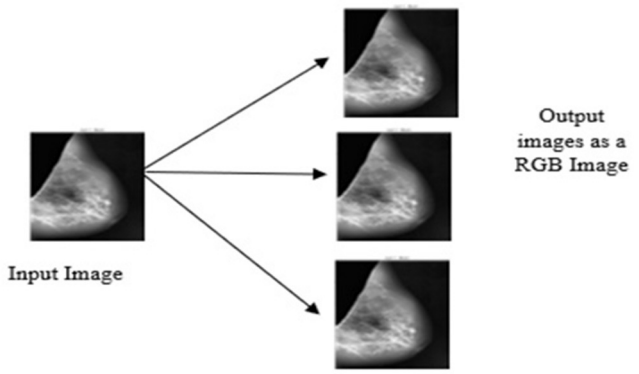

FIGURE 6 | Conversion of grayscale image appears as an RGB.

1. Initially, all the input mammograms are divided into 8 × 8 non-overlapping contextual fields of equal sizes and later a histogram of various contextual regions is calculated.
2. The clip limit (β) is the threshold parameter used to alter the contrast of the image, which is calculated by Equation (1).

$$\beta = \frac{M \times N}{L}\left(1 + \frac{\propto}{100}\left(S_{\max} - 1\right)\right) \quad (1)$$

Where β is the clip termination, calculated as eight by several experiments, M × N is the number of pixels in each field, L is the number of gray scales, and α is a clip factor (0–100). It is the highest allowable slope, which is set to be 4 for this analysis.

3. Each histogram is aligned, so that its maximum does not surpass further than the clip boundary.

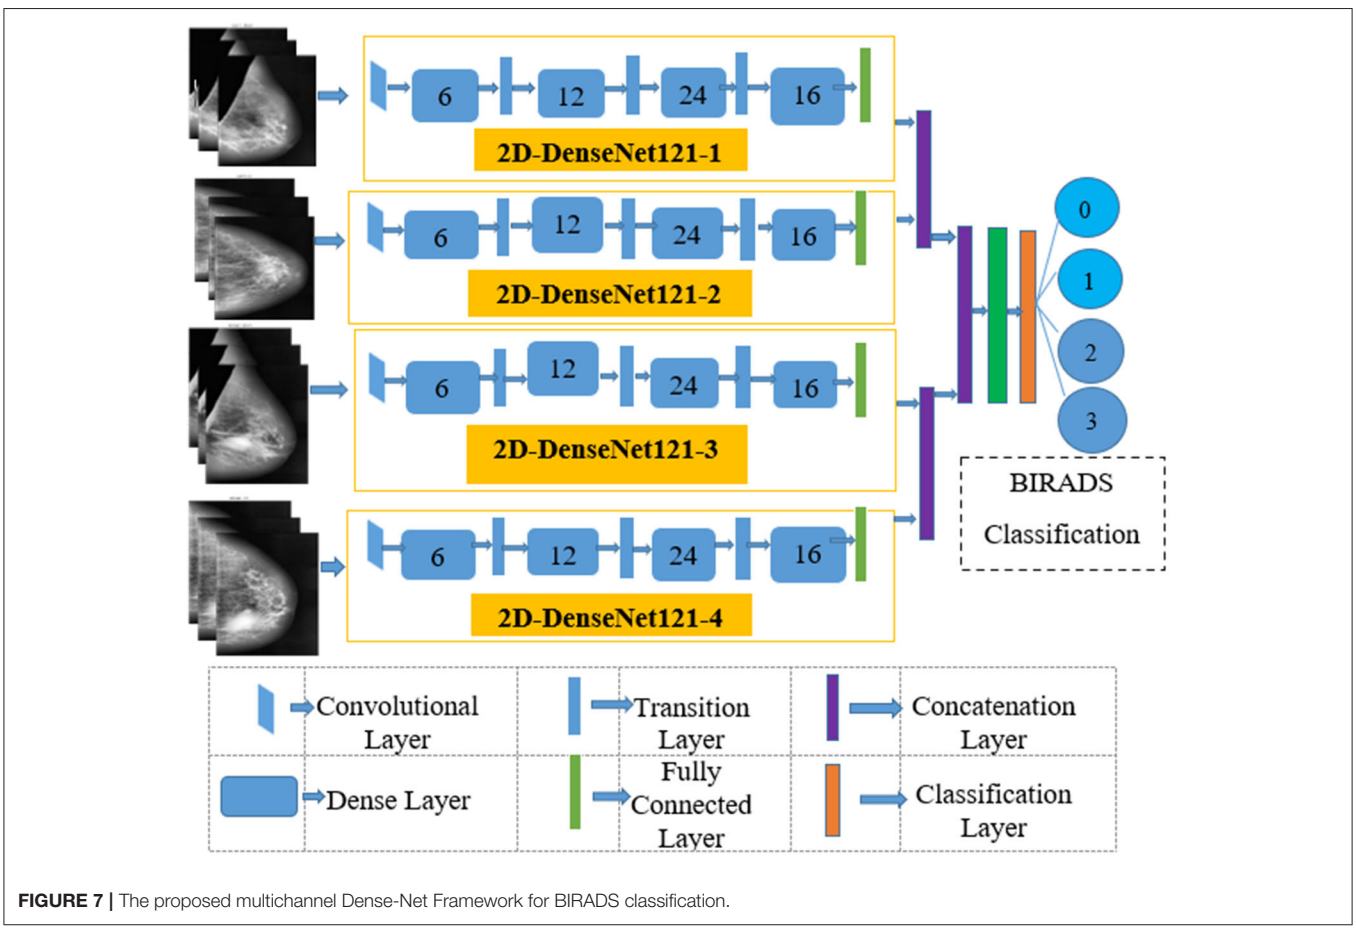

FIGURE 7 | The proposed multichannel Dense-Net Framework for BIRADS classification.

4. The transformation function, which is described below, is used to modify the histogram.

$$t\left(r_k\right) = \sum_{j=0}^{k} p_r\left(r_j\right) \quad (2)$$

$$\text{Where } p_r\left(r_j\right) = \frac{n_j}{n} \quad (3)$$

Equations (2) and (3) describe the probability function of input image gray scale value j, n is a total number of pixels in input mammogram image, and n_j is input pixel number of gray value j.

5. The adjacent tiles were joined by bilinear interpolation and the image gray scale values were altered according to the revised histograms.

In this method, the contrast factor is limited to 0.01 to prevent oversaturation of the image, specifically inhomogeneous areas for optimized output. Furthermore, the number of bins for the histogram structure is restricted to 64 over the uniform distribution for contract enhancing transformations. **Figure 5** depicts the result of contrast enhancement of the CLAHE algorithm on input images.

Multichannel Model Development

This article proposes the feature learning ability of multichannel DenseNet architecture presented by Huang et al. (18) toward MBD classification. The proposed method uses four independent DenseNet architecture as four-channel architecture known as multichannel architecture. This architecture is competent in taking all the four views of an individual patient for the classification of MBD.

Conversion of Gray Scale Image Into RGB

The DenseNet model is pretrained on red, green and blue channel (RGB) images, but the proposed study uses the gray scale image as the input image. To appear gray scale image as an RGB, perform repetition of image array three times due to which the same image appears on the channels. Then, after duplication of the input image, all the input images are resized into 320 × 320 × 3. **Figure 6** depicts the conversion of the gray scale image into a three-channel RGB.

Input Convolutional Layer

The four input channels of the proposed architecture are marked as L_CC, L_MLO, R_CC, and R_MLO. The fundamental merit of this combination is that all the four views of digital mammography are processed concurrently. Each input layer of DenseNet architecture consists of a convolution layer of the kernel of 7 × 7 with a stride of 2. This convolution operation reduces the input size of the images to 112 × 112 × 3. Input image further passes through a pooling layer of 3 × 3 maximum pooling with stride 2 × 2. Thus, the input layer's convolution and pooling operation reduce the input image size to 56 × 56 × 3 and before passing to the dense blocks. **Figure 7** depicts the proposed multichannel architecture.

Design of DenseNet Neural Structure

The DenseNet architecture consists of different design variants such as DenseNet121, DenseNet169, DenseNet 201, and DenseNet 264. The DenseNet architecture's fundamental merit is the structure of dense layers precisely designed to take care of downsampling and feature concatenation. Therefore, out of four variants, the proposed architecture uses the DenseNet121 network structure, consisting of a combination of dense block layers and transition layers. Thus, the proposed model uses 58 convolutional layers and a growth rate ($k = 12$), including four dense and two transition layers. In addition, the proposed model consists of comparatively fewer parameters hence, saving computational memory and reducing the overfitting.

Dense Block Layer

In four dense blocks, the individual layer is responsible for forming a k-characteristic map after convolution, which also maintains feature maps of each layer are in the same size. K convolution kernels extract all the features from the layers. Parameter k is known as a hyperparameter in DenseNet, which is the growth rate of the network. Each dense layer receives the different inputs from previous layers to reduce computation and enhance the efficiency of the dense block. The dense block internally uses the bottleneck layer (1 × 1 convolution layer between batch normalization, ReLU, and 3 × 3 convolution layer).

Transition Layer

This section consists of a batch normalization layer and a one × one convolution layer followed by a two × two average pooling layer. This layer combines two nearby dense block layers to reduce the feature map size. A combination of 4 dense blocks and transition layers converts the image size into 7 × 7 × 3, further provided to the output layer. Each layer connects to the previous stage as an input described by Equation (4):

$$X_l = H_l(\left[x_0, x_1, \ldots\ldots, x_{l-1}\right]) \quad (4)$$

A non-linear transformation function $H_l(.)$ is responsible for combining series output of batch normalization, ReLU, pooling, and convolution operation. **Figure 8** depicts the design architecture of dense layer.

Output Classification Layer

The output layer of the proposed architecture consists of a specific average pooling layer for each channel to extract meaningful features. Extracted features are flattened by the flatten layer and are given to the individual dense layer. MBD features received from four-channel are concatenated together with two concatenation blocks. Subsequently, the third concatenation block joins all the proposed method features together. The three dense layers accept all the features collected together and, finally, the classification layer receives the output of three dense layers for classification. The proposed method uses the SoftMax classifier to classify output into four classes as per the BIRADS Density Classification. **Table 2** presents the specifications of the proposed method.

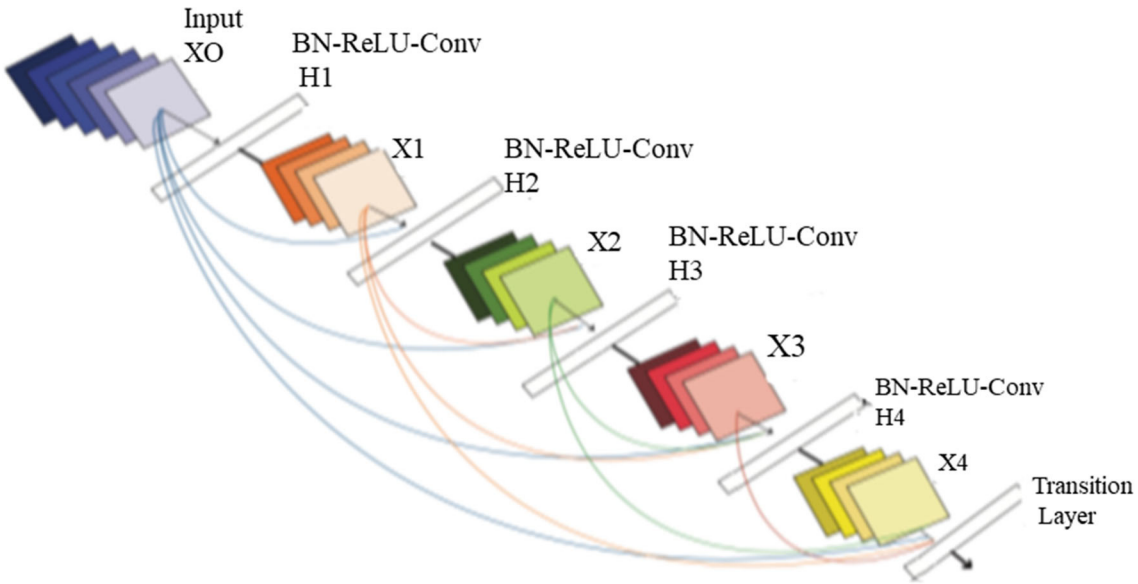

FIGURE 8 | The architecture of dense layer.

ANALYSIS OF EXPERIMENT AND OUTCOMES

The experimentally proposed design is trained and tested upon the PyTorch framework on Google Colaboratory, a free online cloud-based Jupiter notebook environment. The proposed method input dataset is not sufficient to split into the train, validate, and test data sets; hence, training and testing of the model are done in two phases. **Figure 9** depicts the image data distribution during training (phase I) and training and testing (phase II).

Phase I

The entire model is trained with stochastic gradient descent (SGD) algorithm using batch sizes 4 and 30 epoch on the whole dataset. SGD is an optimization algorithm that estimates the error gradient for the model's current state with an example of a training set; after this, it updates the weights of the model using backpropagation (35–37). Equation (5) describes weight updating mechanism in SGD algorithm.

$$w_{new} = w_{old} - n\nabla Qi(w_{new}) \quad (5)$$

Where w_{new} is new weight, is weight at previous iteration is learning rate and weight gradient. The primary merit of this algorithm is that it updates parameters for each training example and performs one update at one time. Thus, SGD is faster and can also learn online. The weight updating step size is the learning rate of the model. The learning rate is a configurable hyperparameter that controls the speed by which the model learns. The initial learning rate for this model is 0.1 (default value) and further divided by ten at 50 and 75% of the total training epochs. The categorical cross-entropy acts as a loss function in this model, quantifying the difference between four probability distributions. This loss function works well with the SoftMax activation function in multiclass classification. Equation (6) describes the categorical cross-entropy mathematically, which is:

$$C.E. = -\sum_{i}^{c} t_i log(s_i) \quad (6)$$

Where $C.E.$ is cross-entropy t_i and s_i ground truth and the convolutional neural network (CNN) score for each class i in c. **Table 3** presents the setting of different hyperparameters used to obtain the optimized results of the proposed architecture.

During the training on the entire dataset, the best classification accuracy score was 96.35% at 18 epochs with a loss factor of 0.1344. **Figure 10** depicts the training phase results on the dataset as a whole.

Phase II

After training the model on the entire dataset, the proposed model performance is validated by spitting the image dataset in a ratio of 80% as training and 20% as testing. The proposed model performed significantly well on all the BIRADS density classes during the testing phase and recorded the best classification accuracy, 90.00%, with a validation loss of 0.3814. **Figure 11** depict the outcomes of validation over the training model.

Results Evaluation

The proposed multichannel DenseNet architecture performance is analyzed from the confusion matrix of the model on the test dataset. **Figure 12A** shows the proposed architecture's heat map (confusion matrix) on the test dataset. The heat map helps to analyze which category is correctly classified by the proposed architecture. The main diagonal darker

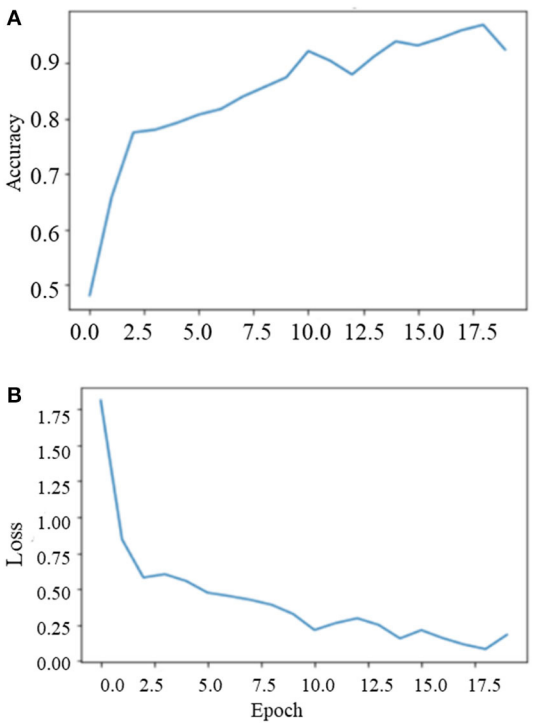

FIGURE 10 | Training phase performance of the model **(A)** model accuracy and **(B)** model loss.

version indicates a better classification rate. Although it is clear that the model is working well in classes A, C, and D, there is some confusion in classifying category class B. Still, this model correctly classifies heterogeneous dense (C) and extremely dense (D), which is the essential bottleneck behind MBD classification. **Figure 12** depict the heat map and the AUC curve, respectively, of the proposed model.

Evaluation of the classification results of the intended architecture is performed in terms of precision, recall, the F1-score, and classification accuracy. Among those parameters, precision is the proportion of samples with optimistic predictions concerning the total number of correct positive samples. The recall ratio of correctly predicted samples to the whole samples and the F1-score are the precision and recall weight. Finally, classification accuracy is the total correct predictions to the total number of samples. Equations (7) to (10) define precision, recall, the F1-score, and classification accuracy, respectively:

$$Acc = \frac{N_A + N_B + N_C + N_C}{N_{All}} \tag{7}$$

$$F1 - score = \frac{2PR}{P + R} \tag{8}$$

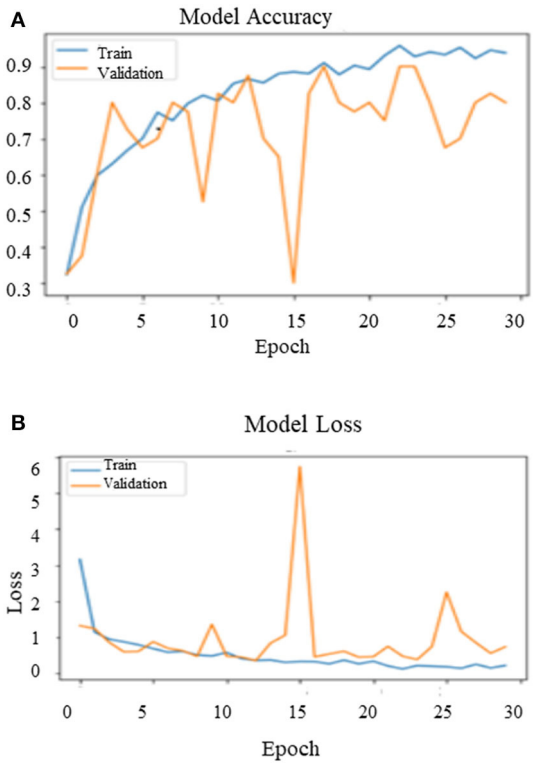

FIGURE 11 | Validation results of the proposed model in phase-II **(A)** model accuracy **(B)** model loss.

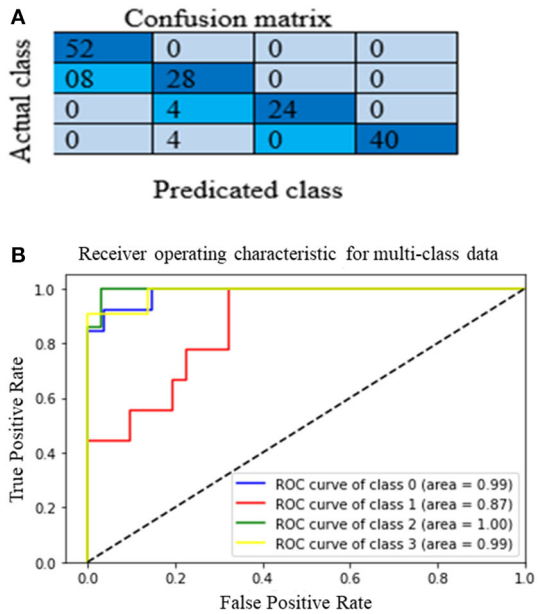

FIGURE 12 | (A) The Heat map **(B)** and the ROC curve of the proposed model.

Where N_{All} *is* the total number of images and *Na*, *Nb*, *Nc, and Nd* signify the number of images in MBD classes A, B, C, and D.

$$P = \frac{N_t}{N_i} \times 100 \tag{9}$$

$$R = \frac{Nt}{Nf} \times 100 \tag{10}$$

Where, Nt is the correct number of predictions of a specific category and Ni is all the number of forecasts of a class and indicates the actual number of the category, among them are precision and recall, respectively. The model accuracy is the ratio of the sum of the diagonal elements to all the elements. Thus, it acts as an indicator of the overall prediction of the model. **Table 4** presents the model's overall performance in detail and variation in precision rate, the recall rate, and the F1-score rate under different categories. The number (or percentage) of accurate positive samples for all the four BIRADS density classes are 92, 75.5, 92.2, and 94.7% of their respective totals. From the results shown in **Table 4**, there is no confusion between classes A and C, B and C, and C and D. The proposed algorithm results are consistent with the results evaluated by the radiologists, which are a positive sign that indicates that deep learning models are helpful for the classification of MBD. Another graphical technique utilized to investigate the realization of computer-aided diagnostic methods is the receiver operating characteristic (ROC), as shown in **Figure 12B**. This curve analysis performance of the prototype should be in terms of true positive rate (TP) and false positive rate (FP). The AUC value refers to the area enclosed by the ROC curve in the [0, 1] period and the X-axis. The higher the AUC content, the more reliable the realization of the model. It additionally highlights the ability of the model to differentiate among the classes.

DISCUSSION

Inconsistency in MBD assessment is the fundamental reason behind unnecessary extra screening procedures and cause for patient anxiety (41–43). Due to improved system architecture and hardware capability, the deep learning model can be an alternative for medical image classification. Still, the need for a larger dataset and vanishing gradient are the primary bottleneck issues to obtain state-of-the art results from deep learning models (44).

Advantages of Proposed Method

This study article proposes multichannel DenseNet architecture for MBD classification to investigate the performance of DenseNet architecture on a smaller dataset. The proposed architecture has recorded good classification performance in four-class classification. Furthermore, the visualization results show that the model can distinguish between all the BIRADS density classes, especially in "scattered density" and "heterogeneously dense category of the BIRADS." Thus, this model can help the radiologists to classify the BIRADS density classes quickly. The main reasons for the excellent performance of this model are as follows:

TABLE 4 | Performance parameter of the proposed method.

BIRADS density classes	Precision	Recall	F1-score	Overall classification accuracy	Overall AUC
Predominantly fatty-class A	1	0.866	0.92	0.9006	0.9625
Fat with some fibro glandular tissue class B	0.77	0.77	0.755		
Heterogeneous dense-class C	0.857	1	0.922		
Extremely dense-class D	0.90	1	0.947		

TABLE 5 | Comparative status of the proposed method with current state-of-the-art methods.

1. Instead of using raw images, the proposed architecture uses preprocessed images. Hence, there are no high-density areas such as pectoral muscle and tags on mammograms, which are helpful to increase the classification accuracy of the proposed architecture.
2. The proposed method uses a contrast enhancement technique to improve the quality of training data.
3. The model contains four DenseNet branches, which extract the features of mammograms from four views of the single patient, so that the network can focus on a broader range of spatial information.
4. Due to multichannel architecture, it is possible to process all the views of a single patient simultaneously.
5. Subsequently, with multichannel and multiview architecture, it is probable to consolidate all the features collectively; consequently, the performance of the intended model is found more reliable than single-view classification.

Comparison With Existing Methods

While there are variations in related datasets and evaluation methods, the straightforward comparison is challenging to researchers. This section compiles the proposed algorithm's comparison state with existing classifications. To study the interobserver variation in MBD assessment, N Kaiser et al. (24) proposed the novel multichannel VGG architecture. This approach uses a total of 8,150 digital mammograms, divided into 600 cases. This method recorded 88% two-class classification accuracy (dense and nondense) with the AUC of 0.954. Besides, these results are also compared with the 32 individual radiologist's panel's density ground truth. This study reveals that the deep learning approach performs better than average radiologists. Thus, we only need to refine the deep learning model for MBD classification. However, the fundamental limitation of this method is that the gradient flows from the final layer to the initial layer; hence, vanishing gradient problem takes place, which increases training time and reduces the classification accuracy. In the proposed method, due to DenseNet architecture, all the layers are directly connected in feed-forward nature, acting as an effective solution for vanishing gradient and reducing training time. Thus, the results of the proposed algorithm outperform this method on a smaller dataset.

Another method directly comparable to the proposed method is the optimized lightweight deep learning architecture proposed by Shi et al. (22). The elemental focus of this method is to overcome the requirement of the larger dataset and vanishing gradient problem of the deep learning algorithm. This method combines three CNN layers, one dense layer, and an output layer to classify MBD. This architecture is tested on the 322 mini-MIAS dataset with different data augmentation techniques and recorded 83.6% classification accuracy. However, due to the smaller dataset, this architecture has limitations regarding moderate classification accuracy and low stability of the network. Therefore, the proposed method used the concept of transfer learning and multichannel architecture to overcome these limitations. As a result, the proposed model outperforms this method in classification accuracy on a smaller dataset. **Table 5** provides the comparative state of the proposed method with other different existing methods.

Limitations and Future Study

Even though the proposed method has improved the classification performance of the BIRADS density classes, some issues still need to be addressed. First, this study uses a smaller amount of image data and no image enhancement strategies are used to expand the dataset. Hence, model performance, especially stability during validation, is affected

due to limited image data and model found it a little confusing to classify classes A and B. Therefore, in future study, data enhancement techniques will improve the model's performance. Second, the proposed study addresses only one type of dataset; hence, this approach does not address the robustness of the model. Future study will address the robustness of the model by training the model with different vendor-specific image datasets and testing results of all the mentioned state-of-the-art methods with the proposed method with the same work environment. The proposed study will be undoubtedly helpful in addressing the issues mentioned above.

CONCLUSION

In summary, the primary objective behind this study is to classify MBD as per the BIRADS classification. This study proposes the novel approach of multichannel architecture with DenseNet121 for the objective assessment of MBD. The proposed framework uses the four views of a single patient to enhance feature learning ability through a multiview approach. In the method, image contrast enhancement and preprocessing of the input image are implemented to enhance the condition of the training image data. The input images are processed through multichannel architecture to extract and fuse all the features. Analysis of the results suggests that the proposed model successfully distinguishes between all the BIRADS density classes, but is predominantly found superior in the two most distinctive and challenging BIRADS categories: "BIRADS_C" and "BIRADS_D." Classification accuracy of the proposed model is recorded at 96.67% during training and 90.06% during testing and the average AUC of 0.9625. The introduced design consists of some weaknesses discussed and will be addressed in future study; with certain modifications, the proposed method is suitable for application in clinical workflow in breast cancer screening to avoid false recalls.

Machine learning algorithms are excellent techniques to develop prediction models to enhance response and efficiency in the health sector. It is the greatest approach to avoid the spread of hepatitis C, especially injecting drugs, is to avoid these behaviors. Treatments for hepatitis C can cure most patients within 8 to 12 weeks, so being tested is critical. After examining multiple types of machine learning approaches to construct the classification models, we built an AI-based ensemble model for predicting Hepatitis C disease in patients with the capacity to predict advanced fibrosis by integrating clinical data and blood biomarkers. The dataset included a variety of factors related to Hepatitis C disease. The training data set was subjected to three machine-learning approaches and the validated data was then used to evaluate the ensemble learning-based prediction model. The results demonstrated that the proposed ensemble learning model has been observed ad more accurate compared to the existing Machine learning algorithms. The Multi-layer perceptron (MLP) technique was the most precise learning approach (94.1% accuracy). The Bayesian network was the second-most accurate learning algorithm (94.47% accuracy). The accuracy improved to the level of 95.59%. Hepatitis C has a significant frequency globally, and the disease's development can result in irreparable damage to the liver, as well as death. As a result, utilizing AI-based ensemble learning model for its prediction is advantageous in curbing the risks and improving treatment outcome. The study demonstrated that the use of ensemble model presents more precision or accuracy in predicting Hepatitis C disease instead of using individual algorithms. It also shows how an AI-based ensemble model could be used to diagnose Hepatitis C disease with greater accuracy.

INTRODUCTION

Hepatitis C is a liver condition caused by the hepatitis C virus (HCV), which affects the immune system. The main reason behind the spreading of Hepatitis C is through the blood contact of an infected person. Life-threatening and serious health issues such as Cirrhosis and liver cancer are the result of chronic hepatitis C. Often, the early-stage symptoms or the sickness don't appear in

people suffering from chronic hepatitis C. When these symptoms appear in patients, they might often show signs of advanced liver disease (1). Unfortunately, there is still no vaccine available in medical facilities to treat Hepatitis C. By not sharing needles and refraining from behaviors that could lead to the spread of this disease, such as injecting drugs, the most effective strategy to stop HIV from spreading is to avoid it. Treatments for Hepatitis C that have been evaluated and found effective can cure a patient infected with the virus within 8 to 12 weeks if administered on time.

Hepatitis C infections may be considered as acute (short-term) or chronic (long-lasting). If the symptoms last for 6 months, then that patient is considered to be suffering from acute hepatitis. Unfortunately, in more than 50% of the cases, the patient's body becomes unable to clear the virus and hence this acute infection transforms into a chronic disease. According to some researchers' projections, the United States will be free of this chronic Hepatitis C infection by the year 2036. When it comes to better understanding a condition and its prognosis, medical practitioners can use their patient's electronic health information to uncover new findings and trends that might otherwise go unnoticed by physicians. Machine learning classifiers are used in this work to predict the diagnoses of healthy controls and patients who have been diagnosed with hepatitis C. Other viral infections and cancers may benefit from the use of genetic analysis and machine-learning techniques to choose the best course of treatment. The hepatitis C virus can cause substantial liver damage when it infects the liver and produces inflammation. Blood transfusions, injectable drug usage, and sexual behaviors that expose people to blood are the most common ways in which this virus is spread. It is a bloodborne virus.

The acute phase of hepatitis C infection is the first stage of a long-term infection. Hepatitis C is often misdiagnosed due to the lack of symptoms associated with acute hepatitis C infection. Within 1 to 3 months of infection, acute symptoms occur and continue anywhere from 2 to 3 months. It's not usually the case that an acute hepatitis C infection becomes chronic.

Hepatitis C spreads through contact with the blood of someone who has HCV. This contact may be through (2):

- Hepatitis C spreads through sexual transmission.
- Assisting someone who has HIV by sharing drug needles or other drug paraphernalia Hepatitis C is most commonly acquired this way in the United States.
- Getting poked by a needle that was previously used on someone with HCV. The same thing can happen in a hospital or medical facility.
- Using instruments or inks that have not been disinfected after being used on someone with HCV to get tattooed or pierced
- HCV-infected blood or open sores can spread the disease.
- Razor blades and toothbrushes that may have come into contact with someone else's blood should not be shared.
- Being born to a mother infected with the human papillomavirus (HPV).
- Sexual contact with an HCV-infected person that is not protected

In the period before 1992, the common causes of the spread of Hepatitis C were through blood transfusions and transplants of organs. Infections spread by these ways are now extremely rare in the United States, thanks to the widespread use of routine blood supply testing (3). The medical experts have highly recommended the screening of hepatitis C even for people not showing any symptoms of this disease as after analyzing the population the researchers have concluded that people suffering from chronic hepatitis C may doesn't show any symptoms until it causes complications (4).

Artificial intelligence (AI) advancements assist clinicians in providing patients with faster diagnoses and more effective therapy. Artificial intelligence (AI) and human diagnostic efficiency have been compared in studies. AI was found to be just as good at diagnosing as humans, and in some cases better, when compared to less-experienced doctors. In this article, we introduce an artificial intelligence technique based on previously acquired data from a large number of patients (5). The main objectives of this study are given as below:

- O1: Develop a novel Ensemble model of Machine learning algorithms for Hepatitis C prediction.
- O2: Predicate the level of Hepatitis C using machine learning where it plays a significant role in accurately predicting the disease in different age groups.
- O3: Implement Ensemble model to Hepatitis C prediction and compare it to existing model.

The objective O1 is being designed for predicting Hepatitis C. Moreover, for finding the accurate prediction of Hepatitis C, the objective O2 is planned. Objective O3 will be fulfilled by applying the Ensemble model to predict Hepatitis C. The results are then compared with existing Machine Learning algorithms. The main output of these objectives is predicting Hepatitis C disease more accurately.

The remainder of this paper is organized as follows: Section Related Work reviews the related work in the body of literature. Section Materials and Methods discusses the data and materials used followed by section Methods which explains the theory behind the algorithms. Section Results and Discussion presents and analyzes the experimental results. Finally, the paper concludes and proposes future work in section Conclusion.

RELATED WORK

To capitalize on this hepatitis information base, scientists utilized a fleeting reflection technique. We offer novel ideas and strategies for abstracting momentary changed and long haul changed tests in light of hepatitis hidden data and information investigation. Information deliberation empowers us to utilize a wide scope of AI methods to distinguish new and intriguing data for clinical doctors (6–9).

Utilizing AI draws near, Mahmoud ElHefnawi et al. (10) fostered an impressively precise prescient model for Egyptian patients' reactions in view of their clinical and biochemical information. The CART characterization calculation was used for choice trees (DTs). Pruning levels of 9, 11, 13, and 17 were

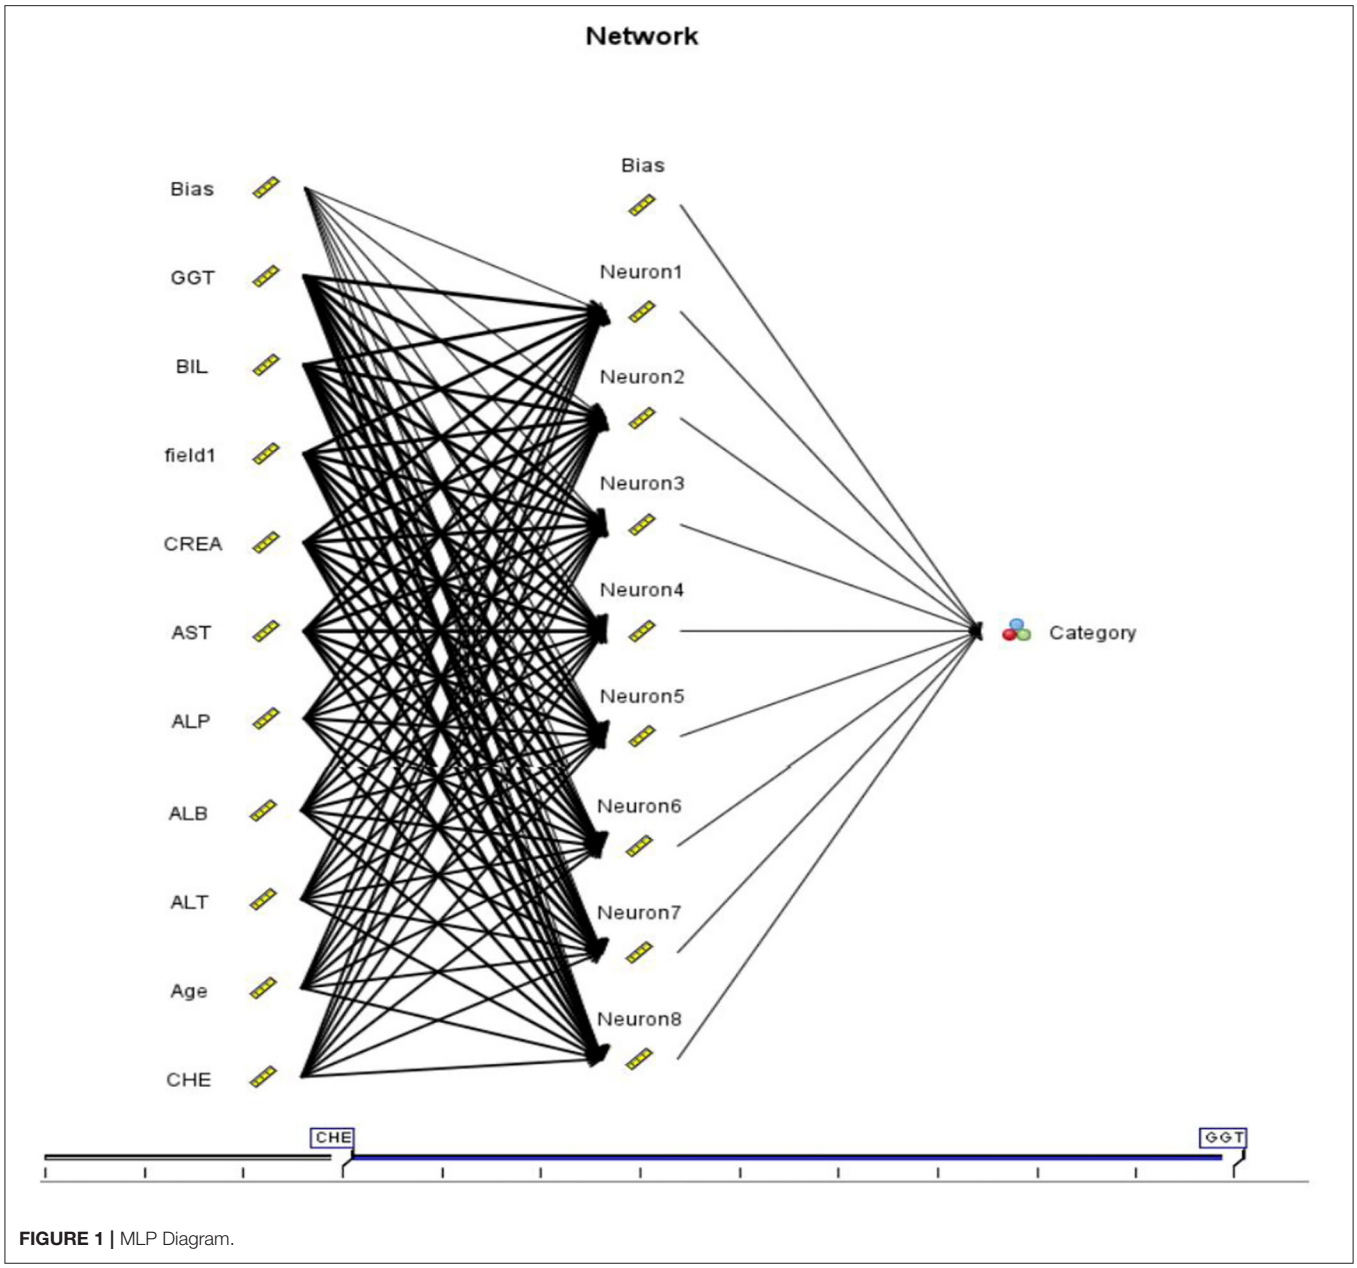

FIGURE 1 | MLP Diagram.

examined, as were hubs going in number from 45 to 61 in every one of the six DTs. Hematology action record and fibrosis, viral burden and Alfa-feta protein and egg whites were the most measurably huge instructive parts of the 12 elements in this examination. At last, a 20% test set was utilized to confirm the models. The ANN and DT models have the most noteworthy and middle exactness of 0.76 and 0.69, separately, and 0.80 and 0.72. This test had an exactness of 0.95 percent, and an explicitness of 0.89 and 0.89%. We've reached the resolution that choice trees are more exact at anticipating reaction and can be utilized to direct patients toward the most ideal course of treatment choices.

The essential justification behind liver transplantation in Latin America is hepatitis C disease. Long haul results, for example, demise are further developed when hepatitis C is treated in contaminated patients. Almost 50% of patients treated with pegylated interferon and ribavirin had a drawn out viral reaction. Over the most recent couple of years, new meds have been fostered that have drastically worked on long haul viral reaction, making triple treatment the norm of care. People with chronic hepatitis C now have a place to go in Latin America thanks to these guidelines.

Using a virtual screening (VS) strategy, Wei et al. (11) discovered new HCV NS5B polymerase inhibitors using a combination of irregular backwoods (RB-VS), e-pharmacophore (PB-VS), and docking techniques. A sum of five mixtures were picked for extra enemy of HCV movement testing and cell cytotoxicity examines from the last hit list. Hindrance of NS5B polymerase by each of the five mixtures was viewed as at IC50

values going from 2.01 to 23.84 M, and hostile to HCV action at EC50 values going from 1.61 to 21.88 M. All compounds, except for compound N2, showed no cell cytotoxicity (CC50 > 100 M), albeit compound N2 showed feeble cytotoxicity at a CC50 worth of 51.3 M. There was a particular file of 32.1 for N2's HCV antiviral action, making it the most intense. NS5B polymerase inhibitors could be created from the five hit compounds with novel platforms that have been distinguished.

Hepatitis C infection (HCV) habitually shapes a constant contamination, which is regularly asymptomatic in the beginning phases of the illness. There are as of now no symptomatic models for deciding if a HCV contamination is ongoing

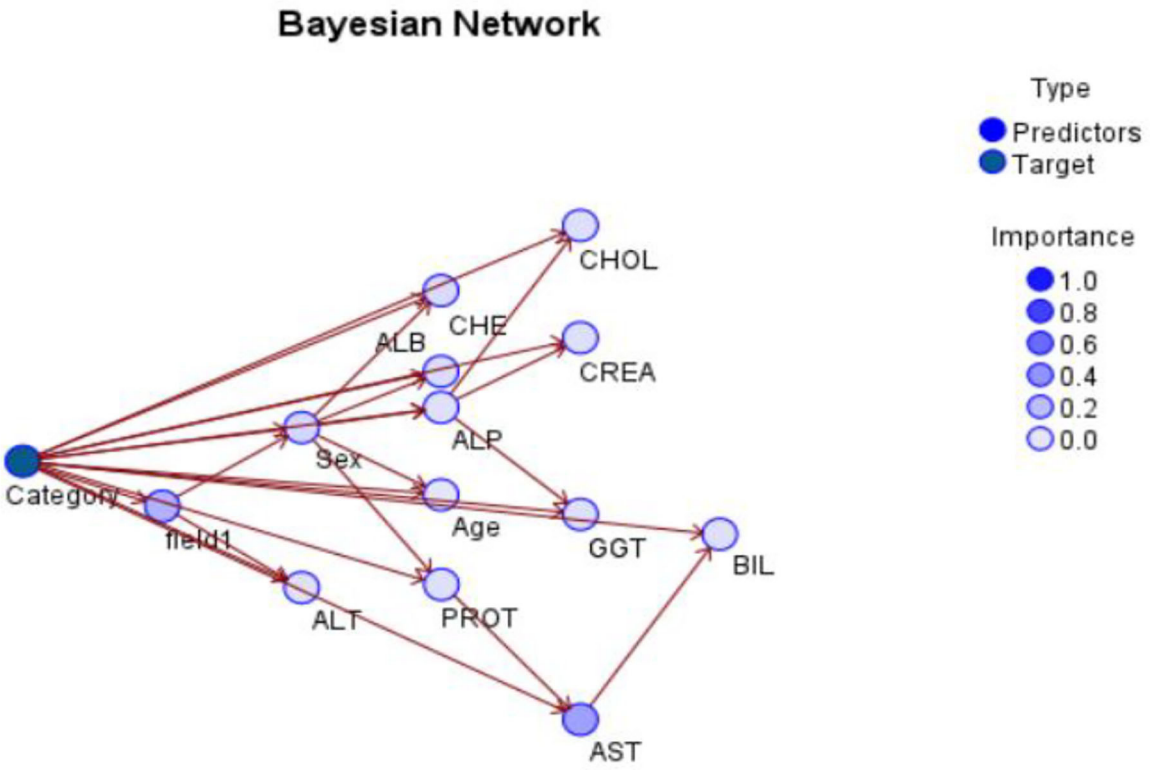

FIGURE 4 | Bayesian network for current problem.

vs. persistent. In light of HCV's inclination to mistake in replication, every tolerant has an assorted assortment of hereditarily unmistakable HCV strains. Therefore, it is for the most part accepted that the degree of intra-have HCV heterogeneity develops over the long haul. Because of elements, for ex-ample, particular breadths and negative choice that happen during persistent disease (2, 12), fundamental measurements for evaluating hereditary heterogeneity are not ex-act enough for HCV contamination organizing in light of the intricacy of the primary improvement of HCV populaces inside has.

In a revelation dataset ($n = 499$) of hepatitis B infection (HBV) patients, Wei et al. (13) constructed and contrasted AI draws near and the FIB-4 scoring. The HBV dataset ($n = 86$) was utilized to test the models' presentation. To test the relevance of these models, we applied them to two separate datasets of hepatitis C (HCV) ($n = 254$ and 230). Angle helping (GB) reliably beat FIB-4 scores (p b.001) and different methodologies in the revelation information for the expectation of cutting edge HF and cirrhosis. HBV-approval information showed that the GB model had a region under col-lector working trademark bend (AUROC) that was 0.918, though the FIB-4 model had a region under beneficiary working trademark bend (AUROC) of 0.841. Two HCV datasets utilized GB-based forecast and higher shorts for both GB and FIB-4 scores were important to accomplish equivalent explicitness and awareness, yet the GB-based expectation actually performed well. A correlation of the GB-based forecast technique to FIB-4 in HBV and HCV partners involving different end values for various etiological groupings showed non-stop upgrades comparative with FIB-4. LiveBoost, an easy to understand web stage, empowers our expectation models to be utilized in clinical examination and applications with practically no limitations.

Patients with ongoing hepatitis C were isolated into two gatherings in light of their METAVIR scores: those with gentle to direct fibrosis (F0–F2), and those with cut-ting edge fibrosis (F3–F4). Progressed fibrosis hazard expectation models in view of choice trees, hereditary calculations, molecule swarm advancement, and multistraight relapse calculations have been made. The proposed models were assessed utilizing collector working trademark bend examination. There were genuinely huge relationships between's cutting edge fibrosis and age, platelet count, AST, and egg whites. With an AUROC of 0.73 to 0.76 and a precision of 66.3 to 84.4 percent, the AI calculations had the option to foresee moderate fibrosis in HCC patients. Ends: Alter-native strategies, for example, AI, could be used to estimate the probability of cutting edge liver fibrosis because of constant hepatitis C disease.

As per Cai et al. (14), an outrageous learning machine was prepared to anticipate the fibrosis stage and aggravation action grade of constant hepatitis C utilizing serum lists information from patients to foster a programmed determination framework for persistent hepatitis C. For instance, the basic design and fast estimation speed of the outrageous learning machine make

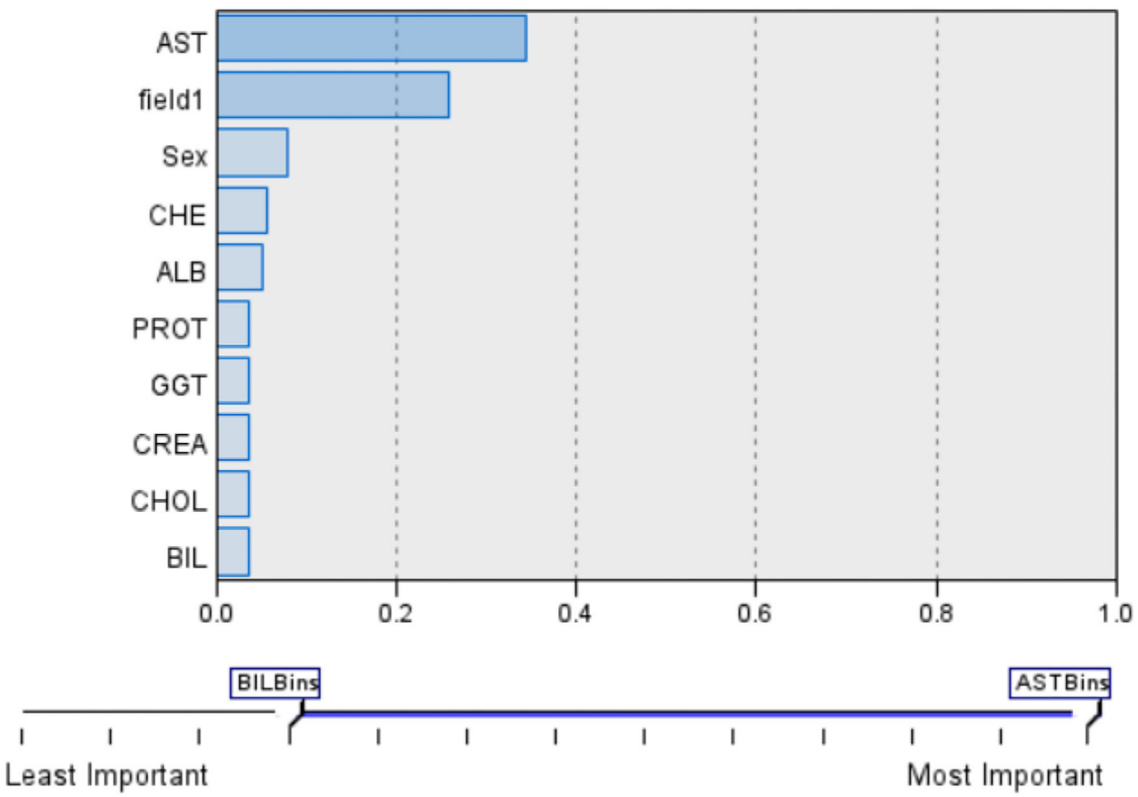

FIGURE 5 | Bayesian network Accuracy.

this independent finding framework work well. Serum markers are utilized to survey the proposed robotized determination framework for ongoing hepatitis C. For the finding of ongoing hepatitis C fibrosis stage and provocative movement grade, trial information show that the recommended method beats current baselines.

Utilizing Non-direct Iterative Partial Least Squares, Self-Organizing Map strategy, and troupes of Neuro-Fuzzy Inference System, Mehrbakhsh estimate the hepatitis infection. Likewise, we utilize choice trees to pick the most important highlights in the exploratory dataset. Utilizing a genuine world dataset, we put our procedure under serious scrutiny and contrast the outcomes with those of prior investigations. Utilizing the dataset, we observed that our strategy outflanked the Neural Network, ANFIS, K-Nearest Neighbors, and Support Vector Machines. As a shrewd learning framework for hepatitis sickness diagnostics in the medical care industry, this innovation has incredible guarantee.

Utilizing an AI approach, Ahammed et al. (15) fostered a calculation that can precisely group the periods of liver sickness in hepatitis C tainted patients. They utilized the UCI AI archive to acquire instances of liver fibrosis sickness in Egyptian patients. Manufactured minority oversampling approach has been utilized to expand the quantity of engineered patients to keep an even conveyance across all classifications. They then, at that point, utilized an assortment of element choice methods to decide the main hepatitis C viral characteristics in this dataset. Classifiers have been utilized to separate patients into bunches in view of whether their HCV cases are adjusted essential, include picked essential, or essential. In the wake of examining the information, KNN ends up as the winner, with a precision pace of 94.40%. Hepatitis C infection irresistible sickness has profited from this present review's discoveries.

NGS (cutting edge sequencing) is a usually involved strategy for delivering top caliber, profound, and proficient arrangement information. The pre-S area of the HBV genome was sequenced in 139 people, including 94 HCC patients and 45 constant HBV (CHB) patients, utilizing NGS innovation. We made two various types of information-al indexes. To begin with, we used an essential nearby arrangement search instrument (BLAST) to

plan every NGS short read and convert every arrangement into an amino corrosive by DNA codon table for the information on amino corrosive event recurrence. The info highlights are the Shannon entropy-based event frequencies of 20 major amino corrosive.

MATERIALS AND METHODS

Dataset

The dataset used in this research work was fetched from the source- Kaggle. The data set includes laboratory values of blood donors and patients suffering from Hepatitis C along with their demographic factor values such as age. The data was collected from UCI Machine Learning Repository: https://archive.ics.uci.edu/ml/datasets/HCV$+$data.

Except Category and Sex values, all other attributes are numerical. For classification, the target attribute is Category (2): blood donors vs. Hepatitis C patients [including its progress ("just" Hepatitis C, Fibrosis, Cirrhosis)].

Methods

Data Processing

In order to transform the fetched raw data in useful and highly efficient format, certain data pre-processing techniques are employed. At this stage, different types of functions are implemented so as to find the missing values, outliers, redundant and skewed features (16).

Missing Values

Once the above pre-processed data is loaded, a function is employed to find the missing values in relation to each feature (17). The term "missing data" refers to values that aren't available, and that would be relevant if they were observed. For example, a data input error or incomplete file might cause a data set to be blank or out of sequence. Missing data is a common occurrence in real-world datasets. For analysis and modeling purposes, you must first convert data with missing data fields. This, too, might be more art than science, as is the case with many other parts of data science. Having an understanding of the data and the context in which it originates is critical. A setback isn't always a setback when you have missing numbers in your data. Although the model is lacking some information, this is a chance to do some feature engineering to help it make sense of what's been omitted. Automated detection and remediation of missing data is possible thanks to machine learning techniques and software packages.

Outliers Data

After the above pre-processing stage, a certain category of data is referred to as noisy data if it may be corrupted, distorted, or cannot be interpreted. This kind of data may have originated from improper procedures or wrong data collection. However, it can be handled by implementing the methods such as regression, clustering or binning (18–20).

Multilayer Perceptron

The feedforward artificial neural network known as a multilayer perceptron (ANN). Multi-layer perceptron (MLP) networks are commonly referred to as feedforward ANNs, but the word is also used more specifically to describe a specific type of ANN with many layers of perceptrons (with threshold activation). The input layer transmits the signal to be processed. Prediction and categorization are under the purview of the output layer. There may be any number of hidden layers between the input and output levels in the MLP's computational engine (11, 14, 21) as seen in **Figure 1**.

For the back propagation process to work, it needs to traverse two different layers of a network in both directions. Pattern or input vector are applied to the input layer, and this effect propagates across multiple layers and generates an output vector in the forward pass The weights of the synapses in the network remain constant during this operation. The weights vary during the backward pass because of the mistake correction rule. Comparing the output signal's present state to the desired state is done (13, 22) as seen in **Figure 2**.

Using MLPs, it is possible to approximate any continuous function, including those that cannot be separated linearly. Pattern classification, recognition, prediction, and approximation are the most common uses of MLP as seen in **Figure 3**.

Bayesian Network

As an alternative, developing a model that preserves known conditional dependence between random variables and conditional independence in all other situations. In a graph with directed edges, Bayesian networks represent the probabilistic graphic representation of a system's known conditional dependence. The Bayesian network seen in **Figure 6** depicts the structure of the problem domain. In order to identify hepatitis illness, the network models a variety of factors, including certain symptoms and a small number of disorder nodes (10, 15, 23–33).

Hepatitis C is more likely in those who have jaundice, and vice versa, as shown by the arcs between the two nodes: jaundice raises the likelihood of Hepatitis C, and vice versa. The model's layout serves as an illustration of the causal links between the many elements involved in the diagnostic process. **Figures 4**, **5** shows the Bayesian network for the problem under study in this paper and its accuracy.

In creating the framework, we drew inspiration from medical fiction, conversations with herpetologists, and the model's numerical elements, including as Hepatitis patients' medical records are mined for prior and conditional probability distributions. **Figure 6** shows the Bayesian network Classification for Category.

Quest

Classification systems and prediction algorithms can be built using decision tree approach, which is commonly used in data mining. Branch-like segments of a population form an inverted tree with a root node, inner nodes, and leaf nodes. Rather than relying on a complicated parametric framework, the method uses a non-parametric approach to deal with large and complex datasets. When the sample size is large enough, training and validation datasets can be segregated from one other. QUEST evaluates a node's predictor variables using a set of criteria based on significance tests. Each predictor at a node may only need to be

tested once for selection reasons. This method does not analyze splits as thoroughly as either C&RT or CHAID does, nor does it study category combinations as thoroughly as either C&RT or CHAID does as seen in **Figure 7**.

This helps to speed things up. The target categories are divided into groups by doing a quadratic discriminate analysis using the specified predictor. When determining the ideal split, this approach is faster than C&RT (Complete and Recursive Search). Quest Diagnostics, a major clinical laboratory test supplier in the United States, provided the data for this study. Also **Figure 8** depicts the Quest Classification for Category.

Ordered HCV antibody immunoassay testing and RNA diagnostic tests for de-identified individuals. When available, data on patient gender and age were incorporated into the study. It was concluded that the data obtained from Quest Diagnostics could not be used to identify any particular person. In the event of a positive antibody test result, all specimens will be sent for HCV RNA quantitative testing.

Proposed Ensemble Learning Model

Combining predictions from multiple models to improve predictive performance is called ensemble learning. As many ensembles as you like may be created for any predictive modeling challenge, but there are only three methods that dominate the field of ensemble learning. Much to the dismay of many, each algorithm has given rise to an infinite number of sub-algorithms. It's important to understand the three main classes of ensemble learning methods before moving on to the math and programming, so that we can understand the underlying concepts.

Typical Ensemble Learning Techniques

Although there are practically infinite ways to accomplish this, there are probably three kinds of ensemble learning approaches that are most frequently studied and employed in practice. Their appeal stems from their ease of use and ability to solve a wide range of predictive modeling challenges. They are:

- Bagging.
- Stacking.
- Boosting.

Each strategy has an algorithm that specifies it, but the success of each approach has crucial to realize that, while these three methods are widely discussed and used, they don't define the scope of ensemble learning on their own.

Bagging Ensemble Learning

It is an ensemble learning method that uses bootstrap aggregation or bagging. Bootstrap and aggregation are the two primary components of Bagging, as their names suggest. An unpruned

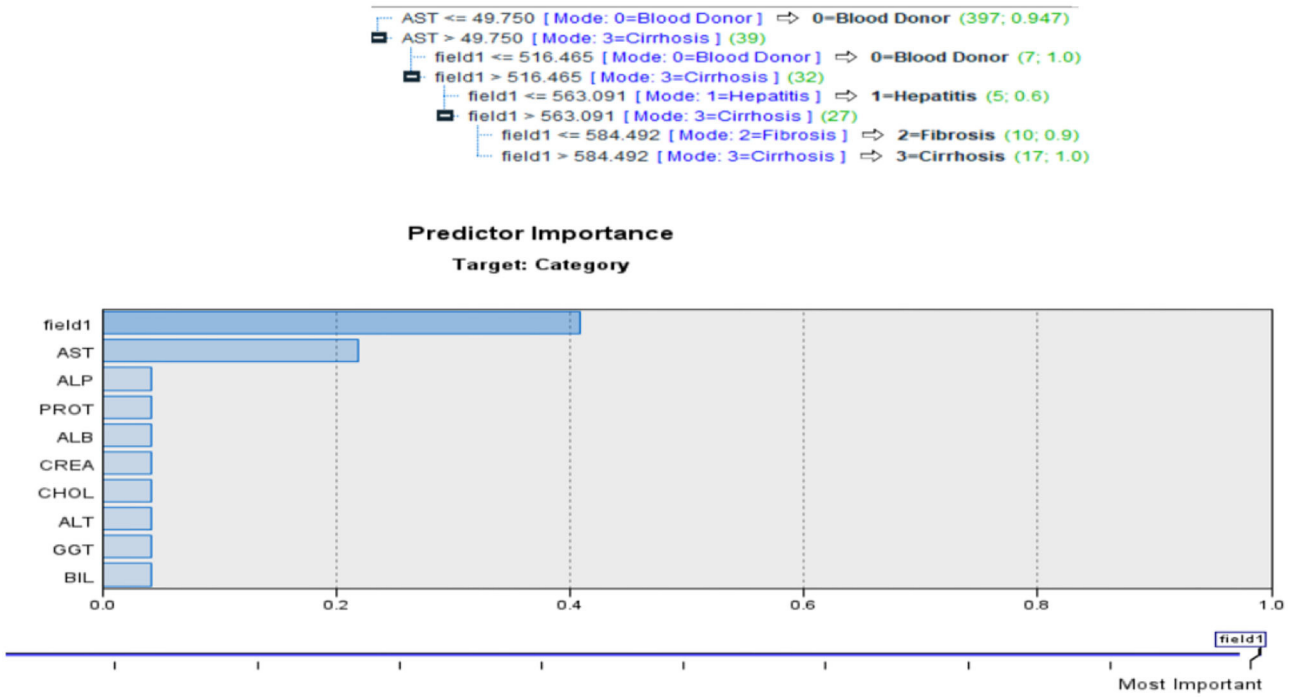

FIGURE 7 | QUEST for current problem.

decision tree is almost commonly used to train each model on a separate sample of the same training dataset in this manner. A basic statistic, such as a vote or average, is used to combine the forecasts of the ensemble members. When training the classifiers, we utilize a weak classifier whose decision boundaries vary significantly in response to even small perturbations in our training data. This ensures that the ensemble has a diverse set of classifiers.

When training ensemble members, the preparation of each dataset sample is critical. The dataset is randomly sampled for each model. In this dataset, the examples (rows) are chosen at random, but replacement is performed on them. The bootstrap distribution is used in bagging to generate alternative base learners. To put it another way, data subsets are collected via bootstrap sampling for the purpose of training the foundational learners.

It's called a bootstrap sample. In statistics, it's a method for assessing the statistical significance of a small sample of data. Rather than estimating directly from the dataset, it is possible to obtain a more accurate overall estimate of the desired quantity by doing many bootstrap sampling. Training datasets for many independent predictive models can be built in the same way and used to make predictions. Rather to fitting a single model directly to the training dataset, averaging the predictions from multiple models is often more accurate. Bagging's most important characteristics can be summarized as follows:

- Samples from the training dataset that have been bootstrapped.
- On each sample, unpruned decision trees fit.
- Simple voting or prediction averaging.

In summary, bagging makes a contribution by changing the training data used to fit each ensemble member, resulting in skilled but distinct models.

Bagging Ensemble

It's a broad strategy that can be readily expanded. More changes to the training dataset, for example, could be made, the algorithm that fits the training data could be altered, and the mechanism that combines predictions might be changed. This method is used in a number of popular ensemble algorithms, including:

- Bagged Decision Trees (canonical bagging)
- Random Forest
- Additional Trees

Next, let's look into stacking in more detail.

Stacking Ensemble Learning

Stacked To find a diverse group of members via generalization or stacking, one can vary the model types that are fit on training data and combine these models' predictions with one another. Stacking is a common technique for teaching a student how to mix up a large group of students. In education, the term "first-level learner" refers to an individual student, whereas "second-level learner" refers to the combined group. Level-0 models refer to the members of an ensemble, while level-1 models describe the

FIGURE 8 | Quest Classification for Category.

model used to integrate the forecasts. The following are a few of the most important aspects of stacking:

- The training dataset has not been modified.
- For each ensemble member, different machine learning techniques are used.
- Using a machine learning model, we can figure out how to combine predictions in the most effective way.

The several machine learning models that make up the ensemble add variety. Using a number of models that are taught or developed in a variety of ways ensures that they make a wider range of assumptions and, as a result, have less related predictions errors (34, 35). In an ensemble method known as "boosting," the training data is manipulated in an attempt to draw attention to examples that previous models that were fitted to the training dataset mistakenly detected. In boosting, the training dataset for each new classifier is progressively narrowed to examples that prior classifiers had incorrectly classified. The idea of correcting prediction errors is an important characteristic of boosting ensembles. To make sure that the first model's predictions are as accurate as possible, subsequent models are fitted and added to the ensemble in a logical order. Weak learners, or decision trees that only make one or a few judgments, are commonly used to do this.

Data can be weighed to signify how much attention an algorithm should give the model while it is being learnt. The following are a few of the most important aspects of boosting:

- Bias training data in favor of difficult-to-predict examples.
- Using a weighted average of models, combine forecasts.

There have been a few different approaches to making it possible to turn a large number of weak students into a small number of strong ones. The Adaptive Boosting (AdaBoost) method proved boosting to be an effective ensemble strategy for this paper. An algorithm known as "boosting" can predict more accurately.

RESULTS AND DISCUSSION

In this research paper, following machine learning algorithms are being used including:

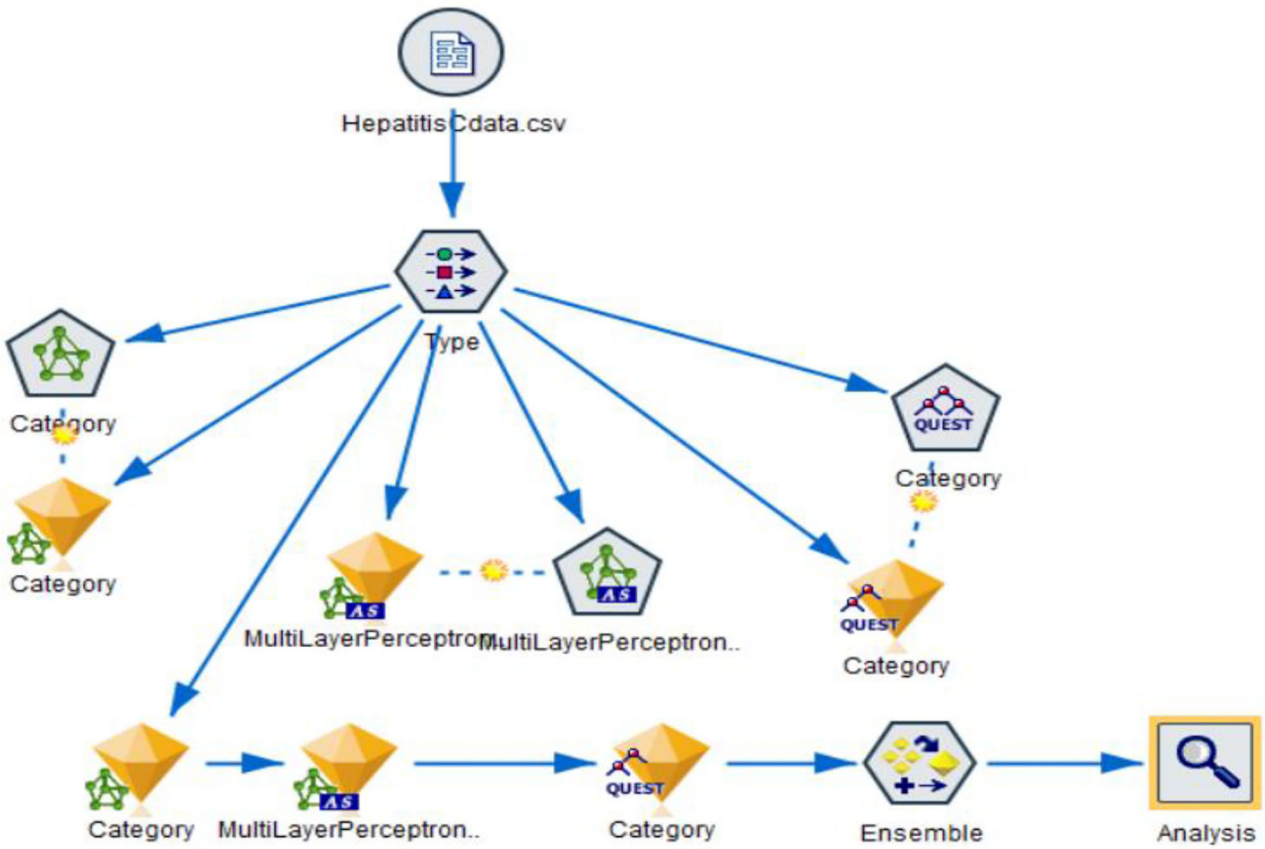

FIGURE 9 | Proposed Ensemble learning model.

- MLP
- Bayesian Network
- QUEST

The **Figures 9**, **10** depicts the working of the proposed Ensemble Learning model. Ensemble node mixes three model nuggets to obtain more accurate predictions than can be derived from any of the individual models (MLP, Bayesian Network & QUEST) (MLP, Bayesian Network & QUEST). By merging predictions from different models, limitations in MLP, Bayesian Network & QUEST models have been eliminated, resulting in a higher overall accuracy. MLP, Bayesian Network & QUEST Models integrated in this manner often perform at least as well as the best of the MLP, Bayesian Network & QUEST models and often better.

Table 1 represents the level of accuracy at 95.59%. This value is more efficient to individual machine learning algorithms as shown in **Table 1**. This is also represented in **Figure 11**.

Then results of this proposed model indicate that the proposed ensemble model can accurately predict the advanced fibrosis stage in chronic HCV patients. The proposed model offers us 95.9% correct results. We can improve the model's efficiency in the future by adding more patient data. In addition, more liver ailments could be investigated in the future. Figures in the paper appeared in sequence.

3	QUEST	94.63
4	Proposed Ensemble Model	95.59

CONCLUSION

In this research paper, different machine learning algorithms are being applied for predicting advanced liver fibrosis in Chronic Hepatitis C patients. It is observed that individual model is capable of providing the accuracy up to 94.67%. Then the ensemble model including Bayesian network, MLP and QUEST decision trees has been developed.

In designing healthcare systems, innovative techniques that carefully balance public health initiatives with limited resources should be taken into consideration. In order to help individuals who don't have health insurance or are underinsured, there should be an

Testing the Stochastic Convergence of Ecological Indicators in BRICS in the Perspective of Public Health

*Jinshun Wu**

Department of Economics, School of Economics and Management, East China Jiaotong University, Nanchang, China

This paper assesses the stochastic convergence of relative per capita ecological footprints within BRICS countries over the period 1961–2017 in the field of Public Health. Our initiatives have targeted ecological Indicator and health behaviors. Using the local Whittle estimator and some of its variants we assess whether relative per capita ecological footprints are long memory processes which, although highly persistent, may revert to their mean/trend in the long run thereby indicating evidence of stochastic convergence, or divergent processes in nutshell. Furthermore, we test whether (possibly) slow convergence or the complete lack of it may be the result of structural changes to the deterministics of each of the relative per capita footprint series by means of the tests of Berkes et al. (1) and Mayoral (2). For the ease of comparison, this paper assesses the stochastic convergence of relative per capita ecological capacities for BRICS as well. Our results show relatively strong evidences against stochastic convergence of ecological footprints. Furthermore, with regard to China and Russia, our results also decisively indicate that a slow or lack of convergence is the results of a structural break in the relative per capita ecological footprint series. However, our empirical researches support stochastic convergence of relative per capita ecological capacities for BRICS. In addition, we can conclude whether the per capita ecological footprints converge or not is dependent on the level of economic development, and the stochastic convergence occurs in those rich countries more probably, indicating that public health is becoming a more serious concern in developing countries.

INTRODUCTION

The convergence implication envisaged by the neoclassical growth model is that if each country has the same savings rate, population growth rate and technological progress rate, the income level gap between countries will gradually disappear. Since the production of most goods and services requires the consumption of energies such as coal, natural gas and oil, energy-producing requires the exploitation of natural resources. The availability of many natural resources at low cost increases the vulnerability of countries' economic development models. Considering the close relationship between economic growth and environmental pollution, Grossman and Krueger (3) first introduced the Environmental Kuznets Curve (EKC). The EKC indicates that the degree of

environmental deterioration will increase with the increase of the per capita income level, but the environmental quality will start to increase when the per capita income level reaches a certain threshold. This hypothesis means that there is an inverted U-shaped relationship between per capita income and environmental impact indicators and economic growth. At the same time, the view that economic growth will promote environmental improvement after a certain critical point has been discussed in many studies. Many studies believe that the income level of developing countries has not reached a critical point. With an increase in incomes, environmental pollution will continue to rise. On the other hand, developed countries are more successful in reducing environmental pollution, as their higher income levels may exceed the critical point or adopt cleaner energy technologies. Brock and Taylor (4) linked the environmental pollution indicators with the EKC hypothesis. Their Catch-up hypothesis means that poor countries have more environmental pollution. Moreover, in the initial stage, the gap of environment indicators between the rich and poor countries is divergent. This difference is rooted in the difference in the initial capital stock of the two countries. However, with their incomes increasing, once the developing countries start to use the advanced technology of environmental protection, the difference in environmental quality between the two countries will be reduced and various environmental pollution indicators will converge. Although the initial stage of economic growth resulted in environmental damage, the environmental quality is bound to be improved eventually.

In the past, air pollutants were used as a single indicator to measure environmental quality, which could not fully reflect the improvement of environmental quality. Now there is a more comprehensive environmental indicator, the ecological footprint. Ress (5) first proposed the concept of ecological footprint (EF), which was then developed by 4. EF is a measure of human demand for natural resources and services, revealing the relationship between human lifestyle, consumption patterns and consumed natural capital (5), which can comprehensively evaluate the feasibility of achieving a country's sustainable development goals. The Global Ecological Footprint Network describes the ecological footprint as: the ecological footprint measures the amount of "biologically productive" land or water that enables human beings to sustain itself. The term "biologically productive areas" refers to the areas with biological productivity that are needed to maintain the survival of individuals, regions or countries, or that can absorb wastes discharged by human beings. The ecological footprint can be used to evaluate and manage resource use throughout the country, measure and assess if people's lifestyles are sustainable, and account how much waste can be absorbed by the ecosystem, also known as "appropriated carrying capacity." EF consists of 6 sub-footprints: carbon footprint, fishing grounds footprint, forest footprint, cropland footprint, built-up land footprint and grazing land footprint. These ecological footprints reflect a country's ownership of natural resources and the ecologically productive area that has been used, and can comprehensively reflect the environmental problems as well. Moreover, the ecological footprint is a resource accounting tool that measures how much renewable energies in the biosphere can be used by human activities. In addition, EF can also measure the ecological cost of goods and services that the nature provides to humans, such as land, and the maximum sustainable population in a given area. In a word, EF indicates the environmental limit and the extent to which human beings exceed the natural limit, which can assist countries to evaluate how the ecological resources are being used.

This study focuses on the BRICS countries for the following reasons:

First, compared with many other emerging countries, the BRICS countries have experienced a rapid transition from an ecological surplus to an ecological deficit. This is mainly due to the rapid economic growth of these countries over the past decade. The BRICS countries contribute 21% of global GDP and have 41% of the world's population. These countries have an average annual economic growth rate of 6.5% (6). Moreover, between 2005 and 2016, the total GDP of the BRICS countries ranged from US$ 218.7 billion to US$ 162.6 billion. The rapid economic growth has also led these countries to consume more than 40% of the global total energies, and they are also the major global CO_2 emitters (7). They are facing both environmental and natural resource stresses due to their rapid economic growth. Their ecological indicators may be long-memory and may not converge. In view of this, in order to reverse the growing trend of carbon dioxide emissions, reasonable policies are needed to ensure that while economic development is taking place, it will not cause huge damage to the ecological environment.

Secondly, despite the huge potentials of renewable energies, BRICS countries still rely excessively on fossil fuels to meet their energy needs, which poses a huge threat to the environment. At the same time, while pursuing high-speed economic development, the region has also experienced a continuous decline in ecological sustainability. In addition, the research on this area can help the policy makers to prevent the environmental deterioration with practical and reasonable policies.

LITERATURE REVIEW

The literature on the deterioration of ecological footprints mainly focuses on developed countries and international organizations mainly composed of developed countries. As far as we know, the first paper on convergence of ecological footprints is Ulucak and Lin (8). They analyzed the random behavior of ecological footprints and each sub-component using Fourier unit root test *via* the dataset of ecological footprints of each state in the United States from 1961 to 2012. The empirical results show that the ecological footprints of states in US are non-stationary, and not mean-reverting processes. Therefore, an impact on these sequences will result in a permanent deviation from the long-term equilibrium paths. Since then, there have been a lot of relevant researches mainly exploring developed countries' ecological indicators. For example, Ulucak and Apergis (9) studied the convergence of the per capita ecological footprints using data samples from 20 EU countries during the period 1961–2013. The results show that there are three convergence clubs. Bilgili and Ulucak (10) studied the convergence of per capita

ecological footprints among G20 countries during 1961–2014 by using bootstrap panel KPSS unit root test and club convergence test considering structural breakpoints. It is concluded that the per capita ecological footprints of these countries will reach random convergence and deterministic convergence, and two convergence clubs are identified. Solarin (11) uses LM and RALS-LM unit root methods to test the stochastic convergence of ecological footprints of 27 OECD countries from 1961 to 2013. They found that the ecological footprints and carbon footprints of 25 countries are stationary. They also performed β convergence and σ convergence test in their research. Among the 25 countries with random convergence, the ecological footprints of 13 countries are β convergent; among them, 15 countries have β convergent carbon footprints. In terms of σ convergence, the ecological footprints and carbon footprints of all countries selected meet the convergence criteria. Studies show that, although not all countries meet the convergence conditions, those countries in which convergence happened already can jointly formulate environmental protection policies to improve convergence among more countries. Yilanci et al. (12) uses the annual data of ecological footprints and each sub-component of 25 OECD countries from 1961 to 2013, and uses various stability test methods to prove that the other footprint sequences except the fishing ground footprint are stationary. Yildirim et al. (13) proposed the Fourier cross-section panel KSS unit root test to study the convergence of ecological footprints among 16 EU membership countries. They further use the rolling window method to consider the time-varying stationarity of the ecological footprint sequences. Through their study on the convergence of the ecological footprints and each sub-component, they prove that the convergence or divergence of the ecological footprints has different states in different periods.

In recent years, there have been a large number of researches on the convergence of ecological footprints between countries with different levels of development, and the relationship between the convergence of ecological footprints and the degree of economic development is discussed. Solarin and Bello (14) studied the convergence of the ecological footprints of 128 countries with different levels of development during the period 1961–2013. The results show that the ecological footprint series of 96 countries (81%) are non-stationary and there is no mean reversion (non-convergence). This means that various environmental protection policies have long-term and permanent effects in many countries. Bilgili et al. (15) selected 15 countries in Asia, Africa, America and Europe to test the stationarity of the ecological footprints, and asserted that the ecological footprints of the Asian group are non-stationary and diverge. Using the club convergence method proposed by Phillips and Sul (16) and Solarin et al. (17) showed that 92 countries' ecological footprints and each sub-component have club convergence. Ozcan et al. (18) used panel KSS and Fourier panel KSS to study the stability and convergence of ecological footprints in 113 countries with different levels of development depending on their national development levels. The ecological footprints of all high-income countries, some low-income countries and upper-middle-income countries are stable, while the ecological footprints of lower-middle-income countries are not stationary. Erdogan and Okumus (19) used the annual sample data from 1961 to 2016 to test the random convergence of ecological footprints and club convergence of different income groups. The FPKPSS panel statistics of the countries in the high, middle and low income groups indicate that the per capita ecological footprints are non-stationary. At the same time, the FKPSS method was also used to test the stability of ecological footprints at the national level. On this occasion, 6 out of 26 high-income countries and 8 out of 38 middle-income countries have stationary ecological footprints. In 8 out of 25 low-income countries ecological footprints are stationary. At the same time, the club convergence method was used to test the convergence of the ecological footprints. It is concluded that there are convergence clubs in different income groups. Işik et al. (20) employed the threshold autoregressive panel unit root test to study the convergence of ecological footprints of NAFTA countries during 1961–2016. The study suggested that EF converges at the latter stage of the threshold, and the second stage accounts for 48.8% of the total sample. The ecological footprints of the first stage are divergent. These conclusions highlight the need for NAFTA countries to formulate common environmental policies to mitigate environmental degradation.

With the rapid economic development in developing countries, the academic community has become more and more interested in the convergence of the ecological footprints of international organizations composed of developing counties in recent years. Yilanci and Pata (21) used the panel data of the five ASEAN countries' per capita ecological footprints from 1961 to 2016, and used two-mechanism threshold autoregressive panel unit root test to study the convergence of ecological footprints. Researches argue that the ecological footprints in the second mechanism are divergent; in the first mechanism they are absolutely convergent. The second mechanism accounts for 80% of the sample, so the results strongly support that the per capita ecological footprints of the five ASEAN countries are absolutely convergent, and they believe that common policies should be implemented to slow down the environmental deterioration. Tillaguango et al. (22) studied the convergence of the ecological footprints of Latin American countries from 1990 to 2016 and found that there exits a per capita ecological footprint club. Using the method of logistic regression, the paper explored the factors that affect the convergence of the ecological footprint clubs and found that economic complexity, shadow economy and abundance of natural resources can significantly affect the formation of the clubs. Their research indicated that there are three convergence clubs in Latin America, and the two clubs are divergent.

As can be seen from the literature review above, a large number of techniques have been applied to test the stochastic convergence and divergence of ecological and environmental indicators (8, 10, 13, 18, 20, 23, 24), but most of these studies only used the time series econometric method to analyze the existence of its stochastic convergence characteristics. From a random point of view, if the per capita ecological footprint sequences tend to converge as time lapses, the impacts of external shocks on the sequence should be only temporary, and the data are stationary. In the presence of a unit root, the external

impacts on the sequence will be permanent, indicating that these sequences are divergent. From the literature review, it can also be clearly seen that the evidence of convergence of ecological and environmental indicators is very complicated. One possible explanation is that the existing literature ignores the possibility that ecological footprints are long memory processes, i.e., they are mean- (or trend-) reverting, but it will take a long time for these processes to arrive at their means or trends. There are two reasons to doubt this view: First, a country's ecological footprints are determinated by a lot of fundamental factors, such as economic size, economic structure and technological level. All these factors may only change slowly as time goes by, so environmental indicators such as relative ecological footprints between countries may also change slowly. Secondly, previous studies have found that GNP and per capita GNP are long memory processes (2). The long memory process means that there exists significant interdependent relationship between two observations over a long time, so the effects of shocks tend to decay slowly, although they are still mean-reverting in nature. If environmental indicators such as ecological footprints are indeed long memory processes, then previous studies might provide misleading results. For example, if the null hypothesis of a unit root has not been rejected in previous studies, this may not mean a lack of convergence, but may reflect that the environmental indicator has the difference order of fractionally integrated processes, which might not be integer. Therefore, this means that the convergence process is taking place, albeit vary slowly.

The analysis in this paper focuses on conditionally stochastic convergence, which does not require every country (region) to converge to the same steady-state level just as β and σ convergence do. When the per capita ecological footprint gap between countries (regions) follows a mean stationary process, i.e., the impact of the relative per capita ecological footprints only brings temporary deviation from their convergent trends. This paper uses the stochastic convergence test approach to determine whether it can be ensured that ecological indicators converge permanently in a country. If such a necessary mechanism does not exist, deviations from trends are permanent. Thus, the concept of convergence is more important to the study of ecological footprints because it can test the durability of impact effects. In this regard, few researchers use unit root test to study whether the impacts on ecological indicators are temporary or permanent. The lack of convergence researches makes it difficult for a country to take joint actions to hinder environmental deterioration. The stochastic behavior and dynamic changes of ecological indicators will help to formulate sustainable development policies. If ecological indicators are stationary, their impacts exerted by external shocks are transient, and these sequences will converge stochastically to their means once these impacts disappear. On the contrary, if the impacts are permanent, the sequences will diverge from their means. If the evolution trend of variables is known, the convergence and divergence of environmental indicators make it easier for policymakers to apply more effective environmental protection policies. In this paper, the fractionally integrated autoregressive moving average model (ARFIMA) is used to estimate the fractionally integrated parameters of the ecological indicators using the 1961–2017 data set. The ARFIMA model is a generalized version of ARIMA and an improvement on the I (0) |I (1) dichotomy. It can estimate the integration order parameters, which can be of any real number in the data generated processes. Because the unit root test can only judge whether the ecological indicators are convergent I (0) processes or divergent I (1) processes, and cannot test the convergence speed, the fractionally integrated model may be more appropriate.

In this paper, for exploring whether the relative ecological indicators per capita contain unit roots (the null hypothesis is a non-convergent process). We leverage the local Whittle (LW) estimation method (25) and its modified versions, e.g., exact local Whittle (ELW) and two-stage detrended (breakpoint) exact local (ELW) estimation method (26, 27) to estimate the parameters of fractionally integrated model. In contrast, the alternative assumption is that they are long-term memory processes that, although highly persistent, may return to their mean/trend over the long term (meaning slow convergence). The existence of structural breakpoints may lead to biased estimation of parameters [see (28, 29)]. In the case of the fractionally integrated processes, this problem is mostly applied to evaluate their expectation performance. From our point of view, there is evidence that the existence of structural breakpoints on the deterministic trend may lead to an overestimation of the order of the fractionally integrated process, so the conclusions drawn are biased in favor of supporting the long memory process [see (30, 31)]. In this study, the structural breakpoints are incorporated into the ARFIMA model by introducing dummy variables into the deterministic components Z_t of Equation (5), including mean breakpoints and trend breakpoints, respectively. Furthermore, the Mayoral (2) test is used to identify the false long memory state in the ecological indicator sequences, i.e., the long memory phenomenon is caused by the existence of breakpoints in the deterministic trend of the sequences. Finally, we use the non-parametric CUSUM statistics of Berkes et al. (1) to determine the points in time when the structural changes of the ecological indicator sequences occur (if there is a breakpoint).

MODEL

In this paper, the fractionally integrated models are used to test whether the environmental indicators, e.g., ecological footprints and ecological carrying capacities in BRICS converge. The idea of this test is that if the per capita environmental indicators are converging between countries, the logarithm of the ratio of the per capita environmental indicators in a country to the average environmental indicators in all countries should be stationary, or at least the mean- (or trend-) reverting. Therefore, referring to Strazicich and List (32), this paper defines y_{it} as the natural logarithm value of the relative environmental indicators per capita in t year of the i country, and its expression is shown in

Equation (1):

$$y_{it} = \ln\left(\frac{PCE_{it}}{J^{-1}\sum_{j=1}^{J} PCE_{it}}\right) \quad (1)$$

The PCE_{it} is the per capita environmental indicator in t year for the i country. J is the total number of countries. In order to test the null hypothesis that per capita environmental indicators diverge, we examine whether the natural logarithm y_{it} of the annual per capita relative environmental indicators in the i country contain a unit root, or whether they can be characterized by trend-stationary and mean-reverting processes.

Discrimination and Test of Convergence of Relative Environmental Indicators per Capita

When a time series has the structural change in its deterministic trend, the standard unit root test method often has the problem of significant level distortion; Moreover, when the unit root of the sequence is close to 1, the performance of standard unit root test is affected substantially. In other words, the unit root test is often unable to decide whether a sequence is highly persistent or infinitely persistent. The test method based on fractionally integrated processes provides a general framework, which can test whether an ecological and environmental indicator is an I (1) process with infinite persistence or with long persistence (which may be not covariance-stationary), but characterized by mean reversion in the long term, indicating that the environmental indicator is an $I(d)$ process with the integration order bounded the domain that $0 < d < 1$. The fractionally integrated expression of a environmental indicator sequence containing a time trend, such as the ARIMA (0, d, 0) model, is shown by Equation (2):

$$y_{it} = c_{i0} + \gamma_i t + x_{it} \quad (2)$$

$$(1-L)^{d_i} x_{it} = u_{it} \quad (3)$$

where u_{it} is a white noise process with zero mean value, d_i is the integration order of a single sequence and a deterministic trend function (there may be breakpoints). According to various values of d_i, we can identify the states of convergence or divergence of relative per capita environmental indicators.

Scenario 1: $-0.5 < d \leq 0$. This is a short memory process, i.e., there is "fast convergence" or "short memory convergence."
Scenario 2: $0 < d < 0.5$. This is a long memory but still stationary process, and also a convergent process with slowly (or smoothly) decaying speed. In this case, a country's environmental indicators might undergo a long period of convergence toward a common long-term trend.
Scenario 3: $0.5 < d < 1$. This is a long memory process, which is non-stationary but still has the property of mean reversion. In this case, the process is characterized by a high degree of persistence. Therefore, the impact of the distant past will still have lasting effects on the present.
Scenario 4: $d \geq 1$. This is a unit root or divergent process. In this case, any initial shock has a significant impact on the future, and the process is unlikely to return to the mean at some point in the future.

The testing approach to the fractionally integrated order allows a richer classification of convergence states, so that stationary convergence and non-stationary convergence but with mean reversion can be distinguished. Another characteristic of this classification scheme is that it can take into account the lasting impact of the previously invoked shock on the present, or the rapid attenuation without any impact on the present, and more importantly, it can take into account the states in between two extremes mentioned above. The simple $I(0)|I(1)$ dichotomy could not capture these states because the standard unit root test can only considers two extreme cases, i.e., persistence or no persistence at all.

Then, we use local Whittle likelihood estimation method (LW) and various improved versions to estimate the parameter of fractional integration d of Equation (2). The advantage of this method is that the estimator is not affected by the non-stationarity of the short-term process. In order to judge whether a per capita environmental indicator is an unit root process or a mean-reverting and long memory process with finite or inflated variance (depending on the estimated $\hat{d}$ value), we conduct hypothesis test of the null hypothesis $H_0 : \hat{d} = d_0$ and the alternative hypothesis $H_1 : \hat{d} \neq d_0$. If the hypothesis holds that per capita relative environmental indicators are mean-reverting, there is enough evidence to prove that these indicators are stochastically convergent processes.

After applying LW, ELW, two-stage detrended ELW (2ELWd) and the 2ELWd method with breakpoints removed to obtain an estimate of the order of the fractional integration $\hat{d}$ of the individual environmental indicator series, we use the Robinson (33)'s LM test framework to test the hypothesis of the environmental indicator series of each country as shown in Equation (4):

$$H_0 : d = d_0 \quad (4)$$

In this hypothesis test, the null hypothesis is the existence of unit root. The alternative is that the per capita environmental indicators have long memory characteristics. Robinson (33) proposed the following statistics and proved that the standard normal distribution is satisfied under certain regularity conditions:

$$\hat{R} = \left(\frac{n}{\hat{A}}\right)^{1/2} \frac{\hat{a}}{\hat{\sigma}^2} \sim^d N(0,1), n \to \infty \quad (5)$$

where,

$$\hat{A} = \frac{2}{n}\left[\sum_{j=1}^{n-1}\psi\left(\lambda_j\right)^2 - \sum_{j=1}^{n-1}\psi\left(\lambda_j\right)\hat{\varepsilon}\left(\lambda_j\right)' \times \left(\sum_{j=1}^{n-1}\hat{\varepsilon}\left(\lambda_j\right)\hat{\varepsilon}\left(\lambda_j\right)'\right)^{-1} \times \sum_{j=1}^{n-1}\hat{\varepsilon}\left(\lambda_j\right)\hat{\varepsilon}\left(\lambda_j\right)'\right] \quad (6)$$

$$\hat{a} = \frac{-2\pi}{n}\sum_{j=1}^{n-1}\psi\left(\lambda_j\right)g\left(\lambda_j,\hat{\tau}\right)^{-1}I\left(\lambda_j\right) \quad (7)$$

$$\psi\left(\lambda_j\right) = \log\left(2\sin\frac{\lambda_j}{2}\right);\ \hat{\varepsilon}\left(\lambda_j\right) = \frac{\partial}{\partial\tau}\left[\log g\left(\lambda_j;\hat{\tau}\right)\right];\ \lambda_j = \frac{2\pi j}{n}.$$

$I\left(\lambda_j\right)$ represents the periodogram of $\hat{u}_t$ as follows:

$$I\left(\lambda_j\right) = \frac{1}{2\pi n}\left|\sum_{t=1}^{n}\hat{u}_t e^{i\lambda_j t}\right|^2 \quad (8)$$

where $\hat{u}_t$ is the least squares residual obtained from Equation (2), g is a known function from the spectral density:

$$f\left(\lambda_j;\tau\right) = \frac{\sigma^2}{2\pi}g\left(\lambda_j;\tau\right) \quad (9)$$

Robinson (33)'s test framework relies on some specific assumptions imposed on the short memory component u_t. If it is a white noise, $g \equiv 1$; If it is a process that follows as the form of AR (1) $u_t = \tau u_{t-1} + \eta_t$, $g\left(\lambda_j;\tau\right) = \left|1-\tau e^{i\lambda_j}\right|^{-2}$, and σ^2=var (η_t). The parameter considered is the long memory parameter d, which shows whether a time series process is long memory. Because that $d < 1$ means the relative per capita environmental indicators converge, the null hypothesis is set as follows in this study:

$$H_0 d = d_0 = 1. \quad (10)$$

This study uses the data set of the BRICS countries from 1961 to 2017 for empirical analysis. Obviously, the data set is a small sample ($n = 57$), so it is necessary to calculate the empirical distribution of various local Whittle estimators. When the sample size $n = 57$ and the truncation parameter α is in the interval [0.65, 0.8], we will give the accurate distribution of the memory parameter d estimators of LW, ELW, 2LWD and the detrended 2LWD method, and then construct the confidence interval of the estimators.

Convergence Pseudo-Long Memory Test of Relative Environmental Indicators per Capita

That relative environmental indicators are long memory processes indicates that it takes a long time for these indicators to approach convergent paths. However, although a time series (as mentioned above y_{it}) is a long-term memory process, it is not clear whether it is indeed a long memory process or a short memory and stationary one with a mean shift (showing the characteristics of long-term memory processes). Although these two cases show that the sequences of relative environmental indicators per capita converge, it is slower for the stationary processes with mean shifts to approach convergence than the real long memory processes. If their means shift toward the upward direction of the sequences, these indicators converge more slowly; If means shift downwards, these sequences converges faster. After obtaining evidence that these indicators are long memory I (d) or infinite memory I (1) processes, this paper will continue to determine whether the potentially slow convergence or lack of convergence is real or the result of a structural change in the mean of an otherwise stationary process.

This paper introduces a test method proposed by Mayoral (2) to solve this spurious long memory problem. If per capita environmental indicators are pseudo-long memory processes, it means that these processes are stationary, but at a certain time point, a structural fracture occurs in the opposite direction of the sequence trend, indicating that the per capita environmental indicator would reach convergence after a shorter time. These two types of models fitting the two processes can be nested together and expressed as Equation (11) below. This paper assumes that the relative environmental indicator data set $y_1, y_2, \cdots, y_n$ are generated from the model listed as follows:

$$y_t = \beta' \cdot Z_t + \delta \cdot V_t(\omega) + x_t \quad (11)$$

Where Z_t is a deterministic component, and $V_t(\omega)$ can be a constant or a trend function. It is used to judge whether the time series has undergone structural changes. The observations of the time series are Z_{t-k} after the break point appears, while they are evaluated as zeros before the break point appears. Meanwhile, the random term x_t is defined as:

$$(1-L)^d x_t = u_t,\ \ \varepsilon_t \sim N\left(0,\sigma^2\right) \quad (12)$$

Based on this data-generating structure, the hypothesis testing should set the following null and alternative hypothesis:

$$\begin{cases} H_0 : d \in D_0,\ \ \delta = 0, D_0 \subset (0.5, 1.5) \\ H_1 : d = 0,\ \ \delta\ \ noconstraint \end{cases} \quad (13)$$

To test the above hypotheses, Mayoral (2) proposed a semi-parametric test method, and constructed a Most Powerful Invariant (MPI) statistics by comparing the log-likelihood ratio under the null hypothesis H_0 and the alternative one H_1. This consistent statistics $R_b^f\left(\hat{d}_n\right)$ is of the form as follows:

$$R_b^f\left(\hat{d}_n\right) = n^{1-2\hat{d}_n}\left(\frac{\hat{\lambda}^2}{\hat{\gamma}_0}\right)^{-1}\frac{\inf_{\omega\in\Omega}\left(y - Z\cdot\tilde{\beta} - V(\omega)\tilde{\delta}\right)'\left(y - Z\cdot\tilde{\beta} - V(\omega)\tilde{\delta}\right)}{\left(\Delta^{\hat{d}_n}y - \Delta^{\hat{d}_n}Z\cdot\hat{\beta}\right)'\left(\Delta^{\hat{d}_n}y - \Delta^{\hat{d}_n}Z\cdot\hat{\beta}\right)} \quad (14)$$

where the order $\hat{d}_n$ of fractional integration is the uniform estimator obtained by ELW and other methods. As a semi-parametric test method, the statistics should be evaluated by resorting to the ordinary least square method (OLS) to estimate the parameters in Equation (11) under H_0 or H_1 hypothesis, respectively. All the parameters of the numerator, including $\tilde{\beta}$ and $\hat{\delta}$ on the right side of the Equation (14) are estimated when the null hypothesis H_0 holds, while $\tilde{\beta}$ and $\hat{\delta}$ in the denominator are estimated under the alternative hypothesis H_1. At the same time, under the null hypothesis H_0, $\hat{\gamma}_0$ represents ε_{it} variance estimator. $\omega = k/n$ is the ratio of the number of sub-sample observations before the possible break point to the total sample. Considering that allowing the break point to appear in the whole interval (0, 1) will cause the test to have a very low power potentially, we adopt the restricted interval $\Omega = [0.15, 0.85]$ suggested by Andrews (34). In addition, the parameter λ^2 in Equation (14) can be obtained from the following formula:

$$\hat{\lambda}^2 = \hat{\gamma}_0 + 2\sum_{i=1}^{q} k\left(\frac{i}{q}\right)\hat{\gamma}_i \tag{15}$$

where γ_i is the i autocovariance function of ε_t, and $k(\cdot)$ is the Bartlett kernel function. q is the bandwidth parameter. According to the method of Newey and West (35), we take $q = 4 \times (n/100)^{2/9}$ as the initial value and select the bandwidth automatically decided by data. Mayoral (2) proved that $R_b^f\left(\hat{d}_n\right)$ is a uniform statistics.

For the initial estimate of fractionally integrated order of a single sequence and the test under the null hypothesis that $\hat{d} = 1$, the Monte Carlo and Bootstrap critical values of the statistics $R_b^f\left(\hat{d}_T\right)$ are given by means of 20,000 repetitions of the simulation of the time series data with sample size of 57. If the value of the statistic $R_b^f\left(\hat{d}_n\right)$ is less than a critical value at a confidence level, this is evidence to reject the null hypothesis, which means that the time series is pseudo long-memory.

Identification of Time Point of Structural Mutation of Convergence Path of Relative Environmental Indicators per Capita

Although the test method proposed by Mayoral (2) has good test effect in identifying true long- memory (including infinite-memory, i.e., unit root processes) processes from pseudo long-memory ones, it is not a accurate break point detection method (23). This means that it can only identify whether a process is a long-term memory (non-stationary process) or a stationary process with a mean shift, but cannot identify the exact location of the break point in the case of "pseudo long-memory processes." Therefore, it is necessary to identify the specific positions of all break points in the sequence by perfecting the above-mentioned test method. For this purpose, this study uses the null hypothesis H_0 proposed by Berkes et al. (1), shown by the Equation (16):

$$\begin{cases} y_t = \mu + x_t, \ 1 < t < k^* \\ y_t = \mu + \Delta + x_t \ k^* + 1 < t < n \end{cases} \tag{16}$$

where k^* is a point in time when the mean-shift happens, and μ and $\mu + \Delta$ is the unknown mean and shift of the potential data generated process respectively. The sequence $\{x_t\}$ is a fourth-order stationary process with a mean of zero. This study uses the non-parametric CUSUM statistics proposed by Berkes et al. (1) and Aue et al. (36) to test H_0 listed below.

H_0: The observations $y_1, y_2, \cdots, y_n$ follow the mean-shift process (21) and x_t is the stationary process with a weak auto-correlated structure.

H_1: The observations $y_1, y_2, \cdots, y_n$ are a long memory process, i.e. their potential model setting satisfies Equation (12).

For defining hypothesis test statistics, we apply the main ideas of Berkes et al. (1) to introduce a break point that occurs at time point $\hat{k}^*$, and estimate it by the following equation:

$$\hat{k}^* = \min\left\{k : \max_{1<i<n}\left|\sum_{1\le j\le n} y_j - \frac{i}{n}\sum_{1\le j\le n} y_j\right| = \left|\sum_{1\le j\le k} y_j - \frac{k}{n}\sum_{1\le j\le n} y_j\right|\right\} \tag{17}$$

Since the identification program is designed for a single break point, we take the minimum $\{\cdot\}$ in the algorithm for detecting possible breakpoints to obtain the position of the strongest mean shift point. Therefore, the entire sample is divided into two sub-samples dependent on the break point $\hat{k}^*$. In each sub-sample, the T_n statistic can be constructed according to the following two formulas:

$$T_{n,1} = \frac{1}{s_{n,1}}\hat{k}^{*-\frac{1}{2}} \max_{1\le k\le \hat{k}^*}\left|\sum_{1\le i\le k} y_i - \frac{k}{\hat{k}*}\sum_{1\le i\le n} y_i\right| \tag{18}$$

$$T_{n,2} = \frac{1}{s_{n,2}}\left(n - \hat{k}^*\right)^{-\frac{1}{2}} \max_{\hat{k}^*<k\le n}\left|\sum_{\hat{k}^*<i\le k} y_i - \frac{k-\hat{k}^*}{n-\hat{k}^*}\sum_{\hat{k}^*<i\le n} y_i\right| \tag{19}$$

In the above equations, the CUSUM statistics is standardized by long-term standard deviations $s_{n,1}$ and $s_{n,2}$ respectively. $s_{n,1}$ is the standard deviation calculated based on the first piece of sample data $y_1, y_2, \cdots, y_{\hat{k}}$; $s_{n,2}$ is the standard deviation calculated based on the second part of sample data $y_{\hat{k}+1}, y_{\hat{k}+2}, \cdots, y_n$. There are several different methods to estimate the long-term variance s_n^2. For example, if the series $\{y_t\}$ has a serial correlation structure, it can be estimated according to s_n^2 as follows:

$$s_n^2 = \hat{\gamma}_0 + 2\sum_{1\le j\le q(n)} \omega_j\left(q(n)\right)\hat{\gamma}_j \tag{20}$$

The $\hat{\gamma}_i$ can be calculated as follows:

$$\frac{1}{n}\sum_{1\le i\le n-j}\left(y_t - \bar{y}_n\right)\left(y_{t+j} - \bar{y}_n\right) \tag{21}$$

Where $\omega_j(\cdot)$ is a weighting kernel function, and $q(n)$ is the bandwidth of the kernel function $\omega_j(\cdot)$. Andrews (34) discussed

seven different types of kernel functions that can be used to calculate the HAC estimator. We select the "Bartlett" kernel function $\omega_j(q) = 1 - j/(q+1)$ according to Berkes et al. (1) and Aue et al. (36) with the optimal bandwidth used by Newey West in the selected kernel function. Once the T_n statistics of the two sub-samples are obtained, the following M_n statistics can be constructed:

$$M_n = \max\left\{T_{n,1}, T_{n,2}\right\} \tag{22}$$

T_n can be used to discriminate whether the sample has been generated by a short or long-range dependent stationary process. Hence, if we split the sample at time $\hat{k}^*$, which is close to the true change-point k^* asymptotically we can assume that $y_1, y_2, \cdots, y_{k^*}$ and $y_{k^*+1}, y_{k^*+2}, \cdots, y_n$ are samples from a stationary sequence with a constant mean. Thus, we can use $T_{n,1}$ and $T_{n,2}$ to test if the samples $y_1, y_2, \cdots, y_{k^*}$ and $y_{k^*+1}, y_{k^*+2}, \cdots, y_n$ have been generated by a short-range or long-range dependent process. The CUSUM statistic compares the sample mean of the first k^* observations with the sample mean of the last $(n-k)$ observations. If we assume a change in the mean at time k^*, the absolute value of the difference of the means should be large for $k = k^*$.

Berkes et al. (1) derived the following asymptotic distributions of the statistics M_n under the null hypothesis:

$$M_n \to^d \max\left\{\sup_{0\le t\le 1}|B^{(1)}(t)|, \sup_{0\le t\le 1}|B^{(2)}(t)|\right\} \tag{23}$$

where $B^{(1)}(t)$ and $B^{(2)}(t)$ is a Brown bridge corresponding to two sub-samples, respectively. If the relative environmental indicator per capita is weakly dependent (there is no change in mean), the statistics M_n will converge to the upper bound of the Brown bridge. However, if an environmental indicator fellows a mean shift or a long memory process, $M_n \to \infty$. The latter case is referred to as a false rejection of the null hypothesis that there is no change in mean. Because the dataset used here is not large enough to achieve an approximately asymptotic distribution. Therefore, we calculate the asymptotically critical values under H_0 at the significance level of 10, 5 and 1% respectively. If M_n exceeds the critical value at a significance level, the null hypothesis cannot be rejected, and the breakpoint identified at the corresponding significance level is reasonable.

This paper follows the procedure shown in **Figure 1** to test whether ecological indicators are convergent in BRICS countries.

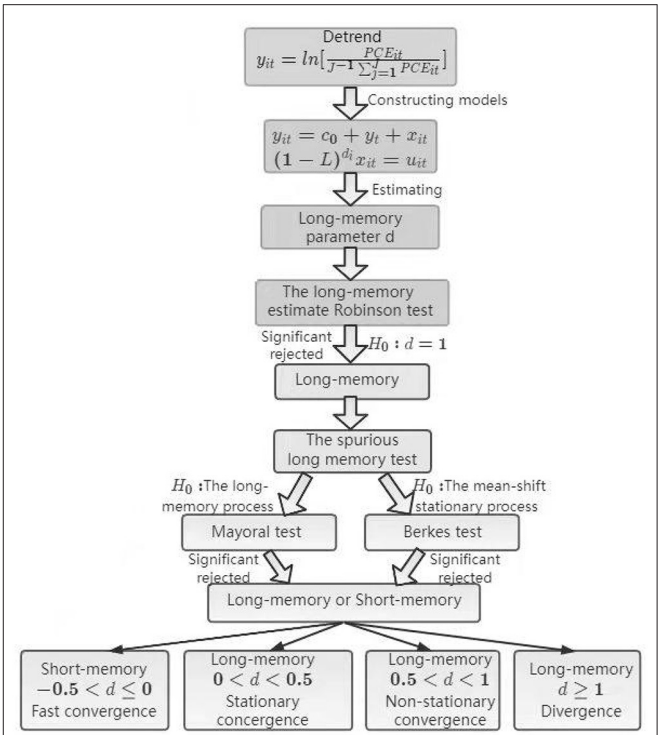

FIGURE 1 | A flow diagram for testing the long-memory of ecological indicators.

DATA

The data used in this paper are from National Footprint Accounts (NFAs). NFAs provides global and national annual accounting of biocapacity (BC) and ecological footprint (EF). This paper collects annual data of EF and BC per capita at the national level. The data range is from 1961 to 2017, with a total time span of 57 years. **Figure 2** shows the trend of per capita ecological footprints and ecological carrying capacities of the BRICS countries (China, Brazil, India, Russia and South Africa) and the world. During the sample period, EFs are larger than the quantities enough to ensure sustainable development in BRICS and the world. In other words, the existing productive land and other resources are insufficient to meet the needs of human food, housing and CO_2 absorption. During this period, around the worldwide, per capita EF increases by nearly 120%. BC per capita decreases by 50% during the same period. In 2017 the ecological deficit fell to 5.26 gha (a measure unit of ecological footprint and ecological carrying capacity), while EF almost doubled. This shows that human activities have been imposing great pressures on the nature. Although the ecological footprint can maintain the trend of not decreasing, the ecological carrying capacity decreases rapidly and the ecological deficit continues to increase every year. All three environmental indicators reveal that globally, human beings consume more resources with ecological productivity than available. For example, from 1961 to 2017, the ecological carrying capacity per capita decreases by 41.4%, from 3.12 gha to 1.83 gha per capita. This fact means that resources available per capita have been decreasing and more people are competing for limited resources (37).

Figure 1 shows that the world's per capita EF was stable in the 1980s and 1990s, and has shown an upward trend since the beginning of the twenty-first century, while per capita BC decreased gradually. Since 1961, the world EF per capita has been steadily increasing at a rate of 2.1% per year, almost tripling from 4.62 gha to 5.24 gha in 2017. **Figure 2** also shows the trend of the per capita EFs and ecological carrying capacities of BRICS countries over time. In most countries, the

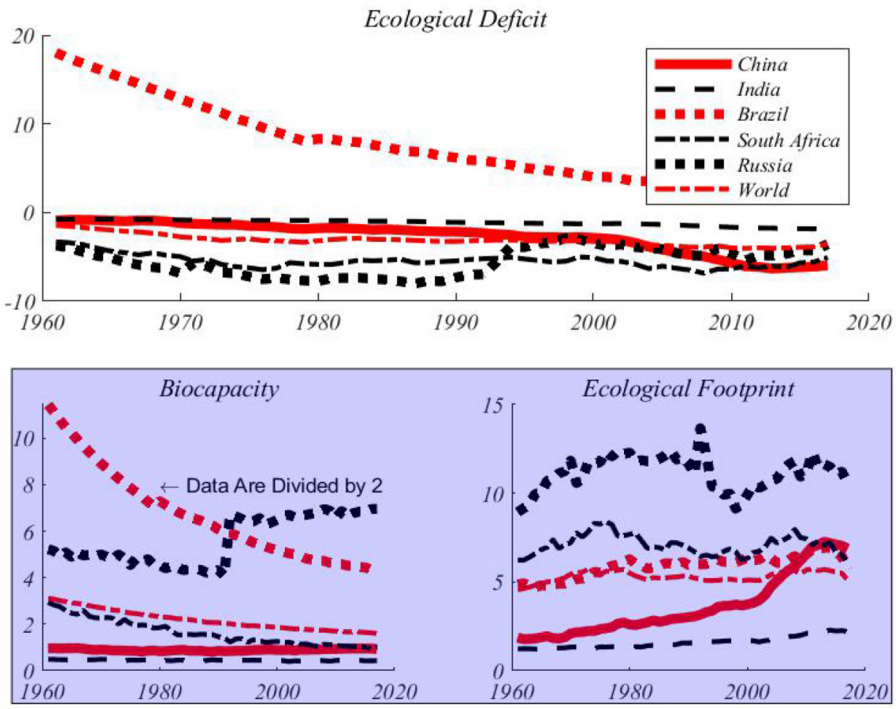

FIGURE 2 | Per capita environmental indicators for BRICS and the world (gha). Russian data before 1989 are replaced with data from the former Soviet Union. So you can see from the fifth chart that there is a jump in 1989.

per capita EFs continue to increase, while the per capita BCs are gradually decreasing or remain unchanged. With the rapid economic development of the BRICS countries, the problem of environmental pollution is becoming more and more serious. In 2017, all BRICS countries except Brazil were in ecological deficit. Compared with previous years, this deficit were very high in most of these countries. Therefore, it is necessary to study the stochastic evolution path of ecological indicators in BRICS. The EFs increase significantly in BRICS except for South Africa, especially after 1985. The per capita EFs have risen sharply in China and India, the biggest economies, indicating that these two countries are rapidly consuming natural resources. Although the trend of increase in per capita EF in Russia is not obvious, the level of per capita EF in Russia is higher than the sum of EFs in China and India. Although Brazil is the only BRICS country with an ecological surplus, its per capita BC is also declining at the fastest rate among BERICS, reaching the brink of an ecological deficit in 2017. Obviously, the level of economic development is closely related to the per capita EF. On the other hand, South Africa's ecological carrying capacity is obviously declining rapidly. In the past decade, China and South Africa have undergone higher ecological deficits than other countries. This means that the two countries with higher per capita incomes have put more pressures on the environment and faced a bigger problem of environmental deterioration. Environmental sustainability requires that the consumption of resources by the present generation cannot pose a threat to the needs of future generations. The imbalance between ecological footprints and ecological carrying capacities means that the present society is using the resources of future generations to live. In order to prevent the trend of further deterioration of the ecological deficit, the close cooperation between countries is required to take actions to improve the modes of production of enterprises and consumption patterns of human beings. **Table 1** shows the descriptive statistics of BRICS and the world environmental indicators. From these summary statistics, we can see that there are also great differences in environmental indicators among BRICS. Russia has the highest per capita EF, while Brazil has the highest per capita BC.

From **Figure 2**, it is also clear that the CFs and BCs are persistent, BCs downwards and CFs upwards. With respect to most of series, the processes might be not mean-reverting, and exhibit long memory properties presumably from the argument proposed by Granger and Joyeux (38) that the aggregation of first order Markov processes leads to a long memory process.

EMPIRICAL ANALYSIS

Analysis of Convergence and Divergence of per Capita Ecological Indicators (EF and BC)

Convergence and Divergence of per Capita Ecological Indicators

Tables 2, **3** report the memory parameter estimates of the fractionally integrated processes estimated using LW, ELW

and the ELW methods with detrended (or with removed breakpoints) for each environmental indicator sequence. The integration order of each environmental indicator in all countries is greater than 0, indicating that all sequences exhibit long memory characteristics. For each estimated memory parameter, a corresponding 95% confidence interval is provided. According to the confidence interval range of fractionally integrated proesses' memory parameters, it can be found that, in general, the confidence intervals of the memory parameter estimates of per capita ecological footprints in all countries have low bounds higher than 0.5, indicating that these indicators may be non-stationary. However, the low bounds of the confidence intervals of the per capita BC memory parameter estimates of BRICS are less than 0.5, which means that the per capita BCs may be stationary. For most countries, the memory parameter estimates of the ecological footprints per capita are greater than 1, which means that they will not converge to their common average of BRICS. Therefore, it is possible to reject both pure stationarity and unit root. In some cases, the effect of a given random shock will be temporary, but the sequence tends to return to its trend and converges slowly at a slower rate than a pure stationary sequence. The memory parameter of per capita BC sequences in BRICS are <1, indicating that these sequences are mean reverting (i.e., convergence). These insights can be analyzed in detail as follows.

As for testing per capita ecological indicators' convergence, the Monte Carlo critical values and bootstrap critical values of the Robinson test make the consistent conclusion, indicating that the per capita ecological footprint sequences of China and India are divergent; The per capita ecological footprints of Russia and South Africa are convergent, but the processes of convergence are quite slow; The per capita ecological footprint of Brazil shows a very weak convergence dynamics. All countries expect for South Africa have memory parameters of per capita carbon footprint series significantly >1, which means that the per capita carbon footprints of these four countries are far from convergence. China's relative ecological footprint per capita has the highest persistence ($\hat{d} = 1.190$); Russia's per capita relative ecological footprint has the lowest persistence ($\hat{d} = 0.643$), indicating that Russia's per capita carbon dioxide emissions are serious. The confidence interval for the estimated fractionally integrated process parameter (long-memory parameter) is very narrow and generally located within a positive interval range. For the relative ecological footprints per capita, the upper bound of the confidence intervals are generally >0.5, indicating that the ecological footprints are non-stationary and some are even mean-reverting, but exhibit long memory characteristics. The two environmental indicators in other countries do not have the feature of mean reversion and are not convergent. For South Africa and Russia, the inference results, i.e., convergence or divergence, are very consistent, no matter Monte Carlo or bootstrap approach is used to statistically infer. Specifically, the range of estimates $\hat{d}$ is between 0.49 and 0.72 (statistically always different from 1), indicating long memory and mean-reverting (convergent) processes, but not covariance stationary processes. Therefore, the per capita relative ecological footprints of China, India and Brazil are not convergent, while those indicators of South Africa and Russia are convergent, although the convergence will take quite long time ($\hat{d} = 1.190$).

However, as for the ecological carrying capacities, it is another story. The upper bounds of the memory parameters $\hat{d}$ of the BC sequences per capita in most of BRICS countries are greater than 0.5, but less than 1, which indicates that these sequences

are mean-reverting, but of not stationary. These results show that in all BRICS countries the BC sequences are convergent, with quite different convergent rates. In China and India, the BC sequences have the longest memory degree, and the estimated memory parameters are $\hat{d} = 0.668$ and $\hat{d} = 0.663$, respectively, which means the two countries have the slowest convergent paths. However, the memory parameter of South African per capita BC sequence is that $\hat{d} = 0.018$, in other words no long memory characteristic, i.e. converging quickly. The memory parameter estimate of the BC sequence of Russia is less than 0.5 ($\hat{d} = 0.287$). The analysis above means that the per capita BC is a stationary process, but a long memory process, converging in a relatively fast rate. From the policy perspective, as long as the government adopts environmental protection and resource use policies designed appropriately, the decline trends of the per capita ecological carrying capacities of BRICS can be reversed and eventually converge. It is not as stubborn as the worsening trend of the ecological footprints, which have put tremendous pressures on the governments of BRICS.

Statistical Test of Convergence and Divergence of per Capita Ecological Indicators (EF and BC)

We now turn our attention to investigating the finite sample simultaneous coverage probability and effectiveness of the critical intervals for the Robinson (33)'s tests. This kind of graphic is very useful for choosing among critical values that have reasonable coverage distortions and effectiveness improvements: it permits to make arbitrage between the coverage distortion and the true effectiveness for each critical values and then to chose the most appropriate. More specifically, we do both the IID and Monte Carlo and bootstrap sampling respectively for 2,000 independent replications with $n = 64$. In each replication, we calculate uncorrected marginal intervals. We then plot the point estimate of the coverage and effectiveness along with simultaneous confidence regions in **Figures 3**, **4**.

We consider coverage plots as suggested by de Peretti and Siani (5) defined as follows. For a nominal coverage x the coverage is calculated as $x_s = 1 - 2\min\{pv, 1 - pv\}$, where pv is equal to

$$pv = \frac{1}{B}\sum_{b=1}^{B} I\left(\hat{\tau} \leq \tau_0\right). \tag{24}$$

With respect to Mayoral statistics shown by Equation (14), empirical critical values are obtained by 2,000 repetitions of Monte Carlo simulation and 2,000 repetitions of bootstrap resample respectively.the corresponding contains of following tables are the same as this table.

where pv is the estimated probability distribution function at the true Robinson (27)'s statistics $\hat{\tau}$, using any of the bootstrap and Monte Carlo strategies described above. τ_0 is the correspoding critical value, and B simulation repetitions. The closer the coverage line is to 45 degree line the better the strategy used to approximate the distribution of Robinson statistics performs. The third column of **Figures 2**, **4** presents the coverage plots of the interval based on inverting (single) bootstrap tests for the five BRICS countries. Not only is the frequency of coverages important to assess the performance of a CI but its length is also a relevant measure of its effectiveness [see (5)]. If two CIs have the same confidence level the shorter is preferable, indicating higher precision in the estimation. The second column of **Figures 3**, **4** presents the confidence level-effectiveness curves of the interval based on inverting (single) bootstrap tests based on the parameter estimates of the five counties. On the basis of confidence level-effectiveness curves, two critical values seem to have the same effectiveness (expect for Brazil) and to be dominated differently. Following the results on **Figures 3**, **4**, the Bootstrap method has the most satisfactory "true" effectiveness for Brazil.

As is analyzed above, **Figure 3** shows clearly that MC critical values should be resorted to judge the Robinson tests for EF indicators, and the confidence interval based on inverting bootstrap tests is by far the best method on the basis of coverage accuracy criterion in China and India. However, the bootstrap critical values should be used to infer Robinson tests in other BRICS countries since these coverage curves approaches 45 degree lines closer, and their confidence intervals are narrower.

It is obvious that the Bootstrap critical value does not perform well for judging the statistic hypothesis test of BC indicators in almost all BRICS countries (shown by **Figure 4**) since the MC plot is closer to the 45 degree line. Consequently, in these countries MC critical values should be employed to infer Robinson test. However, in Brazil, Bootstrap critical values are more appropriate tools to decide the inference of Robinson test at a significance level.

Pseudo-Long Memory Test (Mayoral Test) for Per Capita Environmental Indicator Sequences

Pseudo-Long Memory Judgment of Per Capita Environmental Index Sequence

In the second stage, for achieving the more accurate estimates of the long memory or infinite memory parameters in BRICS, we control the deterministic trend and possible breakpoints of the ecological indicator sequences. **Table 4** provides the statistical test and long-memory parameter estimation results. The Mayoral test shown by **Table 4** identifies which hypothesis is true: non-stationary long memory vs. $I(0)$ + breakpoints for the environmental indicator series. The purpose of this test is to determine the cause resulting in the observed long-term memory processes: whether it is the result of a highly persistent shock, or whether those rare and unexpected events have changed the sequence's potential dynamics, inducing structural breakpoints. For each country, the first line reports the memory

parameter estimates, while the second and third lines report the critical values generated by the corresponding methods, i. e. Monte Carlo and Bootstrap approaches. We discuss presence or absence of structural breakpoints in the context of ARFIMA models, and are particularly interested in the effect of structural breakpoints on fractional integration parameter estimates. The results in **Table 4** show that the inference of whether or not per capita environmental indicator sequences are long memory is very robust. According to the statistics $R_b^f\left(\hat{d}_T\right)$ of per capita ecological footprints of BRICS, there is no evidence to reject the null hypothesis that the per capita EF sequences are fractionally integrated process (FI) with long memory characteristics in BRICS countries. Therefore, we can conclude safely that these fractionally integrated sequences might be non-covariance-stationary, with no significant breakpoints in the deterministic trend detected (as shown in **Figure 1**).

In China and India, with respect to the per capita BC sequences, we cannot reject the null hypothesis that the sequences of Equation (7) are long memory processes by the Mayoral test, depending Monte Carlo and bootstrap critical values. As shown in **Figure 2**, the per capita BCs are really long memory processes. For Brazil and South Africa, the Mayoral statistics is calculated by using the memory parameter estimates obtained from the detrended 2ELWd method. Both Monte Carlo and bootstrap critical values show that there is a breakpoint in per capita BCs, indicating that per capita BCs converge faster. Although the memory parameters estimated by the LW method in Russia show the existence of structural breakpoints, for the LW method is a relatively ineffective method, we generally prefer to the estimation results of the improved LW method. Therefore, it can be concluded that there is no breakpoint for the per capita BC in Russia. The economic implication of this conclusion is very clear: the Mayoral test indicates that there is no breakpoint in most countries' environmental indicators, which means that environmental indicators are highly persistent processes.

Therefore, on the whole, the overwhelming majority of BRICS countries have not undergone structural changes in the per capita environmental indicators, and they are long memory processes. Implications arising from the results above that international multilateral agreements such as the Kyoto Protocol and the Paris Agreement, which restrict greenhouse gas emissions and promote sustainable development, have not played a substantive role.

Pseudo-Long Memory Statistical Test of per Capita Environmental Indicator Sequences

In this paper we use inverting (single) bootstrap tests to construct three confidence intervals named by H0: Monte Carlo, H0: Bootstrap and H1: Bootstrap (see notations shown by legends of **Figures 5**, **6**) for the Mayoral test statistics in 5 BRICS countries and compare with each other and infer whether the H0 hypothesis hold at usual significant levels. The results presented in **Figures 5**, **6** suggest that CIs are constructed more profitably under H0 than under H1.

Of the three confidence intervals, the evaluation of H0: Monte Carlo and H0: Bootstrap is based on their coverage accuracy and average length. Column 2 and 3 of **Figures 5** and **6** show average lengths and the coverage probabilities of the confidence intervals calculated for 2,000 runs, respectively. A shorter average length corresponds to a better effectiveness performance. **Figure 5** shows that the Monte Carlo test statistics produces CIs that are longer (lower effectiveness) than CIs constructed using the bootstrap test statistics for EF indicator in China, India and Brazil; while MC critical values are of minor advantages over Bootstrap counterparts in South Africa and Russian based on effective curves.

The results set out in **Figure 6** show that the confidence interval of the Mayoral test statistics built by Monte Carlo simulation has the better performance on coverage probability compared with that of the bootstrap method for Mayoral test in South Africa and Russia. Just the opposite is true to other BRICS countries. However, the results displayed in **Figure 6** reveal that for the BC indicators' Mayoral test statistics, the average length of the Monte Carlo confidence intervals is longer than that produced by the Bootstrap method in Brazil, indicating worse effectiveness. The inference dependent of Bootstrap critical values is more effective in terms of higher coverage probability and shorter average length than Monte Carlo counterparts of other countries among BRICS. On the contrary, the average length of the Monte Carlo confidence intervals is shorter in South Africa, which means Monte Carlo critical values are more satisfactory inference tools. The effectiveness curves do not show the visually obvious difference in other three BRICS countries. Synthesizing the results of **Figures 5, 6**, and balancing the performance of the effectiveness and coverage probability, Monte Carlo critical values are appropriately able to be used in Mayoral test in South Africa and Russia. Thus, the exact bootstrap method is not recommended for identifying potential break points in the two countries. By contrast, bootstrap critical values are the preferred inference tools to Mayoral test in remaining countries. No matter what environmental indicators are tested, these conclusions from **Figures 5**, **6** are the same.

Breakpoint Identification of per Capita Environmental Indicator Sequences (Berkes Test)

Breakpoint Judgment of per Capita Environmental Indicator Sequences

In order to check the reliability of the results, this paper supplements the Mayoral (2) test by using the CUSUM statistic of Berkes et al. (1) to perform a further test so as to infer the existence of breakpoints and determine the locations of breakpoints. **Table 5** shows the statistics M_n of Berkes et al. (1). Due to the good performance of small samples, we use the Bartlett kernel function and select the optimal bandwidth suggested by Newey-West (see Section **Convergence Pseudo-long Memory Test of Relative Environmental Indicators Per Capita**). The null hypothesis represented by Equation (10) indicates that there is no structural change in the deterministic trend of the ecological indicator sequence. **Figure 7** shows how the ecological footprint statistics M_n for each country evolves over time. Due to the space limitation, the statistics M_n of the BCs per capita in BRICS

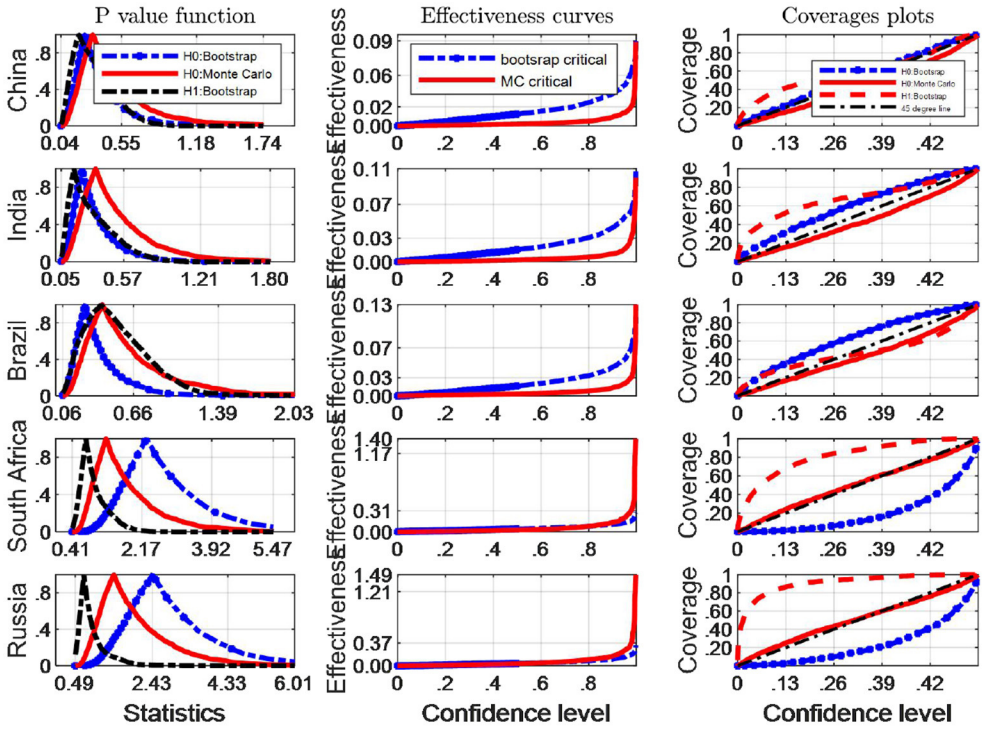

FIGURE 5 | A comparison of confidence intervals of Monte Carlo and counterparts of bootstrap for the Mayoral test using EF indicators.

countries over the sample years is not listed in the present paper. The statistics in **Figure 7** and **Table 5** shows that the maximum value of the Berkes statistics of the per capita EF sequences and per capita BC sequences of the BRICS countries will not be lower than critical values of themselves, which can reject the null hypothesis and there are not any break points identified. Therefore, within the sample region of 57 years, the ecological footprints per capita and BC sequences per capita are either covariance non-stationary process of mean reverting or unit root process, i.e., there is long memory.

Breakpoint Statistical Test of per Capita Environmental Indicator Sequences

Figures 8, **9** show coverage and effectiveness results for EF and BC indicators respectively, with separate plots for Monte Carlo and Bootstrap critical values. These two figures show that the Monte Carlo arbitrament methods tended to provide smaller confidence intervals with better coverage accuracy than the bootstrap arbitrament methods over almost all Berkes test statistics domains (judged by the first column and the third column of **Figure 8**).

The two figures again indicate that Monte Carlo method coverage probability generally compare favorably against those of Bootstrap method based on inverting Bootstrap CIs, and in particular Monte Carlo method intervals seem to emerge with slightly better coverage rates asymptotically from their evolving dynamics as well. However, the Monte Carlo method indiscernibly performs better than does the Bootstrap methods when the Berkes test methodology is employed to the Russian EF indicator and the South African BC indicator. These plots also indicate that, comparing with the Bootstrap method, although the Monte Carlo inference method has similar coverage rates over higher confidence levels, there are obvious systematic differences in overall interval lengths. Over lower confidence levels, we can identify similar effectiveness of the two inference methods generally.

When we test potential breakpoints occurring in BC indicator sequences, in terms of interval lengths, the Monte Carlo method has uniformly narrower intervals, especially when confidence levels are small (**Figure 9**). Following the results provided by **Figure 8**, the Monte Carlo critical values has the most satisfactory "true" effectiveness for the inference of potential break points in almost all the BRICS countries, expect for South Africa and Russia when EF indicators are tested. However, the difference between the average lengths of the various methods is not very large, especially over lower confidence levels. Consequently, the Monte Carlo critical values should be retained to judge whether a long-memory process is true or just a mean-shifted process, on the double basis of the coverage and the average length criteria. With respect to the BC indicator, the confidence intervals for critical values from the Monte Carlo methods are shorter than the bootstrap method at usual confidence levels, e.g., 95%.

Our simulation results indicate that when the BC indicators are tested if they are pseudo-long memory processes, the Monte Carlo critical values have the best performance based on both coverage probability compared with the bootstrap

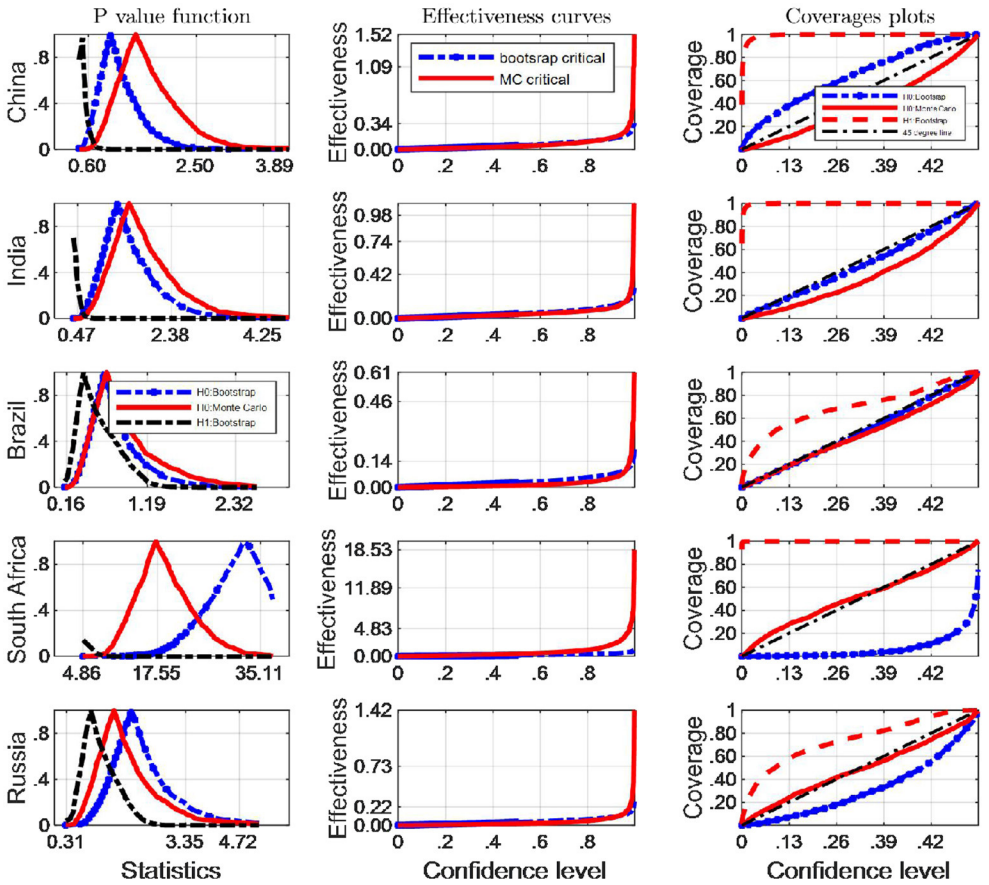

FIGURE 6 | A comparison of confidence intervals of Monte Carlo and counterparts of bootstrap for the Mayoral test using BC indicators.

counterparts, since the coverage plots produced by MC critical values are closer to 45° lines. However, what the second column tells is that more statistory effectiveness curves are produced by bootstrap critical values expect for India and Brazil. A summary statement can be concluded that Monte Carlo CIs generally performed better than their bootstrap counterparts. Based on the analysis above, when the EF indicators are tested pseudo-long memory, the bootstrap critical values should be resorted to in South Africa and Russia, and the Monte Carlo critical values are appropriate to other BRICS countries. Therefore, this study recommends Monte Carlo confidence interval to quantify the uncertainty of the Berkes statistics, and more robust inferences based Monte Carlo critical values.

Combined with the Mayoral and Berkes pseudo-long memory tests of the environmental indicators (EF and BC) of each BRICS country, the results provide consistent evidence that only China and Russia have breakpoints in their per capita EF (the China's per capita EF breakpoint occurred in 1990; The per capita EF breakpoint in Russia occurred in 1993). Therefore, a large number of countries follow the evolutionary trend of long memory processes. These breakpoints correspond to the late 1970s and early 1980s. During this period, the Iranian revolution and Iran-Iraq war broke out in 1978–1979. These two major oil producers, accounting for 6% of the world's oil output, experienced a decline in oil products. The real price of oil doubled between 1978 and 1981, which had a negative impact on the economies of BRICS countries where the ecological indicator breakpoints occurred. In response to the oil price shock, BRICS countries' ecological footprints fell significantly, following their economic recessions. We can also see that the two significant structural breakpoints in China correspond to the 1990s, when events, including the Gulf War and coming into force of the Kyoto Protocol at the end of 1997, affected the ecological indicators. However, the break point in the rising process of Russian per capita EF sequence is due to taking the former Soviet Union data as a proxy before 1991, which resulted in sudden shifts in per capita ecological indicators between 1992 and 1995.

Tables 2, 3 summarize the results judged by the estimated values of *d*. The results show the ecological indicators are long memory in all BRICS countries, and the subjects we selected are good for this study. The BRICS are grouped into three categories in term of the degree of long memory. The first group refers to the countries belonging to the

'mean reversion' case (i.e., South Africa and Russia in term of CFs, and China, India and South Africa in term of BCs with an order of integration significantly smaller than 1); the second group refers to those countries showing evidence of unit roots (i.e., Brazil and Russia in term of BCs with orders of integration around 1); and the third group refers to countries with divergent ecological indicators (China, India and Brazil in term of CFs with orders of integration significantly above 1).

It is not surprising that the per capita ecological footprints of the vast majority of BRICS countries reported in the empirical results are non-stationary and non-mean-reverting. This reflects that the per capita ecological footprints develop along a trend path, usually along an upward trajectory, and does not return to their means during the sample period. However, due to heavily consuming natural resources, in BRICS countries the ecological carrying capacities evolve along the downward trend. This indicates that these countries have continuously imposed more pressures on the per capita ecological footprints and ecological carrying capacities, resulting in the ecological footprints exceeding the biological carrying capacities of these countries. Therefore these countries uniformly fall into an ecological deficit state, as shown in **Figure 2**. Some of these countries have high per capita ecological carrying capacities, but have a higher marginal consumption propensity when they are utilizing the nature. For example, Brazil has the highest per capita ecological carrying capacity, but will still faces the dilemma of an ecological deficit due to excessive demand for natural resources.

CONCLUSIONS AND IMPLICATIONS

The importance of a composite indicator of environmental degradation (ecological footprint) is that it can go beyond exparte discussions of climate change and sustainability, because it can also track demand for services provided by a wide range of natural resources and ecosystems, rather than just focus on the atmospheric carbon accumulation. In the contemporary world, people have used 1.6 earths to produce the resources consumed and dump the wastes discharged. This trend means that it will take the earth 1 year and 6 months to regenerate natural resources used and absorb wastes per year because of human activities. If this kind of consumption pattern is as of old, the total demand for ecosystems is expected to exceed 80% of natural carrying capacities in another 10 years (39).

Environmental economics is paying more and more attention to the convergence of environmental indicators such as ecological footprints, especially the topics related to natural deterioration. There are two reasons why convergence of environmental indicators is important. (1) The need for close cooperation between countries and regions with similar productivity characteristics when formulating and implementing environmental policies. In order to mitigate the threat of global warming, policies should not be limited to the territorial scope of just one country, but should take actions at the international level. The Tokyo Protocol and the Paris Agreement are examples of the international communities' joint resistance to environmental degradation. (2) The consumption patterns, foreign trade and industrial structure of countries or regions

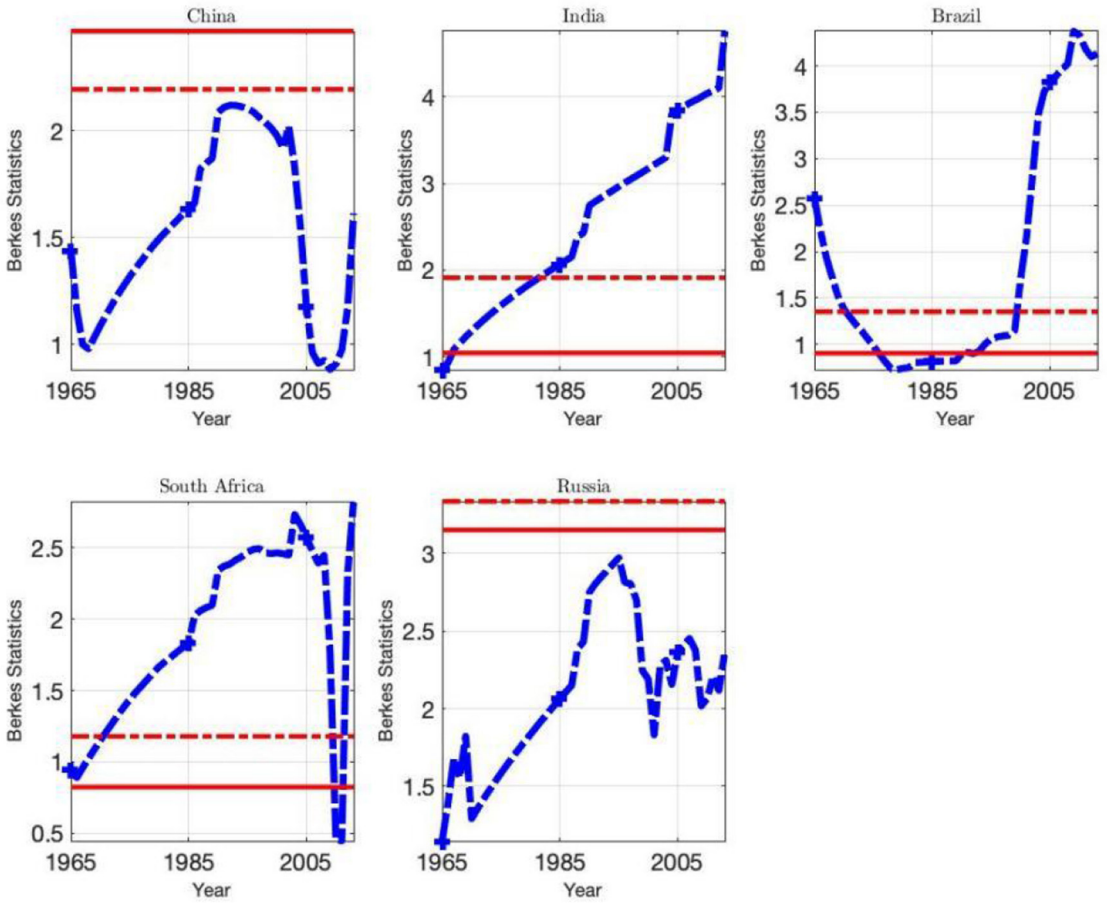

FIGURE 7 | M_n statistics for BRICS. This graph plots Berkes statistics (blue lines) evolving over time. Red solid lines represent Monte Carlo critical values at 5% significant level; while red dash lines represent bootstrap critical values at 5% significant level. When red lines are located above the maxima of *M* statistics, Berkes test reject null hypothesis. With respect to Berkes statistics represented by Equation (22), empirical critical values are obtained by 2,000 repetitions of Monte Carlo simulation and 2,000 repetitions Bootstrap resample respectively.

affect the evolving trend of environmental and ecological indicators. Therefore, it is urgent to identify the factors that determine the convergence or divergence of ecological indicators. Environmental policies to protect the nature have an obligation to change the deteriorating trend of environmental indicators. Therefore, identifying the mechanisms that trace the trajectories of changes in ecological indicators is a topic of interest to both policymakers and academic researchers.

This present paper applies the sample data from 1961 to 2017 to study whether or not the stochastic convergence occurred in the ecological footprint and ecological carrying capacity series of BRICS countries. Two rigorous statistical testing methods are employed to identify whether or not the long memory processes (if exist) characterizing ecological indicators are falsely modeled (i.e., identified break points). Through various frequency-domain Whittle estimators and statistical tests, it is found that the fractional integration parameters of the vast majority of per capita EF sequences are greater than 1, indicating that these environmental indicators are non-mean reverting (divergence); The parameters of fractional integration of BC sequences are mostly within the interval $0 < d \leq 1$, which indicates that the ecological footprints are non-stationary long-memory processes. The fractional integration parameters of ecological carrying capacities are obviously smaller than those of ecological footprints, but they are still in the non-stationary and long memory domain. The significant discrepancy to the EF indicators in most countries, however, is that the BC sequences are convergent processes, namely mean-reverting. By comparisons, it is found that the convergence of ecological footprints and ecological carrying capacities is closely related to the economic development of various countries. Generally speaking, richer countries have a higher convergence rate of these two indicators being discussed; As the world's largest developing countries, the BRICS countries' ecological indicators are mostly divergent.

From the perspective of existing or potential policies that prevent ecological indicators worsening, the conclusions of this study are very informative. For most BRICS countries, the ecological footprints exhibit non-stationary behaviors, which

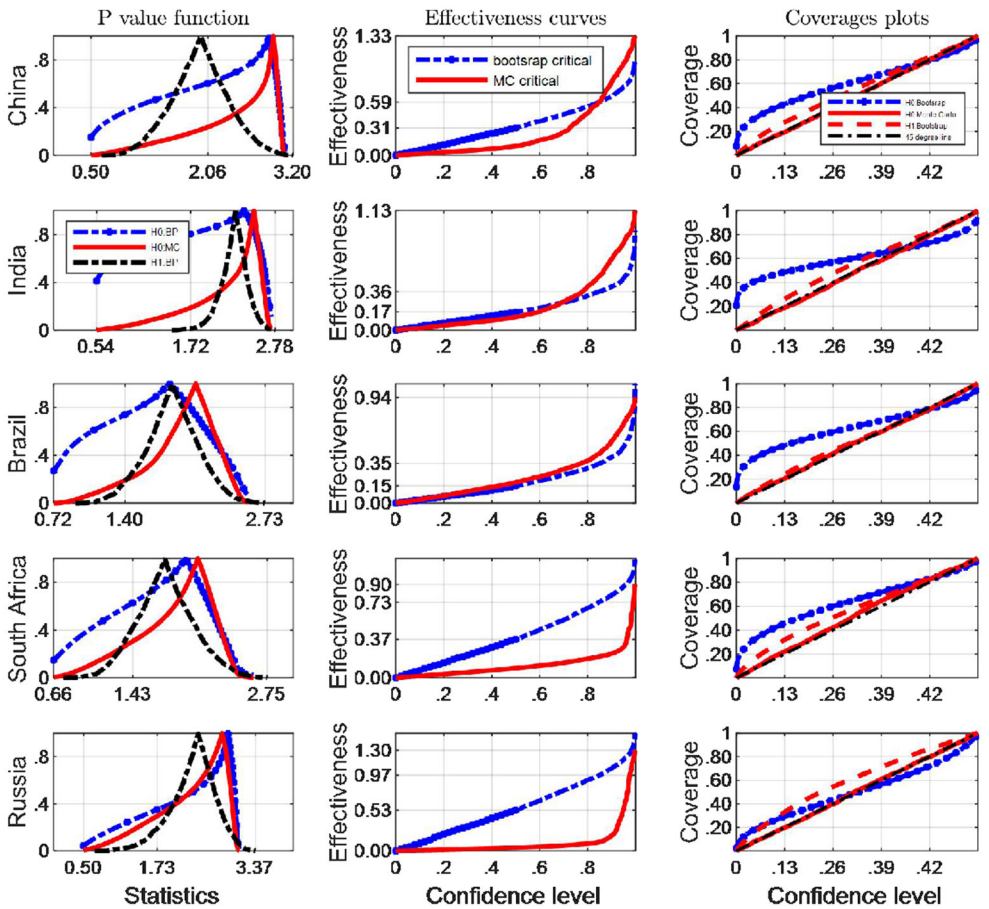

FIGURE 8 | A comparison of confidence intervals of Monte Carlo and counterparts of bootstrap for the Berkes test using EF indicators.

fully demonstrates that policies that affect the ecological footprints actually have long-term and permanent effects. There are several policies that can address the growing ecological footprints. Such a series of policies includes a carbon tax designed to reduce the demand for carbon and governmental subsidies expended to guarantee the consumption of alternative clean energies. Controls on land use should also be strengthened to protect land, forests and other natural habitats. Regardless of whether or not certain environmental policies are temporary in nature, the fact that the ecological footprints are non-stationary ensures governmental policies can take long-term effects on these indicator's dynamics. China's per capita EF series have undergone structural changes during the sample period, indicating that the rising rate is faster than other BRICS countries. Implications arising from this observation a more stringent and long-term policy tool package should be adopted for energy conservation and carbon emission reduction. The per capita BC sequence in South Africa has also undergone structural changes in the process of persistent decline (judged by the Mayoral test), anticipating a faster decreasing rate. Therefore, in the pursue of economic development, Brazil should get rid of over-exploitating nature and adopt stricter environmental protection policies to prevent the further decline of its ecological carrying capacity.

Because the ecological footprints are found to be non-stationary in most BRICS countries, predicting their evolving dynamics based on past behavior may constitute a great obstacle (if not be feasible). However, their non-stationary behaviors means that policies aimed at changing it will have lasting and persistent impacts. As the vast majority of macroeconomic variables are also non-stationary, especially for level values (not differenced values), the ecological footprints may have the same fractional integration order as that of macroeconomic variables, thus indicating the existence of cointegration between these variables, in other words, long-term equilibrium relationship, which can assist in formulating relevant environmental policies.

Convergence of environmental indicators between countries is considered as a fair share of carbon dioxide emission rights. However, different countries have different natural endowments, and furthermore resources can be transferred between different countries. The stationarity of a sequence provides information about whether the effects of a shock to the sequence is temporary or permanent. A stationary sequence manifest itself that the effects of this shock are temporary. Therefore, if the impacts of

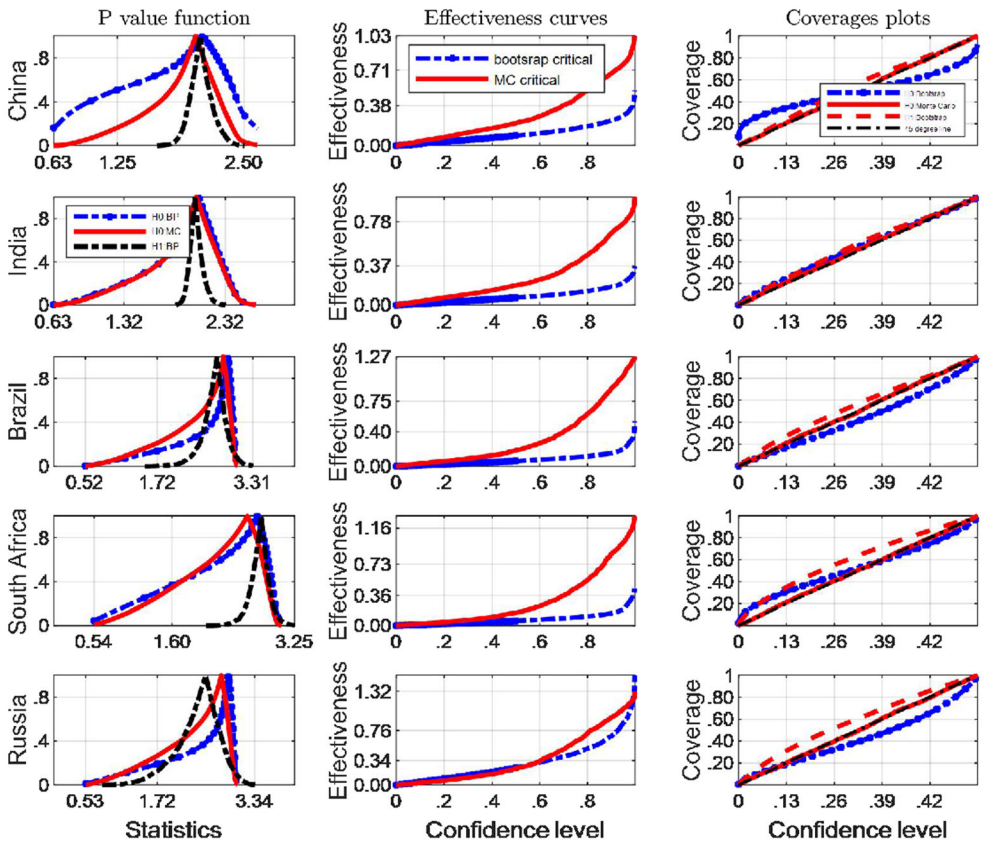

FIGURE 9 | A comparison of confidence intervals of Monte Carlo and counterparts of bootstrap for the Berkes test using BC indicators.

shocks to the ecological footprint sequences dissipate quickly, these sequences of various countries converge to the sample means stochastically. A non-stationary sequence indicates that the effects of the shock hitting it are permanent, i.e. this sequence will deviate from the sample mean eventually. Similarly, when a ecological indicator is non-stationary, environmental policies that affect it have persistent, and even permanent effects. At the same time, the convergence of ecological indicators between countries shows that it is necessary to adopt internationally cooperative policies to protect the vulnerable environment. The lack of convergence indicates that these policies are out of permanent effects and the cross-broad policies are not very powerful.

Due to the long-memory characteristics of environmental indicators, the impacts of a positive shock (usually comes from an environmental policy) will be long-term and this policy effect will be better. For example, specific policies include energy efficiency improvement projects and subsidies for renewable energies. However, the divergence of environmental indicators is more disadvantageous. If an adverse random impact occurs, the impact will be very long-term, and a stronger policy intervention is needed to reverse the trajectory of environmental deterioration. In order to deter the worsening trend of ecological indicators, a steadfast policy stance is necessary. Therefore, we argue that: (1) A policy that is designed to be temporary or eventually revoked cannot expect to have lasting effects. (2) A policy that is either permanent or believed to be permanent will often have stronger and more persistent effects. Based on our empirical results, the degree of commitment is as important or more important than the validity or the potential effects of a policy.

In addition, some country-specific characteristics, such as the degree of economic development, industrial structure and consumption patterns, should also be taken into account. As high-income countries and developed countries formulate some better policies and more effective measures to confront the challenge of the ecological indicator worsening, low-income countries should borrow some advanced experiences of developed countries who share similar evolving trajectories of ecological indicator to achieve greater progress in curbing the deterioration of ecological indicators.

Application of Smart Healthcare in Comparative Analysis of Effect of Early External Fixator and Plate Internal Fixation Treatment on Postoperative Complications and Lower Limb Function Recovery of Patients With Unstable Pelvic Fracture

Hongwei Zhang[1†], *Fang Sun*[2†] *and Yao Li*[3*]

[1] Department of Emergency, The First Affiliated Hospital of Jiamusi University, Jiamusi, China, [2] Plastic Burn Beauty Center, The First Affiliated Hospital of Jiamusi University, Jiamusi, China, [3] Department of Orthopeadic Surgery, The First Affiliated Hospital of Jiamusi University, Jiamusi, China

Objective: To comparatively analyze the effect of early external fixator and plate internal fixation treatment on postoperative complications and lower limb function recovery of patients with unstable pelvic fracture based on smart healthcare.

Methods: The clinical data of 98 patients with unstable pelvic fractures treated in our hospital from August 2018 to August 2021 were collected for retrospective analysis, and the patients were split into group A (plate internal fixation, $n = 49$) and group B (early external fixator treatment, $n = 49$) according to the surgical modalities. The time of operation, intraoperative blood loss, postoperative complications, etc. were compared between the two groups.

Results: Between the two groups, group B had significantly better clinical indicators ($P < 0.001$), a greatly higher good rate of fracture reduction and postoperative Harris score ($P < 0.05$), and obviously lower VAS score and total incidence rate of postoperative complications ($P < 0.05$).

Conclusion: Through the analysis based on smart healthcare, it is found that compared with plate internal fixation treatment, early external fixator treatment presents a better effect in treating patients with unstable pelvic fracture, because it is a reliable method to accelerate fracture healing, reduce postoperative complications, and improve lower limb function.

Keywords: early external fixator, plate internal fixation, unstable pelvic fracture, postoperative complications, lower limb function recovery, smart healthcare

INTRODUCTION

Pelvic fractures account for approximately 3% of all fractures. Unstable pelvic fractures are classified as high-energy injuries (1) and are often associated with other complications, with high mortality and disability rates. Conservative treatment is often selected in clinics to treat unstable pelvic fractures, but the incidence rates of complications such as hypostatic pneumonia and gastrointestinal hemorrhagic stress ulcer are higher (2), which, despite current improvements in medical technology, still affect the prognosis of patients, resulting in a severe reduction in their quality of life (QOL) (3, 4). Since the pelvic bone is not stable and relies mainly on soft tissues such as ligaments, so the key to treatment is to provide it with an environment that is mechanically stable throughout its structure, thus aiding the recovery of both the bone and soft tissues (5). With the progress of Internet technology, China proposes to develop the smart health industry and promote the deep integration of cloud computing, big data, mobile Internet, and the health services industry, under which context smart healthcare was born. Smart healthcare enables a more scientific management model of daily life and production that greatly improves the distribution and utilization efficiency of resources. Plate internal fixation is currently a common method for the clinical treatment of unstable pelvic fractures, and clinical studies (6) have found that although it has a better fixation effect, there are disadvantages such as a long time of surgery, high difficulty in surgical manipulation, long time of incision healing and more postoperative complications. The external fixation technique is mostly used in the first aid of pelvic fractures because it plays an important role in the stability and hemodynamics of pelvic fractures and saves valuable time for the management of combined injuries, and its effect has been demonstrated in some fracture types, such as femur fractures, tibial shaft fractures, and comminuted intra-articular fractures of the distal radius in children (7–9). Currently, there are fewer clinical studies on the external fixation treatment for pelvic fractures. The study, based on smart healthcare, further summarized and concluded the diagnosis and surgical treatment for fracture types to better apply the external fixation technique in pelvic fractures, and meanwhile, measured the best position and angle for external fixator screw installation according to patients' three-dimensional CT images of the pelvis before surgery, in the hope of providing greater theoretical and data support for the surgery.

MATERIALS AND METHODS

General Data

The study objects were patients with unstable pelvic fracture treated in our hospital. All patients received relevant examinations after admission, see **Figure 1** for the technical route. The study met the *World Medical Association Declaration of Helsinki (2013)* (10).

Inclusion and Exclusion Criteria

Inclusion criteria. ① The images met the X-ray signs of unstable pelvic fracture; ② the time from injury to surgery $\leq$ 3 weeks; ③ the patients met the indications of surgical treatment; and ④ the patients had complete clinical data.

Exclusion criteria for the patients. ① Pathological or old fracture; ② complicated with severe head trauma, organic injury, or neurovascular injury; and ③ severe osteoporosis.

Therapies

Patients in group A received internal fixation with steel plate, and the steps were as follows. General anesthesia was performed, before surgery, 0.08 mg/kg of midazolam (manufacturer: Yichang Humanwell Pharmaceutical Co., Ltd.; NMPA approval no. H20067040; specification: 2 ml: 2 mg) was administered via intramuscular injection, and 0.03 mg/kg of midazolam, 3 μg/kg of fentanyl (manufacturer: Jiangsu Nhwa Pharmaceutical Co., Ltd.; NMPA approval no. H20113509; specification: 10 ml: 0.5 mg), 1.5 mg/kg of propofol (manufacturer: Sichuan Guorui Pharmaceutical Co., Ltd.; NMPA approval no. H20040079; specification: 10 ml: 0.1 g) and 0.6 mg/kg of rocuronium (manufacturer: Guangdong Jiabo Pharmaceutical Co., Ltd.; NMPA approval no. H20183109; specification: 5 ml: 50 mg) was given *via* an intravenous drip. For patients with pure anterior ring injury such as separation of the pubic symphysis, the Pfannenstiel incision approach was adopted to expose the pubis and pubic symphysis site, the tissues inside the inguinal canal were well protected, and pelvic reduction was performed with pelvic reduction forceps or screw reduction forceps, the pelvic reconstructive plate was used for fixation, which was placed above the pubic symphysis site. For patients with fractures at the root of the superior branch of the pubis and acetabulum, an ilioinguinal approach was adopted, the femoral veins, femoral arteries, and peripheral nerves were well protected, after reduction, fixation was performed with the reconstructive plate, which was placed above the pubic branch, and C-arm X-ray was used to confirm that the screws were not in the acetabulum. For patients with pubic branch fracture at the anterior pelvic ring or mild separation of the pubic symphysis, if the pelvis was stable after reduction and fixation of the posterior ring, the method of single posterior ring fixation could be adopted (11). For patients with subluxation or luxation of the sacroiliac joint, an ilioinguinal approach was adopted to expose the front of the whole sacroiliac joint and iliac fossa, subperiosteal dissection was performed, the Kirschner wire (manufacturer: Tianjin Jinxingda Industries Co., Ltd.; model: type ZQY) was screwed in sacrum from the outside of L_5 nerve root, and fixation was conducted with 2- to 4-hole steel plate. For patients with sacroiliac joint luxation or sacrum fracture, a posterior exposure approach was performed, the patients were in the supine position, a straight or arc-shaped incision was made along the sacroiliac joint, the gluteus maximus was separated from the attachment point, and the superior gluteal blood vessels and nerves were protected. Closed reduction was mostly adopted for the fixation of iliosacral screws, the patients were in the supine position or prone position, the C-arm system confirmed that the position, direction, and length were appropriate in 3 planes on the lateral part, pelvic inlet, and outlet, and the corresponding screws were selected for fixation of fracture and luxation (12).

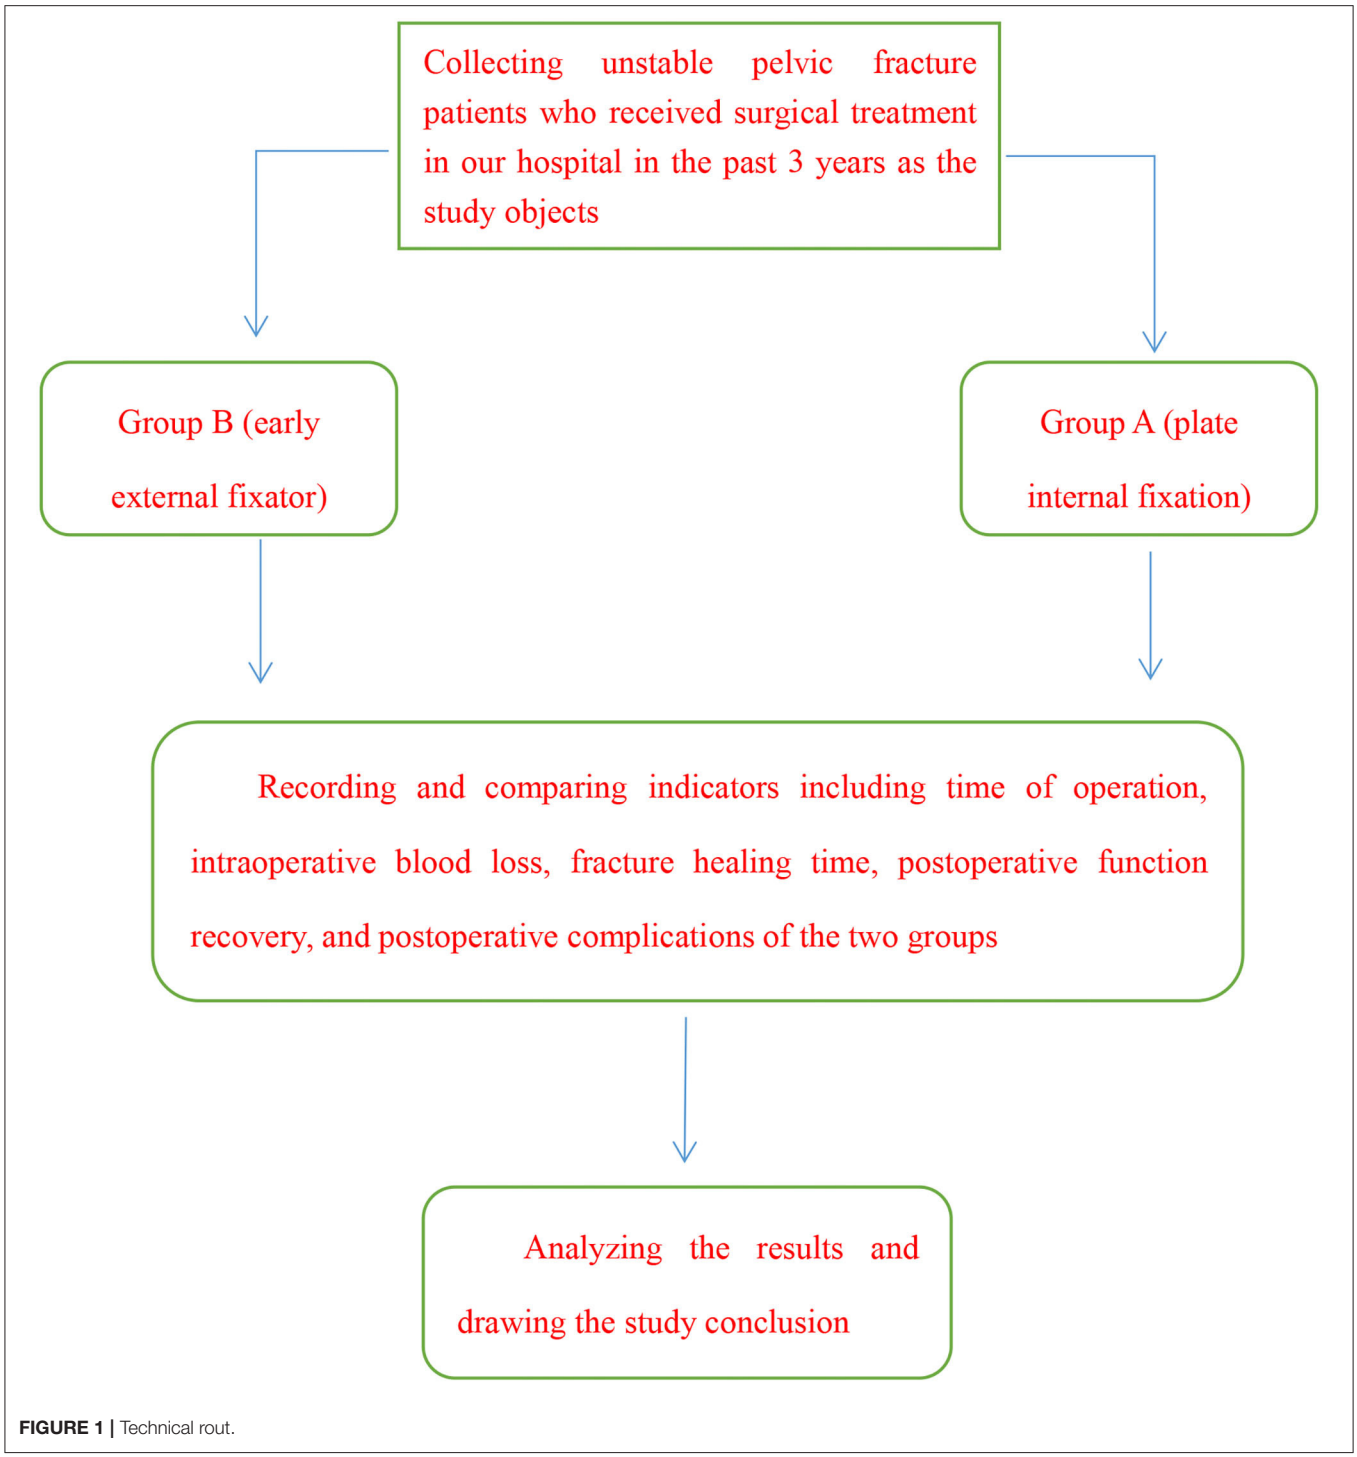

FIGURE 1 | Technical rout.

Patients in group B received early external fixator treatment. After general anesthesia, the patients were in the supine position, routine disinfection and draping were conducted, and before skin incision, 1 g of tranexamic acid (manufacturer: Shandong Yijian Pharmaceutical Co., Ltd.; NMPA approval no. H20043218; specification: 10 ml: 1.0 g) was administered via intravenous infusion. The anterior inferior iliac spine was located by C-arm X-ray, the skin and subcutaneous tissues were cut open, and the lateral femoral cutaneous nerves were protected; intermuscular blunt dissection was performed to expose the anterior inferior iliac spine and place the sleeve and drill holes with a depth over 3 cm (13). After withdrawing the drill, the threaded nails 6 mm in diameter and 150 mm long were screwed in with a depth over 3 cm, and attention should be paid to avoid entering the hip joint.

When the fracture reduction was satisfied, according to the pelvic 3D-CT image before surgery, the best screw installation position and angle of the external fixator were measured, the connecting rod was installed and the nuts were fixed, and then routine suture was performed.

Observation Indicators

Various perioperative indicators of patients in the two groups were recorded, including time of surgery, intraoperative blood loss, fracture healing time, and total length of the incision.

During postoperative follow-up, reduction evaluation was conducted according to the pelvic imaging data and by Matta's criteria for pelvic ring fractures (14), with displacements of less than 4 mm indicating excellent, 4–10 mm indicating good, 10–20 mm indicating fair, and more than 20 mm indicating poor. The scale could be used to evaluate the quality of fracture reduction, and the good rate = (number of excellent cases + number of good cases + number of fair cases) / total number of cases × 100%.

The patients' hip joint recovery after surgery was assessed by the Harris Hip Scale (HHS) (15), which covered four domains, function, pain, absence of deformity, and range of motion. The maximum score was 100 points, with more than 90 points indicating excellent, 80–90 points indicating good, 70–79 points indicating fair, and less than 70 points indicating poor.

The degree of postoperative pain was assessed by the Visual Analog Scale (VAS) (16), to be specific, a vernier slide caliper about 10 cm long was marked with 10 scales on one side and "0" (no pain) and "10" (the worst pain imaginable) at both ends. In clinical use, the side without the scales was faced to the patients for them to pick the corresponding position that best indicated their current degree of pain, and the doctor gave the score accordingly.

The occurrence of complications after-treatment of the two groups was recorded, including venous thrombosis, neural injury, and incision infection.

Statistical Methods

In this study, the data were processed by the professional statistic software SPSS26.0 (IBM, NY, USA), the picture drawing software was GraphPad Prism 7 (GraphPad Software, San Diego, USA), the enumeration data were examined by X^2 test and expressed by [n(%)], the measurement data were examined by t-test and expressed by Mean±SD, and differences were considered statistically significant at $P < 0.05$.

RESULTS

Clinical Data

No significant between-group differences in clinical data including gender ratio, time from injury to surgery, and cause of injury were observed ($P > 0.05$), presenting comparability. See **Table 1**.

Perioperative Indicators

Various perioperative indicators were significantly better in group B than in group A ($P < 0.001$). See **Table 2**.

Fracture Reduction Quality

The good rate of fracture reduction was significantly higher in group B than in group A ($P < 0.05$). See **Table 3**.

TABLE 2 | Perioperative indicators [Mean ± SD].

Group	n	Time of operation (min)	Intraoperative blood loss (mL)	Fracture healing time (d)	Total length of incision (cm)
A	49	105.47 ± 18.83	102.01 ± 12.26	108.82 ± 8.71	23.05 ± 3.09
B	49	69.81 ± 8.43	75.09 ± 7.35	95.93 ± 4.47	19.11 ± 2.90

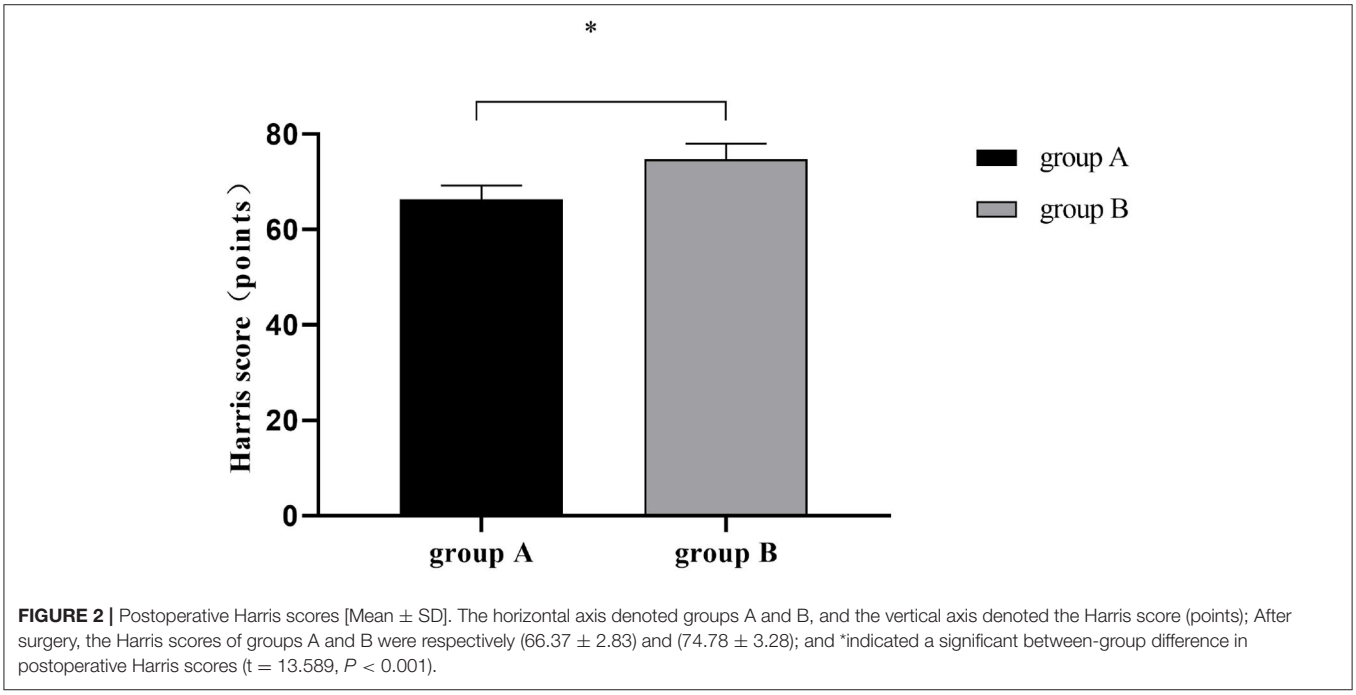

FIGURE 2 | Postoperative Harris scores [Mean ± SD]. The horizontal axis denoted groups A and B, and the vertical axis denoted the Harris score (points); After surgery, the Harris scores of groups A and B were respectively (66.37 ± 2.83) and (74.78 ± 3.28); and *indicated a significant between-group difference in postoperative Harris scores (t = 13.589, $P < 0.001$).

Harris Scores

The postoperative Harris score was remarkably higher in group B than in group A ($P < 0.001$). See **Figure 2**.

VAS Scores

The postoperative VAS score was significantly lower in group B than in group A ($P < 0.001$). See **Figure 3**.

Postoperative Complications

The total incidence rate of postoperative complications was significantly lower in group B than in group A ($P < 0.05$). See **Table 4**.

DISCUSSION

Smart healthcare is a rapidly developing high-tech means of medical treatment in the era of big data, and it has gradually infiltrated into people's daily lifestyles. This technique helps people better solve problems in the field of medical health through artificial intelligence (AI) technology, big data, cloud computing, etc., and then opens up new directions in the construction of medical fields. Each patient is considered as an independent individual in smart healthcare, and multiple diagnosis and treatment modalities depending on different patient conditions can be provided, thereby promoting medical quality. Pelvic fractures are injuries resulting from high energy, which are often accompanied by multiple life-threatening

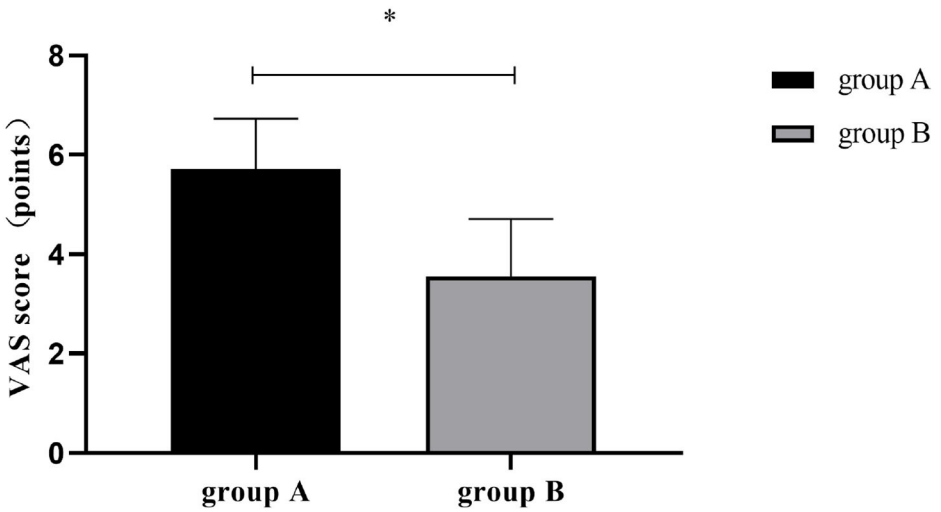

FIGURE 3 | Postoperative VAS scores [Mean±SD]. The horizontal axis denoted groups A and B, and the vertical axis denoted the VAS score (points); After surgery, the VAS scores of groups A and B were respectively (5.71 ± 1.02) and (3.55 ± 1.16); and *indicated a significant between-group difference in postoperative VAS scores ($t = 9.789$, $P < 0.001$).

injuries to other parts of the body, so the implementation of emergency trauma control and restoration of pelvic ring stabilization is essential for patient survival and treatment. Since the deformity caused by pelvic fracture usually triggers long-term dysfunction, surgical reduction and fixation need to be performed to restore the stability of the pelvis (17). Due to the complexity of pelvic structures and fracture types, surgery is often challenging, so there is currently no consensus on the surgical approach and the choice of fixation method. As a simple method of external fixation, traditional complete pelvic fixation has many advantages, such as easy operation and access, making it a common surgical procedure for the treatment of unstable pelvic fractures for a time (18). However, the poor fixation strength and fixation results of this technique make it unsuitable for some complex pelvic fractures. The previously used internal fixation treatment methods have the shortcomings such as a long time of surgery, high difficulty in surgery, long time of postoperative healing, and more postoperative complications. The external fixator technique is frequently applied in the emergency treatment of pelvic fractures and plays a key role in performing reduction, controlling bleeding, and reducing mortality (12). By drawing on previous clinical treatment experience, this study better exerts the application of external fixator technology in a pelvic fracture through a comparative analysis of the clinical effects of early external fixator and plate internal fixation in the treatment of unstable pelvic fracture, presenting a certain reference and guidance significance for the treatment of an unstable pelvic fracture.

The study results showed that the postoperative good rate of fracture reduction was significantly higher in group B than in group A ($P < 0.05$), which was due to the fact that the adjustable external fixation technique can reduce bleeding at the pelvic fracture end and stabilize the condition, providing a surgical opportunity for other combined injuries. In addition, the study also found that, compared with plate internal fixation treatment, an early external fixator can reduce intraoperative blood loss, time of surgery, and total length of incision to a certain extent, and accelerate the fracture healing time, which may be due to the fact that the external fixator treatment causes little skin and muscle damage and only needs to place screws firmly (19), and the efficacy of such easily operative procedure has been demonstrated in multiple metatarsal fractures (20). Moreover, the study results showed that the total incidence rate of postoperative complications was remarkably lower in group B than in group A ($P < 0.05$), and the reason may be that plate internal fixation uses the steel plate to stabilize the anterior and posterior pelvic ring for reconstruction, so as to restore fracture reduction and associated site function with the help of the plate. Some studies have pointed out (21, 22) that plate

internal fixation, although has a good effect, can easily induce damage to soft tissues and nerve tissues and increase the chance of postoperative complications because of the large intraoperative incision and high impact on the body and some soft tissues. Whereas external fixator treatment is highly adjustable because the angulation can be adjusted by the attachment of fixators, which greatly reduces the occurrence of complications and allows the patient to turn over after surgery, alleviates decubital ulcers resulting from prolonged bed rest, and makes nursing more convenient. Meanwhile, it also can increase patient stability during handling and inspection to some extent, and then reduce secondary damage and complications (23, 24). The shortcomings of the study were the small sample size and a single source of cases. So further biomechanical study should be carried out to comprehensively observe the clinical effects of the two different fixation methods, so as to provide an evidence-based basis for the treatment of unstable pelvic fracture patients.

In conclusion, through analysis in the context of intelligent medicine, it is found that early external fixator treatment has better results in treating patients with unstable pelvic fractures. In recent years, with the promotion and improvement of technologies such as minimally invasive surgery and spine-pelvis combined fixation, various new directions have appeared in the treatment of pelvic fracture, meanwhile, with the continuous development of imaging-guided systems and the deepening research of biological models of real pelvic fracture established by computer simulation, conditions have been provided for the broadening of new ideas for clinicians, and the treatment of stable pelvic fractures will continuously develop in the aspects of ease of operation and firmness.

Analyzing the Effect of People Utilizing Mobile Technology to Make Banking Services More Accessible

Jiale Zhu and Manyi Wang*

Capital University of Economics and Business, Beijing, China

Many firms in the modern world utilize m-banking systems to communicate with their consumers. The word m-banking refers to a widespread method of providing financial services and localization to customers. Since m-banking is important to both banks and users, it has been included in numerous literary works. As a result, embracing financial services *via* the m-banking platform is critical. This article's technique is mostly descriptive research that investigates common views, current situations, modern tactics, tangible emerging consequences, etc. The main objective here is to analyze the benefits of this study by investigating the past. Since this article analyzes what exists and is descriptive, the data is being retrieved by conducting a cross-sectional survey method about different features that are relevant by sampling the population. The main aim of this study is to explore the adoption of mobile banking technology by consumers. Based on the values of different variables such as affective commitment (AC), transaction convenience (TC), perceived ease of use (PEU), perceived reliability (PR), pre and post benefits (PPB), service, system, and information quality (SSIQ), bank trust (BT), and profitability (P), the inter-relationship between them and the adoption of m-banking technique by the users in banking technology. The model is investigated by examining the hypothesis and identifying the relationship that exists between these different parameters. A simple linear regression method is implemented using the Statistical Package for the Social Sciences (SPSS) software.

Keywords: mobile technology, banking, financial service, transaction convenience, mobile banking

INTRODUCTION

Nowadays, mobile technology plays a vital role in many industries such as banking on managing stocks and finances, business firms sell their products through applications and websites. Mobile banking services such as payment systems influence people's lives more dramatically than other innovations in the recent times (1). Mobile technology made banking services such as payment, transaction, and other services easy through the online mode instead of offline mode. Even the adoption of mobile banking services increased day-by-day by the consumers, still mobile payments do not become ordinary to many of the public (2). Due to the growth of mobile network technology, there is a need for security infrastructure for mobile payments. The security measures give trust to the consumers to adopt mobile banking at anytime from anywhere.

For achieving a successful outcome in business, mobile technology is recognized as competitive and creative equipment that provides better online transaction options (3). Recently, cellphones are being widely used as a tool by people for online shopping, banking, paying bills, etc. Our day-to-day routine lives have been changed through the adoption and development of mobile technology that modifies the way of communication, approaches for selling and buying goods and services, and also the mode of information collection. Such corresponding correlation arises in a constructive environment that has no limitation regarding the time or place (4).

The rapid development in mobile technology and the protection framework facilitate the people to perform m-banking transactions at any time from anywhere, whereas m-banking comprises financial service which is implemented directly or indirectly over a network of wireless telecommunication (3). In the financial sector, the services applied by mobile are referred to as mobile financial services (MFSs) they also include mobile banking and mobile payment. Several studies were conducted to examine the peoples' mindset in view of understanding the mode of adopting mobile banking as a unique and usual service (5). According to the statistics, the level of usage of smartphones has increased from 35 to 80% in 2020, also worldwide, the number of mobile phone beneficiaries is about 6.8 billion, though each mobile was fully activated with the internet. Thus, mobile banking helps in the development of bank access rates which influences bank perception (6). In the banking sector, it is observed that most of the customers have switched to smartphone, apps, or tablets which are highly utilized in their day-to-day life for shopping, entertainment, learning, socializing, and jobs, and these mobile-centric customers are preferred by more bankers (7). For example, a bank in Japan, Jibun Bank whose principal communication with customers is through the mobile channel and was the first bank that affords their complete banking services and products over mobile channels. With the help of cameras and mobile phone, customer has the facility to start a new account with their bank. This mode of banking enables the bank to improve their customer service over anywhere at any time basis. Also, the different mobile banking services are payment, web-related shopping, fund transfer, and web-related marketing. This Jibun Bank has reached more popular for its efficient services within the short duration of their mobile banking introduction (8). Through this, they have attained above 500,000 new bank accounts in their bank. In the initial days, the bank had the facility to send usual text messages related to money transfer and withdrawal and these services were updated to provide its customer a complete functional banking experience (9).

Mobile banking is adopted by many consumers as it is easy to open an account, pay bills, transfer funds, do mobile-based shopping, etc. Many banks in China and America who introduced mobile banking for all their services experienced high demand for their services through mobile banking (10). But many challenges were faced by these banks due to no face-to-face interactions. Trust is an important factor in mobile banking but lack of interaction led to the risk of uncertainty and anonymity. On the other hand, the consumers also suffer from uncertainty whether the bank is trustworthy are not.

During the last decades, mobile banking became relevant all over the world. The number of fund transfers through mobile banking also increased since last year, but mobile banking has many security problems. Sometimes, the security setting of mobile phones can be overridden by the virus in smartphones (11). Many banks open their banking applications, these apps should be updated frequently otherwise the consumers can be vulnerable to the attacks such as DDoS attacks, phishing, spoofing, corporate account takeover, and skimming (12).

The major contribution of the article is:

- To analyze the benefits of this study by investigating the past.
- To explore the adoption of mobile banking technology by consumers.

The remaining article is arranged accordingly. Section Literature Review presents the related work and the hypothesis is formulated in Section Hypothesis Development and Research Methodology. The results in terms of linear regression and descriptive analysis are provided in Section Results and the article is concluded in Section Conclusion and Discussions.

LITERATURE REVIEW

In the modern world, many firms use systems of mobile banking to communicate with the customers. The payment system in mobile banking services benefited people's lives. This article aims to analyze the effect of people using the technology of mobile to make banking services more accessible. Literature on mobile banking adoption, electronic banking services, mobile payment service user acceptance are reviewed.

Hamidi et al. (13) studied the influence of mobile banking adoption on consumer engagement and satisfaction utilizing the customer relationship management (CRM) system, which is the most essential aspect in banking industry. CRM is also seen as a critical role for enhancing client satisfaction in mobile banking. The statistical study performed evaluated the dialogue between the bank's customer sector and their client. The statistical analysis findings have a favorable influence on consumer interactions and satisfaction.

Geebren et al. (14) investigated the importance of consumer satisfaction in mobile eco-systems that used electronic banking services, particularly in developing nations. This entailed researching consumer satisfaction in mobile banking, with a focus on the importance of trust. To determine consumer satisfaction, structural modeling using partial least squares (PLS–SEM) methods were employed to examine the data, and trust demonstrated that customer contentment had a beneficial influence.

The relevance of an early trust theoretical model in mobile payment service user acceptance was highlighted by Gao et al. (15). The initial trust theoretical model highlighted the facilitators and barriers to user trust in m-payment services. The links in the original trust theoretical model were assessed using partial least squares structural modeling (PLS–SEM). The

findings may be used in m-payment adoption research and practice in a variety of ways. In total, 52.3% of the difference in usage intention was explained by the current model.

Hentzen JK et al. (16) offered a mobile technology that allows for vital involvement, as well as an explanation of how a retirement app might assist people in planning for their post-retirement strategy. The available literature survey data were used to evaluate a sample of 440 Australian pension fund members. The findings show that consumers' perceived financial security, financial self-efficacy, retirement planning involvement, future consequences consideration, and perceived usefulness with a mobile retirement app have direct and indirect effects on their expected engagement through their goal to adopt the app.

Zhu et al. (17) investigated existing technology designs, including mobile banking, used by rural communities in six Chinese regions. According to the findings, interpersonal and mass communication channels have a bigger influence than organizational communication channels. Mobile banking should be examined since it can assist alleviate the lack of access to financial goods and financial infrastructure in rural areas.

Afeti et al. (18) developed a mobile payment technology for payment for micro-businesses. The study draws on the transaction cost theory and the task-technology fit (TTF) theory as the assumed lens. In total, 20 micro-businesses based on qualitative data were analyzed and the research findings denote those micro-businesses adoption of mobile payments results in strategic and operational benefits.

Alamoudi et al. (19) proposed that the mobile technology acceptance lookalike was changed as we investigated consumers' acceptance of mobile shopping in general stores by examining transaction convenience, usefulness, attitudes, ease of use, transaction speed, optimism, and personal innovativeness. A total of 351 respondents completed the questionnaire evaluation. Consumers are willing to use mobile shopping channels if the system is clear and straightforward to use.

Jebarajakirthy et al. (20) used a comprehensive moderated mediation framework to evaluate the influence of online convenience aspects on mobile banking uptake. Covariance-based structural equation modeling and the process macro are utilized to test these predictions. This study examines how convenience characteristics influence mobile banking adoption intentions.

Abdinoor et al. (21) studied the adoption of mobile financial services in Tanzania with the use of a technology acceptance model. To select the sample from data collection, a random sampling technique was used. The user and non-user of mobile financial services were included in the sample. Zhang et al. (3) investigated customers' use of mobile technology to help them with banking services and activities, as well as the variables that impact their adoption and engagement. Here, the analysis is done by the structural equation modeling technique to know the consumers' intentions toward mobile banking. The result examines the adoption of mobile banking apps to facilitate bank consumers' banking services.

Tiwart et al. (22) researched the variable that influences adoption in Commercial Bank Ethiopia. The author used factors such as perceived ease of use (PEOU), infrastructure (INF), security (SEC), trust, and e-banking adoption. Here, a structural equation model based on least partial square analysis is used. The result of this analysis proves that the trust of customers mediates between PEOU, INF, SEC, and e-banking adoption and realized the factors that guess the purpose and adoption of e-banking by Ethiopian customers.

The problem identified in mobile banking services is critical financial services through mobile banking because it has security problems.

HYPOTHESIS DEVELOPMENT AND RESEARCH METHODOLOGY

Participant's Demographic Information

This study is mainly conducted in China by taking the top e-banks that utilize m-banking. The questionnaire is distributed to both the users and staff of the bank. Within 6 months, 293 questionnaires were completed. These details were taken into consideration in this study. The details of the questionnaires were obtained online and also provided to the users on their official bank pages. The information obtained in the questionnaire is provided in **Tables 1**, **2**.

TABLE 1 | Demographic analysis.

Demographics variables	Percentage	Number
Sex		
Female	54.50	121
Male	45.49	101
Age		
1–20	3	25
20–30	59	120
30–40	15	14
>40	23	63

TABLE 2 | Participant details.

Bank types	User rating
State-owned	3.25
Joint-stock	2.14
Postal savings	3.25
Agricultural bank	2.52
Commercial city bank	1.54

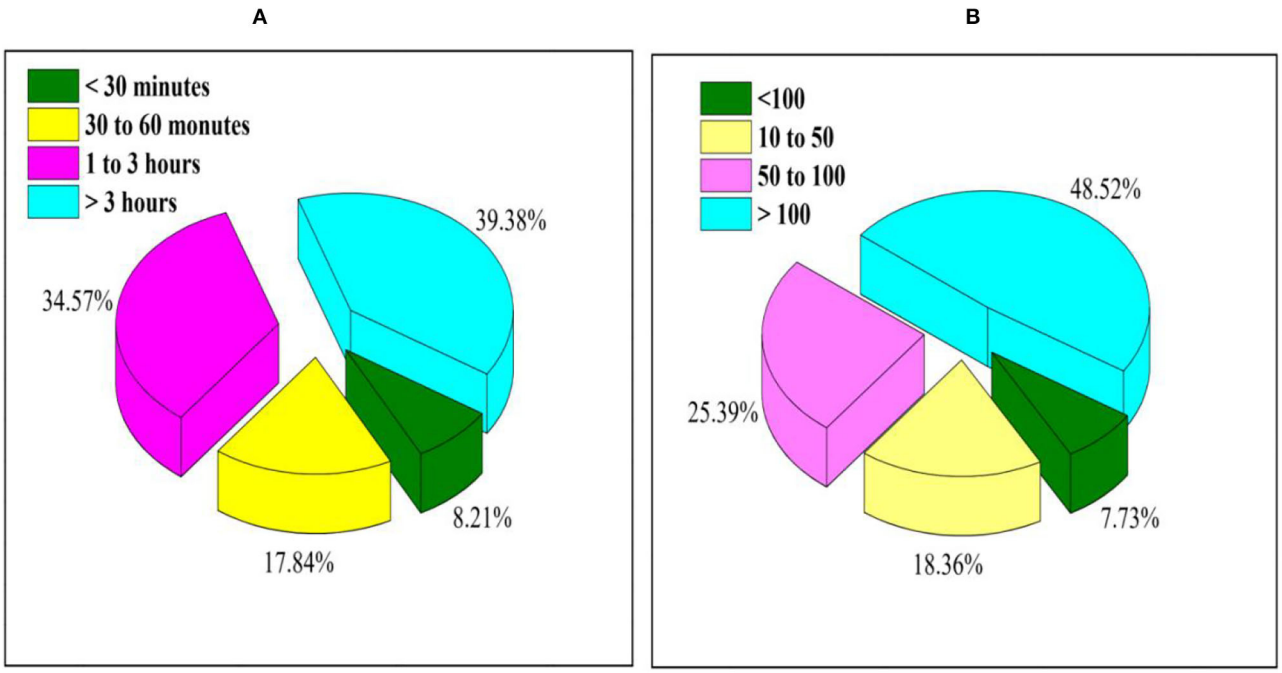

FIGURE 1 | Usage analysis of m-banking application **(A)** Users using m-banking during the day and **(B)** users' friends and references using mobile banking.

Participant Details

The information of the customers is mainly obtained based on their m-bank usage. The five main banks such as state-owned, joint-stock, postal savings, commercial city bank, and the agricultural bank were selected. Each participant was asked to say about their experience of their usage.

The amount of time spent by each user on average is provided in **Figure 1A**. As seen in **Figure 1A**, more than 39.38% of users are using more than 3 h a day and a minimum of is online Conceptual Model for less than 1 h. In total, 8.21% of the users only use the application for a limited amount of time (below 30 min).

Figure 1B presents the percentage of people the users have referred for mobile banking. Based on **Figure 1B**, a total of 48.52% has more than 100 contacts who have been referred to the m-banking. The increase in m-banking contact can improve efficiency.

Conceptual Model

The main aim of this research is to identify the usage of mobile technology of consumers for the banking system. The hypothesis provided for each variable is explained in detail in this section and the conceptual model is provided in **Figure 2**. The measurement instrument used for this study is presented in **Table 3**.

Hypothesis Modeling

Service, System, and Information Quality (SSIQ)"

System quality mainly measures the efficiency of the overall m-banking system in terms of service provider anonymity. The system quality of the m-banking mainly depends upon the ease of use, the attractiveness of the application, trust of the user, etc. If the user trusts the system quality, then they mainly select the system for future transactions. Service Quality mainly relies on the service provided by the m-banking system and it also evaluated the effectiveness of the service in terms of personalization, reliability, delay, etc. Hence, service quality is crucial to improve the quality of m-banking since poor-service quality can result in minimal user trust and satisfaction. Information quality mainly implies that high-quality information is reliable, complete, accurate, relevant, and accessible. The information quality is an important variable that improves the usage, trust, and satisfaction of the customers in the m-banking system.

Hypothesis (H6): The service, system, and information quality had a positive relationship in improving the m-banking quality and user satisfaction.

Affective Commitment

Affective obligations between business partners reflect mental reliance on others and are founded on emotions, loyalty, and dependency. The psychological bond in this example demonstrates an emotional commitment. Support for differences in particular data among new and long-term clients. Based on their differing expectations, new and loyal clients behave in the same way.

Hypothesis (H1): The interaction of customers helps to develop a good relationship with the affective commitment of a person to the bank which is focused on interaction.

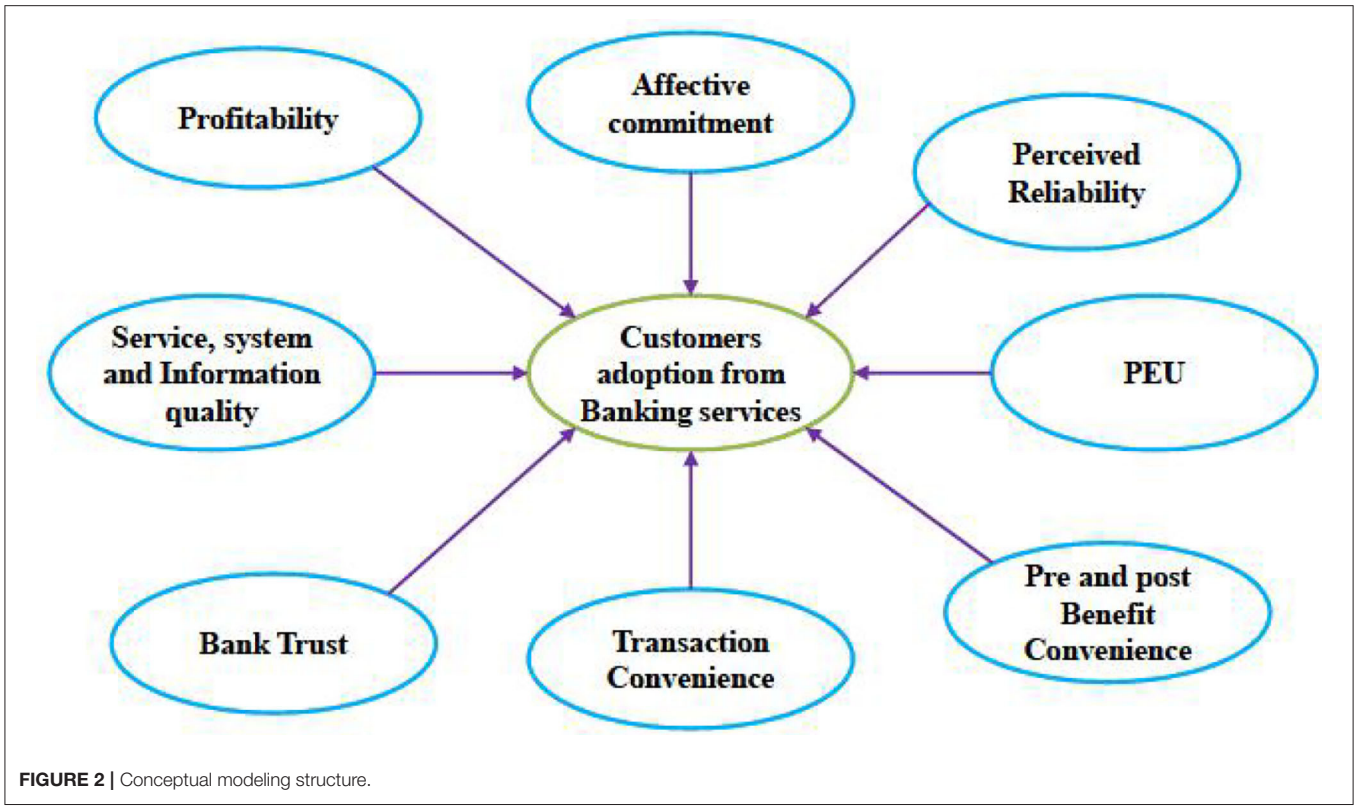

FIGURE 2 | Conceptual modeling structure.

Pre- and Post-benefit Convenience

The time and attempt to acquire some benefits of services is said to be benefit convenience. Some of the components of benefit convenience are fast service, timely services, and bank employee attitudes. Sometimes in banks, the consumer needs to visit repeatedly to avail specific service. But in m-banking, consumers can avail any services on the go from the home itself. So, the time and attempt to acquire the service became very easy. Therefore, benefit convenience shows a positive result in mobile banking adoption (23). The time and attempt to contact a service provider for a particular service is said to be post benefit convenience. In m-banking, the service provider can be contacted and solve the grievances within a few clicks through various means such as email, live chat, and toll-free numbers. But in offline banking, the consumer needs to visit the branch and wait for the service provider to solve the problem in service. So, the post benefit convenience shows a positive result in mobile banking adoption (20).

Hypothesis (H5): The pre- and post-benefit convenience are positively interrelated with m-banking.

Transaction Convenience

The fast and simple way to complete the transaction is said to be transaction convenience. Acquiring the service of transaction in a lesser time is the main component of transaction convenience. Other components of transaction convenience are uninterrupted transaction, transaction confirmation, easy checkout, and price inconsistency. By using m-banking, the transaction can be done in any place at any time in a few clicks and can do several transactions simultaneously. But in offline banking, consumer needs to wait in a queue for availing a transaction service. Hence, transaction convenience shows a positive result in mobile banking adoption (24).

Hypothesis (H2): The transaction convenience is positively interrelated with m-banking.

Profitability

Customer participation in an organization's mobile banking may increase customer value and profitability (25).

Hypothesis (H8): Profitability shows positive results in mobile banking adoption.

Perceived Reliability

Perceived reliability is specified as the limit to which the individual has independently considered the technology as a faithful one. In order to offer a trustworthy technical service, the system reliability is important that enables the user to attain the aimed objective. An undependable technology that is employed by an individual seems to be low confidence and such technology utilization should be restricted (26). Research related to mobile technology and information system has revealed that a technology with perceived reliability possesses has an important impact on customers' perceived satisfaction, detected value, and observed quality. Also, customers' understanding level of trust is examined and analyzed as an antecedent of confidence in an organization through the mobile commerce setting. Though mobile is a wireless technology, it is easily susceptible to

TABLE 3 | Measurement instrument to analyze different parameters.

Variables	Measurement instrument
Bank trust	The bank helps me to use the mobile device of the consumer for accessing the services BT1: The m-banking is trustworthy BT2: The m-banking mainly satisfies the promises and commitments
Pre and post benefit convenience	The m-banking resolves the problems in a fast manner Obtaining the follow-up service is easy The solutions provided by m-banking is fast and reliable The banking service is provided with little effort The services are easier to avail The problem is resolved fastly The time taken by it is reasonable
Service, system, and information quality (SSIQ)	Convenient access of m-banking services Easy navigation of m-banking services Visual attractiveness of m-banking services Accurate information of m-banking services Up-to-date information of m-banking services Dependable services provided Personalized m-banking services Professional m-banking services Timely m-banking services
Transaction convenience	Easier to complete the transaction Fast service access Little effort to complete the transactions
Perceived ease of use	Usability of mobile devices for banking Interaction with the mobile devices for banking Skillset achieved in accessing mobile devices for banking
Perceived reliability	To select the supporting technology for mobile banking Ensuring that the technology supporting m-banking does not fail The technology used is reliable
Portability	Increased customer interaction Increased customer visit

violations or attacks (27). Mostly, the customers were insisted to share their personal data while consuming and shopping services performed through mobile technology such as date of birth, debit and credit card details, funds, and address. The reliability of mobile technology should be improved thereby increasing customers' belief in securing their personal data. The postulated hypotheses are mentioned as follows:

Hypothesis (H4): Perceived reliability in m-banking helps to improve the consumer's trust and ease of use of banking services.

Banking Trust

In this hypothesis, trust is considered as a faith of competence, integrity, ability, and benevolence that the individual has toward each other. Trust has become an important reducing feature of risk, whereas the e-commerce connection is considered as a naturally risky factor (28). Also, trust in banking is specified that it is linked to reliability and perceived privacy. Generally, the primary interaction between the customer and banker will significantly affect the trust progress in them.

Hypothesis (H7): Based on their usage of mobile devices and attitude, the consumer trust toward M-banking increases.

Perceived Ease of Use (PEU)

Perceived ease of use evaluates the increase in the amount of work required to acquire a job utilizing new technologies on an individual basis. In the effort condition, the simplicity of use of mobile innovation is critical for including customers in the co-creation of value experiences (29). Mobile technology's ability to increase advantages for bank clients has been widely shown, and its simplicity of use is a key factor in consumer acceptability. PEU has been linked to advanced tackling new technologies in the banking industry in several research. However, the launch was difficult, and it was claimed that customers' inclination to utilize mobile banking services is not intrinsically related to employment prospects. As a consequence, it indicates that study into PEU and its influence on consumer attitudes, as well as the interactive method, are both worthwhile endeavors (30–32).

Hypothesis (H3): Customers' views about the usage of mobile devices for facilitating financial services are favorably associated with their perceived ease of use (PEU).

RESULTS

Scale Validity and Reliability

The reliability of the scales was assessed using Cronbach's alpha values. Goodness-of-fit approaches were used to assess the overall model fit for confirmatory factor analysis (CFA). The RMSEA was 0.09, the comparative fit index (CFI) was 0.99, the goodness-of-fit (GFI) was 0.98, and the standardized root mean square residual (RMR) was 0.06. The X2 to df ratio was 4.14, the root mean square error of approximation (RMSEA) was 0.09, the CFI was 0.99, the GFI was 0.98, and the standardized RMR was 0.06. As indicated in **Table 4**, the reliability coefficients of all constructs were more than 0.87, which is higher than the 0.9 thresholds. The extracted average variance was used to assess convergent validity (AVE). Because the AVE values ranged from 0.58 to 0.92, convergent validity was not an issue. The AVE scores were lower than the squared correlations between pairs of constructs, indicating discriminant validity in the data set. **Table 4** shows the results of the Cronbach's alpha and AVE tests.

Linear Regression Test

Regression tests are run when the allowable alpha coefficient for the scales has been determined. **Table 5** shows the regression test results for each of the assumptions discussed in the following sections. Affective commitment (AC) and interaction were investigated, and the correlation coefficient 0.297 and likelihood of significance 0.000 indicate that there is a positive and significant relationship between the two. The regression test supports this positive relationship, showing that the interaction variable may be able to predict AC variation.

With a correlation value of 0.333 and a probability of significance of 0.000, the following test demonstrated a positive relationship between perceived ease of use and satisfaction (PEU). The correlation coefficient between the variables perceived reliability (PR) and interaction was 0.172, with a

TABLE 4 | Hypothesis testing.

Variables	Cronbach's alpha	Average variance extracted (AVE)	AC	TC	PEU	PR	PPB	SSIQ	BT	P
Affective commitment (AC)	0.78	0.58	0.77							
Transaction convenience (TC)	0.96	0.87	0.55	0.94						
Perceived ease of use (PEU)	0.97	0.88	0.62	0.68	0.95					
Perceived reliability (PR)	0.98	0.91	0.51	0.52	0.56	0.96				
Pre and post benefits (PPB)	0.98	0.92	0.55	0.74	0.66	0.53	0.97			
Service, system, and information quality (SSIQ)	0.95	0.82	0.47	0.56	0.66	0.44	0.74	0.92		
Bank trust (BT)	0.87	0.68	0.72	0.46	0.48	0.52	0.49	0.42	0.83	
Profitability (P)	0.83	0.64	0.67	0.42	0.44	0.50	0.46	0.39	0.80	0.84

TABLE 5 | The results of the linear regression test.

The dependent variable	Independent variable	Number theory	Test significance *P*-value	The correlation coefficient R^2	Result
Affective commitment (AC)	Interaction	H1	0.000	0.297	Accepted
Transaction Convenience (TC)	Interaction	H2	0.000	0.339	Accepted
Perceived ease of use (PEU)	Satisfaction	H3	0.000	0.333	Accepted
Perceived reliability (PR)	Interaction	H4	0.000	0.172	Accepted
Pre and post benefits (PPB)	Interaction	H5	0.000	0.242	Accepted
Service, system, and information quality (SSIQ)	Satisfaction	H6	0.000	0.430	Accepted
Bank trust (BT)	Interaction	H7	0.000	0.347	Accepted
Profitability (P)	Interaction	H8	0.000	0.230	Accepted

probability of significance of 0.000, demonstrating a positive link between the two variables. The correlation value of 0.430 and the probability of significance of 0.000 indicated a positive relationship between satisfaction and service, system, and information quality (SSIQ) (3).

Descriptive Data

The items in this questionnaire were answered using a five-point Likert scale, with the alternatives being: very low (1), low (2), medium (3), high (4), and very high (5). **Table 6** shows the SD, middle value (MV), and lowest value (LV) of the descriptive data received from the surveys (3).

CONCLUSION AND DISCUSSIONS

Mobile banking is a cost-effective way to reach customers. The different activities that can be performed by the consumers in m-banking are checking their bank balance, making transactions, making investments, getting account statements, paying bills, etc. The motivation for user adoption and use of mobile banking is examined in this research. Positive connections between profitability, trust, and transaction convenience to utilize mobile banking have been found in previous studies. Users' confidence in using mobile banking services, enjoyment, utility of the system, etc., are not the same thing. The participants were unconcerned

TABLE 6 | Descriptive data analysis.

Variables	Standard deviation (SD)	Middle	Highest	Lowest
Affective commitment (AC)	1.208	2.52	5	1
Transaction convenience (TC)	1.081	3.36	5	1
Perceived ease of use (PEU)	1.061	3.21	5	1
Perceived reliability (PR)	1.689	2.92	5	1
Pre and post benefits (PPB)	1.393	2.67	5	1
Service, system, and information quality (SSIQ)	1.206	2.79	5	1
Bank trust (BT)	0.955	3.31	5	1
Profitability (P)	1.220	3.10	5	1

about the danger of fraud, system dependability, or perceived privacy while building and extending faith in their banks and mobile services. Because of today's technology-driven lifestyle, individuals are receptive to embracing new technologies that are compatible with their mobile phones.

To add value to practice, we must obtain convincing and widespread results from both users and mobile banking service providers. Like mobile phones, smartwatches have become more popular among people nowadays. With this wearable technology, banks have the greatest responsibility to fulfill hedonic and social needs. The purpose and use of this research are common to all consumers irrespective of various countries, populations, and socio-economic status. The variables used in this work are, namely, affective commitment (AC), transaction convenience (TC), perceived ease of use (PEU), perceived reliability (PR), pre- and post benefits (PPBs) service, system, and information quality (SSIQ), bank trust (BT), and profitability (P). Consumer behavior such as untrustworthiness, fraudulence, and so on, as well as mobile banking transaction risks such as financial, privacy, and cyber security, are important risk concerns that may be addressed in future research developments.

The problems and risks that arise by the consumers and banking sector for adopting mobile banking services would be reduced by the scientific researchers using various technologies and methodologies in the future. The results in this article show the different statistical surveys and believed that it is true for both mobile banking consumers and non-mobile banking consumers with various socioeconomic environments. But when we consider globally each country had its own rules and regulations regarding mobile banking transactions, services, and products. And these rules and regulations react differently in different countries.

New Media Technologies refer to all kinds of web-related technologies like social networking sites, blogs, online social media networking, and other communication technology forms. The primary purpose of this study is to examine the mediating role of new media engagement in this digital age. Furthermore, this study defines the concept of new media, highlights the characteristics of new media technologies, and analyzes the application of new media technologies in this digital age. To meet the objectives stated, the researchers conduct a questionnaire survey to showcase that new media engagement plays a mediating role between the instructions provided to the newsroom in this digital age and the attitude of people toward social media. Results of the study state that the majority of the individuals in this digital era display positive engagement with new media technologies. People in this age believe that social media is safe and less risky for all individuals with regard to communication and interactions.

Keywords: new media technologies, social networking, digital age, communication technologies, attitude toward social media

Yujie Z, Al Imran Yasin M, Alsagoff SABS and Hoon AL (2022) The Mediating Role of New Media Engagement in This Digital Age. Front. Public Health 10:879530. doi: 10.3389/fpubh.2022.879530

INTRODUCTION

In recent years, there has been growing interest in investigating the role new media technologies play in diverse areas including business, media, education, mass communication, and so on (1, 2). New media technologies are popularly referred to as Web 2.0 technologies. These technologies use web technologies like online social networking, blogs, wikis, and other social media platforms to communicate with a larger group audience. The last few years have witnessed a steep decline in the use of old media such as magazines, television, newspapers, radio, and other traditional media forms, while the internet has taken over the place of old media rapidly; and for that very reason, old forms of mass communication are becoming extinct with each passing day.

Several studies, for instance Lysak et al. (3), Andrus (4), and Boulos et al. (5) have demonstrated that television took the place of life magazines; emails and telephone took over the telegraph; and so forth. From these instances, it can be understood that old media has been replaced by modern communication techniques. New media communication technologies supplemented the different forms of old media by working in parallel to meet the demands of different organizations. Nowadays, any kind of mass communication is available on the internet and at newsstands (5). Mass communication media allows the readers to comment in real-time on blog sites and online social networking sites. Developments in the arena of new media technology permit individuals to participate in public discussions (6). The whole of mass communication technology has changed with the recent developments in the field of technology.

An entirely new shape has been given to the communication process where people began to relate to new media on a personal level unlike the old media forms (7). Many researchers stressed the fact that the concept of virtual identity is growing popular in recent years, as it will help them to understand the role of new media technologies in developing one's own identity in this digital age (7, 8). This will also help the researchers to analyze how people shape their own identity by communicating through online networking platforms. Another interesting fact of new media technology is that it allows users to participate in socially or politically mass discussions. In fact, these technologies provide the user a personal space to comment their opinion on the computer-generated public sphere. New media technologies make it possible for users to generate online content with a carefree attitude.

Preliminary studies on new media technologies primarily focused on limited effects of the modern means of communication (9, 10). In the field of media, for instance, barely a newspaper reporter will be able to understand the significance of blogs; hardly a television producer will be able to know why people moved from network television to online television, and so forth. One of the recent studies on New Media technologies traced the advancements in transforming knowledge in the digital format (11). It was found that users looking for information, irrespective of the place, time, and convenience led to the digital transformation through the mobile-first strategy. Other interesting findings in this field are as follows: (a) young people spend more time on social media platforms to consume information; (b) people began to verify information through the internet; (c) businesses began to promote their brands, products, and services through online social networking platforms and other social media forms; (d) People working in media began using new media to search for a new audience, cross-check the information, promote the coverage of news, and verify the accountability of the news; (e) advertising/marketing channels use new media technology to create branding for their products and services; and (f) academicians also began using different new media technologies for educational purposes (12). Recent studies underline that there is an increase in the percentage of people using various types of new media technologies from 4% in 2008 to 36% in 2018 (13, 14).

For several years, researchers have been focusing on the role of new media technologies in an attempt to understand their impact on the Digital Age. It has been traced that new media technologies build content with the help of the computer-generated public sphere. These technologies are considered an effective tool to maintain engagement in this digital age. Immediacy and cost-effectiveness are the added advantages of such technologies. As an example, one of the recent studies provided evidence of people going live on the Facebook application, which helped them to reach a much larger audience than expected (15). Although there exists no way to measure the engagement of new media, it has been emphasized that the involvement of people, the connectivity aspect between people, and their level of interest in taking participation will help the researcher define and measure the mediating effect of engagement in this digital age. With the help of advanced technologies such as web analytics, organizations from different arenas can monitor the role of people's engagement in those activities filled on new media technologies like online social networking sites, blogs, wikis, and other social media platforms. Counting the number of likes, shares, views, and comments, one can monitor the role of engagement. Processing of healthcare and travel data using machine learning algorithms in place of the traditional healthcare system to identify COVID infected persons (33).

Overall, the aim of this research paper is to investigate the mediating role of new media engagement in this digital age. Furthermore, this study defines the concept of new media, highlights the characteristics of new media technologies, and analyzes the application of new media technologies in this digital age. This study also attempts to provide a framework representing the relationship between new media and engagement in the digital age. As we all know, the twenty-first century is ruled by new media, and therefore its influence on individuals, organizations, disciplines, and so forth is relatively higher than the old media. The present study is structured as given below: Section Introduction provides an introduction to the topic; Section Literature Review examines the existing literature review on the concept of new media, its characteristics, and the impact of new media on individuals, organizations, and other areas. This section also examines the application of new media technologies in various disciplines. Section Methodology presents the methodology adopted for the study. Section Data Analysis discusses the findings and results of the study. Lastly, Section Results and Discussion discusses the conclusions derived from the study.

LITERATURE REVIEW

Understanding New Media

New Media is a new term that is universally applied in multiple ways. Seminal contributions have been made by past researchers on the concept of new media and its contextual use, with regard to communication and technology (7, 10, 16). These studies observed that communication practices, the technology or medium through which the message is communicated, and the social context in which the message is passed are quite important compared to other factors. That is, the message, channel, and source are important to communicate the information. The majority of the literature focused on the above three aspects of new media for a longer duration, besides other advanced practices and technologies like digitization, collaboration, and telecommunication (7, 10, 17). Few other studies defined new media as a web-related technology that uses advanced computer technologies to transmit messages to a larger group audience (18).

From the term new media technologies, it can be understood that such newly developed technologies use specific computer technologies to process the information and communicate it to the audience (19). A networked telecommunication system is used to interact between the users. Communication in the new media technology occurs when two electronic devices are used to share information supported by advanced technologies

and software. Emails, chat rooms, social media services, instant messaging, and so on are the best examples of new media technology communication. These platforms made the communication process easier, resulting in the establishment of a universal networked society. Additional advantages of new media services include allowing the people to work together irrespective of geographical differences, promoting globalization, establish worldwide socio-political dialogues, and framing sociological structures across the disciplines (20). A number of authors have also recognized that communication through new media has changed the whole process of communication. Most importantly, new media is known for convenience and smooth communication processes (21).

Most early studies, as well as current work, stated that the term new media encompasses various aspects like the message, the medium used to transmit the message, the technology used to transmit the message, the time during which the message is transmitted, and the social context in which the message is transmitted (22). Certainly, the term media refers to the technology through which the message is communicated. From the above statements, it is inferred that the medium through which the message is transmitted is more important than the content of the message.

Characteristics of New Media

This section presents a review of recent literature on the characteristics of new media. The wide range of new media technology characteristics includes—communication, collaboration, convergence, creativity, and community. In general, new media technologies are relatively concerned about one or other forms of communication. Blogs, which are known as one form of new media technology, allow the users to publish content on one's own web pages. Hence, the blog is an alternative web-technology communication method of transmitting information to large group audience. Furthermore, blog posts are not one-way communications, and thus demand the readers to interact/comment/post their reviews/opinions online. Therefore, there is a factor of engagement in the whole communication process, which is two-way and interactive in nature. In short, communication through new media can be categorized as collaborative, networked, and unidirectional (23). In this rapid networking age, the term viral is used to indicate the rapid speed of transmission, for instance, viral video, viral marketing, viral branding, and viral posts. Furthermore, the participants involved in new media technology communication play the role of both sender and receiver. They can even post their opinion/feedback with the support of a computer-mediated communication process.

It was reported in the literature that, if not all new media technology, at least a few of them facilitate collaboration through the internet. Much of the past collaboration happened through emails. Multiple documents could be shared with multiple people at the same time, which saves time (22, 24). Although there were minimal disadvantages of such email collaboration, it was one of the most effective means of new media communication. Such collaboration is available on Wikipedia, an online encyclopedia. Unlike wikis and emails, blogs have limited collaboration and can be shared among a specific group of people. Recent studies found that google docs permit users to share documents with each other (24). It also allows two users to work together on the same document. While social networking platforms like Facebook, Skype, WhatsApp, and others, users collaborate on the aspects of virtual communication and audio conversing. The majority of the social media platforms permit users to virtually connect with each other by means of conference calls and chats (25).

Another interesting characteristic of new media is that it fosters a sense of community. New media technologies like Skype, Facebook, Yahoo groups, Usenet, Webkinz, YouTube, and others incorporate a sense of community among the users by creating logins. The creativity of the users is the next surprising feature of new media technologies (24, 25). No user plays a passive role anymore, instead, they play an active role in transmitting the messages through web technologies. New media technologies enable its users to create videos, edit videos, post blogs, post reviews/comments on blog posts, post reviews for products/services offered by brands both national and international, and finally create content on wikis. People in this digital age not only read, listen to, or view the content posted online, but also edit, comment, and posts feedback. Hence it can be stated that there is a factor of engagement or interactivity within new media technologies. The new media technologies are broadly known for their convergence with media, technology, and other forms of web-related communication technologies. Apart from the above characteristics of new media technology, a few other features include digitized messages, multi-way communication, and a smooth flow of information (26).

New Media and Engagement

Over time, extensive literature has developed on examining the role of engagement in new media technologies. It was traced that new media becomes the most significant channel across the arenas to promote news, education, marketing, branding, and so on. Specifically speaking, people use the new technologies to share critical information with a large group audience. Multiple studies also discussed the use of new media and observed that people tend to spend more time on the newly developed technologies to read, listen, view, comment, and share information with one another (27, 28). These studies also found that user engagement plays an important role in transmitting the message to the target audience. Likewise, recent studies in the field traced that most people in this digital age posts activities through various social media platforms. In short, it can be stated that user participation is much important to process any kind of information (29–32). These new media technologies are changing the behavior of people, enabling them to interact online, create online communities, and become socially engaging. Thus, it can be argued that engagement of the audience/users/individuals is crucial in new media technology communication. Negligible studies have tried to examine the mediating role of new media engagement in this digital age and thus, this paper aims to examine the mediating role of new media engagement in this modern digital age. In the light of the above literature, the study proposes the following hypothesis as represented in **Figure 1**.

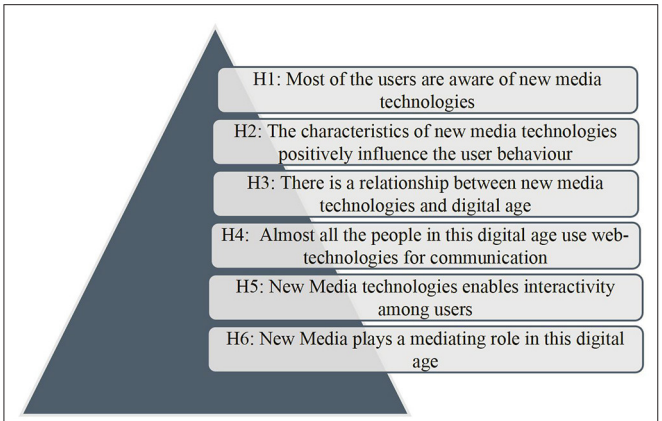

FIGURE 1 | Proposed hypotheses of the study.

METHODOLOGY

The current study mainly concentrates on exploring the mediating role of new media engagement in the digital age. It also examines the concept of new media, identifies the different types of new media technologies, and the characteristics of new media technologies. The study also examines the application of new media technology in a digital age. The analysis of the current study has been conducted through secondary literature and primary analysis as well. The study has developed hypotheses based on the analysis and review of the secondary literature. The formulated hypotheses are tested using a questionnaire. Thus, the current study gathers all the required data using a questionnaire and hence the study is descriptive. Using the results of the questionare the researcher will evaluate the hypotheses. This method involves describing the objectives, defining the population, selecting the sample, and later interpreting the data and results.

The population is nothing but the complete set of individuals or objects bound together by certain common characteristics. The population is of two types- target and accessible. The target population consists of those for whom the researcher wishes to generalize the findings of the study. While the other set of the population acts as the sub-set of it. In the current study, the total population includes all the people who fall under the age group of 18–50. From the total population, the study derives the required sample. The term sample includes the individuals selected to participate in the study. These selected participants are popularly known as respondents/subjects of research. Sampling methods are of two types—probability/random sampling and non-probability. To carry out the research, this study employs a random sampling method. At times, researchers also tend to use purposive sampling with the aim of obtaining required data from a certain area of research.

For the purpose of fulfilling the objectives of the study, the study selects a sample consisting of 100 respondents between the age group of 18–50. Both primary and secondary data are collected to find out the results. The primary data is collected using the structured questionnaire designed to collect the required data from the participants. The collected data will help the researcher to examine the mediating role of new media engagement in this digital age; review the attitude or behavior of users who use new media technologies to communicate, and examine the factor of engagement and interactivity among users with a special focus on the digital age. The researcher collects the secondary data required for the study from research articles and other journals. Besides, the study measures the formulated hypothesis with the help of 3-point Likert Scale. A pilot study is conducted to check the reliability and validity of the questionnaire, for 30 respondents. Finally, all gathered information was collected and analyzed to answer the research purpose. **Figure 2** presents the methodology followed in the study.

DATA ANALYSIS

This section of the article presents the data gathered from the selected respondents through the questionnaire. Firstly, the demographic details of the respondents are presented, along with the duration, context, and other essential details. The duration of the study lasted for 4 weeks, that is from the end of November to December. To all these 100 respondents, the questionnaire was distributed through online sites. All the participants attended the questionnaire with extreme dedication, as they were asked to fill the questionnaire in an appropriate manner. Although the questionnaire was distributed to 150 participants that include young people, employees working in various organizations like marketing, media, press, education, and self-employed; only 130 were received of which 100 were valid. These 100 valid responses were used for further analysis. **Table 1** records the demographic details of the active respondents. **Figure 3** represents the graphical representation of demographic details.

From **Table 1**, the following deductions can be recorded: (1) Most of the respondents (45%) fall under the age group of 21–30; (2) 25% of the respondents fall under the age group of 31–40; (3) 10% of the respondents fall under the age group of 41–50; (4) 10% of the respondents fall under the age group <20. Of all the active respondents, 58% of them were men and 42% of them were women, who were working in different organizations associated with brands, marketing, and so on. The majority of the respondents work in news media followed by education, marketing, students, and self-employed individuals, respectively. The statistics given in **Table 1** clearly state that almost all the participants either work in a large organization or are entrusted with new media technologies in this new digital age.

Table 2 presents the responses to the questionnaire collected from the participants of the study.

From the statistic given in **Table 2**, it can be deduced that the questionnaire was distributed to 150 people that including employees working in marketing, press, media and others, students, and self-employed individuals. Of all 150, 130 questionnaires were completed and 20 of them were incomplete. Of these 130 questionnaires, only 100 were considered valid and reliable.

RESULTS AND DISCUSSION

This section of the study presents the analysis of the data gathered through the questionnaires. The data analyzed with the help of the questionnaire are presented in **Tables 3–6** followed by a discussion of the results. An opinion poll is used to collect the data for the study. All the participants filled out the questionnaire and submitted their results online. These opinions submitted by the participants are analyzed using a 3-point Likert scale. **Table 3** records the details of how many people understand new media technology.

Understanding New Media Technology

From **Table 3**, it can be deduced that of all participants, 40% of them reported that they were fully aware of the term and concept of new media technology, 30% of them reported that they were partially aware of the term and concept of new media technology, 15% of them reported that they were unaware of term and concept of new media technology, and another 15% of them stayed neutral.

Characteristics of New Media Technologies

From **Table 4**, it can be inferred that out of 100 participants, communication features cater to 30%, convergence and community cater to 10%, the creativity of the users cater to 30%, and collaboration caters to 30%, which will positively affect the behavior of an individual/user in this digital age. This shows that almost all characteristics of new media technology impact the behavior of an individual.

New Media Technologies and Digital Age

From **Table 5**, it can be inferred that out of 100 participants 70% of them agreed that there is a positive relationship between new media technology and the digital age, while 20% of them agreed that there is a negative relationship between new media technology and the digital age. often percent stayed neutral.

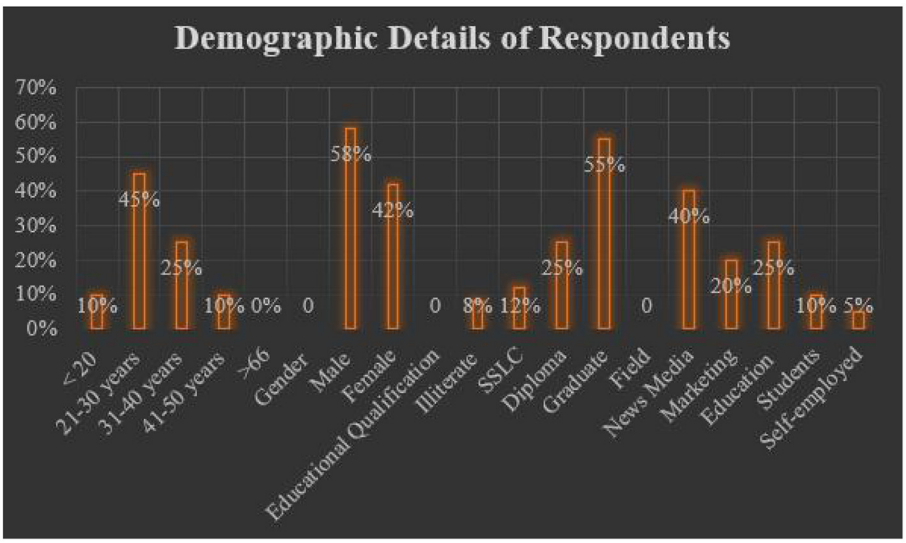

FIGURE 3 | Graphical representation of respondents' details.

TABLE 2 | Responses of the participants.

Distribution of the questionnaire	Number of respondents	Percentage (%)
Total participants	150	100
Fully completed	130	86.6
Valid questionnaires	100	66.6
Total respondents considered for this study	100	

TABLE 3 | Concept of new media technology.

About new media technology	Respondents' responses in percentage (%)
Partially aware of new media technology	30
Unaware of new media technology	15
Fully aware of new media technology	40
Neutral	15
Total	100

TABLE 4 | Characteristics of new media technologies.

Characteristics of new media technologies	Respondents' response in percentage (%)
Communication	30
Convergence and community	10
Creativity	30
Collaboration	30
Total	100

TABLE 5 | New media technology and digital age.

New media technologies and digital age	Respondents' responses by percentage (%)
Positive relationship	70
Negative relationship	20

Total	100

TABLE 6 | Mediating role of engagement and interactivity.

Mediating role of engagement and interactivity	Respondents' responses by percentage (%)
New media engagement	80
New media interactivity	15
Neutral	5
Total	100

This shows that there certainly exists a relationship between new media and the digital age.

Mediating Role of Engagement and Interactivity

From **Table 6**, it can be inferred that out of 100 participants 80% of them agreed that new media plays a mediating or engaging role in this digital age to share information, view content, post feedback on blogs, and so on. Meanwhile 15% of them agreed that interactivity is essential in new media technologies, especially in this digital age, and hence interactivity plays a mediating role. Only 5% of the respondents stayed neutral. This shows that both engagement and interactivity play a mediating role between new media and the digital age. New media engagement is essential to share information

TABLE 7 | Results of rating scale.

with each other, develop creative content, create branding, and so on.

Results of Rating Scale

Table 7 records the statistical analysis of the rating scale selected in this study. The results of the rating scale were analyzed on a three-point Likert scale ranging from "Always" to "Never." **Figure 4** presents the graphical representation of the results of the rating scale.

The findings of the current study are given in the given **Table 8** given below.

Figure 5 shows the assessing the measures for different parameters. The current study analyzed the mediating role of engagement between new media and information in this digital age. The demographic data of respondents were also considered, which helped us to understand if the respondents were aware of the new media technologies that are rapidly spreading in this digital age. The results suggest that people in the digital age are aware of the new media web-communication technologies. Moreover, the results also indicate that almost

also found that there is a positive relationship between new media technology and the digital age. A digital age permits the users to adopt different new media web-communication technologies in their daily life for easier and smooth communication. Results of the study stated that new media plays a mediating or engaging role in this digital age to share information, view content, post feedback on blogs and so on. The study also found that interactivity is essential in new media technologies, especially in this digital age, and hence interactivity plays a mediating role. Both engagement and interactivity play a mediating role between new media and digital age. New media engagement is essential to share information with each other, develop creative content, create branding, and so on. The current study can be seen as a beginning and future researchers can explore mediating role of other factors in the digital age. It is also suggested to extend the number of respondents for more information on this study. User engagement plays an important role in transmitting the message to the target audience. Likewise, it is also traced that most of the people in this digital age posts activities through various social media platforms. In short, it can be stated that user participation is very important to process any kind of information. These new media technologies are changing the behavior of the people, enabling them to interact online, create online communities, and become socially engaging. Thus, it can be argued that engagement of the audience/users/individuals is crucial in new media technology communication. **Table 9** shows the performance measure as shown below.

CONCLUSION

The present article has proposed and tested the mediating role of new media engagement in this digital age. Interactivity is essential in new media technologies, especially in this digital age, and hence interactivity plays a mediating role. Both engagement and interactivity play a mediating role between new media and the digital age. New media engagement is essential to share information with each other, develop creative content, create branding, and so on. This research analyzed the characteristics of new media technologies which affect the communication process in all organizations across various fields. The results of

the study indicated that new media technologies influence the behavior of the people, enabling them to interact online, create online communities, and become socially engaging. Thus, it can be argued that engagement of the audience/users/individuals is crucial in new media technology communication. Future researchers can adopt a scientific approach to understand the mediating role of new media engagement in this digital age. They can focus on the element of interactivity by conducting case studies to have much more appropriate results that can apply across the fields.

Financial Budgets of Technology-Based SMEs From the Perspective of Sustainability and Big Data

Guobiao Zhang[1] *and Tao Wang*[2]*

[1] School of Business, Zhejiang University City College, Hangzhou, China, [2] School of Business, Zhejiang University City College, Hangzhou, China

In this contemporary world, the words data and sustainability play a crucial role in determining the financial budgets of small and medium-sized enterprises (SMEs). Usually, it is stated that the survival of small and medium-sized enterprises (SMEs) is directly proportional to the growth and sustainability factor of the nation. The economic sustainability of a nation is dependent on appropriate functioning of SMEs. Any kind of direct impact on the working of SMEs will have its impact on the whole economy of a nation. There are different factors such as lack of financial capacity, low market demands, restrictions with regard to the capital, and barriers in the supply chain that affect the sustainability of SMEs worldwide. Nevertheless, small, and medium sized enterprises around the world are greatly investing on skills, innovation, and other capital related resources to mark up the demands of the external market. The main objective of this study is to examine the financial budgets of technology-based SMEs from the perspective of sustainability and big data. For this, the study collects data through a questionnaire from 1,800 Small and Medium Sized Enterprises. Based on a detailed and careful examination of the data, only 1,400 of the responses received were considered valid (79.75%). To test the hypothesis stated, the study employs structural equation modeling. This will help the researcher to examine the direct effect of financial budget and technology adaption of SMEs from the perspective of sustainability and big data. Results of the study stated that SMEs sustainability and big data are directly and positively related to the financial budget planning of technology-based SMEs. The study also found that big data plays an important role in the businesses, specifically for their own growth.

Keywords: small and medium sized enterprises, big data, sustainability, finance, financial budgets, technology adaptation

INTRODUCTION

Recently, businesses across the world are facing extreme sustainability issues and thereby adversely impacting the economy of the nations. Due to the current societal circumstances, most of the businesses are enforced to formulate new ideas to deal with the problems associated with the pressurized societal situation. Especially, Small and Medium sized Enterprises (SMEs) recorded the most pressing difficulties including financial and Non-financial. There are other factors like limited market demand, supply chain disruption, and trade discontinuation that will impact the

economy of the nation (1). The current environmental situations in the world critically affected the economy of the nation, nevertheless, the most affected sector was identified as Small and Medium sized Enterprises (SMEs) (2).

Very recently, (3) provided evidence stating that SMEs act as the major driving force in increasing the growth of the nation. SMEs also create employment opportunities, open markets for economic sustainability, and develop trade liberalization. Because of financial and economic crisis, several small and medium sized enterprises are facing challenges. Most of the SMEs are failing to contribute the economic development of their nation. Several studies, for instance (4, 5), have revealed that SMEs are the gravest hit industries, especially during any type of crisis. It was noted that these SMEs knowledge level was low, susceptible, less reliant, and so on. Moreover, SMEs were greatly dependent on financial agents who support them during a crisis (6). Several studies also recorded that SMEs are facing multiple challenges with regard to financial obligation such as paying credit to the financial institutions, identifying shortages in the inventory, and identifying shortage in the operations.

To achieve the goal of sustainability, it becomes equally important for the SMEs to predominantly survive and contribute to the total economy of the country. Although there exist several ways that hinder the growth of SMEs, it becomes crucial for an SME to survive by itself and contribute to the whole economy of the country (7). Despite SMEs have sorted their own methods/ways to deal with survival, it had affected their businesses in a positive and negative manner. Usually, owners of the businesses are concerned about the operations of the SMEs, which included financial budget activities, financial disruption activities, creating unemployment, creating social imbalance, creating security imbalance, and planning the whole production. It was also observed that these operations had had a deep impact on the society (8).

Preliminary studies of SMEs sustainability primarily focused on exploring factors that affected the growth and development of small and medium sized enterprises. Factors such as adopting technology in the SMEs, implementing financial budgets, appropriating financial planning, effective big data management, and so forth affected the growth and functioning of SMEs (9). A growing number of literatures has proved that technology-based SMEs perform well in terms of dealing with sustainability and big data. It was also found that there is a positive relationship between adapting technology and sustainability of SMEs. From the above statement, it can be deduced that the technology-based functioning SMEs find advantages in the market and thus moving toward the path of sustainability (10). Although there exist several studies exploring the relationship between finance and the growth of SMEs, so far, no study has tried to analyze the financial budgets of technology-based SMEs from the perspective of sustainability and big data.

Past studies confirmed that data is regarded as one of valued assets for any business, and it's been increasing rapidly day-by-day. This valued asset is popularly termed as big data that comes with 3 peculiar features. These three features are identified as having high volumes of data, variety of data types, and velocity to process the data. Almost all the organizations in the world are striving hard to discover all the possible ways to utilize this big data and develop their business. Majority of the studies confirmed that big data is quite important in the growth and development of a business (11). It was also added that, both large and small organizations are focusing on accurate and valuable data to make some important decisions related to business development. Likewise, few other studies demonstrated that big data supports SMEs to reach out to their target audience, understand their preferences, identify their needs, and then meet them in new ways (9, 12). Hence, it can be understood that big data plays a significant role in the growth of an SME, which is why SMEs should adopt big data in their business. Therefore, this study focuses on examining the financial budgets of technology-based SMEs from the perspective of sustainability and big data, which are considered as the backbone of a nations' economy. The other objectives of the study are to improve the

business process of SMEs by adopting new technologies and planning for financial budgets, which will effectively promote the growth of SMEs. This study will address the existing research gap by examining the process of planning financial budgets to the technology-based SMEs through the perspective of big data and sustainability. It will also examine the relationship between finance and SMEs; technology and SMEs; big data and SMEs; and try to understand this complex relationship from the perspective of SME sustainability.

LITERATURE REVIEW

Relationship Between Finance and SMEs

The growth of small and medium sized enterprises is directly related to the aspect of finance. Innovations with regard to finance, especially in the smooth functioning of SMEs play a critical role in various forms. In order to perform well, external and internal financial resources are necessary within an SME (13). Generally speaking, the performance of a firm is predominantly determined by intellectual resources and other major decisions. Moreover, any firm seems to face external and internal constraints (14). Past studies advocated that SMEs receive financial support from different traditional sources like merchant banks, development banks, commercial banks and so on. Most of the existing financial institutions were established to maintain the financial budgets of private organizations. For a smooth flow of business, these banks serve them with their effective channels (15). To manage the business in a much effective manner, every organization need loans from bank. From the above it can be understood that there is a direct relationship between credit of banks i.e.,' bank loans and the performance of a company, be it large or small and medium sized enterprises. The economic activity between a bank and an SME, is thus correlated.

Recent studies discussed about the effectiveness of the integration of e-commerce within Small and Medium sized Enterprises and found that latest technologies like mobile banking permits many SMEs the flexibility to settle down their financial transactions through the application (16). These new technologies also help the businesses to effectively perform financial transactions and reduce costs. It was also found that adopting mobile banking services within the small and medium sized enterprises will improve the diversity of business, reduce the cost, maintain the security, provide settlements with regard to finance. To perform monetary transactions, mobile commerce technology uses computer networks and other wireless networks. Previous studies observed that there has been a steady increase in the number of people using mobile applications and devices to buy products/services online. Using smartphone technology within the businesses can reduce the normal risks associated with finance. Hence, the study proposes the following hypothesis:

H1: There is a positive relationship between financing and SMEs sustainability.

Relationship Between Technology and SMEs

Previous studies have shown that technology plays a crucial role in the effective functioning of an enterprise. Adapting to the innovative technology will permit the business entity to establish their brand in the market. It will also boost the competitor factor within the SMEs in the global market (17). As a result of globalization, the economic and financial condition of the SMEs are continuously persisting in terms of attaining large economy scale. Moreover, the revolution created by technology has led to several problems addressing the SMEs and the owners of SMEs had to respond to those issues. Interestingly, it was found that innovations in technology enhanced the business of SMEs and as a result SMEs witnessed a long-term growth. Hence, from this perspective it becomes important to understand the role of technology in achieving SMEs sustainability (18, 19).

Few other studies stressed that certain SMEs export their products/services at international level. They broaden their market with the help of innovative technologies. Technology based SMEs focused on pushing themselves to enter international market and expand their potential. When the SMEs are exposed to the overseas market, equivalently they et an opportunity to expand themselves and efficiently communicate, transport, and trade their services (20–22). Above all, advanced technologies enhanced the internal and external communication process from the organization perspective. It also boosted the competitiveness among SMEs by improving the quality of goods and services. With the advancement of technology, supply chain linkages has also improved by aiding new services.

Another important aspect of using technology in SMEs is that it gives excellent outcome in the market. Use of advanced technology strengthen the condition of firms in the markets at international and national level (23). Recent studies found the strong appeal on adapting technology within the SMEs. For various reasons like social culture, technology adaptation, economic structure, and political condition of nation, sometimes the business can be prolonged. Numerous studies discussed the advantages of implementing technologies in SMEs (24–26). Nevertheless, few other studies aimed to focus on adopting technology within small and medium sized enterprises. Both developing and developed countries are interested in adopting technology to the SMEs, which will enhance the performance of firms. Innovations in technology will enhance the firm performance, thereby making SMEs sustainable. Hence, it can be commented that technology-based SMEs are critical in developing the economy of nation. Thus, the study proposes the following hypothesis:

H2: There is a positive relationship between adopting technology and SMEs sustainability.

Big Data and SMEs

There exists a considerable body of literature on the importance of data within the companies. Data is regarded as an important asset of SMEs. SMEs across the world are exploring different ways to tackle the data, which is usually called as big data. Big data is not only used in large multinational organizations, but also in SMEs. With the aim of improving the quality of a business, SMEs make use of big data to make accurate and quick decision in the need of hour (27, 28). The literature review shows that the use of big data in the business will enhance the whole process of business, and for this reason, SMEs are thinking on adopting big data to businesses (29–31). The use of big data technologies will help SMEs in deriving market value. The best way to deal with the challenges in the business is to adopt big data in SMEs (27). However, researchers have shifted their focus on big data, on discovering the benefits of big data.

A series of recent studies has indicated that multinational organizations are buying big data. Even startups are purchasing big data technologies to understand the new market, new clients, new business and so forth. Big data will also help SMEs to cut down the costs of business and enter the market. Transforming the big data to business applications will cost them real difficulty. Investing capital in the big data hardware and software is high.

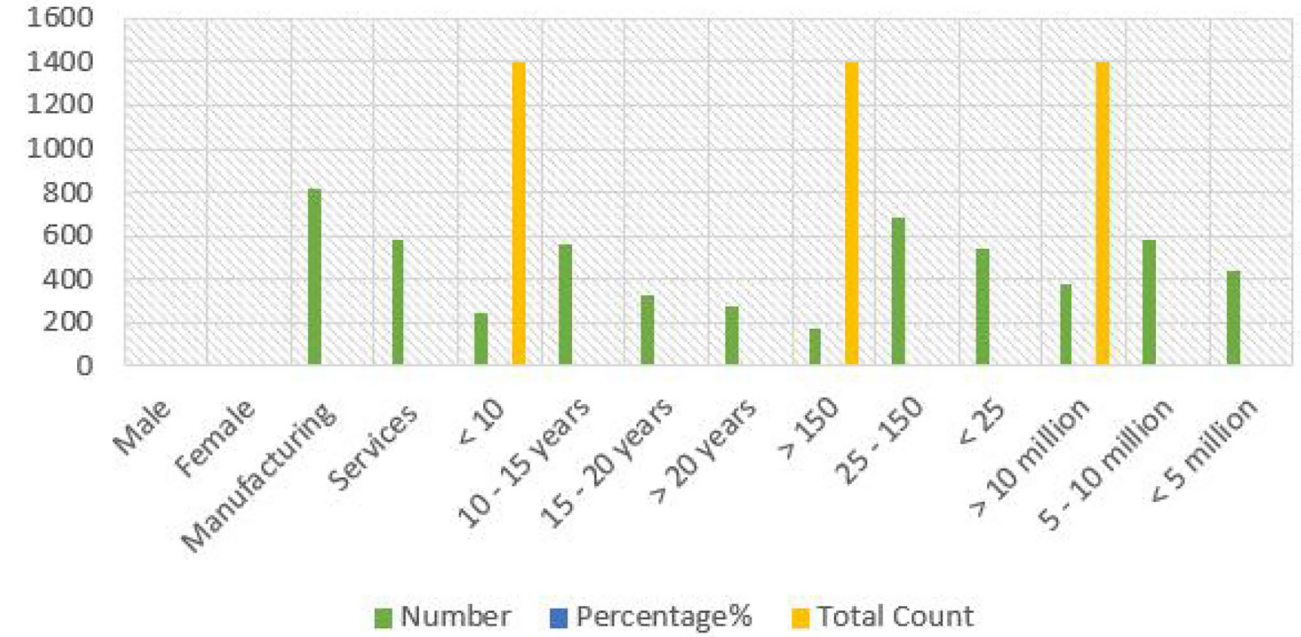

FIGURE 2 | Graphical representation of demographic details of respondents.

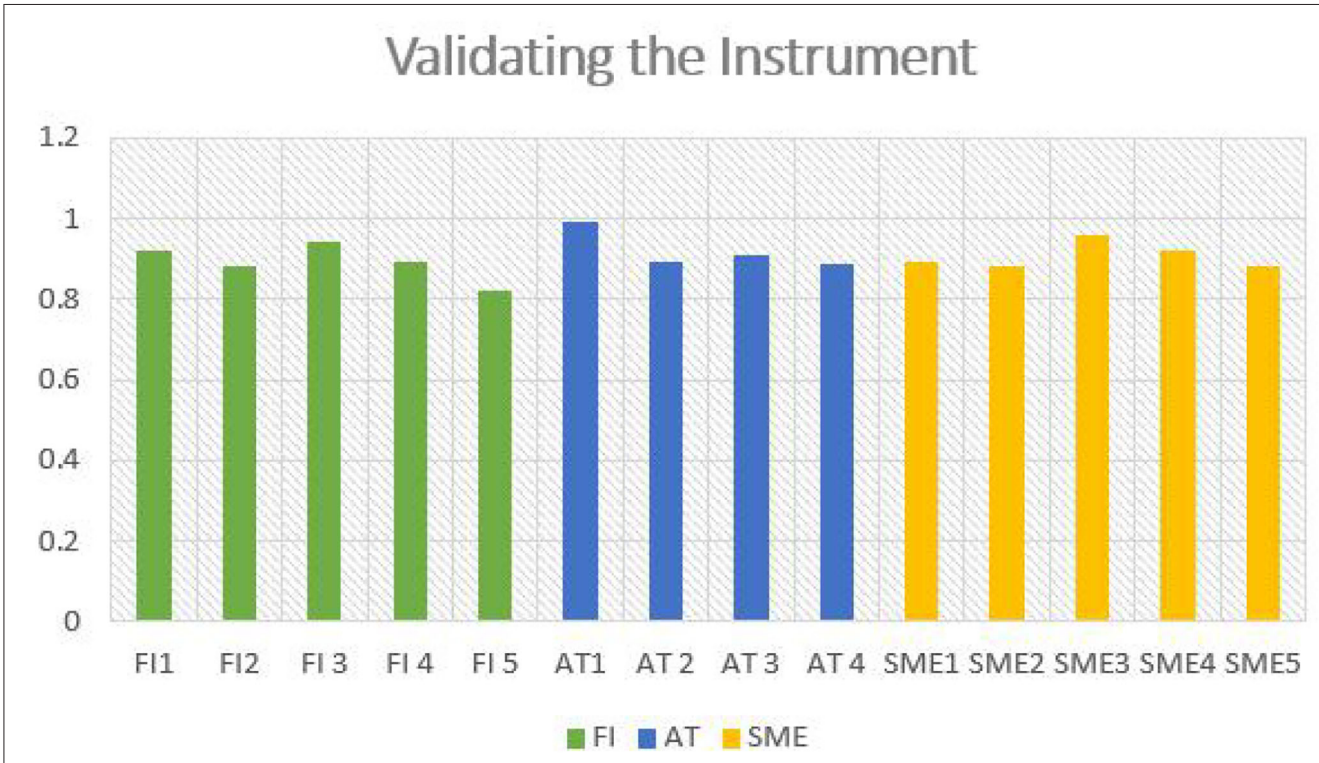

FIGURE 3 | Graphical representation of validating the instrument used in the study.

Few other studies revealed that technology adaptation, financial innovations, and big data are regarded as the strong pillars of SME (14, 16). In fact, organizations that use big data can increase their productivity and growth, which will improve the performance of enterprises. It will also help SMEs to understand the behavior of the market. Therefore, the study proposes the following hypothesis:

H3: There is a positive relationship between Big Data and SMEs sustainability.

H4: Big Data increases the growth and development of SMEs.

H5: Innovative Finance, Technology adaptation and Big Data technologies are essential in SMEs sustainability.

TABLE 5 | Results of hypothesis testing.

Relationships	Path	Std. Dev	*t* Value	*p*-value
There is a positive relationship between financing and SMEs sustainability	0.169	0.121	4.425	0.002

Innovative Finance, Technology adaptation and Big Data technologies are essential in SMEs sustainability	0.19	0.08	2.781	0.124

METHODOLOGY

The current study mainly concentrates on examining the financial budgets of technology-based SMEs from the perspective of sustainability and big data. It also examines the relationship between innovative finance and SMEs, adapting new technologies within the SMEs, adopting to big data technologies from the perspective of SME sustainability. The analysis of the current study has been conducted through secondary literature and primary analysis as well. The study has developed hypothesis based on the analysis and review of the secondary literature. The formulated hypothesis is tested using a structured questionnaire. Thus, the current study gathers all the required data using questionnaire and hence the study is descriptive. Using the questionnaire's results the researcher will evaluate the hypothesis. This method involves describing the objectives, define the population, select the sample, and later interpret the data and results. Population is a complete set of individuals who are bound together by certain common characteristics. Population is of two types- target and accessible. Target population consists of those whom the researcher wishes to generalize the findings of the study. In the current study the total population include 7.2 million SMEs in China. From the total population, the study derives the required sample. The term sample includes the individuals selected to participate in the study. These selected participants are popularly known as respondents/subjects of research. Sampling methods are of two types–probability/random sampling and Non-probability. To carry out the research, this study employs random sampling method. At times, researchers also tend to use purposive sampling with the aim of obtaining required data from certain area of research.

For the purpose of fulfilling the objectives of the study, the study selects the sample consisting of 5,210 SMEs located in China. This study focused on those SMEs in China that were relatively easy to connect using an electronic channel. Prior to the administration of the questionnaire prepared, consent from the SMEs was imitated as the first step. Only after the participants acknowledgment, the questionnaire link was distributed to the selected sample. Out of 5,210 sample, around 4,000 of them acknowledged and agreed to participate in the study. So, in total 4,000 SMEs sent their prior consent, out of which only 2,000 were considered valid. Based on the analysis of the secondary literature, the researcher prepared a structured questionnaire, which addressed the factors like innovations in finance, adapting new technologies within the SMEs, adopting big data within SMEs from the perspective of SME sustainability. This structure questionnaire will allow the selected respondents to share their views, opinions, beliefs, attitudes, and values on the research topic. The data was collected during the period of November 2021 to December 2021 and sample of 3,000 was considered along with their responses. **Table 1** presents the technical details of the research. In total, 1,800 responses were collected back and after the screening process, data of 1,400 respondents were finalized and considered for further analysis. Both primary and secondary data is collected to find out the results. The primary data is collected using the structured questionnaire designed to collect the required data from the participants. The collected data will help the researcher to examine the financial budgets of technology-based SMEs from the perspective of sustainability and big data. The researcher collects the secondary data required for the study from research articles and other journals. Finally, all gathered information was collected and analyzed to answer the research purpose.

The present identifies different variables like innovative finance, innovative technology, SMEs sustainability, and Big Data technology along with the measurement model. This model is presented in **Table 2** and its graphical representation is presented in **Figure 1**.

To analyze the data collected, the researcher employs SPSS and AMOS −26.0 version. To study the relationship between the variables identified, the study adopts structural equation modeling. Furthermore, the selected SMEs will be able to provide accurate and precise information on the questions covered in the questionnaires related to the research topic. As the SEM method is highly resilient and efficient in modern times, the researcher decided to use the same. This method will help the researcher to examine the relationship between the variables identified by testing the proposed hypothesis. This method also

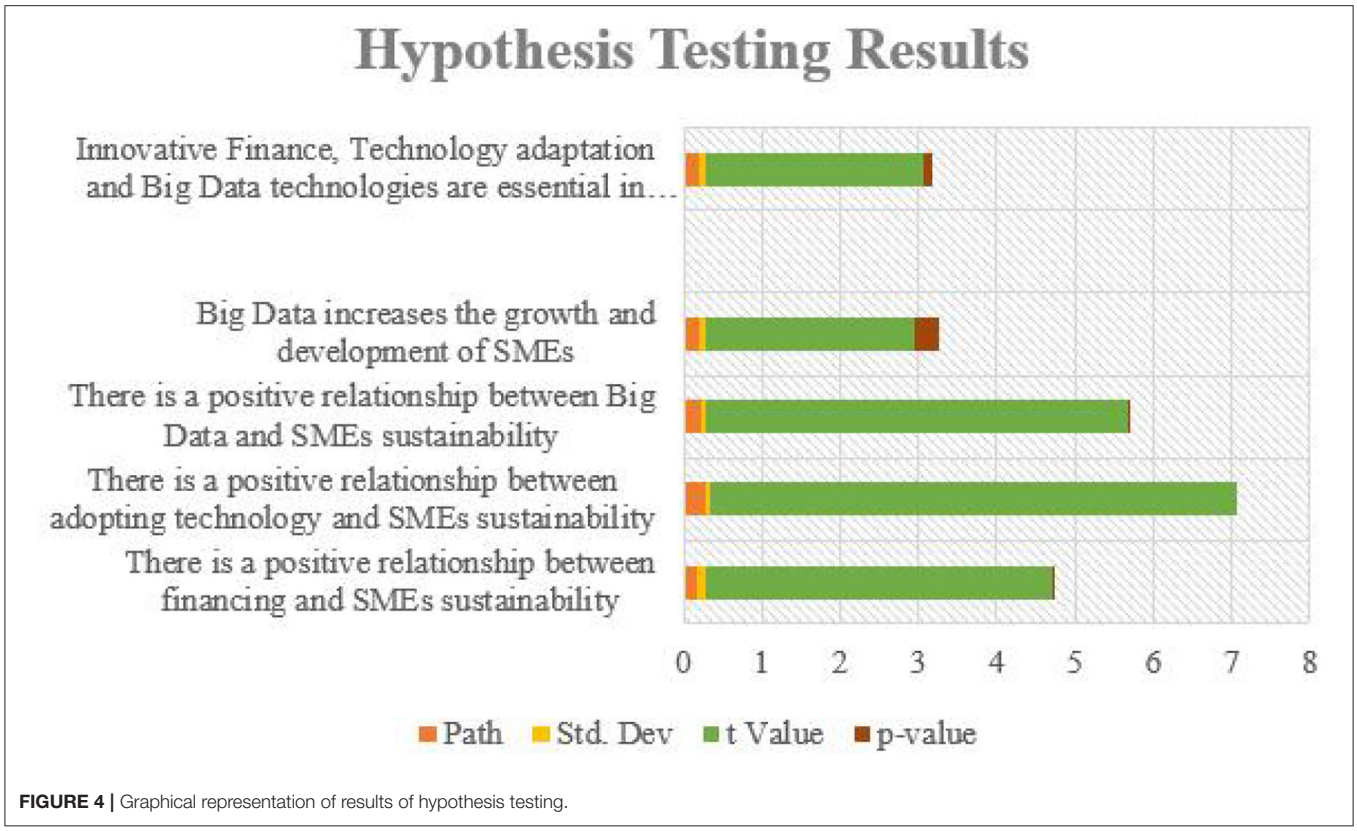

FIGURE 4 | Graphical representation of results of hypothesis testing.

focuses on the appropriateness of the results and hence was taken into consideration.

Although the owners of SMEs were reluctant to share the details of firms such as firm performance, innovations in finance budgeting, adopting innovative technologies, and adopting big data technologies, from the perspective of SME sustainability initially, later, they understood the need to evaluate the financial budgets of technology-based SMEs from the perspective of big data and sustainability and thereby opened, which helped the researcher to record the accurate data. Past researchers also tried to measure the sustainability of SMEs, which were in line with the opinions of the respondents, marked in 5-point likert scale, scaling from extremely poor to extremely good. The study also recorded responses from the participants on innovative ways to manage finance in SMEs from the perspective of sustainability and big data, and even their attitude toward the concept of innovative finance on the 5-point likert scale. Lastly, the study also recorded the responses of the respondents on adapting to innovative technologies and big data within SMEs that will enhance the sustainability on a 5-point likert scale.

RESULTS AND DISCUSSION

The current study confirmed the following findings. **Table 3** records the demographic details of the respondents, who participated in the structured questionnaires. When analyzing the data of SMEs, it was understood that 65.75 of them are males and 35.1 of them are females, spread across business units like manufacturing and services, fashion houses, units of handicraft and boutique. 52.01% of the respondents come under the manufacturing businesses and 47.12% of them belong to service units like beauty parlor, fast food, book shops and so on. Likewise, 40.10% of the SMEs were established for almost more than 10 years and come in between 15 years, 22.09% of the SMEs were established for more than 15 to 20 years, 19.61% of the SMEs were established for more than 20 years, and least 18.12% of them were established for <10 years. With regard to employee count, 49.21% of them disclosed high level of engagement in operations, 39.41% them disclosed a mediating level of employee engagement, and 13.01% exhibited low levels of employee engagement. Lastly, with regard to the employee revenue, 42.60% of them earned almost 5–10 million in a year, followed by 32.23% (<5 million) and 27.21% (<10 million).

The validation of the instrument used in the study is recorded in **Table 4**. From the table, it can be understood that the skewness test range results suggest that innovative finance, adapting technology within SMEs from the perspective of big data and sustainability are equally distributed. The extreme loading values presented in the table state that the instrument used is highly reliable and valid, which is calculated as 0.7. in terms of implementation. Moreover, the results presented in **Table 4** also confirm the absence of multicollinearity in the data gathered. **Figure 2** presents the graphical representation of validating the Instrument used in the study.

The result of the empirical study shows that innovative ways to manage finance within the SMEs will play a crucial role from the perspective of SME sustainability, as the coefficient value seems to be higher than the cut-off value. Likewise, the results associated with variable adopting technology within the SMEs also confirmed that they seem to significantly impact the smooth functioning of the SMES, especially when advanced technologies are implemented in line with SME sustainability and big data. Al the identified variables seem to efficient and hence the results can be considered as reliable. The findings of the study also disclosed that there is no reliability and validity issue with regard to the identified constructs. The **Figure 3** shows the Graphical Representation of Validating the Instrument used in the study.

In addition to, the study presented the results in measurement models including all the identified various variables. **Table 5** presented the measurement model results of the study, which indicate that there exists a relationship between the constructs–innovative finance, adopting technology within the SMES, adapting to big data technologies from the perspective of SME sustainability and big data. **Figure 4** represents the results of Hypothesis testing.

The study found that the hypothesis proposed in the study have high impact on the SME sustainability. Results of the study document that there is a positive relationship between SME and innovative finance, adapting to technological innovations, adapting to big data technologies, especially from the perspective of SME sustainability and big data. The study also found that the SME in China are high in number and hence the operations of the SMEs should focus on adopting to innovative finance, technology from the perspective of big data and sustainability, which stay significant for the survival of SMEs in this modern world. Even big data technologies will create new challenges and opportunities to the SMEs in contemporary world. Furthermore, there is a positive relationship between adopting technology and SMEs sustainability, which will expose SMEs to new opportunities and challenges. In short, it can be summarized that Innovative Finance, Technology adaptation and Big Data technologies are essential in SMEs sustainability.

CONCLUSION

The present article has proposed and tested the relationship between Innovative Finance, Technology adaptation and Big Data technologies, which play an essential role in SMEs sustainability. Hence this study examined the financial budgets of technology-based SMEs from the perspective of sustainability and big data. The results of the study indicated that there is a positive relationship between SME and innovative finance, adapting to technological innovations, adapting to big data technologies, especially from the perspective of SME sustainability and big data. There is a positive relationship between adopting technology and SMEs sustainability, which will expose SMEs to new opportunities and challenges. Thus, it can be argued that can be summarized that Innovative Finance, Technology adaptation and Big Data technologies are essential in SMEs sustainability.

Blockchain is a recent revolutionary technology primarily associated with cryptocurrencies. It has many unique features including its acting as a decentralized, immutable, shared, and distributed ledger. Blockchain can store all types of data with better security. It avoids third-party intervention to ensure better security of the data. Deep learning is another booming field that is mostly used in computer applications. This work proposes an integrated environment of a blockchain-deep learning environment for analyzing the Electronic Health Records (EHR). The EHR is the medical documentation of a patient which can be shared among hospitals and other public health organizations. The proposed work enables a deep learning algorithm act as an agent to analyze the EHR data which is stored in the blockchain. This proposed integrated environment can alert the patients by means of a reminder for consultation, diet chart, etc. This work utilizes the deep learning approach to analyze the EHR, after which an alert will be sent to the patient's registered mobile number.

1. INTRODUCTION

In this modern period, many clinicians do not maintain the physical ledger of a patient's information, diagnostic details, and treatments. Instead, they keep health records electronically. These records hold the patient's complete information such as his history, allergies, treatment taken, etc. It can be viewed by clinicians, hospitals, and healthcare providers for any cause. These records require the utmost safety and security in order to prevent misuse by third parties or cyber attackers (1, 2). It contains confidential information about medication, symptoms, scan reports, and even biometrics. This work uses blockchain-based storage for Electronic Health Records (EHR) to provide privacy and security for the data. It is very crucial that EHR be maintained because it contains sensitive information (3, 4). There are some drawbacks in existing EHR maintenance which include:

1. Whether to trust an organization that stores EHR.
2. Hacking and medical data breaching.
3. Difficulty in retrieving the patient's history for treatment suggestion.
4. In case of emergencies, how to get the patient data, and if it can be trusted.

To overcome all these drawbacks, the work proposes a storage method using a blockchain-hyperledger fabric to store the patient data with enhanced security and privacy. The medical report of any patient cannot be accessed without their permission. Other users like doctors, healthcare providers should have a digital certificate from the government to join and access EHR in the blockchain network. Only doctors, healthcare providers, and clinicians would be able to perform CRUD operations in the block. The data from the block is retrieved using the hash value. Next, the retrieved patient's block is analyzed using Recurrent Neural Network-Long Short-Term Memory (RNN-LSTM). Then the performance of RNN-LSTM is compared with RNN-GRU. Once the patient's block is analyzed, an alert will be sent to the patient's registered mobile number.

1.1. Motivation

The Electronic Health Records contain very sensitive information, and the chances of cyber attackers misusing the reports are very high in the centralized storage environment. Furthermore, the patients track their reports for regular consultation, medication, diagnosis appointments, etc. The motivation of this proposed work is to analyze the patient's EHR witha deep learning mechanism stored in the Blockchain and to create an alert system for the patient.

1.2. Contribution

To incorporate the reliable Hyperledger fabric blockchain to store the medical records of the patient. It also analyzes the blocks(the patient's EHR) using the RNN-LSTM and RNN-GRU mechanism. An alert system is created for the patients welfare, for activities like an alert for the next consultation, medication, and for diagnosis. The behavior and efficiency of the RNN algorithm is analyzed. Asa result, a reliable Hyperledger fabric is utilized for storing the EHR. Those medical records are analyzed by the deep learning Recurrent Neural Network algorithm, and it creates an alert system to monitor the patients remotely.

1.3. Organization of the Paper

The rest of the paper is organized as follows: Section 2 describes related works. Section 3 explains materials and methods. Section 4 discusses the results. Finally, Section 5 concludes the work.

2. RELATED WORK

Blockchain is a booming technology which has been incorporated in many areas like industry and academic scenarios (3, 5). The diet recommendation system was created for patients affected by heart disease and to avoid heart disease (6), while also checking for the family history. Kutia et al. (7), Plastiras and O'Sullivan (8), and Shabbir et al. (9) studied the impact of different parameters that influence the adapting to and use of the online health facilities in Ukraine and China, such asallergies, food preferences, age, blood pressure. It utilizes machine learning algorithms for the recommendation system. The authors (8) proposed a tailored recommendationfor patients based on different parameters, with reference to their health records using Artificial Intelligence.

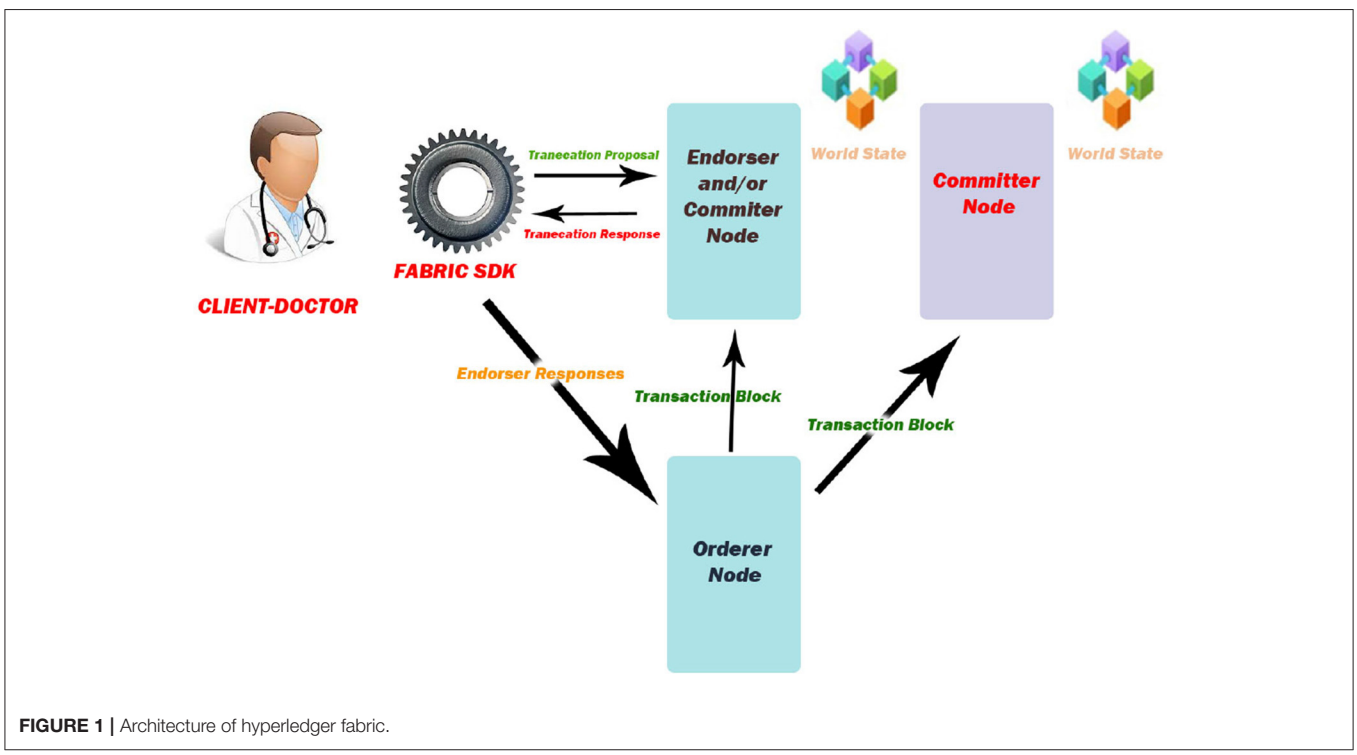

FIGURE 1 | Architecture of hyperledger fabric.

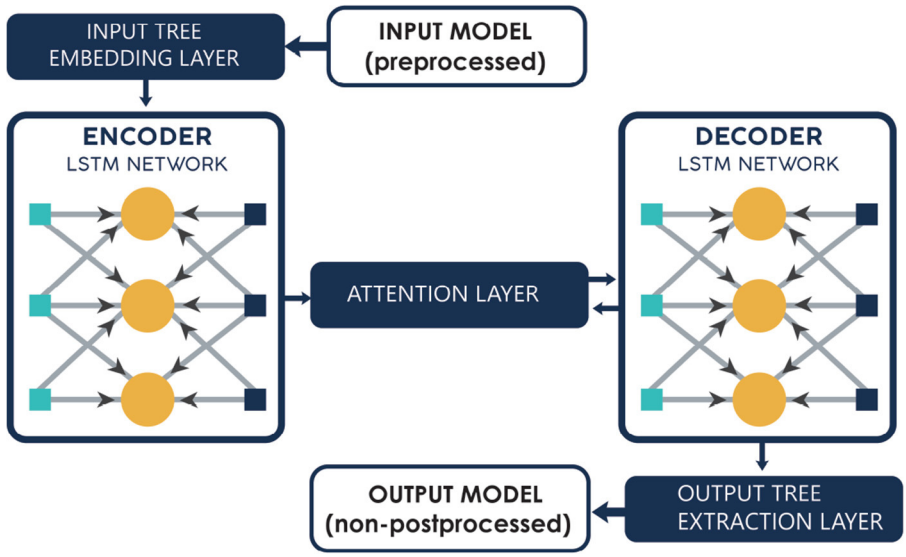

FIGURE 2 | Architecture of the LSTM RNN.

FIGURE 3 | Model of the system.

TABLE 1 | Reference summary.

S.no	Health information system	Challenges	Area to be concentrated
1	Electronic health records [21]	Interoperability, access control, data integrity	Shared decision making
2	Electronic health records [22]	Interoperability	Health data recording, storing, and sharing Access control
3	Electronic health records [23]	Interoperability	Sharing of healthcare information for clinical and research purposes Access control
4	Electronic health records [24]	Data integrity, access control	Sharing healthcare data between health institutions
5	Electronic health records [25]	Data integrity	Sharing healthcare data between health institutions
6	Electronic health records [26]	Access control, interoperability, data integrity	Sharing healthcare data for clinical and research purposes
7	Electronic health records [27]	Access control, interoperability	Sharing healthcare data for clinical and research purposes
8	Electronic health records [28]	Access control, interoperability and administrative	Sharing healthcare (health record) information for clinical, research[economic] purposes.
9	Electronic health records [29]	Access control, data integrity, interoperability	Patients collection, archiving and sharing of healthcare data for clinical purposes
10	Electronic health records [30]	Patient data management and storage	Environment Access control, data integrity, data provenance

The study (10) proposes a literature survey of machine learning algorithms that are used in a recommendation system. Agapito et al. (11) proposed a diet organizer system, which can be utilized by both healthy people and patients with chronic diseases. The authors in Mani et al. (12) and Singhal et al. (13) utilized the blockchain, Hyperledger fabric storage using Inter Planetary File Storage (IPFS) protocol to save data in the blockchain. Wang et al. (14) showed how bigdata analytics can be utilized for

the healthcare industry, with the pros and cons of the model. The use of predictive data mining algorithms to recommend healthy diets was proposed by Jaiswal (15). A data mining model was developed to provide users with information about healthy food habits and eating patterns, such as the number of calories burned, the amount of macronutrients consumed, and so on. Patients' dietary preferences are predicted by the patient diet recommendation system by taking into account their eating habits and body measurements. In spite of its effectiveness in predicting healthy diets for patients and nutritionists/doctors, the study is limited by its lack of a flexible model and minimally tailored solutions to fit the patient's needs. Argaw et al. (16) briefly explains that clinical documents and hospitals are very prone to hackers and cyber attackers. There are scalability issues as the data is stored in an on-chain database, which makes the system unstable. However, the author in Egala et al. (17) proposed a ring structure-based access control that ensures privacy. Alsufyani et al. (18) proposed a system to manage data intelligently in a cyberspace environment. Decentralized storage and access to records, as described in Singh et al. (19), are efficient ways to utilize the network's power and resources. In Peng et al. (20), the author employed high-end privacy-enhancing technologies, such as homomorphic encryption, that prevent vulnerabilities due to the processing of data while it is encrypted. To ensure nodes did not engage in malicious behavior, the Agrawal and Jain (21) used zero-knowledge proof and proof authority consensus for mutual authentication as a privacy enhancement technique. There is no doubt that blockchain technology provides a cryptographic solution to the security issue, but there are challenges such as privacy, scalability, and interoperability. Large medical data centers have experienced record breach episodes in the past two decades, which have left medical companies with additional challenges (21). When blockchain technology was newly invented, MedRec (22) became the first recommendation system for an electronic patient record management system that would be made possible with blockchain technology. Ether blockchains are capable of backing up detailed accessibility data. Healthcare providers maintain third-party databases, not the blockchain. This means that the records can still be hacked or misused. A healthcare management system as in Ivan (23) encrypts patient keys as data is recorded on the blockchain. Researchers and hospitals decrypt the data with a patient's public key after receiving consent from the patient. In contrast, we empower our patients to control their own data, so they are the only ones who have access to them.

3. MATERIALS AND METHODS

3.1. Hyperledger Fabric

Hyperledger fabric is an open-source platform which builds the distributed ledger, with a plug-and-play architecture (modular) that facilitates a high level of security, privacy, and confidentiality of the data. The architecture of Hyperledger fabric is shown in **Figure 1**. The client capitulates the transaction pool through the fabric SDK to the endorser. Endorsing peers verify and execute the transaction, and generate the read and write sets. The response is then sent back to the client. All replies from peers are collected by the client, and they are sent to the "orderer." In this case, all transactions are ordered by the orderer in ascending order and then formed into a block. Each committer validates this block and adds a new block to their own copy of the ledger as a result. The fabric consists of four components, namely:

1. Membership Service Provider (MSP)
2. Client
3. Orderer
4. Peer

Membership Service Provider is the main component of Fabric which defines a rule to allow members in after authentication and verification. It manages the User ID and the authenticity of the client. The client is the person who initiates the transaction proposal. All transactions have to be written in the shared ledger in blockchain in a consistent order. In order for updates to the world state to be valid, the order in which they are made must be determined.

TABLE 2 | List of abbreviations.

HR	Health Record
P1	Patient
D1	Doctor
U1	User
PPK	Patients Private key
PUK	Patients Public Key
Sk	Session Key
DPK	Doctors Private key
PV	Patient View of data

3.2. RNN-Long Short-Term Memory

A Recurrent Neural Network is a special kind of deep learning where the output of the previous step will be the input of the subsequent step. LSTM is a special type of Recurrent Neural Network which enables the system to learn the long-term dependencies of data. This type of learning is achieved by the repeated module of the LSTM, which has a combination of 4 different layers connected to each other. **Figure 2** explains the method, and the three-layeredarchitecture where the embedding layer gives the pre-processed data to the Encoder-LSTM network. It then passes to the attention layer that acts as the intermediate layer, where it facilitates the decoder to pay more attention to the specific parts of the fixed-size vectors.

3.2.1. RNN-GRU

The Gated Recurrent Unit (GRU) is another type of Recurrent Neural Network. It is very similar to the Long-Short-Term Memory RNN.

3.2.2. System Model

This work utilizes the blockchain to store all the EHR of the patients, which cannot be accessed by third parties or cyber attackers, because of its high security and privacy of medical data. Hyperledger Fabric can be used to save these types of

medical data. It uses Inter Planetary File System (IPFS) which provides a solution for the file storage problems. IPFS can store and retrieve large files efficiently. Health records are encrypted using symmetric key cryptography to ensure privacy. To protect the record, it is stored in an encrypted format on an IPFS server under the appropriate supervisory authority. To access the patient's record, an entity must first be given the authorization to do so.

1. A private key is used to decrypt the record.
2. RSA key pair public key and symmetric key are used to encrypt the key.

Access to a health record may be removed if:

1. The symmetric key is decrypted by the private key associated with the EHR owner.
2. The symmetric key is used to decrypt the EHR.
3. A new symmetric key is used to re-encrypt the record.
4. Encryption of the symmetric key is completed using the public keys of all authorized users.

Figure 3 describes the model of the system it takes the Input (EHR) from clinicians, doctors, and healthcare providers which is stored in the Hyperledger Fabric using the protocol Inter Planetary File System (IPFS) using **Algorithm 1**, where from the data is retrieved by a deep learning agent for analyzing the EHR, after analyzing the data in EHR the RNN-LSTM will send the alert for several activities like doctor's consultation, medication, and diagnosis schedule to the patient's registered android device, this was explained in the **Algorithm 2**.

This proposed work uses nine different features from EHR to provide an effective alert system. These features are listed in **Table 1** above. Considering all these features, we can design an efficient alert system, through whichregular monitoring of thepatient can be done.

18. End if
19. End For ()
20. End procedure Store_EHR

3.3. Data Preprocessing

Data pre-processing is an essential task to be carried out. It helps to achieve the maximized efficiency of the model. At this stage, the dataset is pre-processed by four important steps which include:

1. Data cleaning
2. Data integration
3. Data transformation
4. Data reduction

These four steps have to be followed sequentially to get the required pre-processed data to train the model. At first, the dataset is cleansed by assigning missing values, null values, eliminating the nosy data, resolving the inconsistency,and removing outliers. The cleansed data is then used for data integration, which refers to the merging of data from multiple sources into a single larger data store, such as a data warehouse. Inthe data transformation step, wetransform the value, structure, or format of quality data into alternative forms, according to some strategies such as generalization, normalization, attribute selection and aggregation. Finally, the data reduction is carried out to find the appropriate dataset model proposed to achieve the maximum efficiency.

3.4. Evaluation Metrics

Many evaluation metrics are used to evaluate the performance of our model

$$Accuracy = (AZ + AN)/(AZ + AN + CZ + CN) \quad (1)$$

$$Precision = AZ/(AZ + CZ) \quad (2)$$

The objective of precision is to examine the True Positive (AZ) units in connection with False Positive (CZ) units.

The objective of recall is to examine True Positive (AZ) units in connection to False Negative (CN) units that are not classified. The arithmetic arrangement of recall is stated in Equation below:

$$Recall = AZ/(AZ + CN) \quad (3)$$

Sometimes, the assessment of performance may not be very efficient with recall and accuracy. For example, if a mining algorithm has high precision but low recall, then another algorithm is needed. Then comes the question of which algorithm is more effective. This challenge is solved utilizing F1-measure

Algorithm 2: Creating an alert for health records in Hyperledger blockchain Alert ().

Input: HR from BLOCKCHAIN
output: Recommendation in Mobile
Procedure Recommendation
Initialize V,U;
Preprocess content of items;
For I to N do
    Foreach (X_{sample},V_{sample}) ϵ samples do
        trainAutoencoder (X_{sample},V_{sample});
    end
    theta $\leftarrow$ Autoencoder(X);
    $U_tU \leftarrow U^TU$;
    For each I ϵ items do
        $U_tU \leftarrow U_tU + \alpha U_{OB} *^T U_{OB} + \lambda_V I$;
        $U_{tr} \leftarrow (1+\alpha)\ U_{OB}r_{OB} + \lambda_v$theta
        $V_i \leftarrow$ Solve (U_tU,Utr$_{ob}$)
    End
    VtV $\leftarrow V^TV$;
    Foreach u ϵ users do
        VtV $\leftarrow$ VtV+$\alpha\ V_{OB} *^T V_{OB} + \lambda_U$I;
        $V_{tr} \leftarrow (1+\alpha)\ V_{OB}r_{OB}$
        $U_U \leftarrow$ Solve (U_tU,Utr$_{ob}$)
    End
End

that gives a mean recall and precision. F1-measure can be calculated as follows:

$$F1score = 2 * (Precision * Recall)/(Presiion + Recall) \quad (4)$$

TABLE 3 | Features used in the model.

S. No	Features	Type of feature values

3.5. Experiments and Results

In the proposed model, the personal alert system is designed for patients registered mobile numbers. The alert is created for certain activities like the next consultation date, medication, diet specification, and diagnosis date. Initially, the patient's EHR is stored in the Blockchain using IPFS protocol. The data saved in the blockchain will be more secure and distributed. The

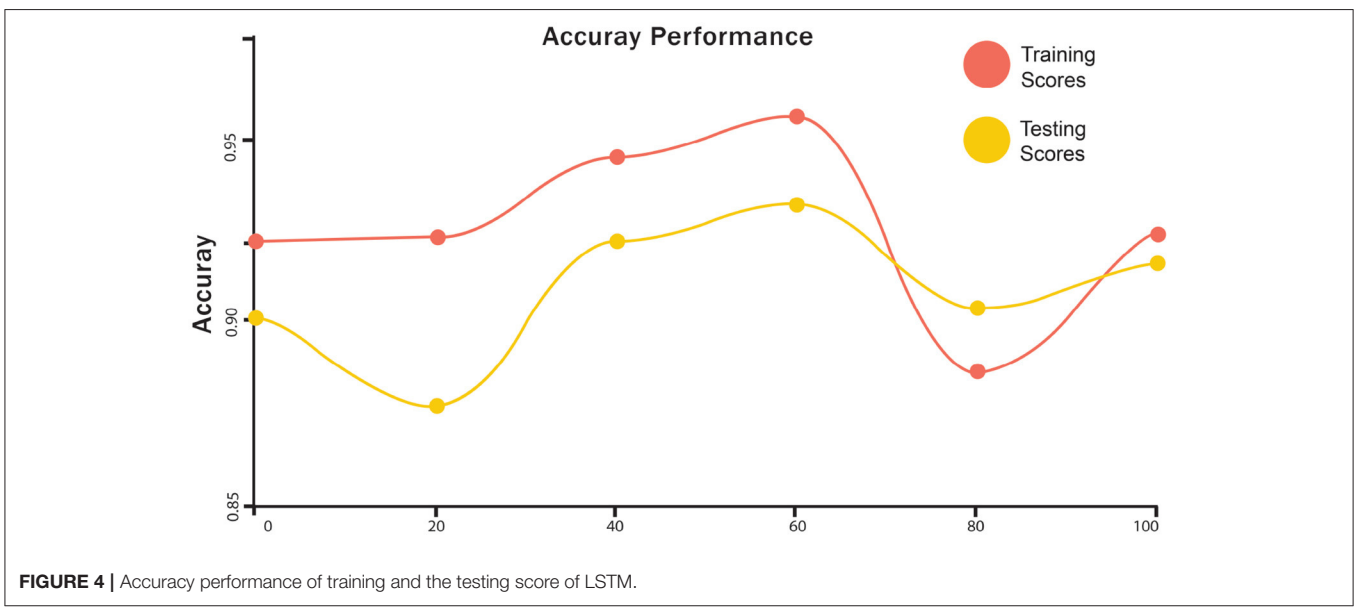

FIGURE 4 | Accuracy performance of training and the testing score of LSTM.

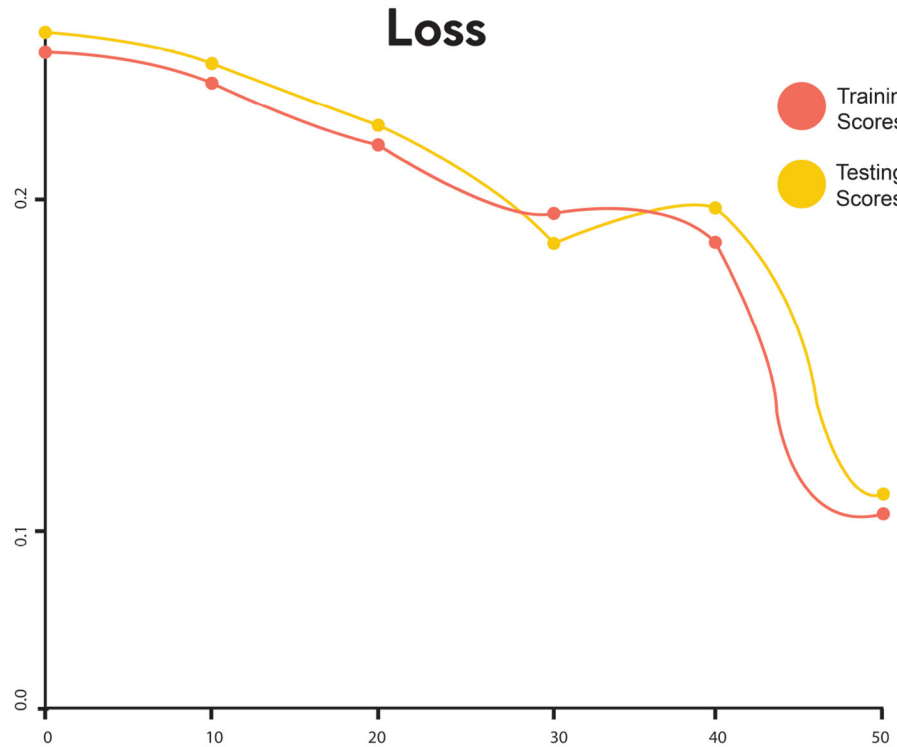

FIGURE 5 | Loss performance of training and the testing score of LSTM.

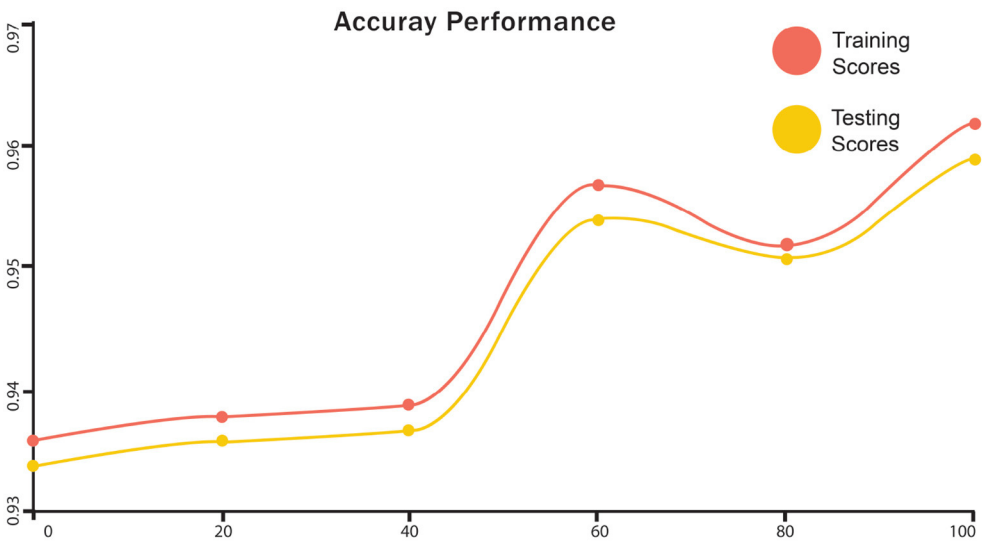

FIGURE 6 | Accuracy performance of training and testing score of GRU.

data that is saved in the blockchain is retrieved by the deep learning mechanism, Long Short-Term Memory for analyzing the data. After analyzing the patient EHR, a tailored alert system is triggered to the registered mobile number.

The proposed work uses nine features from the dataset, the features are ID, age, gender, disease, weight, consultation date, medication, diagnosis, and diet specification. The taxonomical analysis is done with several featuresto give accurate results.

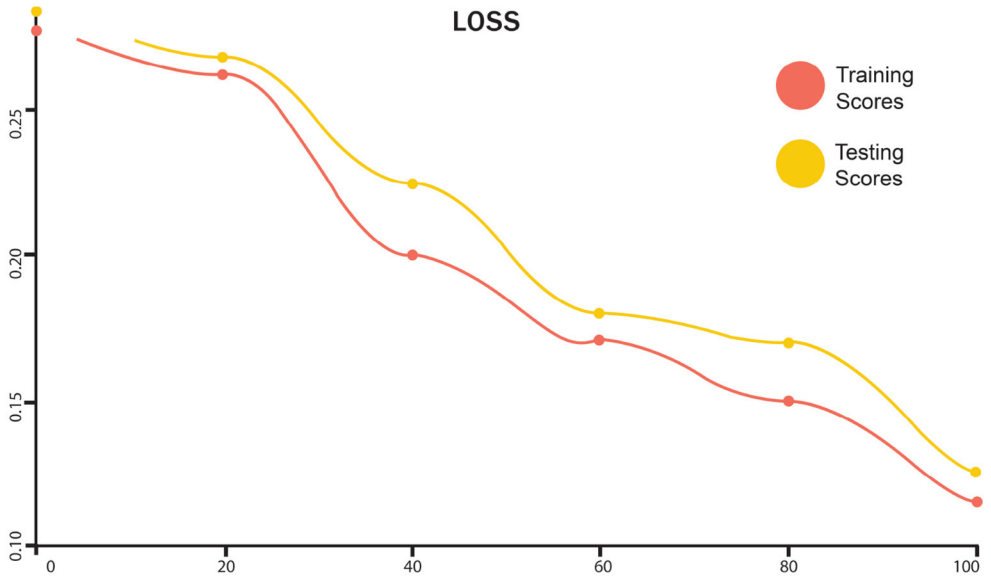

FIGURE 7 | Loss performance of training and testing score of GRU.

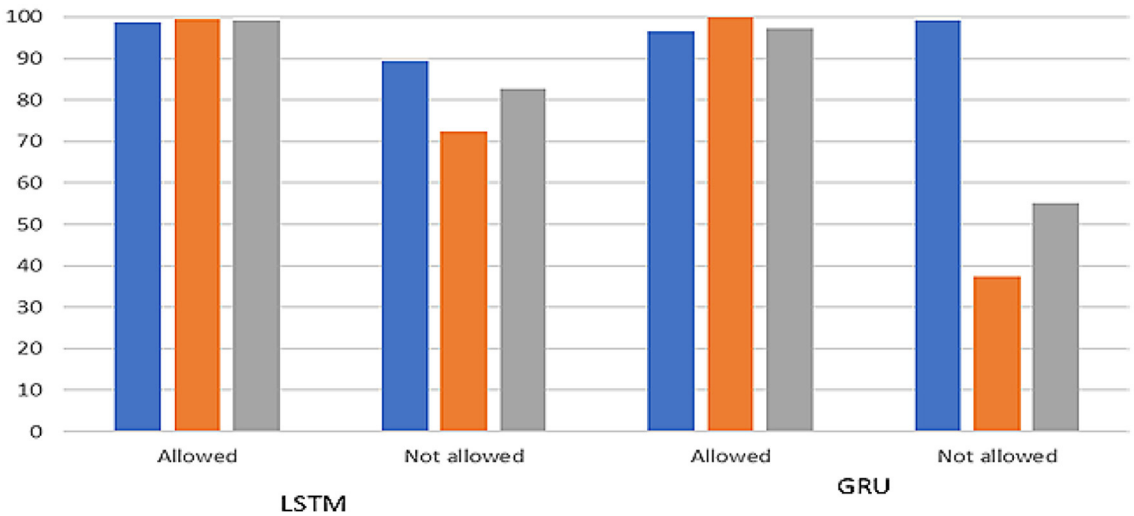

FIGURE 8 | Classification report of LSTM and GRU.

The analysis of the EHR is done using the deep learning techniques Long-Short Term Memory (LSTM) and Gated Recurrent Unit (GRU) which are Recurrent Neural Network techniques. **Table 2** shows the list of abbreviation and **Table 3** shows the features used in the model. Therefore, the comparison between the two integrated blockchain and Recurrent Neural Networks in analysing the EHR is given in **Table 4**, in terms of precision, recall, and F1 score.

The training and testing scores for LSTM are shown in **Figure 4**. In the graph, the red line represents the training curve and the yellow line represents the testing curve. Training curves start from 93.6% and after 50 epochs, they reach 95%. For the testing curve, it starts at 94% and goes to 97.4%, then goes down to 96%. Training and testing losses for LSTM are shown in **Figure 5**. The training loss is represented in red, while the testing loss is displayed in yellow. The training loss begins at 0.27 and reduces to 0.128. The testing loss begins at 0.23 and decreases to 0.075. **Figure 6** shows the scores obtained during the training and testing for GRU, while **Figure 7** shows the losses obtained during the training and testing for GRU. The red curve in **Figure 5** represents the training curve. It starts at 93% and goes up to 97% testing and training scores for GRU. Similarly, the yellow curve representing the LSTM's testing score starts at 94% and goes up to 97%. **Figure 7** shows the training loss starts at 0.3 and decreases

after 50 iterations. It reaches 0.1 after that. Likewise, the testing loss starts at 0.2 and decreases until it reaches 0.05.

Table 2 shows that the LSTM model outperforms another modelin terms of recall, precision, and F1 score. The Allowed LSTM had 98% precision, 99% recall, and F1 measure scores, respectively. The Not Allowed class had 87% precision,77% recall, and 81% F1 measure score, respectively. The other model Integrated Blockchain-GRU also performs well but not as well as LSTM. Finally, the result of the model is shown for both Allowed and Not Allowed classes in **Figure 8**.

4. CONCLUSION

The study proposes an integrated blockchain-RNN algorithm for storing the EHR in the Hyperledger Fabric using the protocol Inter Planetary File System. The stored EHR is analyzed with the deep learning mechanism, Recurrent Neural Network algorithms, namely Long-short-Term Memory and Gated Recurrent Units. The integrated model gives an alert to the registered mobile number of patients regarding the consultation reminder, diagnosis alert, medication, diet chart specification. It uses 9 features, i.e., age, sex, weight, disease, medication chart, appointment date, diagnosis date, and diet specification. This proposed work focuses on an integrated model to automate the alert system for various activities of the patient. Finally, experimental results show that the LSTM outperforms the other models in terms of precision, recall, and F1 score. This work is practically possible but the maintenance cost is more when compared to the traditional model. In the Future, the alert system can be improved by collaborating with the calendar application in android mobile with fitness applications and to provide a solution for a cost-efficient model.

Yang S, Zheng L, Sun Y and Li Z (2022) Effect of Network-Based Positive Psychological Nursing Model Combined With Elemene Injection on Negative Emotions, Immune Function and Quality of Life in Lung Cancer Patients Undergoing Chemotherapy in the Era of Big Data. Front. Public Health 10:897535. doi: 10.3389/fpubh.2022.897535

Background: With the development of big data, big data interpenetrate in every person's life. Health care is no exception to this trend, especially in regard to nursing analytics. The data that is analyzed and leveraged in this field is gathered from a variety of sources, including electronic health records (EHRs), medical histories, provider notes and mobile applications, creating an accumulation of personalized health information around each individual.

Objective: To explore the effect of the network-based positive psychological nursing model combined with elemene injection on negative emotions, immune function and quality of life (QOL) in patients with lung cancer (LC) undergoing chemotherapy.

Methods: The clinical data of 90 LC patients who underwent chemotherapy in our hospital from December 2020 to December 2021 were retrospectively analyzed, and the patients were equally split into experimental group (EG) and control group (CG) according to the order of enrollment. The patients in CG received routine nursing intervention during chemotherapy, while those in EG received the network-based positive psychological nursing model combined with elemene injection to compare negative emotions, immune function and quality of life (QOL) between the two groups.

Results: Compared with CG, EG had notably higher immune function indexes ($P < 0.001$), lower serum VEGF and MMP-2 levels ($P < 0.001$), lower HAMA and HAMD scores ($P < 0.05$), and higher scores of PTGI, physiological function, psychological function, social function and physical function ($P < 0.001$).

Conclusion: The network-based positive psychological nursing model combined with elemene injection is a reliable method to enhance the immune function and QOL of LC patients undergoing chemotherapy and alleviate their negative emotions, which has a high clinical application value.

Keywords: network, positive psychology, elemene injection, lung cancer chemotherapy, negative emotions, immune function, quality of life (QOL)

INTRODUCTION

Lung cancer (LC), mainly occurring in bronchial epithelial cells, is a common clinical malignant tumor with a high incidence (1) and seriously threatens human health. Thoracoscopic radical resection of lung cancer is a common surgical approach to treat LC (2), and postoperative chemotherapy is an indispensable adjuvant therapy. However, chemotherapy can trigger serious adverse reactions in patients, such as gastrointestinal reactions, vomiting and diarrhea (3, 4). In addition, patients during the period of chemotherapy often experience negative emotions due to worries about postoperative recovery and fear of tumors. In addition, the prevalence of the concept of cancer fear and the harm of LC itself expose patients to great psychological pressure, such as anxiety and tension. Besides, studies have found that immune function plays an important role in the disease development of malignant tumor patients, and cancer cells seriously affect the immune function of patients after the occurrence of tumors. At the same time, the toxic reactions of chemotherapy drugs also damage the normal physiological function of patients and result in a series of severe stress reactions, further damaging the immune system of patients, resulting in the decline of immune function and seriously affecting the quality of life (QOL). Therefore, how to alleviate the negative emotions of LC patients undergoing chemotherapy, enhance the immune function and QOL, and prevent disease recurrence is an urgent problem to be solved in clinic (5, 6). Routine nursing measures are carried out from health education, cognitive management and emotional support, which can hardly stimulate the potential of patients and leaves an unsatisfactory effect. Based on the theory of positive psychology, positive psychological intervention taps individual positive factors and stimulates the intrinsic potential of patients through their positive emotional experience and effective social support (7, 8). The development of Internet technology effectively solves the current lack of nursing resources in China. A report (9) shows that the network-based positive psychological nursing model enables patients to understand their diseases and maximizes the effect of psychological intervention through the instant push function of mobile phone APPs. A current study (10) has found that elemene injection can reduce the mitotic ability of tumor cells and induce their apoptosis, thus inhibiting their growth and proliferation, changing their immunogenicity, and strengthening the immune response of the body. Chemotherapy causes great physical and psychological pain to LC patients. In order to alleviate the pain of such patients, this study can play a guiding role in the clinical treatment of lung cancer, effectively improve the negative emotions of patients undergoing chemotherapy, reduce the economic burden of their families, and provide theoretical support for further research in the future. At present, few studies have confirmed the intervention effect of the network-based positive psychological nursing model combined with elemene injection on LC patients undergoing chemotherapy. In order to fill this gap and provide evidence-based evidence for more patients, this study is reported as follows.

MATERIALS AND METHODS

General Information

The study subjects were 90 LC patients who received chemotherapy in our hospital from December 2020 to December 2021, and were equally split into experimental group (EG) and control group (CG) according to the order of enrollment. This study was approved by the ethics committee of *Jimo Nanquan Health Center*, following the Declaration of Helsinki (2013) (11).

Inclusion and Exclusion Criteria

Inclusion Criteria

(1) Patents meeting the diagnostic criteria of LC and receiving chemotherapy; (2) patents with no history of epilepsy or cognitive impairment; and (3) patents with the stable condition and the approval of the attending doctor.

Exclusion Criteria

(1) Patents with a deteriorating condition and unstable vital signs; (2) patents with inability to understand the purpose of the researchers and the content of the questionnaire, and with severe cognitive impairment; and (3) patents who were allergic to the research drugs.

Methods

Patients in CG received routine nursing intervention during chemotherapy through health education and professional guidance, including the pathogenesis, clinical manifestations and stages of disease development, precautions during chemotherapy, side effects of chemotherapy drugs, and dietary guidance (12, 13).

Patients in EG received the network-based positive psychological nursing model combined with elemene injection. The network-based positive psychological nursing model was carried out as below. (1) A network-based positive psychological nursing team was established, with 1 attending physician, 1 head nurse, 3 whole-course nurses, and 2 assistant nurses, aiming to organize the training on related knowledge of LC,

chemotherapy and positive psychology, and carry out the assessment. The nurses could take the post only when they passed the assessment. (2) Register on the mobile APP. The LC health management platform was established, including modules such as chemotherapy period, psychological communication and patient assistance. The patients were guided to enter the platform and each module. The head nurse was the platform administrator and the whole-course nurses were responsible for the specific operations. (3) Online knowledge learning. According to the relevant content of positive psychology, combined with the psychological problems of LC patients undergoing chemotherapy, the head nurse organized and compiled the network courses of positive psychological intervention. The whole-course nurses pushed the contents on the WeChat public account weekly to guide patients to learn and use positive psychology to face the discomfort after chemotherapy. (4) Sharing of positive emotions on the platform. The patients were encouraged to write gratitude logs and upload them to the platform to cultivate their positive attitude. (5) Online mindfulness decompression training. The whole-course nurses led the patients to carry out online mindfulness decompression training, and guided them to exchange their feelings and ideas and express their psychological pain. Elemene injection (manufacturer: CSPC Pharmaceutical Group Co., Ltd.; NMPA approval No.: H20110114; specification: 10 ml: 0.2 g × 5 vials/box) was injected into patients, 400 mg/time, 1 time/d. With 21 days as a course of treatment, the patients received the continuous treatment of three courses. The dosage was appropriately adjusted according to the actual situation of patients during the treatment process.

Observation Indexes

The fasting elbow venous blood of both groups after treatment was collected and centrifuged to prepare serum samples. The serum matrix metalloproteinases (MMP-2) and vascular endothelial growth factor (VEGF) were measured by ELISA. A protein immunoassay analyzer (model: CS-AutoBlot 48; manufacturer: Hunan Zhongrui Huxin Medical Technology Co., Ltd.) was used to detect the levels of immunoglobulin (Ig) G, IgA and IgM.

Hamilton Anxiety Scale (HAMA) (14) and Hamilton Depression Scale (HAMD) (15) were used to evaluate the negative emotions of both groups. The total score was 56 in HAMA and 68 in HAMD. Higher scores suggested worse emotions of patients.

Post-traumatic Growth Level

The Chinese version of Post-traumatic Growth Inventory (PTGI) (16) was applied to evaluate the post-traumatic growth level of patients, including life perception (4 items), personal strength (4 items), new possibility (3 items), relationship with others (6 items) and self-transformation (3 items). The Likert 6-level scoring method was adopted with 0–5 points from "no" to "very much", and a total score of 100 points. A higher score indicated a higher post-traumatic growth level.

Quality of Life (QOL)

The Quality of Life (QOL) scale was used to evaluate the patients from psychological function, social function, physical function and physiological function, with each scoring 100 points. A higher score denoted better QOL.

Statistical Methods

The data were processed by the professional statistical software SPSS26.0 and graphed by GraphPad Prism 7 (GraphPad Software, San Diego, USA). Enumeration data were tested by X^2 and expressed as [n (%)], while measurement data were tested by t-test and expressed as Mean ± SD. When $P < 0.05$, the differences were statistically significant.

RESULTS

Clinical Data

No obvious differences in sex ratio, times of chemotherapy, histological types and residence were observed between the two groups ($P > 0.05$) (see **Table 1**).

Immune Function Indexes

All immune function indexes were notably higher in EG than in CG ($P < 0.001$), as presented in **Table 2**.

Negative Emotions

The HAMA and HAMD scores in EG were remarkably lower compared with CG ($P < 0.05$) (see **Table 3**).

Serological Indicators

The VEGF and MMP-2 levels were markedly lower in EG than in CG ($P < 0.001$) (**Figure 1**).

Post-traumatic Growth Levels

The PTGI score in EG was notably higher when compared with CG ($P < 0.001$), as shown in **Figure 2**.

QOL

The scores of physiological function, psychological function, social function and physical function in EG were obviously higher compared with CG ($P < 0.001$), as shown in **Table 4**.

DISCUSSION

Lung cancer (LC), the most common cause of cancer death, is also an important contributor to the damage and great economic pressure (17). Though playing an important role in the clinical treatment of LC, radiotherapy and chemotherapy trigger serious side effects, such as symptoms such as fatigue, cough, shortness of breath, and decreased appetite after chemotherapy, resulting in a serious decline in QOL of patients (18). Therefore, how to reduce or alleviate the side effects of chemotherapy and enhance the QOL of patients has become an urgent problem to be solved. With the insufficient understanding of the disease, LC patients are often accompanied by serious negative emotions such as annoyance, fear and depression with the clinical manifestations of distress, reduced self-esteem and crying once they are informed of the disease (19). While seriously disturbing the

clinical treatment, these negative emotions also affect the sleep and QOL of patients. Supported by the Internet and based on the positive psychology, the network-based positive psychological nursing mode aims to alleviate the negative emotions of patients undergoing chemotherapy through the implementation of the positive psychological intervention, so as to explore their advantages, help them establish the confidence and courage to actively face the disease, alleviate negative emotions, and boost the QOL. A recent study (20) has confirmed that cognitive-behavioral therapy in network groups can effectively improve the anxiety and depression of LC patients after chemotherapy, and help patients to face treatment with a positive attitude. However, this study only discusses the psychological emotions of patients, and lacks in-depth discussions on their immune function and QOL. Elemene injection is an anti-cancer drug developed independently in China. With certain curative effects on a variety of malignant tumors, it can enhance the immune function of patients, and interfere with the synthesis of DNA and RNA in tumor cells accompanied by less effects on normal cells, which has been confirmed in tumor diseases such as malignant pleural effusion, advanced gastric cancer and esophageal cancer (21, 22). This paper discussed the effect of the network-based positive psychological nursing model combined with elemene injection on LC patients undergoing chemotherapy, and analyzed the immune indexes and serological indexes of patients, so as to clarify the clinical application value. Based on the above method, this experiment selected 90 LC patients treated with chemotherapy in our hospital as the research subjects, in which the EG group received the network-based positive psychological nursing model combined with elemene injection to analyze the effect of different treatment methods on the patients and clarify the clinical application value by comparing the immune function indexes, serological indicators and other indexes after treatment between the two groups. As shown in **Table 1**, no obvious

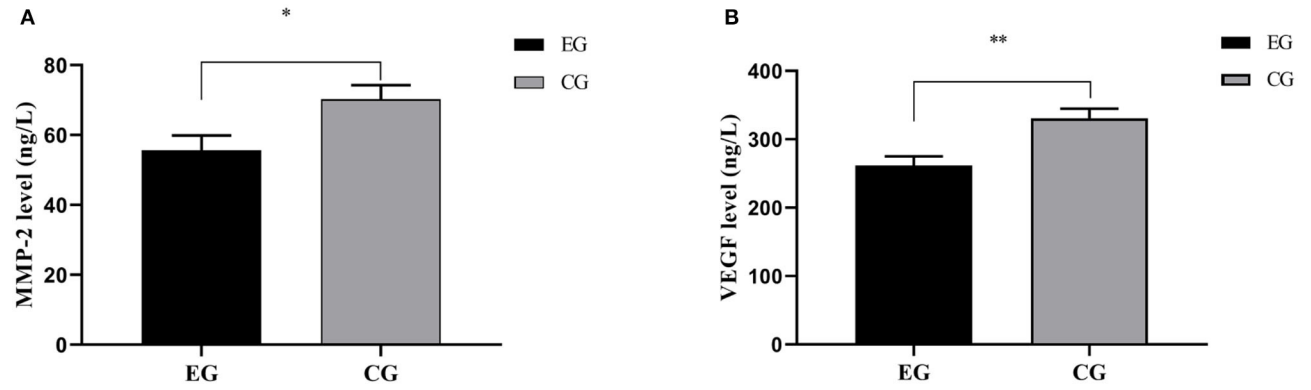

FIGURE 1 | Comparison of serological indicators [Mean ± SD]. **(A)** Comparison of MMP-2 levels. The abscissa represented EG and CG, and the ordinate represented the MMP-2 level (ng/L). The MMP-2 levels of EG and CG were (55.61 ± 4.28) ng/L and (70.27 ± 4.06) ng/L, respectively. *Indicated an obvious difference in the MMP-2 levels between the two groups ($t = 16.670$, $P < 0.001$). **(B)** Comparison of VEGF levels. The abscissa represented EG and CG, and the ordinate represented the VEGF level (ng/L). The VEGF levels of EG and CG were (261.86 ± 13.29) ng/L and (330.83 ± 14.09) ng/L, respectively. **Indicated an obvious difference in the VEGF levels between the two groups ($t = 23.887$, $P < 0.001$).

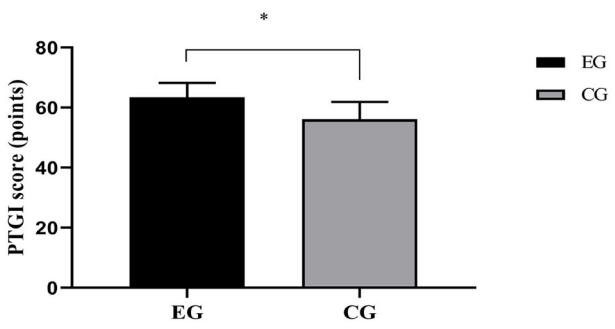

FIGURE 2 | Comparison of PTGI scores [Mean ± SD]. The abscissa represented EG and CG, and the ordinate represented the PTGI score (points). The PTGI scores of EG and CG were (63.42 ± 4.78) and (56.18 ± 5.69), respectively. *indicated a notable difference in the PTGI scores between the two groups ($t = 6.536$, $P < 0.001$).

differences in age, BMI, times of chemotherapy and histological types were observed between the two groups ($P > 0.05$), which met the requirements of clinical trials.

Under pathological conditions, activated MMP-2 can degrade the extracellular matrix components and break through the matrix barrier, leading to tumor invasion and metastasis. VEGF is a highly specific angiogenic growth factor to promote the formation of new blood vessels, which maintains a high level in many tumor diseases (23). This study showed that the VEGF and MMP-2 levels after treatment were obviously lower in EG than in CG ($P < 0.001$), suggesting that this therapeutic schedule can significantly reduce the VEGF and MMP-2 levels in LC patients undergoing chemotherapy, possibly because elemene injection with the effect of anti-angiogenesis can effectively inhibit the proliferation, invasion and migration of tumor cells (24). In terms of the improvement of negative emotions, the HAMA and HAMD scores in EG were markedly lower compared with CG ($P < 0.05$). This is because the network-based positive psychological nursing model takes individual negative psychological level as the research goal and adopts positive emotions to resist negative emotions, so as to stimulate personal potential, tap personal advantages, help patients actively face the setbacks and misfortunes, and urge them to experience the joy and success experience brought by positive actions. Therefore, their self-worth and sense of identity are enhanced to fundamentally improve the negative emotions. As for immune function and QOL, they were notably better in EG than in CG after intervention ($P < 0.001$). The reason may be that elemene injection is metabolized through the lungs and has a high concentration in lung tissues with less side effects and good tolerance in patients, which can effectively prolong the survival time and enhance the QOL of patients. These effects of elemene injection have been confirmed in the third-line treatment of advanced non-small-cell lung cancer (25). In addition, an animal experiment (26) has shown that elemene injection can improve the T lymphocyte functions of mice, and

TABLE 4 | Comparison of QOL scores [Mean ± SD].

Group	*n*	Physiological function	Psychological function	Social function	Physical function
EG	45	71.96 ± 3.75	75.44 ± 4.27	76.80 ± 4.64	77.60 ± 4.82
CG	45	67.91 ± 3.36	64.93 ± 3.14	67.82 ± 3.89	70.18 ± 4.74
t		5.396	13.302	9.949	7.363
P		<0.001	<0.001	<0.001	<0.001

enhance the antigen presentation and expression of immune-related factors. The network-based positive psychological nursing model pushes network courses about the positive psychological intervention to patients via mobile APPs, and encourages them to write gratitude logs to imperceptibly cultivate their optimistic attitude toward life, transfer the pain caused by adverse reactions of chemotherapy, and boost the QOL. Contributions: After the network-based positive psychological nursing model combined with elemene injection was applied to LC patients undergoing chemotherapy, this study was aimed to effectively alleviate the negative emotions of such patients, reduce the impact of chemotherapy on their immune function, and enhance QOL by evaluating the clinical indicators of patients after treatment. This nursing model also provides an important basis for improving the treatment confidence osf cancer patients, reflects great progress and development of clinical nursing and has comprehensive guiding significance in modern health education and clinical practice, which will undoubtedly become the future direction of medicine. However, psychological nursing based on positive psychology has not yet formed a unified operation mode, which needs to be continuously expanded and deepened. In addition, its localization research under the cultural background in China needs to be further strengthened.

CONCLUSION

In conclusion, the network-based positive psychological nursing model combined with elemene injection is a reliable method to enhance the immune function and QOL of LC patients undergoing chemotherapy. This intervention is beneficial to patients and is superior to routine nursing intervention in improving patients' negative emotions, reducing their serological indicators and enhancing their QOL, with significant effects.

Research on Diagnosis and Management of Postgraduates Mental Health Status Based on BP Neural Network

Jiangning Xie[1,2]*

[1] School of Management, Shandong University, Jinan, China, [2] Graduate School, Shandong University, Jinan, China

As a special group facing the huge pressure of study, employment, life, and other aspects, graduate students have had fierce psychological conflicts. Their mental health status has been greatly affected. Postgraduate mental health problems are related to students' normal life and study and the scientific research work during graduate study. Because of this, this paper uses the BP neural network to establish a diagnostic model for postgraduate mental health status with the dependent variables of SCL-90 psychometric test results to realize the diagnosis of postgraduate' mental health status. The accuracy of the training, validation, and test process of the BP neural network is 98.448, 97.373, 98.128%, and the overall fitting accuracy of the model is 98.273% and the prediction accuracy of graduate mental health is 97.93%. Finally, according to the mental health status of graduate students to ensure the smooth progress of scientific research during graduate students.

INTRODUCTION

The importance of postgraduate mental health is self-evident, whether to the postgraduate or the school, society, and the country. Nowadays, the pace of study, life, and postgraduate scientific research are accelerating. In addition, it is difficult to find a job after graduation, and the psychological pressure of students is increasing rapidly. In many aspects, such as daily study and scientific research, interpersonal communication, emotional life, depression, anxiety, inferiority, and other different psychological problems, which have caused a significant impact on the growth of graduate students. Therefore, attaching great importance to the mental health education of graduate students has become a critical task in graduate student training in various universities.

Research on the Mental Health of Graduate Students

Since the late 1980s, there have been more and more studies on the mental health problems of college students at home and abroad. However, most of these studies focused on the mental health status and related factors of undergraduate students, while relatively few studies on the quality of mental health in the graduate population. Research on graduate mental health can be roughly divided into two aspects. The first aspect is the causes, performance, and countermeasures of graduate student mental health problems. Ma et al. (1) investigated the mental health status and life pressure of 340 graduate students in a university. The SCL-90 results showed that the detection rate of psychological problems in graduate students was 44.16%, which explains the

prevalence of mental health problems in graduate students. Shanmuganandapala (2) also noted that nearly 25 percent of graduate students have mental health problems, such as symptoms of depression, anxiety, or seasonal affective disorders. Posselt (3) constructed a hierarchical clustering model, studied the mental health problems of nearly 20,888 graduate students in 69 universities and compared the prevalence of depression and anxiety in different research fields. The results showed that graduate students majoring in humanities, arts, and architecture have a significantly higher probability of depression and anxiety than graduate students in other majors. On the psychological status of the Chinese Academy of Chinese Medical Sciences, Wang et al. (4) found that the psychological problems of graduate students were coercion (14.02%), interpersonal disorder (7.32%), depression (8.54%), and anxiety (5.49%).

Research on Management Strategies for Graduate Mental Health Problems

Given the mental health problems of graduate students, many scholars put forward the corresponding management strategies. Among them, Huang et al. (5) discussed the impact of group counseling guided by positive psychology theory on the mental health level of graduate students. The research results show that group counseling based on positive psychology theory can improve the mental health status of graduate students, reduce their negative symptoms and perceptual stress level, and improve their self-acceptance degree. Based on the positive psychological thought, from the perspective of psychological health promotion, Liang et al. (6) constructed a four-level promotion model of graduate mental health that is based on the needs survey of graduate mental health, classification needs as the goal, promotion mode as the core, and effect evaluation as the feedback means. The results showed that good results were achieved.

To sum up, the current graduate mental health problems are mainly from the causes of mental health, the current situation of mental health education, and countermeasures. Most of these studies are theoretical, and few experts quantify the graduate mental health problems and predict their mental health problems through the relevance of the data. Because of this, this paper takes the mental health status of graduate students as the primary research line, obtains the pressure capacity of graduate students in the face of various factors through questionnaire survey, and obtains the mental health evaluation score of graduate students through the SCL-90 questionnaire. Finally, the BP neural network model with the former as the input variable and the latter as the output variable is used to diagnose and manage graduate mental health status.

QUESTIONNAIRE AND THE MODEL

Acquisition of Graduate Mental Health Data Based on Questionnaires

Questionnaire Design

For the analysis of the factors affecting graduate mental health, this paper from the social, family, school, and individual level summarizes the following 15 influencing factors such as social adaptation, social temptation, employment, future choice, new environment, economy, competition, research, interpersonal communication, scientific research, others, parents expectations, family background, character defects, conflict of interest. According to the 15 factors that affect graduate psychology, the questionnaire is formulated as follows (**Table 1** is the main content of the questionnaire):

Self-Testing of Graduate Mental Health Based on the Self-Rated Scale of the SCL-90 Test

Symptoms Self-evaluation Scale SCL-90 (7–9) is one of the world's most famous psychological test scales. It is widely used in consultation clinics or hospitals to understand the psychological situation of the patients or patients. It can also evaluate the efficacy of the evolution of the condition before and after consultation. This scale consists of 90 items, including feeling, emotion, thinking, consciousness, behavior, living habits, interpersonal relationship, diet, and sleep, and nine factors are used to reflect nine aspects of psychological symptoms. The S-Assessment Scale SCL-90 judged the mental health status.

The Neural Network Model

An neural network model consists of some nodes/neurons, set at multiple layers: the input layer, one or more hidden layers and the output layer. Each node/neuron has an activation function, which calculates how much neuron is "stimulated" (10, 11). At each layer, the collections of nodes/neurons transform the input parameters; these parameters are distributed to the next layer, which is described as (1), (2) and (3):

$$z_j^n = \sum (w_{ji}^{(1)} x^{n-1} i + w_{j0}^{(1)}) \tag{1}$$

$$a_1^n = \sum (w_{ij}^{(2)} z^{n-1} i + w_{10}^{(2)}) \tag{2}$$

$$y_1^n = F(a_1^n) \tag{3}$$

Where x represents the input to the first layer; z represents the first layer's output; i, j represents the neural network node index; $w_{ji}{}^{(l)}$ represents the weight between the jth node in the ith layer and the ith node in the $(i + 1)$th layer; $F(a_i^n)$ represents the output value of ith node in $(n + 1)$th layer after being activated by the activation function; w and w_0 represent the weight and bias between the neurons, which measures the significance of the data passed along the link (synapse). $F(a)$ employs the activation function, which employes the hidden layer's aggregated output to calculate output y.

The initial weights and biases randomly assigned, the training process continues until the desired output is obtained, which is evaluated by the cost function (4):

$$Ew = \frac{1}{2} \sum_{k=1}^{K} y(x_k, w_k) - t_k^2 \tag{4}$$

TABLE 1 | Main contents of the questionnaire.

	Influence factor	Importance and self-assessment					
1	With the rapid development of today's society, the conflict between modern ideas and traditional ideas, and the differences between positive ideological education and popular secular views, make it difficult for you to adapt to society. For the pressure to adapt to society, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
2	In today's social society, harmful social phenomena such as value loss and moral decline, and irrational thoughts and behaviors such as hedonism, money worship, and extreme individualism affect others all the time. Do you feel about the pressure of resisting social temptation?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
3	With the introduction of competition mechanisms, enterprises have higher and higher requirements for the first degree of graduate students. Facing the pressure of employment, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
4	In the face of the reform of the personnel system of social institutions, society has put forward more stringent employment standards to graduate students. With the expansion of graduate student enrollment, the gold content of master's graduate students has become lower and lower, and the employment pressure is becoming greater and greater. Many students face difficult choices in doctoral study and employment. Do you feel about the pressure on this choice?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
5	Entering the environment, everything needs to adapt again, leaving their parents to live alone. Some students even leave their city to come to a strange town, facing the pressure caused by such environmental changes, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
6	With the rising prices and the continuous expenditure of various expenses during the graduate years, do you feel about the economic pressure?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
7	Graduate students are talents selected by the university. They are all talents with excellent academic performance in the class. After coming to graduate school, they come to a new competition stage, and almost everyone has the same starting point of competition. In the face of this competitive pressure, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
8	Facing the triple pressure of graduate scientific research, study, and tutor, do you feel too burdened? Secondly, there is a graduate school, the examination of various qualification certificates, etc. In the face of this learning pressure, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
9	The students come from different regions, with different political and cultural backgrounds and personal habits, especially those in the dormitory. Due to regional differences, there will inevitably be friction in the process of getting along. In the face of these interpersonal pressures, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
10	The postgraduate period is the enlightenment stage of scientific research. Much scientific research work is not conducted during the university. Do you feel about the pressure of facing new knowledge and new fields?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
11	For students with excellent performance and outstanding performance, it is easy to get various awards from the school, such as scholarships, exceptional student honor, etc., which will inevitably be envied by other students and thoughtfully calculated by others. In the face of these pressures, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
12	For graduate students, they are all the pride of their parents. Many parents let their children prepare to go abroad, study a doctoral study and seek a high salary job in advance. Are they facing the pressure of their parents' strong expectations?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
13	Each student has a different family background. Those students with ordinary family conditions hope to graduate as soon as possible, work hard, and earn money to support the family. Some families even give up the idea of studying because of financial problems. Do you feel about the pressure of family economic conditions?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee

(Continued)

TABLE 1 | Continued

	Influence factor	Importance and self-assessment					
14	People will inevitably have personality, cowardice, inferiority, withdrawn, narrow, impulsive, irritable, self-centered nature will be reflected in the individual. This kind of personality is often challenging to get along with others. Do you feel about the interpersonal pressure caused by personality defects?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee
15	There is inevitable friction between students, but many students tend to take themselves as the center, think that others have to consider themselves, especially when they cannot meet their expectations in the psychological imbalance, in the face of the pressure caused by this conflict of interest, do you feel?	Score	A	B	C	D	E
		Evaluation	Giant	Big	Normal	Small	Wee

459	1	4	1	2	5	2	3	4	1	2	5	5	5	5	5	176
460	5	2	1	5	5	5	1	5	1	4	3	3	2	4	3	169.6
461	5	1	3	4	4	5	1	2	3	1	1	4	5	4	5	156.8

Where y represents the output; t represents the desired output, w represent the weight, Levenberg–Marquardt (LM) algorithm is utilized in the neural network training process, which is a variation of gradient descent. The weight and bias of the neural network model are changed during the training process to minimize the error, which is described as function (5):

$$w^n = w^{n-1} - \left(J^T J + \mu I\right)^{-1} J e^{n-1} \tag{5}$$

Where $J=\frac{\partial E}{\partial w}$represents the full-scale Jacobian matrix related to w; I represents the identity matrix; m represents a combination coefficient; e represents the prediction error.

The Levenberg–Marquardt algorithm starts with a forward computation by (1), (2) and (3). The prediction errors of the output layer and the hidden layer are calculated by (6), (7) and (8):

$$e^{(3)} = y_1 - t \tag{6}$$

$$\delta_1^3 = e_1^3 \tag{7}$$

$$\delta_j^2 = w_{1j}\delta_1^3 \tag{8}$$

As shown in function (9) and function (10), the Jacobian is calculated by a back-propagation process:

$$\frac{\partial E}{\partial w_{ji}} = \delta_j^{(2)} x_i \tag{9}$$

$$\frac{\partial E}{\partial w_{1j}} = \delta_1^3 z_j \tag{10}$$

In the training process of the sample, the learning sample should be processed to make it fluctuate in a certain range. The normalization method is adopted in this paper to process the data to ensure that the data is between 0 and 1, which is written as (11):

$$x_i = \frac{\bar{x}_i - x_{\min}}{x_{\max} - x_{\min}} \tag{11}$$

Where $\bar{x}_i$ represents the average value, $x_{\max}$ represents the maximum value, $x_{\min}$ represents the minimum value.

RESULTS AND DISCUSSION

Questionnaire Results Statistics

The respondents of this questionnaire are 500 graduate students coming from different schools and majors. Five hundred questionnaires were sent out, 487 were recovered, and 461 were valid questionnaires, with an efficiency of 92.2%. For the 15 questions in the questionnaire, options A-E correspond to 1–5 points, respectively, and a higher total score indicates more significant psychological stress. The questions 1–15 and the corresponding SCL90 scores are shown in **Table 2** (partial results).

Attention

According to the score standard of SCL90, the total score is more than 160, should be further examination, the standard is more than 200 points that there are obvious psychological problems, can turn to psychological counseling, more than 250 is more serious, need a detailed medical examination, is likely to do targeted psychological treatment or take medicine under the guidance of a doctor.

Graduate Student Mental Health Diagnosis Model Establishment

Fifteen factors affecting graduate psychology were used as independent variables based on the above questionnaire. The corresponding SCL-90 mental health diagnosis scores were dependent variables to establish the BP neural network model. The data for the training model has randomly selected 400 sets, with 80% training set, 20% test set, and 20% validation set. The remaining 61 sets of data were control groups, and the error between the SCL-90 score and the actual SCL-90 score was analyzed to verify the model's utility (12).

The training procedure of this model is shown in **Figure 1**.

The training process of the BP neural network model is shown in **Figure 1A** and improves the above neural network configuration. The regression model is initialized in the training process, with the ideal error convergence rate in step 40. **Figure 1B** shows that high fitting accuracy is obtained after the training process. Then, the accuracy of the training, validation, and test process is 98.448, 97.373, 98.128%, and the overall fitting accuracy of the model is 98.273%. The model's accuracy is high, especially in the test, where the predicted values of the output parameters are close to the reference value. Results show that the relationship between the input and output parameters is modeled correctly. Further prediction/estimation is reliable. Moreover, the error histogram of the model is shown in **Figure 1C**. For all models, 20 bins are distributed according to Gaussian rules, proving the representativeness of the training data.

Application of the Graduate Mental Health Diagnostic Model

By establishing the BP neural network model, the mental health of the remaining 61 students was diagnosed, and the questionnaire results of these 61 students were input into the prediction model to obtain the following output results and

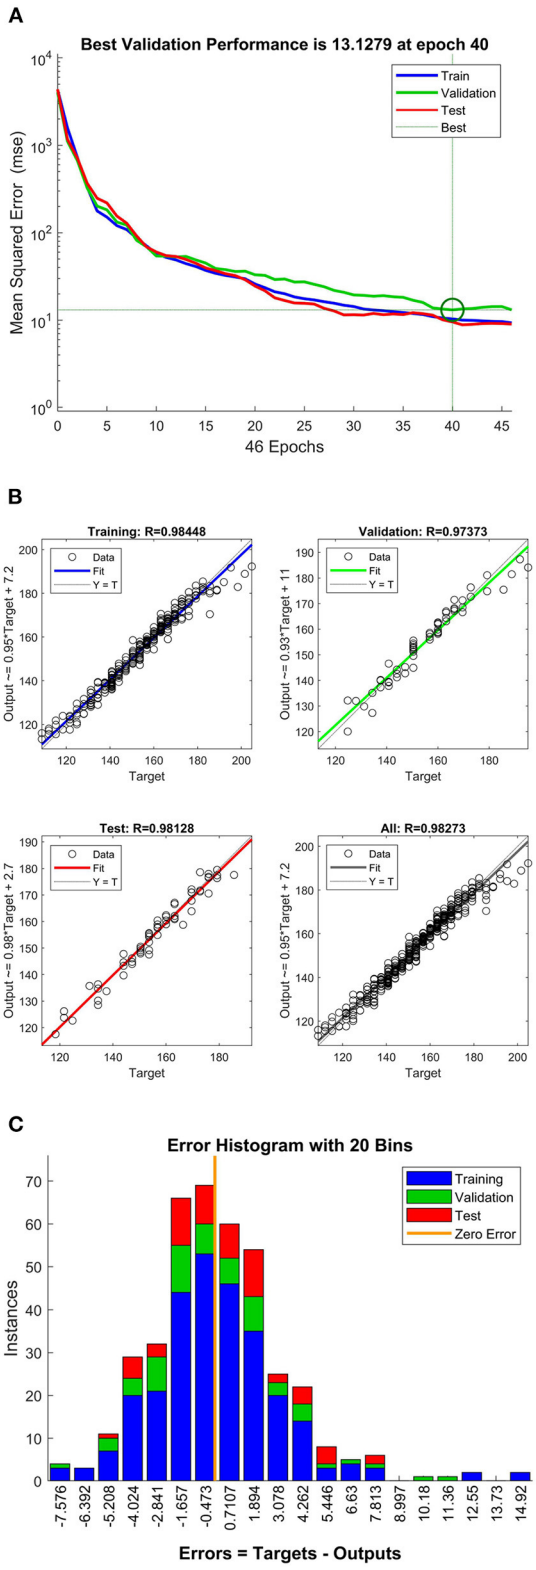

FIGURE 1 | Training process of the model; **(A)** convergence characteristics; **(B)** regression performance of the model; **(C)** error histogram of the model.

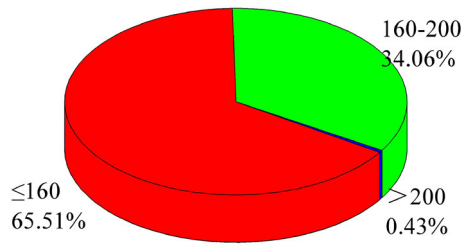

FIGURE 2 | Statistics of mental health scores for graduate students. Data source: Author organizes.

compare the output results to the actual results of SCL-90, as shown in **Table 3**.

As shown in **Table 2**, the trained diagnosis model achieved an excellent diagnostic effect in practical application. The overall accuracy reached 97.93%, an average error of 2.07%. Among them, the largest diagnostic error of 7.10%, through the above analysis, it can be seen that the mental health diagnosis model in practice or has very high practical value, the judgment of students with psychological problems is more accurate, achieved the expected effect.

Management of Graduate Mental Health Problems

Figure 2 shows the mental health diagnosis scores of the 461 graduate students in this survey. As shown in **Figure 2**, 34.06% of graduate students had mild psychological problems in the survey results, and 0.43% had obvious psychological problems. Still, they could be solved through psychological counseling. No students in this survey scored more than 250 points, indicating that the surveyed graduate students could solve their psychological problems through positive guidance methods such as psychological counseling.

It can be seen from this survey that the psychological problems of graduate students are common, but they can be solved through positive guidance.

Given the above analysis, this paper proposes the management strategy of graduate psychological problems:

(1) Improve the tutor responsibility system

During graduate school, the relationship between tutor and graduate student is the most important interpersonal relationship. In the training process of graduate students, the communication between tutors and graduate students is the closest. Attention should be paid to building an excellent psychological contract between "mentor and graduate students." Colleges and universities should improve the tutor responsibility system, give full play to the guiding role of tutors, and clarify the importance of tutors for enhancing the comprehensive ability of graduate students. Graduate tutors should always be strict with themselves in teachers' ethics, set an example in scientific research work, and abide by the principle of integrity.

The tutor has a subtle influence on students 'mental health problems in scientific research and life. The tutor's guidance

and evaluation will directly affect the self-efficacy of graduate students. Sometimes the tutor's sentence can greatly encourage students' enthusiasm for scientific research. When students encounter scientific research problems, they should give timely guidance. When students have mastered the experimental techniques and principles in the field, they should lead students to study the significant cutting-edge problems in the area appropriately.

Due to the expansion of graduate enrollment, the number of tutors increases, so it is difficult to consider all graduate students. In order to improve the quality of graduate training, the relevant departments can appropriately control the number of students. According to relevant surveys, some tutors use the "free-range" mode for graduate students and meet less often, so it is difficult to timely understand the students' scientific research status in time, it is difficult for students to get reasonable guidance, and it is easy to cause too much pressure on scientific research. So suggest tutor according to their own and team, appropriate increase for graduate research guidance and humanistic care time, can be through group form, once a week or once every 2 weeks, timely understand everyone's scientific research and life situation, give full play to the mentor lead and research guidance, create a good relationship between teachers and students, reasonable reduce and avoid graduate mental health level, reduce or relieve the pressure of medical graduate research.

Due to the expansion of graduate enrollment, the number of tutors increases, so it is difficult to consider all graduate students. To improve the quality of graduate training, the relevant departments can appropriately control the number of students. According to relevant surveys, some tutors use the "free-range" mode for graduate students and meet less often. So it isn't easy to understand the students' scientific research status in time timely. It is difficult for students to get appropriate guidance, and it is easy to cause too much pressure on scientific research. Therefore, according to their situation and the research group, the tutors can appropriately increase the time of scientific research guidance and humanistic care for graduate students. They can timely understand everyone's scientific research and life situation and give full play to the role of the tutors in the guidance and scientific research guidance. Finally, it will create a good teacher-student relationship, reasonably reduce and avoid the low level of mental health of graduate students, and reduce or relieve the scientific research pressure of medical graduate students.

(2) Strengthen the mental health education in colleges and universities

Graduate mental health education is crucial in the graduate training stage. We should start from the actual situation of mental health education in colleges and universities to strengthen the mental health education of graduate students and effectively help postgraduate students to relieve psychological pressure. Colleges and universities can establish mental health counseling rooms or online consultation topics by psychological doctors. Graduate students can timely solve their problems in life and scientific research and prevent them from deteriorating into psychological issues.

(3) Increase the scientific research support for graduate students

The generation of scientific research results is inseparable from the support of universities for scientific research work. Therefore, to reduce the pressure of students in scientific research, the schools need to provide vital support in the foundation of scientific research. According to the research subject direction of the institute, each department buys perfect public scientific research facilities so that students can obtain scientific research results through experiments and reduce their burden on scientific research.

(4) Counselors actively carry out psychological counseling work

College counselors are a high-quality team with strong combat effectiveness. They should give full play to the role of counselors and strengthen the attention of graduate students. College counselors should pay attention to graduate mental health education. As a healthy vulnerable group, their mental health level is generally low. Female graduate students have delicate and rich feelings, are sensitive to any stimulation, have a changeable mood, have relatively fragile psychology, and are prone to dependence, inferiority, depression, and other psychological problems. Therefore, counselors should pay attention to the mental health of graduate students, especially the mental health of female graduate students, including family situations and love situations. Counselors can set up a mutual aid group for graduate students to fully play the exemplary role of senior teachers and senior brothers.

CONCLUSION

Under the background of graduate mental health tension, through the study of the graduate mental health factors, and based on design graduate mental health evaluation questionnaire and SCL-90 mental health evaluation, using the BP neural network model to graduate mental health diagnosis, and verify the feasibility of the diagnostic model. After the final model validation, the prediction accuracy of graduate mental health is 97.93%, which indicates that the mental health diagnostic model established in this paper can evaluate reasonably the mental health status and is feasible.

Social Intervention and Governance of Youth School Bullying—Based on Computer Medical Data Analysis

*Jiahui Zhao**

School of Government, Shanghai University of Political Science and Law, Shanghai, China

The rise of computational social science provides a new method for campus bullying research based on large-scale data collection, calculation and analysis. Governing the bullying behavior of a middle school through social intervention, and closely observe the service needs and existing problems of the school youth group. This paper analyzes the characteristics, inducements and negative effects of school bullying. Combine drama courses and working group education methods to intervene in school bullying. Intervention work includes making teenagers aware of bullying behavior and identifying bullying types. To achieve the purpose of empathy through role play, bullies can effectively control irrational thoughts, understand their own cognitive biases, and reconcile their own emotions and behaviors. So that the victims can identify the bullying behavior around them in time, and cultivate their resistance and self-protection awareness in the event of bullying. Based on the empirical analysis of social work to intervene in the practical dilemma, and put forward the corresponding countermeasures to reduce the negative impact of school bullying on all aspects of youth, so as to reduce the various social risks brought by school bullying.

INTRODUCTION

At present, campus bullying is common. Campus bullying is a kind of behavior that intentionally injures the personal and property safety of others, including beating, intimidating, cursing, isolating, controlling, insulting, laughing and so on. Rodríguez-Muoz et al. (1) investigated the phenomenon of bullying in local primary and secondary schools. After in-depth analysis, he believes that intimidation is the main manifestation of bullying behavior among teenagers in school. Bullying is a behavior that continuously harms others. Due to the imbalance of social and physical and mental strength between the victim and the abuser, the victim suffers long-term and continuous harm in the process of bullying (1, 2).

In terms of school bullying (2), stated that bullying means that "in the same group, the powerful party uses words and behaviors to intentionally bring physical and mental stress and harm to the vulnerable group members". Japan's education ministry in the early 1990s defined bullying as "unilateral, sustained physical and mental attacks that can cause great pain to others".

Park et al. (3) points out that "Bullying is a pervasive aggressive behavior. This behavior is often characterized by threatening or intimidating others." Webb et al. (4) believes that school bullying refers to the intentional and violent assault, including physical and psychological assault, on others by means of beating, harassment, isolation and

other means. According to Ran et al. (5), campus bullying refers to the continuous bullying of the strong against the weak and the large group against the small group in the campus, which is in conflict with or directly related to the high school students (3, 4).

According to the above literature description, it is not difficult to find that although there is no unified definition of school bullying, it can directly or indirectly reflect the asymmetry of power between the bully and the bullied. Carreira et al. (6) believes that bullying is a common social phenomenon with the characteristics of concealment, diversity, repetition, imbalance, universality and indistinguishable (5). Georgiou et al. (7) believes that bullying is characterized by diverse forms, violent behavior, fragile object and extensive influence (8).

To effective governance adolescent bullying behavior, improve the adolescent bullying phenomenon, at the middle school has carried on the empirical research, this paper adopts the social work intervention combined with drama class, effectively improve the middle school campus bullying problems, and analyze the intervention of social work practice difficulties, some countermeasures are put forward. Finally, it provides references for enriching bullying-related theories. The research on campus bullying in my country started late and the pace is slow, the literature is not concentrated and the understanding is not comprehensive, and most of them are analyzed and studied from the perspective of psychology and sociology. This research adopts practical investigation, analyzes the situation and influencing factors of the problem with the help of theoretical tools, and tries to put forward strategies of management, implementation and guarantee for the prevention and treatment of school bullying from the perspective of pedagogy theoretical research.

STUDENT GROUP NEEDS AND SOCIAL WORK INTERVENTION METHODS

The Needs of Student Groups in the Context of School Bullying

In recent years, the incidents of campus violence have been frequent, which has aroused widespread concern in the society (9, 10). The Office of the Education Supervisory Commission of the State Council issued a special action plan on cracking down on school bullying in May 2018, calling for a severe crackdown on intentional intimidation and bullying by primary and middle school students using physical, verbal and online technology. In addition, a survey on the harmonious situation of teenagers in 10 middle schools in a certain area was conducted. The self-reported bullying rate was 22.3%, the self-tested bullying rate was 13.8 and 33.5% of students said they had witnessed bullying, indicating that it was more serious (11, 12). School bullies seem to be everywhere, and they have different degrees of influence on the growth of teenagers. Even the "mass psychology" of bullying leads children to use similar solutions and imitate the bully to behave in unsafe ways. It threatens the physical and mental development of primary and middle school students. On this basis, the author believes that it is necessary to teach the bully and the victim to express their thoughts from the perspective of emotional control, irrational expression and control, replace violence with correct expression, help the bully and the victim to establish a good relationship, and ultimately reduce the occurrence of bullying (13, 14).

Working at a social workstation in a middle school, I got to know the details of the middle school as follows: Grade 7 was divided into 6 classes with 260 students, Grade 8 was divided into 8 classes with 340 students, Grade 9 was divided into 8 classes with 240 students. The school provides educational resources not only for registered students, but also for children of migrant workers with excellent academic performance. So the students come from different sources (15, 16). The ratio of family enrolments to migrant students is currently about 6:4. In addition, classes will be arranged for students, including those with learning disabilities and disabilities, in a number of classrooms.

Through questionnaires and observations, social workers have found that different groups in schools will need different services by 2019–2020. Group service and demand analysis are shown in **Tables 1**, **2**.

This suggests that eighth-graders, students on loan and students with different behaviors are more likely to have school bullying (17, 18). Without further research, the author reached a consensus with the school to organize eighth grade students to participate in street campus bullying exhibition and campus bullying prevention drama working group, so as to help control campus bullying and create a harmonious campus.

Combined with the results of the unstructured interview, it is concluded that there are both bullies and victims in the working group. Most of them have four problems. Problem 1: Bullies, victims, and bystanders do not recognize that some of the actions they are dealing with are bullying, and do not know how to deal with bullying. Problem 2: At the family level, there are problems such as poor family communication, inadequate family structure, lack of care or inappropriate parenting methods, which are all factors that lead to violent behavior. Bullies often believe that their parents do not understand them, there is a lack of communication and a generation gap. The families of the victims lack communication, they don't like to talk at home, so the parents can't observe the inner changes of the children. Problem 3: In school, teachers tend to pay more attention to students who are good in grades and obedient. Bullies often think that teachers always take themselves as targets or negative teaching materials, so they don't listen to the teacher's orders, and arouse the teacher's attention and recognition by singing the opposite. Problem four: in interpersonal relationships, bullies and victims cannot find intimate friends, they are low self-esteem, lack of confidence. Cowardly and cowardly students are often bullied and ostracized; Students who bully others often hope to establish their status through violence. Bullies believe that power makes people obedient, afraid, safe, and valued. So, the members of the task force have several requirements: First, be aware of bullying. Secondly, it is necessary to understand interpersonal relationships and interpersonal communication skills. The second is to learn how to prevent school bullying and how to protect yourself when it happens (19, 20).

TABLE 1 | Group services and demand analysis.

Group	Demand
Seventh grade students	1. Environmental adaptation needs: freshmen in the seventh grade cannot adapt to the middle school life due to the changes in learning content, work and rest rules and campus environment. 2. Running-in needs for interpersonal communication: Because teenagers are in a special stage of growth and development, belonging to the running in period of self and society, their hearts are more sensitive, it is difficult to integrate into the collective and establish a stable interpersonal relationship with classmates. 3. Adolescent attention needs: Grade 7 students are in a critical period of physical and psychological development, which can also be called the rebellious period. During this period, great changes occur in body and mind, which requires more attention from parents and teachers.
Eighth grade students	1. Running-in needs of interpersonal communication: Grade 8 students have not left the growth and development period of teenagers, so it is difficult for them to integrate into the group and establish a stable interpersonal relationship with their classmates, and some bullying behaviors may occur. 2. Adolescent Guidance Needs: Grade 8 students have adapted to their physical and mental changes during adolescence. However, due to their ignorance of the opposite sex, they tend to have puppy love or stay away from the opposite sex. 3. Learning objective planning needs: Due to the physical and mental changes, the eighth grade students' attention is easy to be shifted, it is difficult to focus on learning, lack of learning goals and learning motivation, so they can not keep up with the curriculum, resulting in inferiority complex.
Ninth grade students	Planning of learning direction: Grade 9 students have initially formed an independent personality. Due to the change of puberty, students are focusing on interpersonal relationship, which leads to their loss of learning goals and motivation, and they have no specific plan for future study.

TABLE 2 | Special group services and needs analysis.

Group	Demand
Students	1. Adapting Habits: As the student still has the habits brought by the former campus and interpersonal environment, these habits may be in conflict with the habits of the students in the current campus, such as hygiene habits, work and rest rules, dialect, etc., which hinders the student's integration and adaptation in the new environment. 2. The need to enhance family attention: due to the changes of study and interpersonal environment, students are more sensitive and prone to inferiority, so parents need to pay more attention to the changes. 3. The need for acceptance among classmates: due to the changes in the new environment, students hope to make new friends as soon as possible and keep up with the new pace of study, so they need to be accepted by classmates.
Poor students	1. Increase the need for self-confidence: due to the lack of economic conditions, poor students are very likely to have a sense of inferiority, or extreme conceit. 2. Material needs: Compared with other types of student groups, poor students lack material conditions more. They need basic material conditions from their families to reduce the gap between them and their classmates.
Students with different behaviors	1. Constraint and guidance needs: Because parents and teachers do not pay attention to students' different behaviors, students do not know that some of their behaviors are wrong, resulting in students' cognitive and behavioral bias. 2. The need to be tolerated: because their individual behaviors are not understood, other students will label them, and even discriminate against and misinterpret them. Therefore, such students need to be treated with tolerance.

Purpose and Method of Social Work Intervention

Recruit bullies and victims of bullying and use professional social work tools to intervene in bullying and violence incidents. To understand the psychological needs of students, give appropriate treatment, so as to achieve better results, improve the extreme psychology of bullies, so that they reduce aggressive behavior. Develop the victim's confidence in the outside world so that he or she can seek help when confronted with bullying problems (21, 22). A good campus environment helps to correct students' personal behavior, so the construction of a "harmonious campus" environment can enable students to receive good education, so that students have normal interpersonal relations, conducive to the overall development of body and mind.

The use of social work intervention to deal with campus bullying is the main way of social work. The form of social work intervention can promote the working group and its members to achieve their needs, so that students can accelerate their own social transformation through working group. Coordinate and develop interpersonal relationships between individuals and working groups; So as to play the social functions of organizations and groups, improve the social psychology of bullying and victims, so that they can get a sense of social identity and belonging. After establishing a clear goal, team members can help each other and collectively obtain more resources. It makes the members of the working group actively communicate, understand each other, have the courage to take responsibility and get treatment in the mutual cooperation, so as

to promote positive changes in the attitude and behavior of the team members (23, 24).

The working group always adopts the way of role play. Role-playing is to understand a variety of behavior habits and norms in the society by playing the role of others, learn to understand the psychological activities and behavior content of others, and finally realize the social transformation of team members. By playing different interpersonal roles, we can gain insight into the positions and psychological activities of the roles we play. In the process of empathy, we can get a better way to deal with campus bullying and interpersonal relationship.

Drama courses are also the basis for social work interventions. Through the drama course, the working group realized the interpretation and correction of school bullying. Drama courses should not only learn the knowledge and interpretation skills of drama, but also enable students to understand the society, think about life, control behavior and protect themselves through drama. Drama course is to introduce drama activities into the field of education and use drama background to achieve educational purposes.

The purpose of drama course in social work intervention is to change the common phenomenon of campus bullying. So that the bully can understand the hurt of the bully through scene modeling, role playing and other methods, and make the bully brave to ask for help when hurt.

ANALYSIS OF SCHOOL BULLYING BEHAVIOR

Characteristics of School Bullying Behavior

Bullying is not an occasional argument or fight. It is an unfair behavior where one party constantly puts pressure on the other. Whether the bystander, the bully or the bullied, campus bullying will bring profound physical and mental harm. In recent years, there have been media reports of "a dispute case concerning the right to health accepted by a certain court". Some junior high school girls beat up another girl, leaving her handicapped. The incident started when the victim did not pay attention to personal hygiene during school, which caused hostility from other female students in the dormitory. Five schoolgirls slapped her in the face to "educate" her, resulting in a grade 10 disability.

After finishing the junior high school Chinese test, 16-year-old Xiao Huang endured great pain and continued to take the senior high school entrance examination. For 4 years, he kept a secret from his parents: Starting in the fifth grade, he was regularly caught in "unprovoked attacks" by several other students. This kind of school bullying is not uncommon in the media.

A simple message can tell us that bullying is insidious, persistent and communal. School violence is frequent and hidden. Bullying often takes place out of the reach of teachers and parents. For example, dormitory and toilet, whose daily use is relatively private, it is hard to be found by others. Many victims have been bullied for years but do not have the courage to ask their parents and teachers for help. This cowardice makes the bully more aggressive, less moral, and more stubborn. School bullying has a fixed pattern, that is, victims are always bullied; Bullying is not an individual act. It occurs in small groups and groups. They have similar characters and imitate each other in their actions. Bullying behavior is a group behavior formed by a person under multiple individual pressures.

Causes of School Bullying

Middle school students are in a critical stage of physical and mental development, they often do not have enough experience to deal with problems harmoniously, and they cannot empathize with others. So the way they deal with some of these problems is to emulate other students. Personality traits also play an important role in bullying behavior. Bullies generally have strong personalities and need external recognition and "face saving". They believe that bullying can make them stronger and save face more. Bullies are introverted and timid. They dare not ask for help when being bullied. They can only swallow their pride and become the objects of long-term bullying. There are also some victims of bullying who have birth defects or bad habits. They are often mocked and insulted, but their innate condition makes them unable to resist.

Bullying is not only a personal problem for students, family relationships are also an important cause of school bullying. Every family has a different way of raising children. Some parents do not care about their children's life and psychological state, lack of guidance and education for children's growth, resulting in the lack of correct supervision and guidance of children's behavior, it is easy to lead to bullying behavior; In some families there is tension and parents often scold their children. This leads to a lack of security and the belief that violence is the only way to solve the problem. Lead to bullying behavior to solve conflicts with peers; In some families, the parents are very bossy and don't care about the inner needs of the children. They only demand obedience and obedience from the children. The child who receives this kind of family education will become weak, self-abased, unsociable, etc., and the child will often become the object of bullying. Therefore, the family relationship and parents' education style will decide the child's growth performance (25, 26).

The school environment, as the cradle of children's education and growth, is another factor that leads to bullying behavior. The strict management mechanism of the school will greatly restrict the bad behavior of the school, so that good communication between teachers and students is not only the responsibility of teachers, but also an important condition for students to grow up. To enhance teachers' sense of mission in education, make them pay attention to students' academic performance and psychological state, so as to reduce students' bullying behavior. Or when bullying behavior occurs, teachers can perform their duties, effectively curb the continuation of bullying behavior, communicate with parents in time, and do a good job in family work between the bully and the bullied, so as to solve the problem of bullying on campus from the root.

The Negative Effects of School Bullying

The primary problem of school bullying is that the victim is physically bullied. These include beating, shoving and other acts that may cause physical injury to the victim. Because trauma is especially easy to spot, it's also easy for the media to see physical

bullying. Because bullies fear that the outside world will find out about their bad behavior, they choose to beat their victims by avoiding obvious places, such as the face and limbs. Most of the victims have wounds in the abdomen and lower body, leaving internal wounds that are hard to see outside. The health of the victims has been greatly affected.

Moreover, the victims have suffered irreparable psychological trauma. Bullies have been abused, beaten and teased for a long time. Because of the imbalance of power, he will endure hidden psychological pressure and pain for a long time, which will lead to the formation of a pessimistic personality, negative, cowardly and fearful character, not only difficult to maintain their studies, they often fear in life, do not know how to live, do not know how to get along with others. Some victims of intolerance turn to extreme behaviors, such as suicide or self-harm, which can have a devastating effect on their mental health and development. Bullies, on the other hand, usually have poor grades and are "face-saving", and they use violence to prove their authority. In addition to forming "cliques" among their peers, they also have difficulty communicating with others and often threaten vulnerable groups with violence. It is easy to break the law and crime after becoming an adult, which has a negative impact on social development.

SOCIAL WORK INTERVENTION

Working Group Intervention Objectives

The overall goal of the task force's intervention was to reduce the irrational thinking and behavior of bullying participants through drama lessons and role-playing, to develop a more comprehensive understanding of bullying, and to identify appropriate skills to deal with bullying. Establish good interpersonal relationship and promote campus harmony.

The phased objectives of the intervention by the working group are as follows: firstly, to improve the students' overall awareness of school bullying, so that the working group members can understand the concept, types, hazards and manifestations of school bullying. The second is to change the irrational thinking of bullies, break through the communication barriers between bullies and teachers, parents and classmates, learn interpersonal communication skills, and establish a good interpersonal relationship. The third is to enable the victims of bullying in the group to learn not to let others hurt them, let the bullies know that they have the ability to control their own aggressive behavior, and promote them to establish the values of helping others and harmonious progress together.

Working Group Intervention

Working Group Name: "Peace Elite" Campus Drama Curriculum Working Group

Intervention period: 2:00–4:00 p.m. every Wednesday from March to June 2020

Number of activity classes: 6

Duration: 120 min per session

Group size: 6 people

(1) Section 1: Establishment of working group relationship. See **Table 3** for details.

The first drama course is the first step in the development of social work, marking the initial stage of social work intervention in the treatment of school bullying. Since the working group has just been set up and the members are not familiar with each other, the social workers will choose sand tools and sand paintings to let the members show themselves and get to know each other, and to create an atmosphere of mutual trust and ease in the group. Understand and interact with team members on their work goals and expectations to increase their participation and sense of belonging.

Course summary: After the social worker introduced himself first, some team members were gradually led to introduce themselves, but some team members did not adapt to the team atmosphere, and their performance was relatively cold. Working groups should start with ice-breaking sessions so that members can interact more and have more opportunities to get to know each other. The members of the later working group have reached the stage of mutual understanding, and have a certain impetus to the working group, from which the cohesion gradually formed. After that, the communication and motivation between team members will be further strengthened through role playing.

(2) Section 2: How to identify school bullying. See **Table 4** for details.

Course Analysis: As the second stage of social work intervention, this course solves the problem of members' lack of participation and unity in the early stage of working group construction through the ice breaking link. At the same time, in order to make the team members know more about campus bullying, the working group should also be responsible for organizing the interaction and questioning among the team members, and explaining the relationship between drama course and campus bullying for the team members. It is also necessary for the members of the group of social work organizations to watch the film, share their impressions and encourage them to express their views through sharing. And in the process of watching the film, the freeze frame screen specifically analyzes the specific types of campus bullying, so that the students participating in the working group can better understand the knowledge of campus bullying. The second section of the course reduces the resistance of group members to the intervention of social work, and the internal vitality of the working group increases with the deepening of the course, gradually forming cohesion (27, 28).

Course Summary: Compared with the first working group course, in the process of carrying out the second course, the team members have eliminated the formality and constraints. Therefore, compared with the first course, this course has been recognized by more team members, and the interaction within the group is gradually frequent. At the beginning of the course, participants were not very active, but when the social worker shared the meeting, participants were attracted; When watching the video, I was very focused. After watching the film, the group members can enthusiastically discuss its content. So the social worker must personally instruct the team members,

TABLE 3 | Working group activities and establishment of group relations.

Number of sessions	Working group objective/working group activities content	Material
Section I	Working group goal: the team members are familiar with each other, understand each other, establish the working group goal. 1. Introduction to staff and members 2. Use sand table and sand painting activities to organize group members' internal interaction and improve group members' sense of identity. 3. Determine the activity content and stage goal of the working group, and obtain the expected effect of the team members on the working group. 4. Establish the contract of the working group and the implementation standard of the activity 5. Notice in the next section.	Sand table, white paper, marker pen, sand ware

TABLE 4 | Campus bullying identification course.

Number of sections	Working group objective/working group activities content	Material
Section 2	Working group goal: To enable all team members to identify what constitutes bullying and to distinguish the types of bullying. 1. The warm-up game: Who's undercover 2. Discuss in pairs, put forward what you think about school bullying, and share your understanding of drama courses. 3. Play the school bullying movie "Teenage You", share your impressions and introduce the bullying knowledge in it. 4. Pause some scenes in the movie, and analyze the type characteristics of such bullying behaviors. 5. Summary speech and the next section notice.	Stool

prepare more cases to share with them, and use multimedia to attract them into the team. Second, members of the working group responded strongly to the video and could easily ask or answer other less relevant questions during the discussion. In this lesson, due to the divergent thinking of middle school students, it is necessary to bring the subject of the course back to the issue of school bullying in time when the course is off topic.

(3) Section 3 Working Group: To recognize their own irrational thoughts. See **Table 5** for details.

Course Analysis: The working group has entered the third session on intervention in school bullying. In this lesson, the focus is to understand the irrational thinking of the bully. To understand what irrational thinking is, let the group members find irrational thinking in their daily life. Further strengthening the contact and communication between the groups provides more opportunities for communication and interaction between the groups, and also enables the bullies in the group to learn to solve the problem in a more reasonable way. Bullies reflect on their daily behaviors and thoughts, so that group members can have a deeper understanding of themselves, learn how to deal with irrational thinking, figure out how to control and reduce irrational thinking, and learn how to rebuild rational thinking in group intervention. To fundamentally solve the extremist thoughts of the bully to lay a certain foundation of the course.

Lesson Summary: Bullies in groups tend to be more actively involved in thinking and acting, and they have difficulty staying silent during interactions with others. Bullies like to "rhythm" and interfere with others' sharing, and tend to stray from the group's theme. Social workers need to remind and emphasize the working group's curriculum themes, as well as discipline issues in the curriculum. Because social workers need to spend a lot of time and energy on maintaining the theme and order, their ability to grasp the course schedule is relatively weak. In order to consolidate and practice the daily communication skills and methods of the working group in the teaching of the course, before the end of the course, the social workers assigned some assignments on the subject of the course, and shared their experience in the next class, so as to ensure that the team members understand the consequences of irrational thinking.

(4) Section 4 Working Group: Emotion Control and Interpersonal Communication Skills. See **Table 6** for details.

Course Analysis: The fourth part of the working group continues to focus on the issue of emotional control for bullies. The bullies in the group shifted from the resistance group to the acceptance and trust group. In this lesson, the task force shares several ways to calm down a bully in an irrational mood. In addition, through role-playing skills, the team members simulated the psychological activities they experienced in different environments, used "I" to express

TABLE 5 | The unrational behavior courses for understanding the bullying self.

Number of sessions	Working group objective/working group activities content	Material
Section 3 (Bullies)	Task group goal: Make the bully aware of his irrational thoughts 1. Ask the bully in the group to share the irrational thoughts that they have on a daily basis and explain why. 2. Use the self-questioning method to ask the school bully some of his own irrational thoughts, do I have to do this? If I was injured, what should I do? And discuss new solutions with everyone. 3. Through some irrational behaviors in real life, this paper analyzes the thinking process of self rhetorical question through cases, and then puts forward a reasonable approach through discussion. 4. Make a summary speech and encourage the bullying participants to make a difference. 5. In the next section.	Work notes

TABLE 6 | Emotional control and interpersonal skills.

Number of sessions	Working group objective/working group activities content	Material
Section IV (Bullies)	Working Group's goal: to enable school bullies to effectively control their emotions and acquire interpersonal skills. 1. In the emotional more excited, through effective skills to gradually calm down. 2. Role-playing is adopted to set up a specific social environment so that the bully can play a student who can solve his own emotional problems. 3. Express yourself in soothing, gentle, and polite language by introducing your ideas. 4. Summarize the speech and affirm the change of the bully's behavior.	Work notes, water pens

their thoughts every day, and strengthened their control over bad emotions. Let the bully represent the bullied, learn to put yourself in others' shoes, so as to achieve the thinking change of "putting yourself in others' shoes", understand the harm of school bullying behavior, and reject bullying behavior from the heart.

Course Summary: The content of the working group is very complete. In this course, the group members have learned how to calm down their emotions, get rid of the control of irrational emotions, experience the inner changes in the role so as to achieve the requirement of self-reflection. Bullies can actively participate in the interaction when they play other roles. Although some students with good face avoid interaction because they are afraid of making a fool of themselves, they finally complete the role playing through the persistence of social workers and the encouragement of their peers. Through communication and interaction, the team members' trust in the team and the friendship among them are enhanced. The group work is progressing smoothly, but there is a lack of negative emotion venting and mature emotion control system in the course. Therefore, we need to adopt appropriate incentive policies and reasonable material rewards, so that team members can more actively participate in the interactive activities of the working group.

(5) Section V Working Group: Behavior Attribution of Bullies. See **Table 7** for details.

Course Analysis: The subject of this course is the victim of bullying. First, ask the victim to share positive things in their life, as well as brave things in their daily life. According to the characteristics of the victims, the thinking mode of the victims when they encounter school bullying is analyzed from different perspectives. The teaching video "Know Yourself" and "Snack Fight" were shown. The victims were asked to describe the personality and mood of each character in the video, as well as the influence of their way of doing things. Share the bullying behavior and its characteristics in the video, so that they can get the opportunity to understand themselves in the communication, and lay the foundation for changing the bullying.

Lesson Summary: When the victim joins the work group, the group members have no emotional involvement and are only attracted to the group when they watch a short film shown by the work group. The group members were relatively quiet and could not relax during the activity. Social workers must play ice-breaking games at the beginning of classes, as well as more interactive sessions. Make the team members who have been bullied have confidence in the working group, and more conducive to enhance the cohesion of the group.

(6) Section 6 Working Group: How to say no to school bullying in terms of behavior. See **Table 8** for details.

Course Analysis: This course is the last course of social work intervention, and also the last stage of school bullying management. The last class of the working group went smoothly and recorded the school bullying play performed by the whole group by means of photography and video. Members of the team create mementos by recording the scripts they create, produce and execute themselves into video clips. At the end of the stage play, the social workers arranged all the members to write a letter from the heart, put the letter in a time capsule and buried it under the tree on campus. Because of the active participation in the group, the team members unite, trust and encourage each other in the course, and finally learn to correctly understand campus bullying, how to reasonably control emotions and protect themselves. Finally, the staff

TABLE 7 | Behavior lying of bullied behavior.

Number of sessions	Working group objective/working group activities content	Material
Section V (Bullying)	Working group goals: To understand the thoughts of the bullied, analyze the bully's situation and behavioral attributions. 1. The victim shares their positive energy of being brave in life. 2. Games: the right interpretation. 3. Examples are given to illustrate some thinking patterns and behavioral logics in the individual environment of different team members. 4. Conduct behavioral attribution questionnaire and boundary perception expression 5. Play teaching videos "Know Yourself" and "Battle for Snacks" to analyze the time, roles, emotions, ideas and influences in the videos. 6. How can I protect myself after sharing lessons. 7. Summarize the speech and encourage the victims to fight back and seek help.	Work notes, water pens

TABLE 8 | Say no to bullying on campus.

Number of sections	Working group objective/working group activities content	Material
Section 6 (All team members)	Working Group Goal: Show how the bully's real thoughts can be expressed properly through role play, and how the bullied can say no in the face of school bullying. 1. Theater stage performance. 2. Each team member writes a letter from his heart, puts it in a time capsule, and buries it in the campus together. 3. The staff members share and summarize the changes of the team members in the activity. 4. Take photos to commemorate. 5. Finish the job.	Camera, camera, work notes, time capsule model

shared the changes of all team members in this course, and encouraged and recognized all the students who participated in the working group.

Summary: The working group has entered the final stage of intervening in school bullying. At this stage, the members have been able to independently recognize their responsibilities and unite with each other. Compared with the initial stage of the group, the group members' identity with the group and with each other has changed remarkably. During this period, the group members had a deeper understanding of school bullying in the development of group courses, and they also recognized the teaching methods of drama courses more. In the process of sharing and interacting with each class, social workers actively guide students' thinking direction and respond to students' questions. Actively guide the students to summarize their own learning results, so that they can flexibly use the interpersonal skills learned in the drama course in real life. In this for the intervention of social work, draw a perfect full stop.

Drama Course Effect Evaluation

At the end of the drama course, students participating in the drama course were asked to fill in the drama course effect self-scale, and the impact of drama course on school bullying was evaluated according to the proportion of students in the drama course. The results are shown in **Table 9**.

As shown in the table above, In the self-assessment, most of the team members are very clear about the meaning of campus bullying, and have a good understanding of the skills and knowledge of drama course. Through the drama course, the team members have a better understanding of the thinking process of the bully and the bullied, and learned to think in other places, which can improve the bullying behavior on campus. Thirty percent of the students think that they can solve problems with their own methods, which shows that the knowledge taught by the working group cannot be easily used in practice. But more than half of the team members clearly realized that violence did not solve the problem. And realize that violence is a kind of behavior that brings negative influence to the students around them. Only one member passed the scale with full marks. He thought that he could better understand himself through this group. It can also make other team members realize some of their own ideas and understand others' positions and behaviors by themselves and others. Most of the group members don't want to encourage their friends to join the working group, but they are happy to participate in other activities of the social workstation.

SOCIAL WORK INTERVENES IN PRACTICAL DIFFICULTIES

Diversity of Types of School Bullying

There is a wide variety of types of bullying and bullying behavior is not fixed. School bullying can be divided into three main categories: the first is verbal bullying. Verbal bullying is a common phenomenon in daily life on campus. Abuse, personal attacks, nicknames and so on are all verbal bullying; The second category is behavioral bullying. Behavioral bullying

TABLE 9 | Drama course effect self—scaletitle.

	Number of people	Proportion (%)
I can identify the types of bullying on campus.	6	100

means that the bully intimidate others for a long time and cause physical harm to others, such as beating, deliberately pushing, tripping, punching and kicking, or even intentionally harming others' economic interests and life and property safety. Use blackmail, isolation, defamation, and coercion to do something against one's will. The third category is cyberbullying. With the progress of science and technology, the Internet has become an indispensable "necessity" for people, and the phenomenon of bullying comes along with the Internet. There is less pressure and constraint in online communication, so teenagers are more likely to vent their negative emotions without any cost when using platforms such as online social media, such as maliciously slander others and make rumors. Even in school forums, post-bars and other environments, there is bullying both online and offline. Therefore, it can be seen that the role types of school bullying are diverse.

Personal Cognitive Biases of School Bullying

Students' personal factors play an important role in the prevalence of campus bullying. The cognition between people directly affects people's behavior. From the perspective of cognitive behavior theory, among the three factors of emotion, cognition and behavior, cognition plays a role of neutralization and coordination in emotion and behavior. Understanding and observing the same things in many ways will lead to different behaviors. Different cognitive biases of the same behavior can also lead to this result. In terms of campus bullying, with the deepening of bullying, the bully becomes more and more bossy and arrogant; However, the bullied become more and more cowardly. Some people fight against Campus bullying, while others choose to avoid self comfort. People's different views on campus bullying are also due to cognitive bias. The bully usually pursues power and face, thinks that he can get the experience of maximizing ability in bullying, and pursues security and sense of belonging through personal authority; Those who are bullied are often timid, dare not face the bullying, dare not speak up. Lead to their own long-term threat and injury, and ultimately that resistance is useless. Obviously, these are caused by personal cognitive bias.

When social workers asked students, "What is bullying in your mind?", the students will only one-sided answer: being beaten, coercion. Most students don't realize that verbal abuse, teasing and isolation are also bullying. In order to better solve and prevent the problem of school bullying, schools need to train students to have a correct understanding of school bullying. The task force's research includes the recognition of irrational thoughts and attribution of thought and behavioral outcomes, the use of therapy to correct emotions, change false cognitive biases, and thus transform the way school bullies and victims think and behave, and develop interpersonal skills and confidence. To empower young people to speak up and reject bullying.

The Emergency Management Mechanism of School Bullying Is Not Perfect

As a social worker, the author went to a high school and proposed to set up a school bullying working group. However, after the school learned of the author's intention, the school did not agree to set up educational courses and working groups on the subject of "school bullying". Later, after the author found social workers, the school decided to change the theme of the working group to "harmonious campus". During the drama class of school bullying working group, the author observed the students in each class and found the occurrence of campus bullying. There was a slight bullying incident on campus, which was only handled by the teaching director alone. When the bullying on campus is serious, the head teacher will contact the parents to give oral education. The results show that schools have no ability to control campus bullying due to the imperfect emergency management system.

SUGGESTIONS ON COUNTERMEASURES FOR SCHOOL BULLYING

Improve Teenagers' Perception of Bullying

Teenagers are in the special period of adolescence, which is the key stage of psychological development. Many times, teenagers' misunderstanding of things will lead to cognitive bias. If young people want to understand things without one sidedness, they must first understand themselves correctly and form a correct outlook on life and values, which is manifested in dignity, self-confidence and love. First, teenagers must know how to deal with interpersonal relationships, learn interpersonal skills,

respect others, especially in middle school life, and learn to control irrational thoughts. When there is conflict with others, we should be able to deal with the problem rationally. We should not use violence and bullying to solve the contradiction. Second, strengthen students' consciousness of self-protection; When they are bullied, they know how to actively resist and take the right way to protect their own interests and security.

Establish a Good Family Relationship and Educational Environment

Parents are children's first teachers, parents' behavior will affect the children's life. The difference of family relationship and family education mode has an imperceptible effect on the development of adolescent personality. Parents should set an example and guide and educate their children to abide by laws, regulations and moral norms. They should not take a rude, non-interference and intolerant attitude toward the difficulties and setbacks their children encounter in the process of growth. Be patient, responsible and careful to teach them. At the same time, family members should communicate with each other at any time to create a harmonious and equal family atmosphere and family relations, promote family harmony and enhance parent-child relationship. Parents must keep close contact with schools and social workers, keep an eye on the phenomenon of school bullying, understand their children's behavior and life in school, track their children's psychological state and correct their psychological differences, so as to eliminate school violence. It is necessary to correctly guide and educate teenagers in the way of interpersonal communication, enhance their awareness of self-protection and prevent the occurrence of school bullying.

Improve the Emergency Management Mechanism of School Bullying

In the case of school bullying, schools must take the main responsibility. In order to prevent the occurrence of campus bullying, the campus should take the following measures to manage bullying incidents. First, the campus should use billboards, broadcasts, publicity boards, forums, official websites and other media to create a campus atmosphere of mutual assistance, friendship, respect for teachers and education. The second is to set up the legal education and mental health class for middle school students, so as to popularize the legal knowledge and establish the legal awareness, so that students can know, abide by and understand the law, do not use violence to threaten the safety of other people's lives and property, and do not use bullying to coerce others into harmful behaviors. To cultivate students' good psychological quality, learn to release bad emotions and pressure, and educate students to reduce bullying behavior on campus. Third, teachers should pay more attention to the phenomenon of school bullying. The phenomenon of school bullying is mostly caused by teachers' neglect of students and students' incomprehension of teachers. Therefore, teachers should be fair to every student and can't ignore them. Do not despise or discriminate against school bullying, maintain sensitive contact, timely intervention to the school and parents, education, care and protection of students. Fourth, schools must cooperate with social workers to hold regular class meetings to discuss the problem of school violence. For students who have all kinds of bullying behaviors on campus, social workers should guide them to follow up and observe or intervene, and use professional theoretical knowledge and skills to solve the problem of school bullying, so as to change their thoughts and behaviors in an all-round way.

Construction of Social Workstations and Multiple Network Mutual Assistance Mechanisms

To reduce the incidence of school bullying, social workstations should combine school and network to establish multiple mutual assistance mechanisms. Through the linkage and mutual assistance of "social work, school, family, network, and community", we should give full play to the advantages of all aspects and mobilize all forces to protect the victims of bullying to the maximum extent and curb the phenomenon of school bullying. Through the school, family, network, community and other platforms, provide advanced services, use professional social work methods, distribute school bullying brochures at the school gate, to promote and identify school bullying education; To prevent and respond to bullying, schools should work with social workers to provide students with regular training on how to deal with bullying on campus. To clarify teachers' responsibilities and pay more attention to students' physical and mental state, so as to provide strength for the elimination of school bullying; Social workers must maintain contact with parents and guide parents in educating and protecting children within the family, properly dealing with bullying and avoiding bullying behavior (29, 30).

CONCLUSION

At present, the phenomenon of campus bullying is becoming more and more serious. School bullying has become an important problem faced by schools and society. Therefore, the education department and scholars are very concerned about the problem of campus bullying, and the state has constantly issued laws and regulations to combat campus bullying, which can prevent the spread of bullying to a certain extent. As a social worker, we have the obligation to use professional theory, professional methods and social work practice skills to intervene in the core of campus bullying, and to intervene and control campus bullying from the root.

As for the problem of campus bullying, this paper combines social work intervention with drama therapy theory. The purpose is to change teenagers' cognition of campus bullying, make teenagers really understand the root of campus bullying, and improve teenagers' ability to deal with campus bullying. At the same time, for the bullies, the drama class carried out by the working group has improved their self-confidence and communication skills; For bullies, the key is to learn to control bad emotions and change irrational thoughts. The essence of the work of the working group is not only to improve the self-development of the group members, but also to pay attention to

the bullying behavior inside and outside the campus to prevent its spread. However, due to the lack of theoretical basis and practical experience of social work, campus bullying has not been completely and effectively solved. The efficiency of the working group on school bullying needs to be improved.

Therefore, it is very important to combat campus bullying from all aspects. This is not only from the perspective of social work intervention, but also from the perspective of school, family and government, so that young people have a good and healthy learning and growth environment. To lay a solid foundation for the construction of harmonious campus and harmonious society.

The Relationship Between Adjustment and Mental Health of Chinese Freshmen: The Mediating Effect of Security and the Moderating Effect of Gender

*Liu Cao**

School of Physical Education, Xuzhou University of Technology, Xuzhou, China

During the COVID-19 pandemic, many universities are confronted with campus lockdown or even school closures to reduce the risk of infection. However, these measures pose a threat to the mental health of adolescents. In particular, freshmen who have just entered the university campus may suffer from more serious mental health risks. In this study, 1,818 freshmen were analyzed by using the Chinese College Student Adjustment Scale (CCSAS), Sense of Security Questionnaire (SQ), and Symptom Check List 90 (SCL-90) of the qualitative method. The results showed that adjustment had an impact on mental health. Firstly, there was a significant negative association between adjustment and mental health. Secondly, adjustment had a significant predictive effect on mental health. Finally, a sense of security and gender affected the relationship between adjustment and mental health. Collectively, adjustment, sense of security, and gender exerted impacts on the mental health of freshmen, suggesting that we should create a warm and harmonious campus environment for students and conduct targeted education for male and female students.

Keywords: adjustment, mental health, security, moderating effect, mediating effect

INTRODUCTION

Data from recent years indicate that mental health issues have constituted significant burdens affecting a considerable number of people worldwide. Particularly, in the context of the novel coronavirus disease 2019 (COVID-19) pandemic, the mental health and wellbeing of people are experiencing critical challenges, leading to a global mental health crisis (1). A variety of COVID-19 pandemic-triggered mental health problems has been reported in different groups in society, such as stress, anxiety, depression, and sleep disorders (2–4). What's more, negative emotions and related problems in daily life, work, or study continue to rise with the spread of the epidemic. To curb the spread of the virus, many countries have to practice different social distancing measures, such as a lockdown of the campus and a shift to distance or online learning (5). Sifat et al. (6) have noted that adolescents are more susceptible to mental health issues during the lockdown. University freshmen are a special population enduring a critical period of exploring the campus and socializing with peers. However, the school closure brought by the COVID-19 pandemic forces them to adapt to online learning and exams and reduce interactions with peers (7), which is unfavorable to the mental health of adolescents and psychosocial development (8). Therefore, the research on the

relationship between adjustment and mental health has received increasing academic attention. The present study aims to investigate the relationship between adjustment and mental health among Chinese university freshmen, hoping to provide a basis for the school and society to give accurate psychological aid to university students.

Adjustment is primarily the response to psychosocial stressors or multiple stressors, which is accepted as an important response indicator of mental health. According to the diagnostic criteria provided in the Diagnostic and Statistical Manual of Mental Disorders-5th edition (DSM-5), individuals with adjustment disorders are accompanied by significant emotional and behavioral symptoms (9). Evidently, there is a high correlation between adjustment and mental health. Accumulating studies have elucidated the significant negative correlation between mental health and adjustment in college students (10–12). Such negative correlation has also been validated in other groups. For instance, the study by Melero et al. (13) has suggested that adults who are adopted during childhood tend to develop more adjustment problems and present a higher incidence of depression, anxiety, and personality and behavioral disorders than the general population. A study of young adults who have experienced stress events demonstrates that higher levels of mental health are correlated with fewer symptoms of adjustment disorders (14). A literature review has revealed a negative relationship between adjustment and mental health, but there are few studies on freshmen. Herein, this study proposes hypothesis 1: adjustment exerts a significant effect on the mental health of freshmen.

A sense of security is considered to be an important influencing factor in regulating the relationship between adjustment and mental health (15). A sense of security is a sense of control over life, which reflects an individual's ability to deal with life problems and the belief that an individual is liked and accepted by himself and others (16). Maslow believes that people with a low sense of security tend to remain alert, feel isolated, and often exhibit tension and introversion (17). Emotional Security Theory states that maintaining and preserving a sense of security is the most basic task of an individual (18). When a negative interpersonal environment (e.g., interpersonal blocking) undermines personal security, individuals take various measures to defuse or avoid these threats to maintain their security (18, 19). Accordingly, Jia et al. (20) have noted that a sense of security is a key mediator between adjustment (e.g., interpersonal relationships) and problem behaviors. Geng et al. (21) have also found that a sense of security is a mediator between interpersonal sensitivity (e.g., shyness) and depressive symptoms. Moreover, the mediating role of security between peer relationships and internet addiction has been documented (20). The generation of a sense of security is a complex process, in which the environment is a pivotal influencing factor that has an impact on the individual's physiology and psychology. Among students, those with a higher sense of security and belonging have a higher level of mental health (22). Therefore, based on the Emotional Security Theory, the study proposes hypothesis 2: a sense of security plays a mediating role in the relationship between adjustment and mental health.

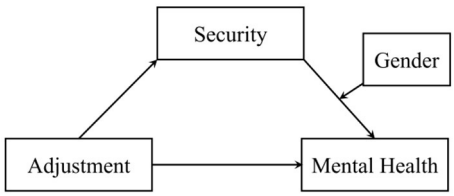

FIGURE 1 | Relationship between adjustment and mental health: the effect of security and gender.

Age and gender are significant psychological and physiological variables (23). During the COVID-19 pandemic, adolescents suffer more social isolation and family stress and experience more depression and anxiety, and furthermore, the severity of mental health problems in women is much higher than that in men (4). Accordingly, this study proposes hypothesis 3: gender moderates the relationship between a sense of security and mental health. Based on the hypotheses, this study proposes a conceptual model map, as shown in **Figure 1**.

MATERIALS AND METHODS

Participants

The freshmen from six universities in Jiangsu Province were investigated by random sampling. This study was approved by the college ethics committee. The subjects were informed of the purpose of the survey and informed consent was obtained before the survey. A total of 2,000 questionnaires were distributed and 1,873 were received, with a questionnaire response rate of 93.7%; the final number of valid subjects was 1,818, with an effective rate of 97.1%. Among the valid subjects, 816 (44.9%) were male and 1,002 (55.1%) were female, ranging from 17 to 24 years old, with an average age of 19.47 ± 1.18 years old.

Instruments

Chinese College Student Adjustment Scale (CCSAS), Sense of Security Questionnaire (SQ), and Symptom Check List 90 (SCL-90) were adopted.

(a) Chinese College Student Adjustment Scale (CCSAS). Fang et al. (24) prepared the scale with 60 items, including 7 dimensions of interpersonal adjustment, academic adjustment, campus life adjustment, career choice adjustment, emotional adjustment, self-adjustment, and satisfaction. A 5-point scale was used, ranging from 1 point (disagree) to 5 points (agree), but some entries were reverse-scored. A higher score was indicative of a higher level of adjustment. This scale had good reliability and validity, with the Cronbach's alpha ranging from 0.67 to 0.82 for the 7 dimensions and 0.93 for the total scale.

(b) Sense of Security Questionnaire (SQ). Cong and An (25) formulated the scale with 16 items, which were divided into 2 factors: interpersonal security and certainty in control. The scale was scored on a 5-point scale from 1 point (very consistent) to 5 points (very inconsistent), with a higher

TABLE 1 | Comparison of the differences in SCL-90, CCSAS, and SQ among freshmen of different genders (n = 1,818).

Variables	Female	Male	t
SCL-90	1.70 ± 0.43	1.57 ± 0.40	6.67***
CCSAS	3.31 ± 0.55	3.39 ± 0.56	−3.17**
SQ	3.55 ± 0.67	3.75 ± 0.68	−6.33***

**p<0.01; ***p<0.001.

score indicating a higher sense of security. The Cronbach's alpha was 0.75 for interpersonal security, 0.72 for certainty in control, and 0.80 for the total scale.

(c) Symptom Check List 90 (SCL-90). The scale was prepared by Derogatis and revised by Liu and Zhang (26). The scale contained a total of 90 items, including 9 factors such as somatization, obsessive-compulsive, interpersonal sensitivity, depression, anxiety, hostility, phobia anxiety, paranoid ideation, and psychoticism, and 1 other factor, and these 10 factors constituted the total mental health score. A 5-point scale was used, ranging from 1 point (none) to 5 points (severe). Higher factor scores and total scores were associated with more prominent psychological problems. The Cronbach's alpha of the 10 factors for secondary school students ranged from 0.70 to 0.88.

Procedures

The test was conducted by team members who had received systematically training and obtained a qualification in measurement before the test. The test was conducted as a group of a class, and the time limit was about 30 min. All questionnaires were distributed and recovered on the spot. The recovered questionnaires were checked by a team member and then a database was created. The data were analyzed and processed using SPSS27.0 and the Macro Program Process developed by Hayes. The gender differences in adjustment, sense of security, and mental health were analyzed using the independent sample t-test, and the correlation between adjustment, sense of security, and mental health was analyzed using Pearson product-moment correlation coefficient. The mediating effect of security and the moderating effect of gender were analyzed using the Macro Program Process developed by Hayes. The bootstrap method was used, with a sample size of 5,000 and a confidence interval of 95%.

RESULTS

Difference Comparison

As shown in **Table 1**, there were significant differences in the scores of SCL-90, CCSAS, and SQ scales between male and female students. Specifically, female students got higher scores than male students in SCL-90, and male students got higher scores than female students in CCSAS and SQ. According to the difference comparison results and previous analysis, it could be concluded that gender played a moderating role in the relationship between SQ and SCL-90.

TABLE 2 | Descriptive statistics and correlation analysis of the variables.

*p<0.05; **p<0.01; ***p<0.001.

Descriptive Statistics and Correlation Analysis

The correlation analysis revealed (**Table 2**) that CCSAS, SQ, and SCL-90 were significantly correlated with gender. CCSAS, SQ, and SCL-90 showed a significant negative correlation, while CCSAS and SQ showed a significant positive correlation.

Moderating and Mediating Effects Analyses

According to the test method of the structural equation model and the results of correlation analysis, the conditions for testing moderated mediation model were satisfied, so the mediating role of SQ and the moderating role of gender were examined in the relationship between CCSAS and SCL-90. CCSAS, SQ, and SCL-90 were standardized before the analysis, with female = 0 and male = 1, and then, the effect test was performed.

The analysis found (**Table 3**) that CCSAS, SQ, and gender had a significant main effect on SCL-90 [effect = −0.17, $p < 0.001$, 95% CI (−0.22 to −0.12); effect = −0.52, $p < 0.001$, 95% CI (−0.58 to −0.46); effect = −0.15, $p < 0.01$, 95% CI (−0.22 to −0.07)]. The main effect of CCSAS on SQ was also significant [effect = 0.67, $p < 0.001$, 95% CI (0.63–0.70)]. SQ interacting with gender showed a significant predictive effect on SCL-90 [effect = 0.09, $p < 0.05$, 95% CI (0.02–0.16)]. The main effect and interaction effect analyses indicated that the mediating role of SQ and the moderating role of gender could be further analyzed.

The analysis revealed the moderating effect of gender in the relationship between SQ and SCL-90, wherein in the male group, the effect value of SQ on SCL-90 was significant [effect = −0.52, $P < 0.001$, 95% CI (−0.58 to −0.46)] and in the female group, the effect value of SQ on SCL-90 was also significant [effect = −0.43, $P < 0.001$, 95% CI (−0.49 to −0.37)]. The slope analysis showed

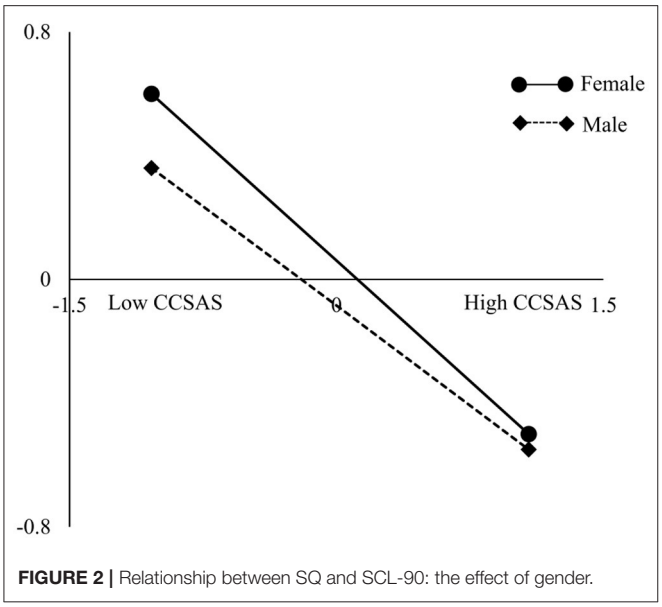

FIGURE 2 | Relationship between SQ and SCL-90: the effect of gender.

TABLE 4 | Relationship between CCSAS and SCL-90 of freshmen: the effect of SQ and gender.

	Female		Male	
	Effect	**Ratio of indirect to total effect**	**Effect**	**Ratio of indirect to total effect**
Indirect effect	−0.35	67.3%	−0.29	63%
Direct effect	−0.17	32.7%	−0.17	37%
Total effect	−0.52	–	−0.46	–

(**Figure 2**) that the level of SCL-90 was elevated with the increase of SQ, but the change in the female group was more obvious than that in the male group.

Further mediating effect analysis (**Table 4**) demonstrated that the indirect effect of CCSAS→ SQ→ SCL-90 was −0.35 for the female group, accounting for 67.3% of the total effect and the indirect effect of CCSAS→ SQ→ SCL-90 was −0.29 for the male group, accounting for 63% of the total effect. It was indicated that a sense of security was a vital mediating variable in the relationship between adjustment and mental health.

DISCUSSION

The study revealed the mechanism of adjustment in mental health. Security played a mediating role in the relationship between adjustment and mental health and such mediating effect was moderated by gender. The main contribution of this study is to analyze the relationship between adjustment and mental health, especially the role of security, and also provide further evidence for understanding the role of gender in the above relationships.

It was found that adjustment was positively correlated with a sense of security, and security was negatively correlated with mental health. The sense of security refers to an individual's sense of anticipation of possible physical and psychological risks and a sense of power/powerlessness in difficulty, mainly in the form of interpersonal security and certainty in control. Adjustment, on the other hand, is a reaction or state in the face of a stressor. When facing a new environment, individuals will make predictions and find ways to make active adjustments. If individuals can gain a sense of security during adjustment, they will continue to promote adjustment and maintain healthy psychology; if not, they will have difficulties in adjustment, leading to mental health problems. Therefore, security is a major variable linking adjustment and mental health. Consistently, Geng et al. (21) have validated Emotional Security Theory and Davies et al. (19) have stated that maladjustment is related to interpersonal stress and it is the personal security crisis caused by maladjustment and stress that leads to mental health problems. Especially university freshmen are facing interpersonal and academic adjustments, but the blockade brought by the COVID-19 pandemic triggers interpersonal and academic stress, which can lead to mental health problems such as depression and anxiety. In this process, the role of a sense of security becomes prominent. If the school gives students a sense of belonging and security and guides them to adjust positively, the emergence of mental health symptoms will be retarded (22).

More importantly, this study identified the role of gender in the relationship between mental health, adjustment, and security. Gender moderated the relationship between security and mental health, thus exerting an important influence on the relationship between the three, with greater changes in the female group in comparison to the male group. A survey has shown that the prevalence of any mood disorder in Chinese women is higher than that in men (27). Lu et al. (28) has also observed a higher prevalence of depressive disorders in Chinese women than men. Similarly, this study explored the role of gender in the relationship between CCSAS, SQ, and SCL-90 and also found greater changes in females. In the context of Chinese culture, the female is usually defined as tenderness, kindness, and introversion, among which sensitivity is a major trait. Male, on the other hand, are usually characterized as masculinity, self-confidence, and a sense of responsibility, among which perseverance is a major trait. The different male and female traits have different effects on the adjustment, sense of security, and mental health of students. In addition, in Chinese society and culture, men have more social and competitive opportunities than women, which also leads to gender differences. It is evident that gender continues to be an important factor in life change in China.

CONCLUSION

This study explores the relationship between adjustment and mental health and determines the multiple effects of security and gender. The relationship between adjustment and mental health can be mediated through a sense of security, and gender moderates the relationship between security and mental health. The findings of this study provide a direction for the current mental health education.

Based on the above findings, we call on universities and relevant responsible departments to make full use of social networking platforms to guide freshmen to communicate and also create a healthy and positive social networking environment to cope with the obstacles brought by school closures. Teaching activities and social communication activities should be actively carried out within the limited space to enable freshmen to integrate into the new environment as soon as possible. On the premise of ensuring safety, universities should actively organize various campus activities to enrich students' after-school life and help them cope with the boring and isolated campus life. In addition, our results suggest that future school mental health education should be committed to creating an environment with a sense of security and belonging, and provide different educational activities for male and female students.

The production, testing, and processing of signals without any interpretation is a crucial task with time scale periods in today's biological applications. As a result, the proposed work attempts to use a deep learning model to handle difficulties that arise during the processing stage of biomedical information. Deep Conviction Systems (DCS) are employed at the integration step for this procedure, which uses classification processes with a large number of characteristics. In addition, a novel system model for analyzing the behavior of biomedical signals has been developed, complete with an output tracking mechanism that delivers transceiver results in a low-power implementation approach. Because low-power transceivers are integrated, the cost of implementation for designated output units will be decreased. To prove the effectiveness of DCS feasibility, convergence and robustness characteristics are observed by incorporating an interface system that is processed with a deep learning toolbox. They compared test results using DCS to prove that all experimental scenarios prove to be much more effective for about 79 percent for variations with time periods.

Keywords: biomedical signals, deep learning, Fourier filters, sensors, cross points

SURVEY OF CONVENTIONAL MODELS

As many researchers have contributed their works for changing advancement that is associated with real-time effects, this part describes and contrasts numerous models that are related to developments in the biomedical field industry. Several modes of operation have been investigated even in past generations without the use of computer-aided design, and the end-stage results are insufficient for confirming the effective models. As a result, the colloquium began with a communication and signal processing toolbox (1), which uses a machine learning technique with a complicated dynamic nature and distributed optimization. However, in all case studies, a random technique is used, with a focus on sixth-generation networks, and even high sensing conditions have been made practical using these types of ideal procedures. A comprehensive review

strategy is established using several case studies, including neuron science and cardiovascular image processing techniques, where significant influence has been demonstrated under various algorithmic settings (2). However, because analytic information is required for all representation scenarios, photos are not processed using the training model. Even though 60% of the reference model is operational, the presentation of biological disease with various picture models cannot be compared under extreme situations.

Aside from the case studies stated above, a deep learning method with high feature extraction has been shown to be an effective technique for geometric scale analysis (3). The main drawback of geometric scale analysis is that dynamic state measurements do not work with baseline health data because differences are noticed at stage 2. Even feature state analysis has been investigated using weight transformations, and such state changes have been shown to operate with a variety of deep representations. However, data augmentation using end networks only works when there are numerous learning problems (4), which are not present in this type of deep learning technique. Furthermore, the physiological expression of signals is categorized using random value creation, and the values are observed, resulting in heavy noisy data (5). As signals are reconstructed as the value pushes lower down to the source point, this noisy data will have a significant impact on biomedical signals, with more physiological sources having computational consequences as signals are recreated. As morphological data is varied throughout separate time intervals, the aforementioned drop in source point can be convalesced using a soft max function. Data will be split into five separate forms for soft max functions, enhancing the capability of the abstraction process.

Furthermore, the firefly algorithm (6) can be used to handle issues and challenges linked to biological applications, where all health problems are studied in-depth, resulting in creative answers through data fusion. Many parametric measures are still displaced due to insufficient access information from other networks, necessitating realistic experimentation with data generated from a centralized perspective. After detecting minimal parametric changes in the firefly method, real-time signal generator algorithm updates are made with incoming signal validation (7). Protocols are also framed for the generation of algorithms using the layered decomposition technique, which allows signals to be partially communicated. This partial signal transfer will be accomplished using a decoding technique that is based on binary values. As a result, a unique formulation is required for converting a standard arrangement to a binary system, which can be accomplished using training procedures seen in transmission lines with epoch iterations. Despite the fact that real-time algorithms are more efficient than 70% of the time, data sets are not established in a good initialization model, thus a primate algorithm with high extraction features and parametric stabilizations is used with a longer overall testing time (8). Due to the fact that stabilizations are prepared in a dual mode of operation, relative errors are further lowered to optimum values, which on average fall below 82. Despite the intricacy of temporal representations, two different data sets will be presented, enhancing the risk of misinterpretation during extensive analysis.

Furthermore, biological signals are integrated at a massive scale utilizing gate count technology (9), and various signals are handled using system architectures. The operating frequencies of various signals are not determined due to the presence of diverse designs, resulting in a miscount of separate integration gates. As a starting point, neural networks are useful for processing crucial signals because they take advantage of a variety of compositional properties of biological points of representation (10). Furthermore, if any problems are found in a large structure, ECG and EEG data will be isolated, allowing for future orientations and change. Between 2012 and 2018, there were numerous techniques that used sensor equipment and permitted the feel and touch method during the communication process (11). Electroencephalography data are evaluated in this feeling, which is modeled as a new technique with seven distinct layers. In accordance with the aforementioned issue, the 7-layer technique is carried out in parallel units, with programming written at high rates employing processor units. Many advantages can be seen for biomedical applications with such high rates, where justification can be processed before pre-processing phases (12–14). These advantageous systems are created using wearable devices where auto-learning models are activated. This type of automated process will allocate signals that move at different frequency periods with a classification mechanism (15). However, it is much easier to separate different signals at unique frequency periods but a wearable device must be created for separating the individual monitored values rather than signals. Further biomedical signals are tested for the prediction of cardiovascular disease using conventional neural networks where a short-term memory coder is implemented in the system (16, 17). The major disadvantage is that if signals are processed, then high memory is required for storing the information that can be accessed at later stages.

Research Gap and Motivation

All the different approaches (1–14) that are discussed using different methods for processing biomedical signals which are not accurate in the field of medical diagnosis. The biomedical signals cannot be passed without the presence of proper communication units at both the transmitter and receiver sides. However few efforts (15–17) have been made by some researchers to prove the complete effectiveness of biomedical signal processing in various applications and they have achieved 63% of accuracy in considered cases. Therefore, the proposed method witnesses the abovementioned gap and provides a solution for effectively utilizing biomedical signals in medical applications. The process functions using a Deep Conviction Systems (DCS) which is an automated procedure for capturing the image of a particular individual using low power technology. This type of implementation system reduces the risk of implementation as high resistance is provided with tracking mechanisms. Also, the data gathering path using biomedical signals is faster and it is replaced with some units in the existing system. This adds an advantage as the entire system is built with low-cost networks

that provide more than 80% accuracy on the input side even if the signal strength is at the intermediate stage.

Objectives

The proposed work on biomedical signal processing is a three-stage objective process that aims to solve the following,

- To incorporate a pre-processing stage that incarcerations the input images to a small matrix type
- To maximize the distance of measurement by transmitting the biomedical signals with recorded output type
- To generate a data augmentation procedure for apprehending the information that is processed using DCS

SYSTEM MODEL: GEOMETRIC ANALYSIS OF SIGNALS

In this section, the system model that supports the generation of signals with respect to algebraic equations is framed using two types of instability models. The major reason for selecting unsteady models is that the signals will be generated using the spectral mode of transmission and it varies for several operating cases. Thus, a segment of sensors is integrated for monitoring huge variations of input signals therefore all recorded output signals will be represented using a non-specific Equation which is represented below,

$$d_a(t) = \sum_{i=1}^{n} s_t\,(i) + n_i(t) \tag{1}$$

Where,

$d_a(t)$ indicates the acquired data that changes with time periods

$s_t\,(i)$ and $n_i\,(t)$ represents true stable and noisy signals respectively

From Equation (1) the noisy signals will have Fourier filters as discrete noise from individual signals is divided with time period representations. Further filters are applied in the case where different time scales are observed for periodic scales as biomedical signals are supplied with a data attainment approach. Thus the time scales can be varied using Equation (2) as follows,

$$t_i = \sum_{i=1}^{n} d_a\left(t - \frac{s_t}{2}\right)\left(t + \frac{s_t}{2}\right) \tag{2}$$

Where,

$t - \frac{s_t}{2}$ and $t + \frac{s_t}{2}$ represents positive and negative time samples

Equation (2) is represented in the form of significant variant properties thus the concession matrix can be used for normalizing all the connected signals. This can be represented in mathematical form as follows,

$$\rho_i = \frac{1}{2} \sum_{i=1}^{n} w_i\,|c_{in}| \tag{3}$$

Where,

w_i denotes weight factor of applied bio-signals

c_{in} indicates the number of connected networks in the signaling process

The connected networks in the signal processing technique will have upper and lower boundaries which are represented using shifting boundaries using Equation (4) as follows,

$$c_{in} = \sum_{i=1}^{n} \frac{u_{in}\,(t) + l_{in}(t)}{Total\ period} \tag{4}$$

Where,

$u_{in}\,(t)$ and $l_{in}\,(t)$ represents the upper and lower limits

Equation (4) is also characterized as mean values of signals and appropriate integer values cannot be obtained in any case. Therefore, the quantization of integers at each step period can be represented using Equation (5) as follows,

$$q_i\,(t) = \sum_{i=1}^{n} \left[\frac{min(in)}{max(in)}\right] * (S_i - 1) \tag{5}$$

Where,

$\min(in)$ and $\max(in)$ denotes minimum and maximum quantization values of signals

S_i represents the data size of signals

In Equation (5) data size of signals is considered using an array of the matrix as 16*16 as the convolution of signals can be carried within the corresponding network frame. Subsequently, the defined array size can provide errors and it can be solved using the probability density function of signals as represented in Equation (6) as follows,

$$\sigma_i = \sum_{i=1}^{n} \log P_t(i)(1 - \log P_o(i)) \tag{6}$$

Where,

$P_t(i)$ and $P_o(i)$ represent true probability and original values of signal positions

The geometric analysis of biomedical signals is used for solving both minimization and maximization problems that can be represented using the objective function as given in Equation (7).

$$Obj_i = min \sum_{i=1}^{n} C_{in}, t_i\ and\ max \sum_{i=1}^{n} dist_i \tag{7}$$

Equation (7) indicates that two minimizations and one maximization problem will be solved using the proposed DCS algorithm for processing the biomedical signals at high strength to monitor all necessary parameters.

OPTIMIZATION ALGORITHM

The major advantage of DCS as compared with other non-fusion algorithms is that it is not highly robust to noise and the learning rate of DCS is much higher as compared with other algorithms. Since there is a necessity to learn and update different characteristics of biomedical signals as it varies for every time period a DCS will be much support to correct the raw data behavior (18). The process involved in DCS saves the learning time as multi-tasking is performed with automatic feature learning behavior as the structure of DCS is designed in an anatomical way (19). Deep learning methods are used

for biomedical signal processing in this part because many significant features may be extracted within reasonable bounds. Even with the use of a deep learning algorithm, a wide range of complex data can be extracted using various learning patterns. As a result, one sort of deep learning algorithm known as a DCS is used since numerous learning parameters can be changed as time passes. In DCS, one visible and hidden vector is chosen at the outset, and the energy parameter is represented using a probability distribution as shown in Equation (8).

$$P\left(o_i,s_i\right) = \sum_{i=1}^{n} \frac{e^{-o_i,s_i}}{\omega_i} \tag{8}$$

Where,

o_i and s_i represents the observable and secret bound values

ω_i denotes the energy representation matrix

To make use of the energy constraint, the probability values must remain at 1. As a result, it is used as a persistent significance in observable bounds, with coordinates that can be changed in the order of j. Equation (9) can be used to represent j^{th} order variation in expectation form as follows:

$$E\left(i,n\right) = \sum_{i=1}^{n} \frac{j_i}{z_i}(1-j_i) \tag{9}$$

Where.

j_i indicates a sub-variance matrix with the change of order

In case the order in Equation (9) is recurrent then to identify the similarity index a mathematical model is framed using Equation (10) as follows,

$$j_i = \sum_{i=1}^{n} \frac{(1-\partial)^2}{\partial} log(e_{in}) \tag{10}$$

Where,

∂ denotes similarity index of the matrix

e_{in} indicates an error in the processing of similar values

Using an unvarying distributed matrix, Equation (10) shows a logarithmic control where all comparable values can be ignored. In addition, the distance between biomedical signal processing can be determined using Equation (11) as follows:

$$distance_i = \sum_{i=1}^{n} d\left(a,b\right) + d\left(x,y\right) \tag{11}$$

Where,

a, b, and x, y denote the four points of inter-section between biomedical signals

The abovementioned signals can be activated with a learning rate using maximized function values which can be defined using Equation (12).

$$r_f\left(i\right) = \begin{cases} 0 \; if \; \max(0,1) \\ 1 \; if \; \min(0,1) \end{cases} \tag{12}$$

Where,

r_f indicates the Relu function with maximization and minimization values

The Relu function in Equation (12) will be varied with binary values 0 and 1 using the tanh activation task as follows,

$$\tanh\left(i\right) = \sum_{i=1}^{n} \frac{e^i - e^n}{e^i + e^{-n}} \tag{13}$$

Where,

e^i and e^n represents tasks that are performed before and after pre-processing stages

In the presence of a distinct learning rate adjustment parameters must be defined with updating of parametric values where iteration variables are used and represented using Equation (14) as follows,

$$R_a\left(i\right) = \sum_{i=1}^{n} \frac{R_a\left(\max\right) - R_a(\min)}{number\ of\ iterations} \tag{14}$$

Where,

R_a indicates fine-tuning of parameters

After certain parametric tuning, the loop values of DCS will be produced as output with a description of the learning rate. The flow chart of DCS for biomedical signals is deliberated in **Figure 1**.

RESULTS AND DISCUSSIONS

In this section, the results of the system model presented in section 2 are simulated using an experimental setup consisting of Fourier filters and geometric signal processing. The experimental setting is constructed in such a way that the total number of physical quantities measured by a sensing device is minimized. Because polluted noise in biomedical signals is decreased, the sensors play an important role in the monitoring process. Both front and rear end sensors are used in the suggested method, and the compatibility of numerous signals is examined at the same time. A deep learning toolbox in MATLAB is used to convert the hardware setup to real-time simulation, with the major data being collected using a reference data set stored on the local disc. The following scenarios also show cross-validation of biomedical signal processing:

Scenario 1: Reconnaissance of recorded data
Scenario 2: Variation of time scale periods
Scenario 3: Configuration distance
Scenario 4: Task of activation
Scenario 5: Cost of implementation

All of the aforementioned situations are carried out with signals that are recorded in a hardware setup and compared to reference signals in computer-aided design. During this comparison, it is decided to use Fourier filters to separate the signals in a regular manner, hence decreasing noise. A full description of all scenarios will give you a good understanding of the seven-layer process.

Scenario 1

In this situation, the recorded data at output units is measured using non-specific time-series samples. Different dynamic ranges are identified without any labels of numerous

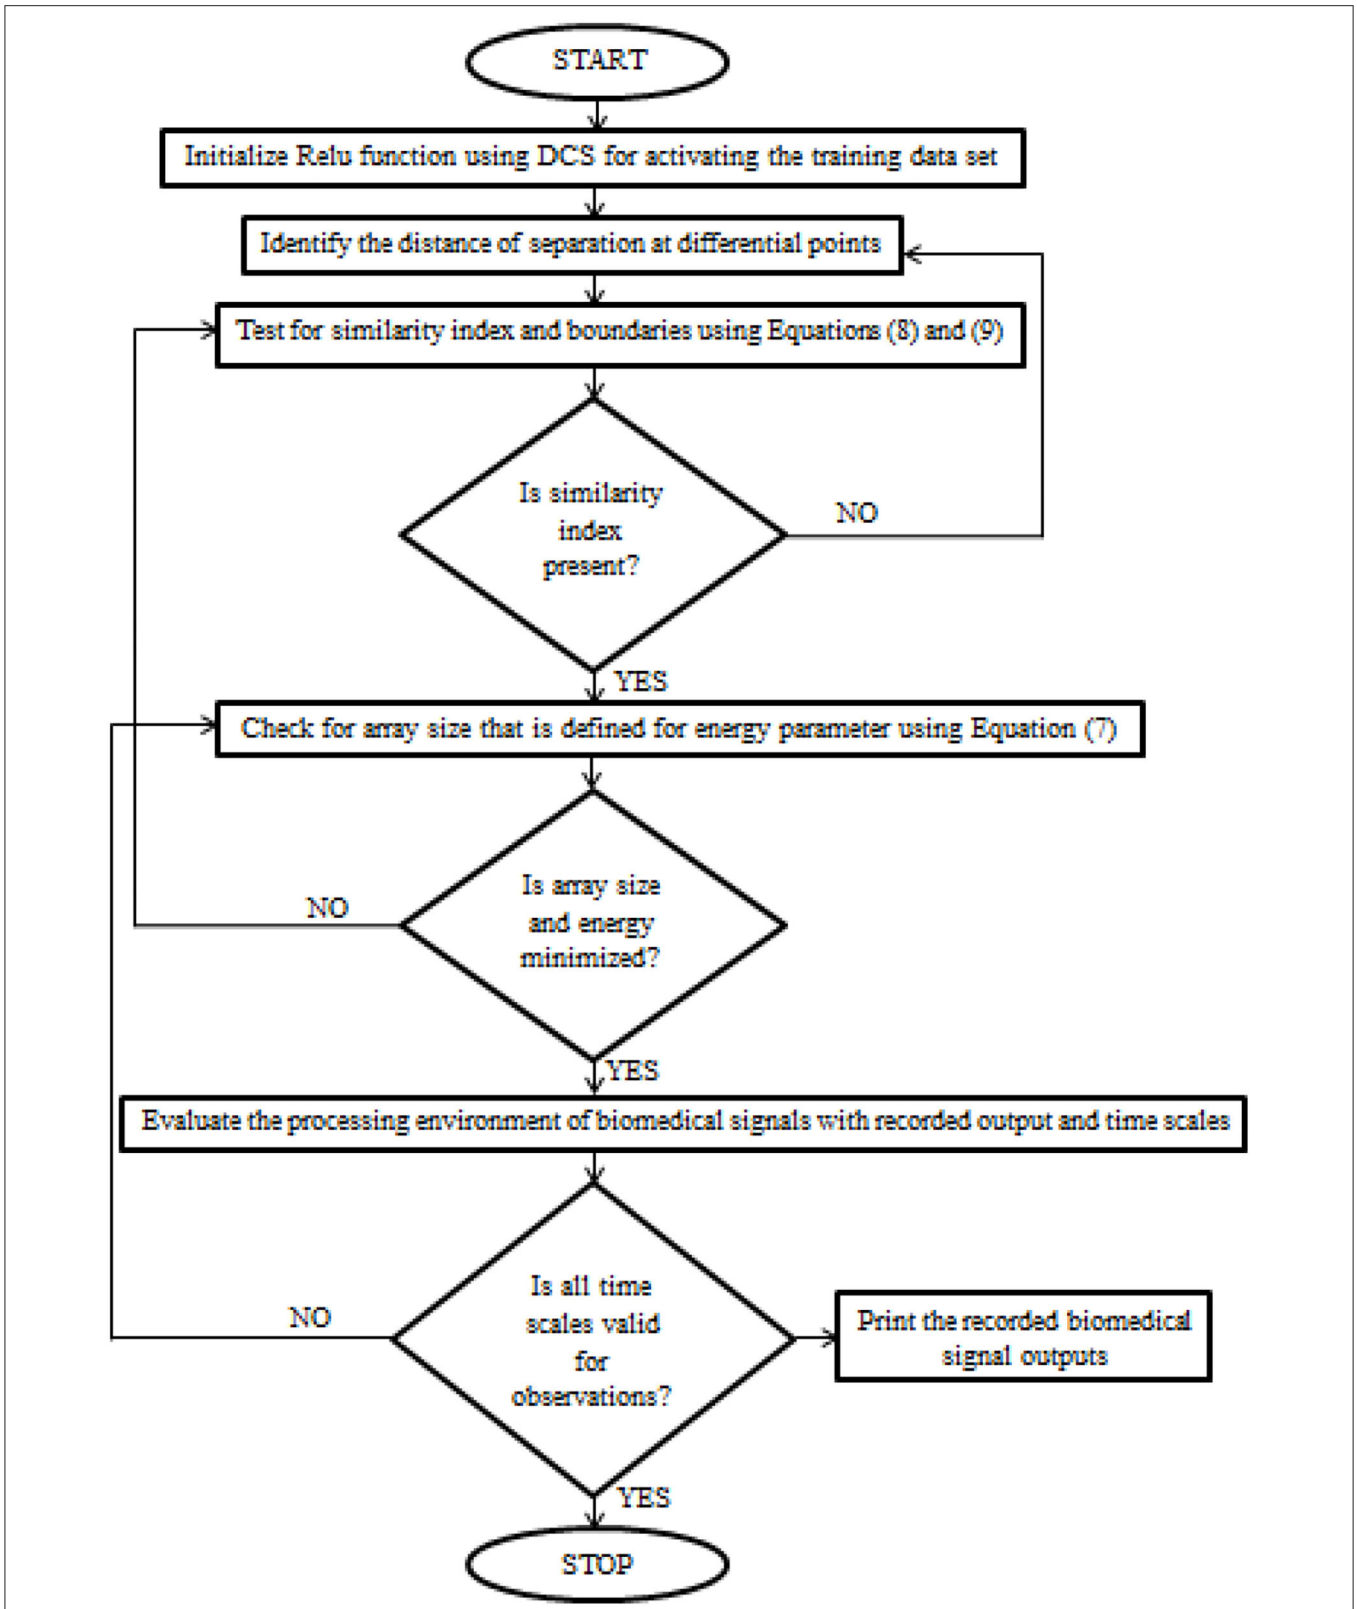

FIGURE 1 | The implementation procedure of Deep Conviction Systems (DCS) for realizing biomedical signals.

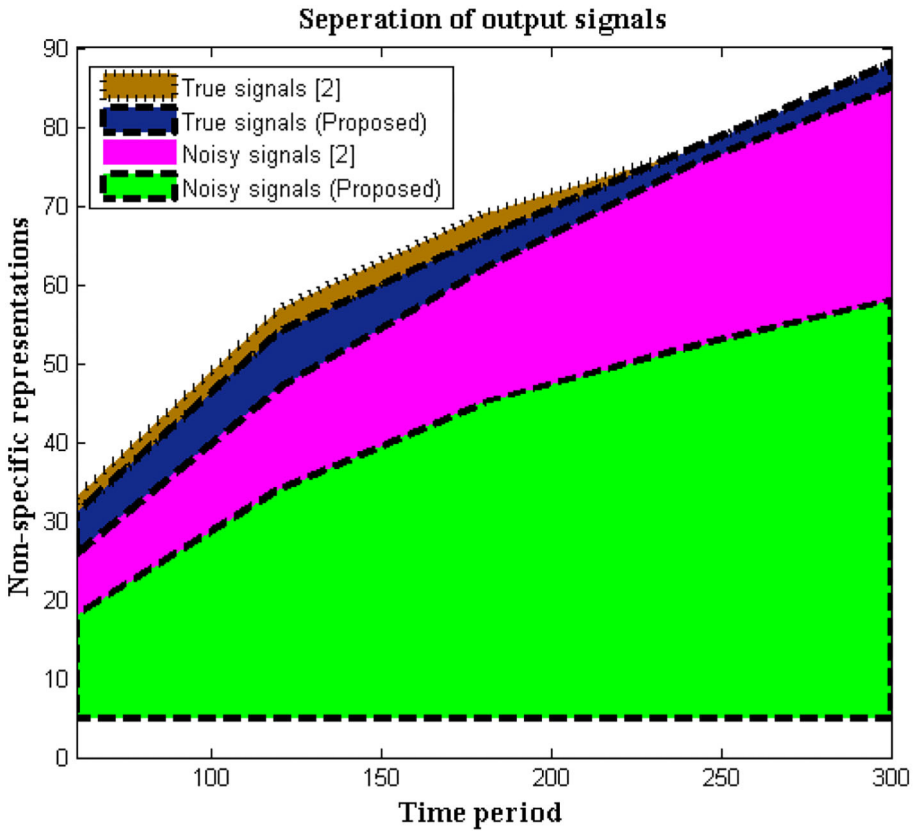

FIGURE 2 | Representation of recorded data.

signals, hence the output units are measured using a 16-bit sample period. Signals are delivered to the receiver without interruption because no tag action is done during the signaling interval. However, in biomedical signal processing, it is necessary to utilize tags to distinguish between real and noisy signals, as shown in Equation (1), and this may be viewed as a unique mechanism used in the execution of the suggested method. This type of separation protects the signal until it reaches the endpoint and allows users to choose channels based on their priority. If any caveat signals are recognized, time periods will be represented at a higher stage, resulting in a faster signal propagation speed. As limited appropriation is used, the above-mentioned technique is verified every 5 s. **Figure 2** depicts the simulation results of recorded output unit data.

Figure 2, **Table 1** show that the initial stage of representations can be achieved using these periodic representations over time durations ranging from 60 to 300 s. The number of true and noisy signals is limited throughout these periods, and the effective signal epoch boundary limits should be between 40 and 60. In addition, a comparison was done with conventional approaches using different system models, and it was discovered that the average number of real signals is formed (2), but true signal representation is determined to be at high levels in the deep learning process. In the projected technique, rather than random changes, the amount of noisy signals is reduced at the conclusion of time periods (2).

Scenario 2

It is necessary to execute the unpredictability of time periods in addition to the separation of biological signals, which is presented in this scenario. The evolution of biological signal representation is accomplished through a stationary process in which modest changes in time periods cannot be tracked over a short period of time. However, because the suggested method produces non-stationary signals, it is possible to track and adjust the signal properties even during the automatic recording step. This benefit can be used during the pre-processing step because the collected images are clear before they reach the channel state. Furthermore, this creates a lively trade-off between frequency signals, which is visible at peak values. Due to the employment of Fourier filters, a transformation strategy using sequential resolution is used, with a large window size being recommended. Furthermore, utilizing a single matrix form, the time resolution of various signals will be exploited to separate positive and negative samples. Both positive and negative signals will be normalized with a combination factor after the pre-processing stage, as shown in **Figure 3**.

The separation of data from time scales that twitch from −2 to +3 when the transformation technique is adopted is depicted in **Figure 3**, **Table 2**. Additionally, the same amount of positive

4	8	32.4	38.7
6	12	47.8	53.1
8	16	52.3	62.4
10	20	59.5	66.9

If the maximum rate is not obtained, it means that some stages of signal separation are not being processed, implying that loop depiction must begin at the beginning. According to the contrasted combined rate values, the projected technique employing deep learning models optimizes the rate at 589 signals per second, whereas the existing method can only maximize up to 416 signals per second, which is significantly less than the planned adaption.

Scenario 3

The distance of monitoring between numerous variations is an important case study after the representation of time scale in biological signals. The suggested technique considers four discrete samples, with the point of inter-section providing the actual distance. When the separation distance increases by a positive factor, it is referred to as scaling with regard to the time factor since the value of the signal representation changes. Furthermore, if deep learning is not used, the procedure might be defined as manual because positive variables must be multiplied by time scales. To avoid such manual procedures, a point of inter-section is chosen that has no effect on frequency variations. However, this method is limited since every 30 s inter-section interval, signal rotation is required. During this 30 s time period, over 1,000 signals are sampled within the channel without any data set augmentation. **Figure 4** depicts the imprecise distance separation values that were simulated.

Figure 4, **Table 3** show that two sets of values were chosen as input, the first of which differs by two value points and the second of which differ by four. These two sets are combined, and a point of inter-section is provided, as well as values at each midway, resulting in automatic distance configuration. For biological signals, a sensing device must be placed at each midway to maximize the separation distance. If the separation distance is not maximized, data will be augmented, which is a severe flaw in traditional models without deep learning techniques. However, the proposed system model solves it using five different points of touch, reducing the number of sensing devices from ten to five. Furthermore, 5 sensing devices are sufficient for viewing the representation signal at all phases, as evidenced by the last data set, where the suggested method achieves a distance of separation of 66.9, whilst the conventional methodology achieves a distance of separation of 59.5.

Scenario 4

This scenario is implemented utilizing the activation function, which is represented using Equation, for further analysis of the data set (13). The number of iterations considered in this sort of initiation varies for each defined data set. It is characterized

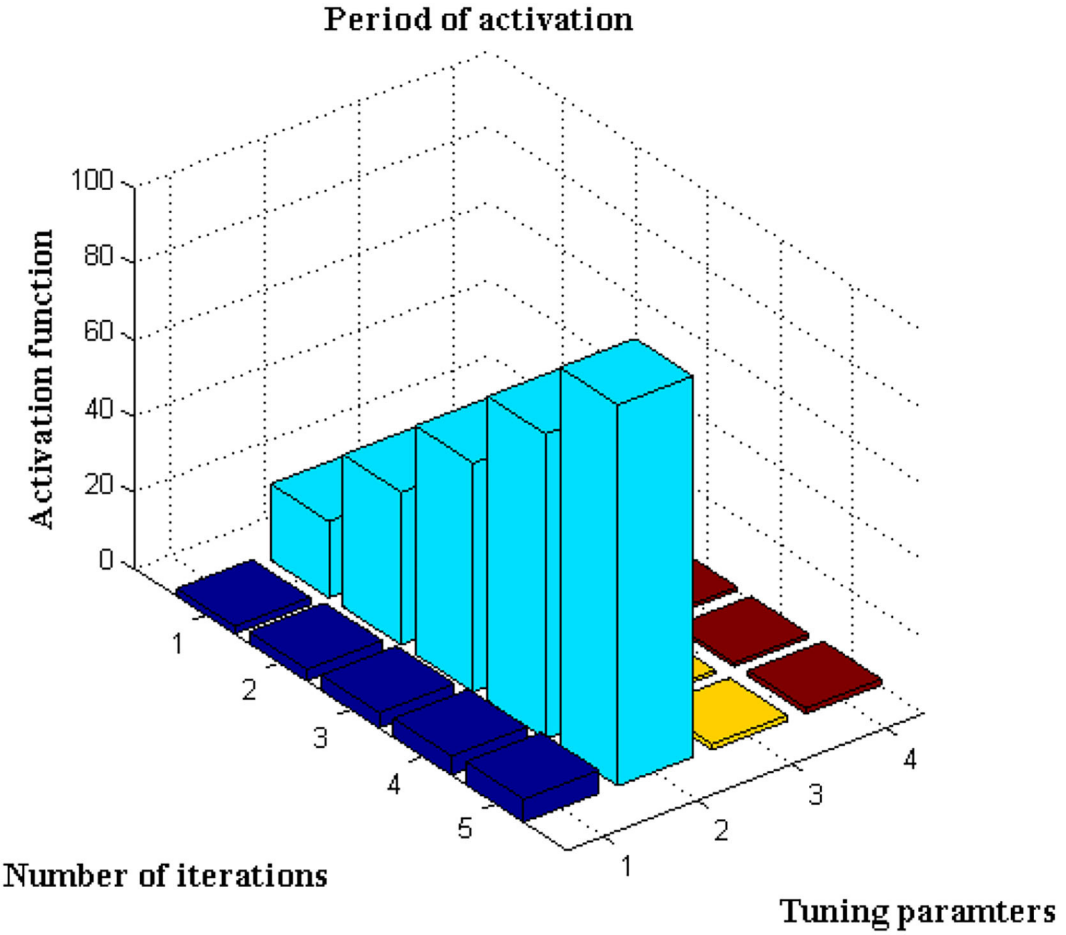

FIGURE 5 | Activation function with iteration periods.

TABLE 4 | Iteration and activation function.

Tuning parameters	Number of iterations	Activation function (9)	Activation function (Proposed)
2	20	0.5	1.5
3	40	0.5	2
4	60	1	2
5	80	1	2.5
6	100	1.5	3

as an exact network if the activation period is obtained at negligible iteration, hence the maximum iteration period is set to 100 with a variation of 20 predetermined periods. The main rationale for choosing 20 defined periods is that during this sample, error values are decreased to 0.001, resulting in the best rate of concealed and output markers. Only if the following constraints are present, such as <4k Hz for variable activities and >30kHz for constant activities, will the training function be active. If any value exceeds a specific range, it means that the visual representation's border condition is incorrect, and testing data cannot be activated. After extensive testing, it was discovered that the proposed method's boundary conditions are met, and a visual representation is obtained, as shown in **Figure 5**.

Figure 5, **Table 4** show that the bar that rises to a large extent is labeled as the activation period, whereas there is no rise in activation functions at three different stages. Aside from this activation function, the number of tuning parameters must be chosen in a ratio that is appropriate for the number of iterations. The proposed method increases the ratio to around 1:15, resulting in the best activation function within the time constraints. This is demonstrated at iteration 80, where a high activation function is achieved for 2.5 scaling periods.

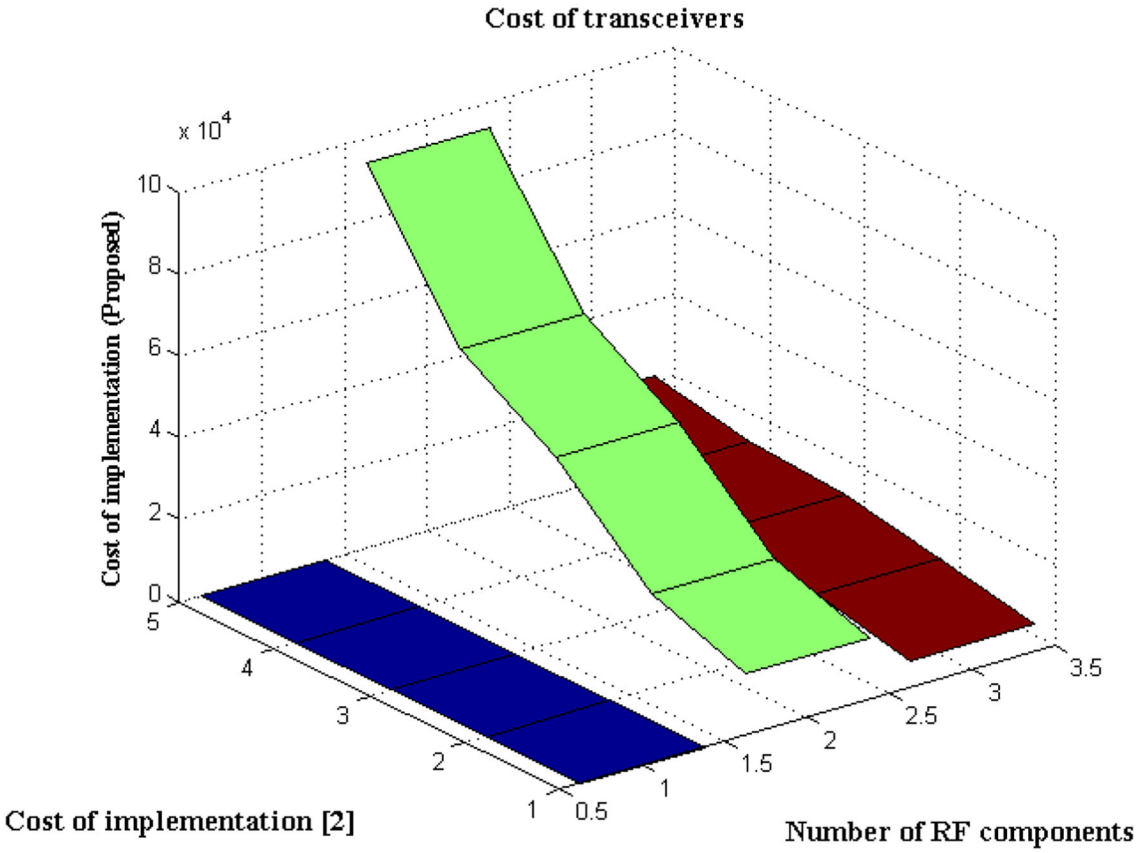

FIGURE 6 | Implementation cost.

Because the proportion ratio in the existing model (9) is not properly defined, the activation period remains at 1 for even two iteration periods. This demonstrates that the projected deep learning model produces the best iteration results with the best activation functions.

Scenario 5

This Scenario depicts the cost of implementing observation units with hidden fragments. It is self-evident that the cost of implementation is decreased due to the minimal number of sensors deployed at junctions.

The type of transceiver used in the proposed technique is determined by the communication between different receivers and the control power of the stations. A radio frequency component is used as an external controller in the transceiver, and a series of recordings are made. This radio frequency component will raise the cost of signal acquisition, but a Nanoscale module is used in the deep learning process. **Figure 6** depicts the simulated implementation cost with comparison. **Figure 6** and **Table 5** show that the cost of implementation increases as the number of radiofrequency components increases for both proposed and existing methods (2). However, with the same number of components, the existing method has a high implementation cost of INR 95000. However, the proposed method is implemented with INR21500 as the transceiver is designed properly at appropriate stages using the same components. Even the power constraint is met at the same cost of installation, resulting in cost savings. This demonstrates that the cost of real-time implementation may be significantly reduced, and medical enterprises can readily obtain it.

TABLE 5 | Cost of existing and proposed methods.

Number of RF components	Cost (2)	Cost (Proposed)
3	15000	6700
6	23000	11300
9	45000	15600
12	60000	17200
15	94000	21500

Performance Analysis

Since DCS are implemented in the proposed model it is essential to check the performance characteristics in addition to the above-mentioned scenarios. The major intention for checking the enactment is that DCS will have more than one

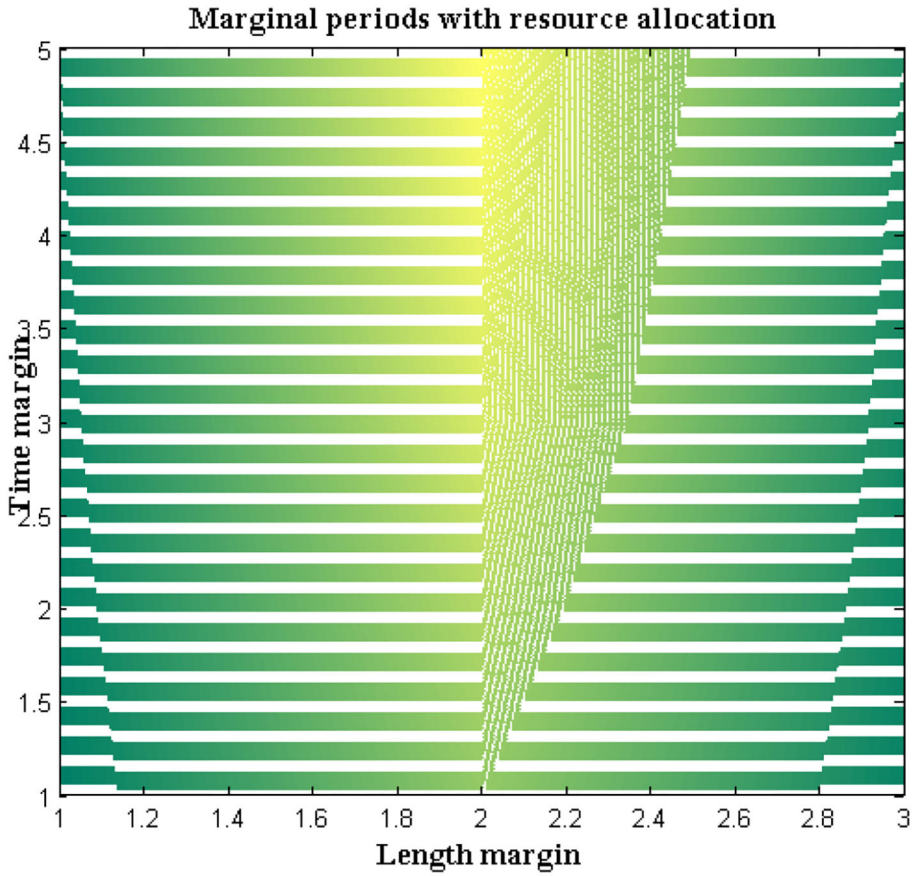

FIGURE 7 | Marginal periods with the allocation of resources.

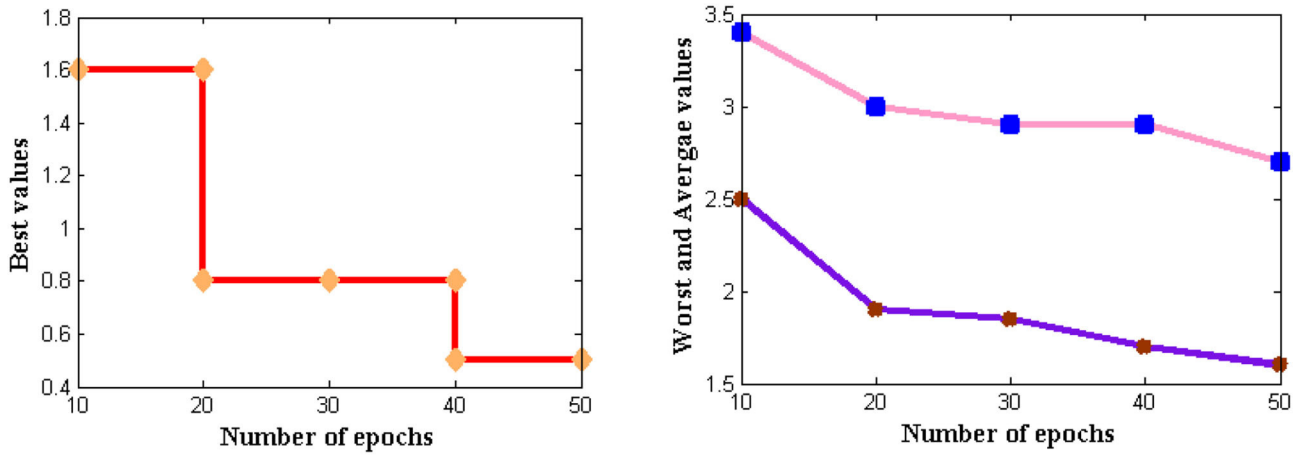

FIGURE 8 | The complexity of time intervals.

output representation and in this case, the best output must be selected and it should be compared with reference data. This output representation wills ensemble the fitness function and it should be terminated after a certain number of algorithmic steps. Also, the implemented algorithm must provide high feasibility to all system representation techniques. Therefore three different performance analyses are carried out in this section as listed below,

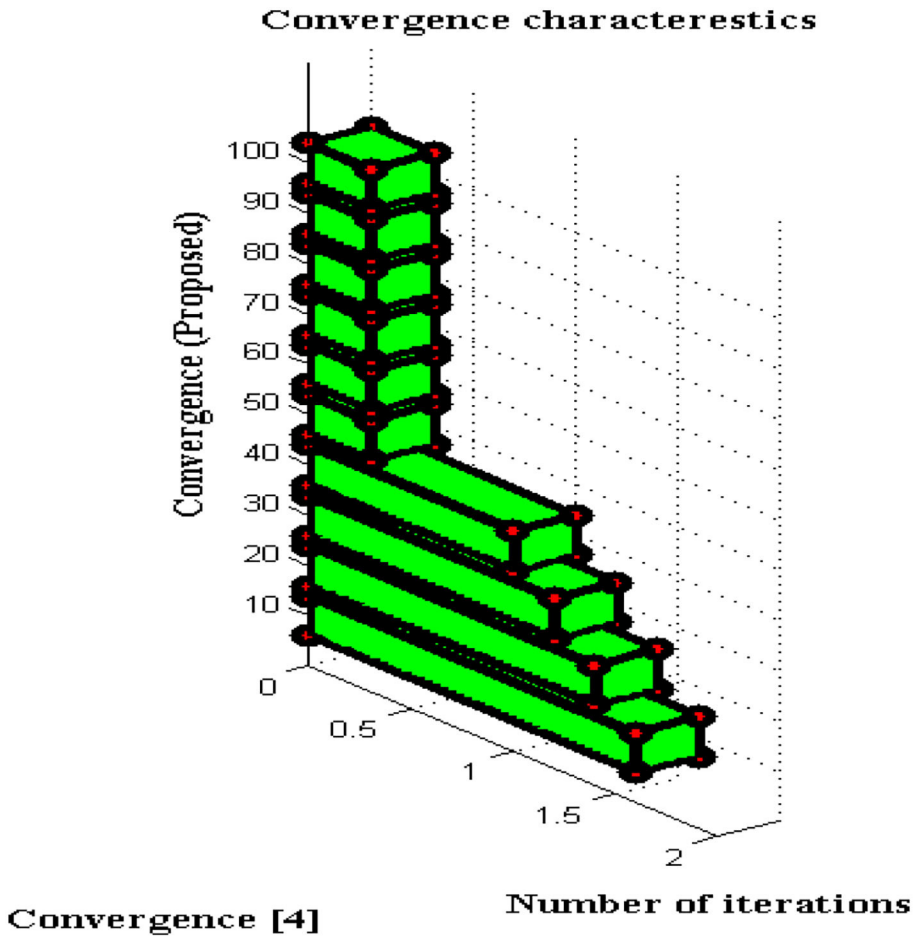

FIGURE 9 | Convergence characteristics.

Feasibility of DCS

In the proposed method a separate programming code is inscribed where step-by-step directions are included in the loop. The pre-defined loop features must be available with highly effective resources and a matching technique will be represented to check the allocation of resources at exact location points. Also, the probability distribution of a value must be defined with finite cases where both length and time margins are provided with an average value set.

For all the data sets a non-trivial solution will be achieved with two different exponential functions. Additional sub-exponential functions are also derived to determine the performance of DCS using entropy function determinations where a feasible solution can be achieved. The accomplished solutions are deliberated in **Figure 7**. From **Figure 7** it can be observed that a number of resources are varied from 4 to 20 and for each resource, both time and length margins are measured. For the proposed method both margins are kept as a minimum at the constraint for margins are satisfied as compared to reference values. However, comparisons are not made with any existing method due to unavailable resources in the selection process. Even the time margins which are represented in seconds are much lesser and the same can be applied to conjunction characteristics at border length margins. This can be proved with a maximum resource where length margins are 204 meters and, in this case, the maximum time period is 34 s. The above-mentioned values are much lesser as in the absence of resources more than 80 s time periods are observed.

Computational Complexity

If the feasibility of the proposed method is higher, then complexities that are present in time periods can be analyzed. Thus, complexities in time periods are measured in addition to memory requirements where for large input size three different values such as best, worst, and average are represented. In the projected model, the time for executing each statement is found and it is determined using the asymptotic function. The complexity in time periods is measured using several external factors such as the size of the input, processor speed, etc. The computational complexity for DCS is simulated in **Figure 8**.

From **Figure 8** it can be observed that a number of iterations is considered from 10 to 50 and all three values are plotted where

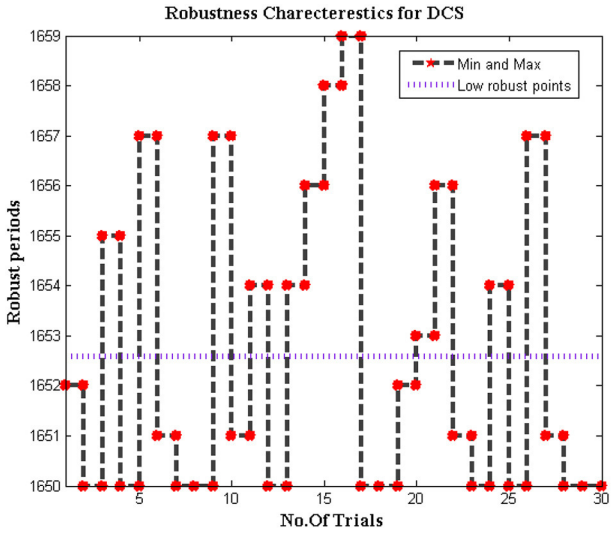

FIGURE 10 | Low robust points of DCS.

best values are shown in subplot 1, worst and average values in subplot 2. From these two subplots, DCS values are varied where low complexities are found as best values reach 0.5 s and further reduce after several iteration periods. If zero measurements are found then it indicates that time complexity is not present in the system. The same situation is observed for DCS after 80 iterations but until it reaches the corresponding iteration value complexities remain constant at 0.5 s. This proves that at constant speed DCS can able to reduce complexities in time.

Convergence Characteristics

For all non-linear system models, it is essential to perceive the convergence characteristics where persistent phases must be observed. In DCS two types of characteristics are analyzed with respect to definite and captivating problems. This will give a clear solution to address the problems that arise during a long period of time where if convergence is not achieved then that particular time period will be separated. Furthermore, the separated time periods will be analyzed in several ways such as fault communication module, signal transmission properties, sensing capabilities, etc. If any one parameter fails to provide precise results then convergence cannot be achieved and it indicates failure of the model. The convergence characteristics of DCS are deliberated in **Figure 9**.

From **Figure 9** it can be perceived that DCS is converged immediately at 50 iteration periods whereas the existing system converges only at 80 iteration periods. Therefore a large difference in convergence can be observed in the value determinations such as 0.3 and 0.5. Even after attaining fast convergence, the proposed method can be able to reduce the period of signal transfer to the receiver. This in turn helps the users to get a high signaling rate at shorter periods but fabrication parameters must have concurred with DCS. With the fabrication parameters, it is much easier to install a signal processing sensor thereby making DCS converged at initial point conditions.

Robustness of DCS

Since the dataset of the proposed method is varied as different bio-medical signals are transferred to end systems. In addition, the biomedical signals that are passed from individuals are much different when it is compared with distinct parameters. Therefore for change in signal representation, it is essential to check whether the system is robust to all input conditions. Further error in DCS must be reduced to increase the effectiveness of the proposed model as the trained inputs must achieve much closer outcomes during deduction segments. Thus the simulated model for checking the robustness is plotted in **Figure 10**.

From **Figure 10** it can be observed that the number of iterations varied from 10 to 100 and for each representation, a midpoint robust values are achieved. These midpoint values are considered as the initial design of the biomedical signal representation must not be changed as local points will provide information about missing values in the system. For all changes in iteration periods, the proposed method operates under low robust conditions whereas the conventional systems are highly robust against input conditions as local points cannot able to identify distinct data set points.

CONCLUSIONS

This paper examines a real-time augmentation biomedical signal that is used in the testing and classification mechanism of a human interface system. The application of biomedical signals in medical applications provides clear insights into future developments under the automatic mode of operation in a wide range of research fields. As a result, the proposed method prepares an automatic process using a sensing device that can be accessed in simple environmental conditions. However, a few sensors that monitor biomedical signal parameters must be fabricated in order to provide precise data and transmit signal data to the control center. In the proposed method, a pre-processing technique is used at stage 1 to classify and train the images, with the result that any incongruent signals will be detected quickly. In addition, for the training set, the previous data set has been integrated, and a comparative analysis has been performed using two algorithms: firefly and gate count technology. Since biomedical signals in the transceiver are detected using a deep learning algorithm, which includes DCS with several learning parameters in the 2.5-time scale period range. As a result, the generated data set is observed for three discrete periods using weight transformations, resulting in deep image representation extensions.

Furthermore, real-time simulation results show that biomedical signals are activated without any peripheral intrusion, even after several different classifications. To gain a better understanding of DCS, five different scenarios are divided and tested using a hardware setup that yields effective results. Biomedical signals can be used as a

building block for all knowledge transformation techniques in the future, resulting in a significant reduction in data augmentation measures.

Background: Pancreatic cancer (PC) is a highly malignant tumor of the digestive system. The number of elderly patients with PC is increasing, and older age is related to a worse prognosis. Accurate prognostication is crucial in treatment decisions made for people diagnosed with PC. However, an accurate predictive model for the prognosis of these patients is still lacking. We aimed to construct nomograms for predicting the overall survival (OS) of elderly patients with PC.

Methods: Patients with PC, older than 65 years old from 2010 to 2015 in the Surveillance, Epidemiology, and End Results database, were selected and randomly divided into training cohort (n = 4,586) and validation cohort (n = 1,966). Data of patients in 2016–2018 (n = 1,761) were used for external validation. Univariable and forward stepwise multivariable Cox analysis was used to determine the independent prognostic factors. We used significant variables in the training set to construct nomograms predicting prognosis. The performance of the models was evaluated for their discrimination and calibration power based on the concordance index (C-index), calibration curve, and the decision curve analysis (DCA).

Results: Age, insurance, grade, surgery, radiation, chemotherapy, T, N, and American Joint Commission on Cancer were independent predictors for OS and thus were included in our nomogram. In the training cohort and validation cohort, the C-indices of our nomogram were 0.725 (95%CI: 0.715–0.735) and 0.711 (95%CI: 0.695–0.727), respectively. The 1-, 3-, and 5-year areas under receiver operating characteristic curves showed similar results. The calibration curves showed a high consensus between observations and predictions. In the external validation cohort, C-index (0.797, 95%CI: 0.778–0.816) and calibration curves also revealed high consistency between observations and predictions. The nomogram-related DCA curves showed better clinical utility compared to tumor-node-metastasis staging. In addition, we have developed an online prediction tool for OS.

Conclusions: A web-based prediction model for OS in elderly patients with PC was constructed and validated, which may be useful for prognostic assessment, treatment strategy selection, and follow-up management of these patients.

Keywords: nomogram, elderly patients, pancreatic cancer, SEER database, online application

INTRODUCTION

Pancreatic cancer (PC) is one of the most dangerous malignancies in the world and is a lethal disease with dismal survival rates, with a 5-year overall survival rate of <5% and a median survival of ∼6–8 months after diagnosis. It is the fourth most common cause of cancer death in both men and women due to the difficulty of early detection and poor prognosis (1–3). In addition, PC is the main disease of the elderly population, as aging intensifies, the number of elderly with PC is expected to rise in the future. At the same time, it is difficult for physicians to stage and predict the prognosis of PC because it exhibits a variety of tumor behaviors and symptoms (4). Despite the continuous introduction of new surgical techniques and medical therapies, and the evolving concept of integrated management of PC, the prognosis of PC patients has improved modestly, but the 5-year survival rate has not improved significantly (5). So the poor prognosis of PC remains a major challenge for mankind.

The tumor-node-metastasis (TNM) staging system of the American Joint Commission on Cancer (AJCC) 8th edition, is commonly used for prognostic evaluation of pancreatic ductal adenocarcinoma. However, researchers have found the staging system inadequate (6–8). It only incorporates some features of the tumors into the staging system, and its prognostic factors go far beyond these. Shi et al. constructed a nomogram for predicting the overall survival (OS) and cancer-specific survival (CSS) of young patients with PC and found that primary site, pathological types, AJCC stage, and surgery were independent factors affecting CSS (8). Although many studies have confirmed that the clinical characteristics and prognosis of older patients with PC are different from young patients (9–11), the nomogram of PC in previous studies cannot accurately predict the OS of elderly patients with PC (12–14). Therefore, technically feasible and easily clinically accessible nomograms that predict the OS specifically for elderly patients with PC are still urgently required.

At present, nomograms have been developed and proposed as an innovative alternative tool for prognostic assessment of many cancers (15–17), which can combine important demographic and clinicopathological features to estimate individual survival for patients with cancer. A nomogram for patients with PC over 65 years old or older derived from population-based data, to the best of our knowledge, has never been reported. The Surveillance, Epidemiology, and End Results (SEER) database serves as the definitive cancer database in the United States. It contains data related to cancer prognosis such as age, race, marital status, histologic grade, tumor size, surgery, radiation, and chemotherapy (18). Based on the SEER database, we aim to investigate the risk factors for OS in elderly patients with PC and establish a web-based prediction model for predicting OS, which might be helpful for the prognostic prediction, and treatment strategy selection. It also can help doctors and patients to make follow-up decisions.

PATIENTS AND METHODS

Patients and Variables Inclusion

The clinicopathological data of all patients with PC from 2010 to 2018 were downloaded from the SEER database. We put the original data in **Supplementary Material** and put the relevant code on GitHub, see the link for details https://github.com/xiaoyang11223/pancreatic-cancer.git. It collects information on patient demographics, year of diagnosis, marital status, tumor size, histopathological grade, TNM stage, surgery, radiotherapy, chemotherapy, post-operative AJCC 7th staging, and follow-up for survival. The inclusion criteria were as follows: (1) age≥65years; (2) International Classification of Diseases for Oncology, 3rd edition [ICD-O-3] code 8150, 8151, 8152, 8154, 8155; (3) those with a confirmed pathological diagnosis from 2010 to 2018; and (4) those with unknown data about the grade. The exclusion criteria were as follows: (1) unknown diagnostic confirmation; (2) unknown marital status; (3) unknown insurance recode; (4) survival time <1 month; (5) tumor size≥990; and (6) unknown whether radiotherapy was performed. Finally, 6,552 eligible elderly patients with PC were included in this study. The following variables were analyzed: age, insurance, grade, surgery, radiation, chemotherapy, TNM stage, and AJCC. The detailed flow chart was shown in **Figure 1**. For this study, we have signed authorization and received permission from SEER to access and use the SEER information. The SEER database is publicly available and the data for all patients are deidentified, so institutional review board approval and informed consent were not required in this study.

Statistical Analysis

To construct and validate the nomogram and ensure the robustness of the prediction model, we divided the data into the training set and verification set according to 7:3 through the SAMPLE function of R. we randomly assigned 70% ($n = 4,586$) of patients from 2010 to 2015 and 30% ($n = 1,966$) of patients from 2010 to 2015 to the training and validation cohorts, respectively. A total of 1,761 patients in the SEER database from 2016 to 2018 were included in the external validation cohort. A chi-square test was used to compare the clinicopathological characteristics between the training set and the validation set. OS referred to the duration of PC from diagnosis to death, and patients who were alive at the point of the last follow-up were considered

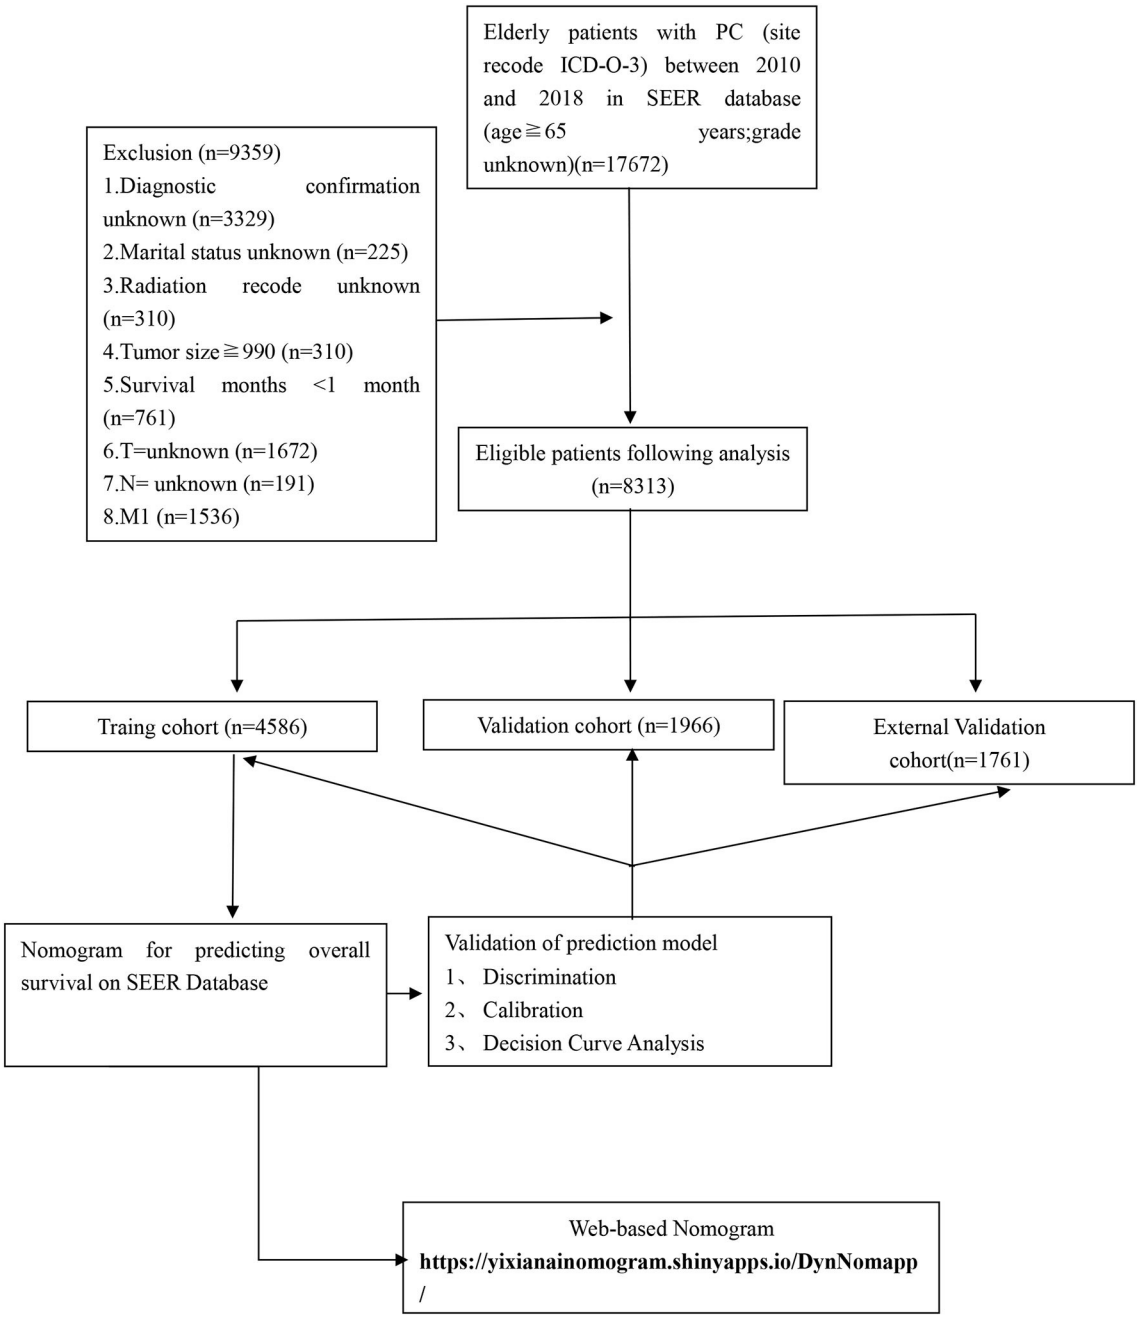

FIGURE 1 | The flowchart of including and dividing patients. Github: https://github.com/xiaoyang11223/pancreatic-cancer.git.

censored events. Variables related to OS for which $p<0.05$ in the univariable analysis or with important clinical value were entered into a multivariate logistic regression model based on proportional subdistribution hazard models to determine risk factors independently associated with the development of PC in elderly patients, which was performed using a Cox proportional hazards regression model. Discrimination of the nomograms was measured by the concordance index (C-index) and receiver operating characteristic (ROC) curve with its respective 95% CI, which quantifies the level of consistency between the observed OS and the predicted OS probability.

Clinical prediction models can provide doctors and patients with quantified risk value based on current health status to predict future health status utilizing non-invasive, low-cost, and easily collected indicators, which has important health economics significance. Decision curve analysis (DCA) is a new calculation method that estimates the net benefits under various risk thresholds to evaluate the clinical value of the

model. We used DCA to evaluate the clinical practicability of our nomogram. Based on the cut-off value calculated from the total score of our nomogram, we divided patients into a low-risk group and a high-risk group. We applied Kaplan–Meier curves and log-rank tests to compare patient survival between different groups. The nomogram, C-indices, ROCs, calibration curves, DCA curves, Kaplan–Meier curves, and a web application for survival prediction were by utilizing R software. For all statistical analyses, p-value < 0.05 was considered statistically significant.

RESULTS

Patients Characteristic

Our study flowchart is shown in **Figure 1**. Finally, there were a total of 6,552 cases of elderly patients with PC diagnosed in the SEER database between 1 January 2010 and 31 December 2015. These patients were randomly divided into a training set (N =4,586) and a validation set (N = 1,966). The demographic and clinicopathological information of patients were listed in **Table 1**. Of these patients, 3,702 cases (56.50%) were 65–74 years old, 2,850 cases (43.50%) were >74 years old, 5,501 (83.96%) were white, 3,284 (50.12%) were male, 5,945 (90.74%) were married, and 4,683 (71.47%) were T3 stage. The histological tumor grades were 1,395 (21.29%), 22,839 (43.33%), 2,209 (33.71%), and 109 (1.66%) for patients with tumor histological grades I, II, III, and IV, respectively. Their AJCC stages were IA: n=640 (9.77%), IB: n=823 (12.56%), IIA: n=1,724 (26.31%), and IIB: n=3365 (51.36%), respectively. There were 3,348 (51.10%) underwent local or pancreatectomy, 3,649 (55.69%) underwent chemotherapy, and 5,043 (76.97%) did not receive radiotherapy. Detailed patient clinical characteristics were summarized in **Table 1**. There were no significant differences in clinicopathologic characteristics between the training and the validation set. Characteristics of patients in the external validation cohort are shown in **Supplementary Table S1**.

Univariable and Multivariable Cox Regression Analysis

Univariate Cox regression analysis was used to screen the prognostic factors of PCC in elderly patients, namely, sex, age, insurance, Fuhrman grade, surgery, radiation, chemotherapy, T stage, N stage, and AJCC stage (**Table 2**). Then we developed multivariate Cox models using the selected factors to identify independent risk factors. The hazard ratio (HR) is used to quantify its effect on OS. Multivariate analysis found that age, insurance, grade, T stage, N stage, surgery, radiation, chemotherapy, and AJCC stage were significant independent risk factors for the prognosis of patients. The results of univariate and multivariate factors are shown in **Table 2**.

Nomogram Construction for 1-, 3-, and 5-Year OS

The multivariate Cox regression analysis identified the independent risk factors used to construct a nomogram to predict elderly patients with PC at 1-, 3-, and 5-year OS (**Figure 2**). The nomogram indicated that surgery and grade are still the most significant factors affecting the prognosis of patients, followed by age, T stage, AJCC stage, and chemotherapy.

Validation of the Nomogram

The C-index of the training set and the validation set were 0.725 (95% CI: 0.715–0.735) and 0.711 (95% CI: 0.695–0.727), respectively, indicating that the nomogram has good discriminatory power. In the external validation cohort, C-index was 0.797 (95% CI: 0.778–0.816). The calibration plots for the training cohort and the validation cohort used to predict OS show an excellent consistency between the actually observed and nomogram-predicted survival (**Figures 3A–C**). In the training cohort, the AUC of the predicted nomogram for 1-, 3-, and 5-year were 0.787, 0.766, and 0.35 (**Figure 4A**). In the validation cohort, the AUC of the predicted nomogram for 1-, 3-, and 5-year were 0.771, 0.751, and 0.777 (**Figure 4B**), respectively. Furthermore, most patients do not survive longer than 35 months. In the external validation, the AUC of the predicted nomogram for 1 year was 0.828 (**Figure 4C**).

Clinical Application of the Nomogram

Decision curve analyses (DCAs) showed that the clinical application value of nomograms was superior to that of the traditional TNM stage system (**Figures 5A,B**). In addition, we constructed a risk stratification system based on the total points of patients on a nomogram. All patients were divided into a risk-low group (overall score ≤185.1) and a risk-high group (total score >185.1). The Kaplan–Meier curves of the validation and training sets demonstrated that there were significant differences in the survival of patients in each risk group (**Figure 6**). That is to say, Kaplan–Meier curve results well-proved the discriminant ability of the nomogram prediction model.

Online Application for OS Prediction

Based on this nomogram, we have developed a network calculator to predict the OS of elderly patients with PC, which can be accessed at https://yixianainomogram.shinyapps.io/DynNomapp/. Enter the clinicopathological characteristics of the patient, you can immediately get the predictive survival probability of the patient. In conclusion, this online prediction tool is simple, easy to understand, and easy to use in clinical practice.

DISCUSSION

In this study, we used abundant clinical samples to establish a nomogram to effectively predict 1-, 3-, and 5-year OS in elderly patients with PC based on the SEER database. At the same time, we build the nomogram model and validate the performance of the model by screening clinically significant variables. We determined that surgery, grade, radiation, T stage, N stage, AJCC stage, chemotherapy, age, and insurance were independent factors affecting the OS of elderly patients with PC by univariable and multivariable regression analysis based on the SEER database. Furthermore, a combination of key elements of traditional staging systems and other tumor-associated indicators, such as age, grade, surgery, and

conventional staging system in different populations (8, 13, 14). Although many studies have confirmed that the clinical characteristics and prognosis of older patients with PC are different from young patients (9–11), the nomogram of PC in previous studies cannot accurately predict the OS of elderly patients with PC (12–14). Compared with patients with PC of

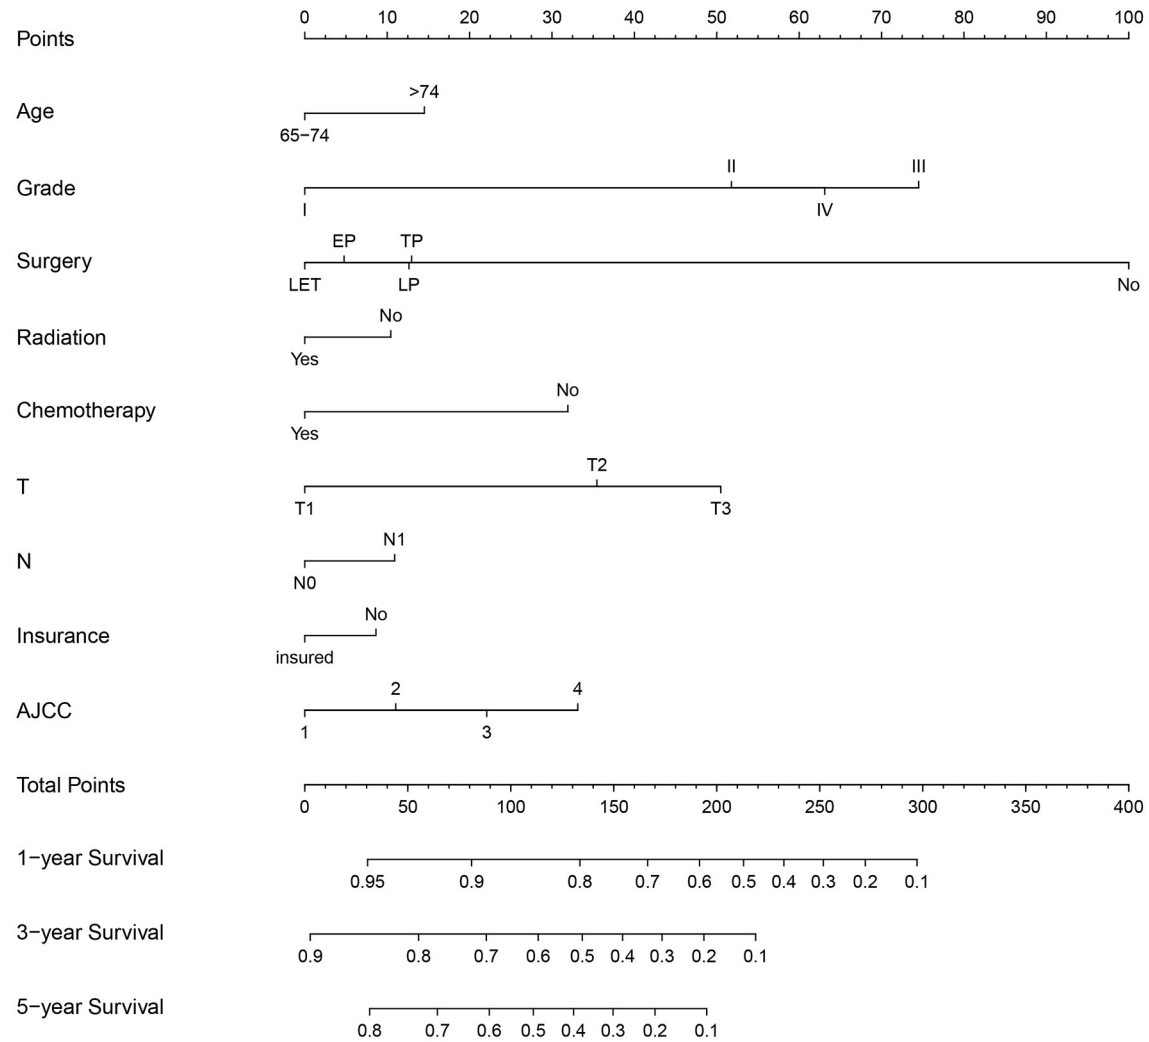

FIGURE 2 | Nomogram for 1-, 3-, and 5-year OS of elderly patients with PC.

younger ages, elderly patients with PC have unique physiological characteristics. These characteristics include more comorbidities, less life expectancy, and worse life expectancy. Therefore, it was clear that there was an urgent need to develop predictive models for elderly patients with PC. Previous studies have found that age was an independent factor affecting OS in patients with PC (12–14, 21). Shi et al. (8) have found that the nomograms could effectively predict OS and CSS in young patients with PC, which helps clinicians more accurately and quantitatively judge the prognosis of individual patients. Li and Liu (13) have found that their nomogram for OS predicting can serve as an efficacious survival-predicting model and assist in accurate decision-making for patients over 40 years old with surgically resected PC. The clinicopathological features and prognosis of young patients with PC are not quite the same as those of elderly patients with PC (9–11, 22, 23). Another study used several variables of age, differentiation, TNM stage, surgery, and lymph node surgery to construct a nomogram predicting OS rates in patients with PC having age groups of 25–39, 40–59, 60–79, and 80+ (8). But the study still had some restrictions, they did not include patients who have undergone chemotherapy or radiotherapy. To our knowledge, previous studies found that radiotherapy and chemotherapy can effectively improve the prognosis of post-operative patients with PC (24, 25). Our study found that among elderly patients with PC, those who had received chemotherapy and radiotherapy accounted for ∼55.69% and 23.03% of the total number of patients, respectively, which was consistent with the previous study. Therefore, it is necessary to establish and validate a reliable prognostic model for elderly patients with PC with better applicability.

Survival was estimated by the Kaplan–Meier method, and any differences in survival were evaluated with a stratified log-rank test. Multivariable analyses with the Cox proportional-hazards model were used to estimate the simultaneous effects of prognostic factors on survival. Interactions with prognostic factors were also examined with the Cox proportional-hazards

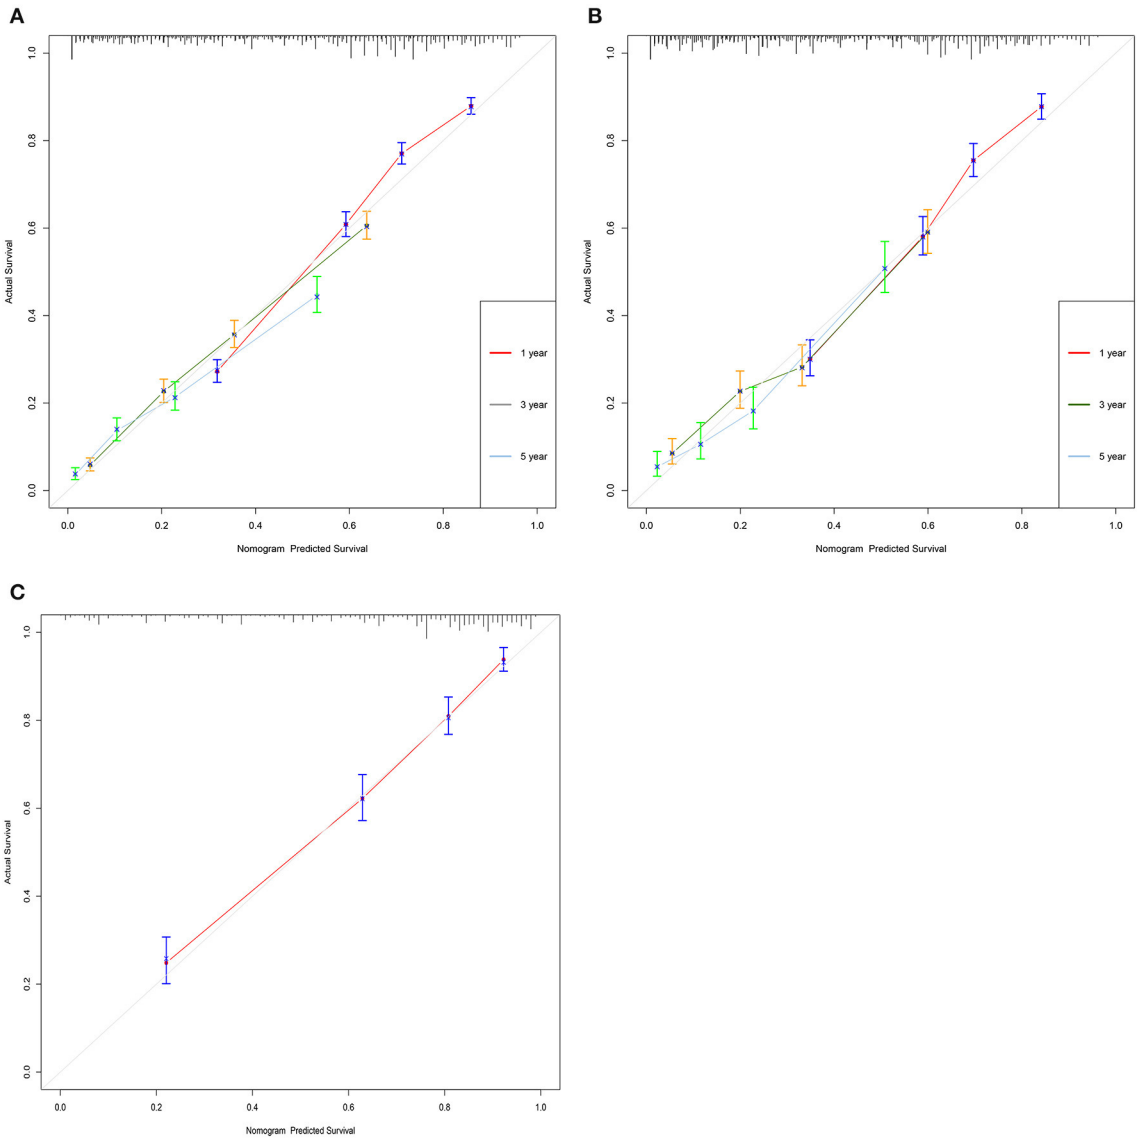

FIGURE 3 | Calibration curves of the nomogram. **(A)** For 1-, 3-, and 5-year OS in training cohort; **(B)** for 1-, 3-, and 5-year OS in validation cohort; and **(C)** for 1-, 3-, and 5-year OS in validation cohort.

model. Kaplan–Meier curves and log-rank tests study the relationship between a single variable and survival, and Kaplan–Meier and log-rank tests are only applicable to categorical variables, but not to numerical variables. The advantage of Cox proportional hazards regression analysis is that it can analyze categorical and numerical variables, and expand the scope of survival analysis from univariate to multivariate analysis (26). By univariate and multivariate Cox proportional hazard regression, several independent prognostic determinants were found to significantly affect OS, namely, age, T stage, histological grade, surgery, radiotherapy, chemotherapy, insurance, and stage of AJCC. We used these factors to construct and validate such prognostic nomograms to predict the probability of OS, and it is gratifying that the model manifested good discrimination and calibration, which meant it might act as a quantitative model to assess the probability of OS in patients with PC. At present, surgery is usually considered the optimal curative option for PC. It would always be recommended if the tumors were resectable. In our study, surgery had the greatest influence on OS in elderly patients with PC, followed by grade, AJCC stage, and T stage. As shown in this study, in most patients, resection of the masses was still the first option to achieve a longer OS with a significant p-value <0.001, indicating that extended pancreatoduodenectomy or local excision of the tumor should be considered even if the procedure is hard to conduct (27). Overall, surgical treatment has better OS than non-surgical treatment. The variance of tumor location in the pancreas can often be tackled in different ways, which determines the prognosis of

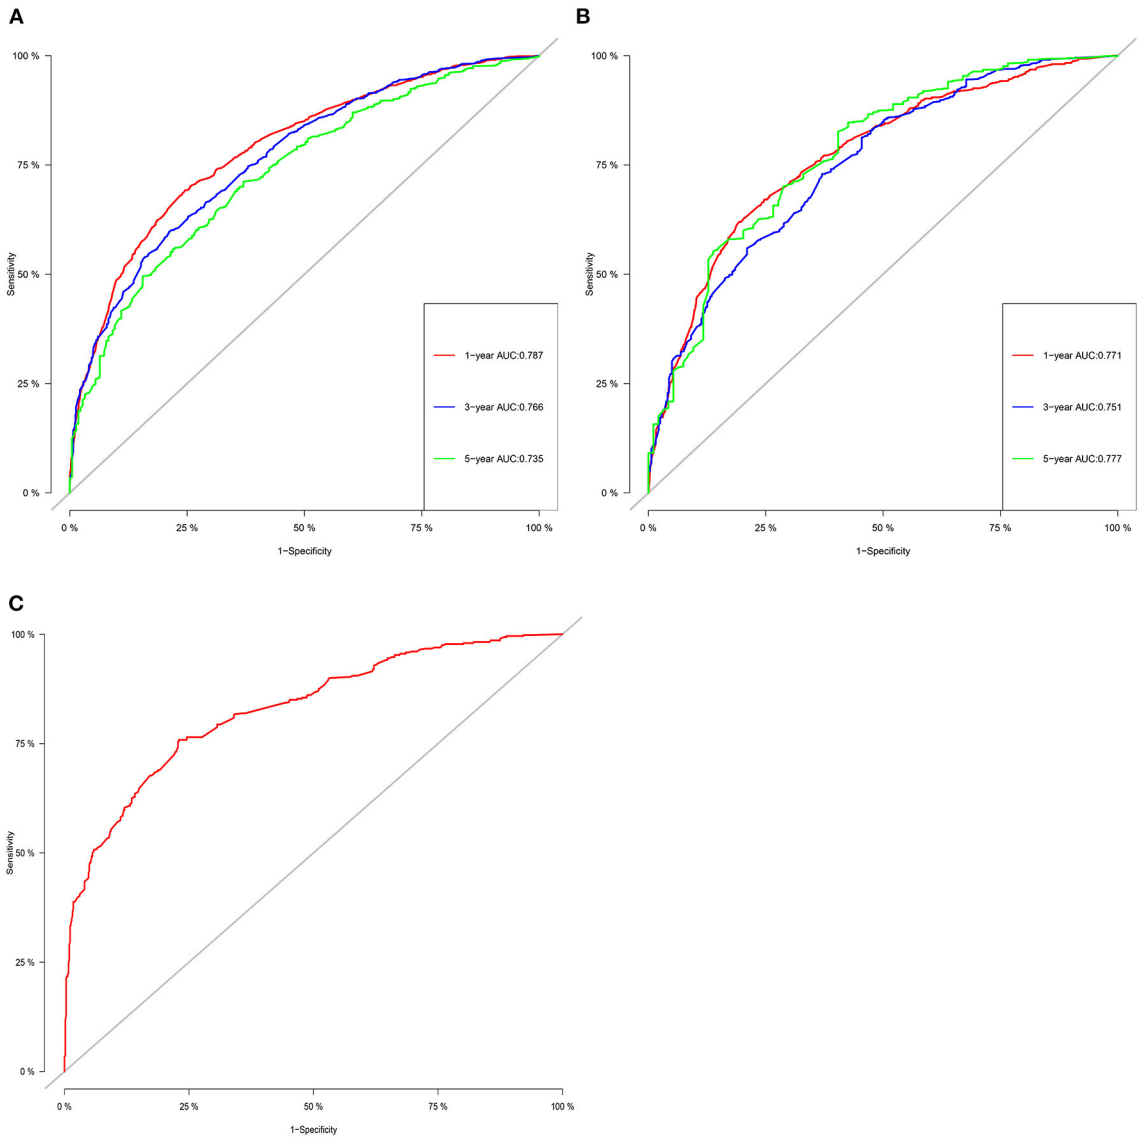

FIGURE 4 | The ROC for OS of 1-, 3- and 5-year of training cohort **(A)**, validation cohort **(B)**, and external validation cohort **(C)**.

patients. There still needs to be a larger randomized clinical research to further confirm it. Thus, the therapy selection of surgery decision was another robust indicator for prognosis in terms of the C-index.

The majority of patients with pancreatic adenocarcinoma are over 60 years of age (28, 29). In addition, it has been indicated that increasing age appears to be an important prognostic determinant that directly affects tumor-specific mortality. Further stratified survival analysis showed that patients older than 74 years had lower survival rates compared with those ages fell between 65 and 74 years old. This result resembled other studies which suggested that increasing age might helpful for the mortality of patients (14, 21). Furthermore, the previous study found that three-fourths of non-cancer-specific mortality was observed in elderly patients (13). Age-related comorbid conditions or complications may contribute to non-cancer-specific mortality in elderly patients with PC. This may be related to the decline in the function of the immune system caused by the aging of the patient, which in turn leads to the deterioration of the tumor and shortens the survival time of the patient. Therefore, it is of great significance to take non-cancer-specific mortality into account in the analysis of prognosis, especially in elderly patients.

As we knew, the TNM staging system or differentiation grade is a conventional method for doctors and researchers to evaluate cancer prognosis and select appropriate treatment strategies with respect to the survival of individual patients was still imprecise owing to it being relatively heterogeneous (30, 31). Therefore, the prognostic prediction model seems to be particularly valuable, especially for those who suffer from PC disease. In recent years, studies about the prognosis of PC

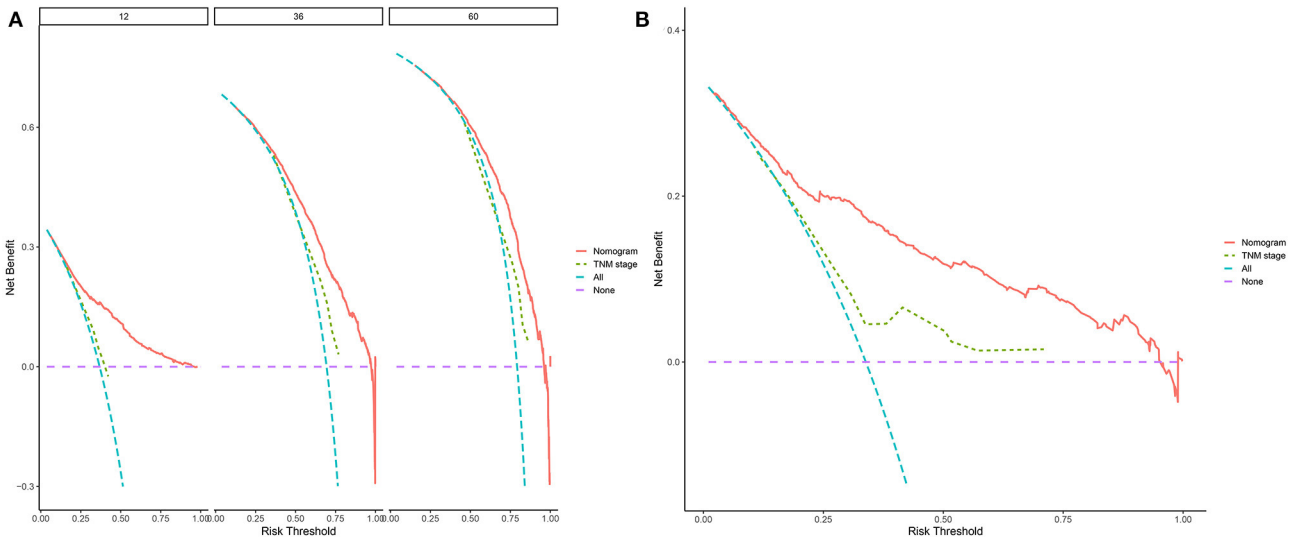

FIGURE 5 | Decision curves of the nomogram predicting OS in validation cohort **(A)** and external validation cohort **(B)**. The y-axis represents the net benefit, and the x-axis represents the threshold probability. The purple line indicates that no patients have died, and the blue line indicates that all patients have died. When the threshold probability is between 20 and 60%, the net benefit of the model exceeds all deaths or no deaths.

had been reported after the patients received surgical resection, chemotherapy, or radiotherapy (32–35). Tumor differentiation and TNM stage were commonly regarded as important factors in many cancers and some recent reports even combined these factors with other biomarkers to improve the prediction power (36–40). The performance of the nomogram was measured by the C-index and the area under the receiver operating characteristic (ROC) curve (AUC). All nomogram C-indices were >0.7, the larger the C-index, the more precise was the prognostic prediction, indicating that the model had good discriminatory power. AUC was used as a performance indicator to measure the merit of a machine learning model or a predictive model, a larger AUC (range 0.5–1.0) reflected a more accurate prediction. As indicated in this study, the ROC curves demonstrated that the nomogram showed better discrimination and the ability to provide an individualized prediction for patients. We proposed a nomogram that contains easily measurable clinical features, it is superior to the existing TNM staging system and is more conducive to patient counseling and the promotion of personalized treatment. Univariate analysis and logistic regression were performed to evaluate the impact of clinicopathologic and treatment variables on survival and find potential risk factors. Patients with advanced T stage and AJCC stage suffered from higher mortality and poorer survival rate as demonstrated by multivariate Cox regression analysis. Consistent with previous studies, carcinoma grade is a significant prognostic risk indicator (41). The nomogram model suggests that showed worse clinical outcomes when carcinoma grade shifted to poor differentiation from good differentiation.

Previous studies revealed that female, black, and unmarried patients had a worse OS (8), which was inconsistent with our study. Our study found that no significant difference existed in OS between patients with different marital statuses, gender, and race. Moreover, the multivariable analysis found that insurance has a significant impact on the OS of patients with PC. It is not difficult to imagine that medical insurance will directly affect the patient's choice of treatment, which will contribute to directly affecting the OS. Decision curve analysis (DCA) is a new calculation method that estimates the net benefits under various risk thresholds to evaluate the clinical value of the model. DCA was used to assess the clinical practicability of the model and compare it with T staging, which was a method for evaluating alternative diagnostic or prognostic tools that had advantages over others (42, 43). In this study, we used DCA to validate the accuracy and predictive ability of nomograms for elderly patients with PC, good clinical utility was indicated in the proper range. Validation of the nomogram was significant to avoid overfitting the model and determining representativeness (44). Calibration plots were used to assess the predictive accuracy of the model. In this study, the calibration curve described revealed excellent predictive performance, DCA showed superior net benefits than those of the TNM staging system, which could effectively guarantee the reliability of the constructed nomogram. Moreover, Kaplan–Meier curves showed that the OS of patients in the risk-low and risk-high groups was significantly different from each other, indicating that our model provides accurate surgical intervention and monitoring for high-risk groups, which implied good clinical application potential. Furthermore, we used data from 1,761 patients between 2016 and 2018 as external validation. The survival prediction showed that our prediction model has good accuracy and reliability. They formulated an online application for OS prediction with common and easy-accessible factors, which is convenient for clinical use.

Nevertheless, some limitations to our study should be considered as follows and also some remaining issues for the

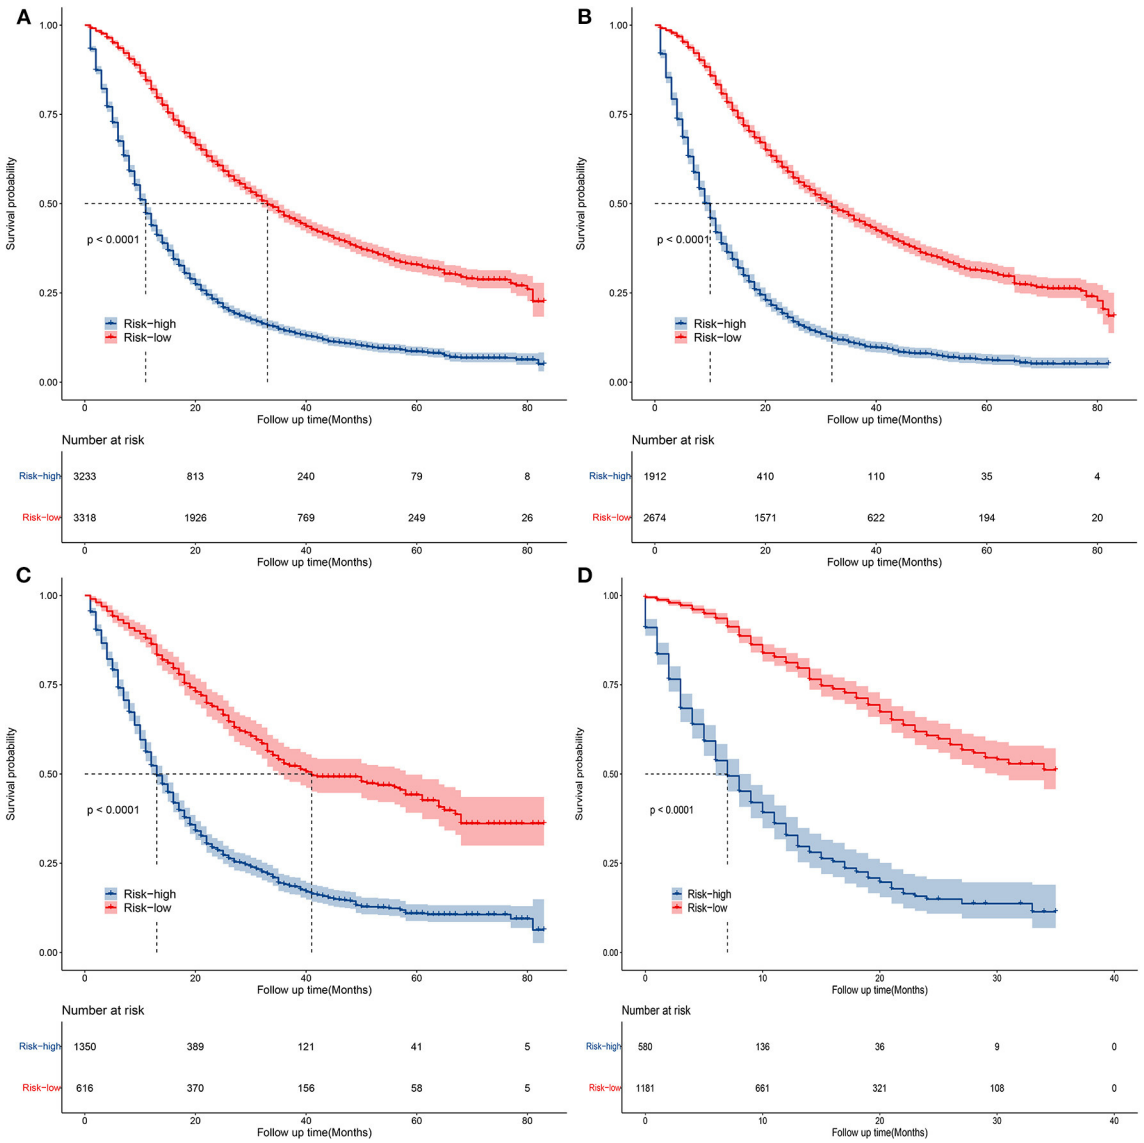

FIGURE 6 | Kaplan–Meier curves of OS for patients in the low- and high-risk groups in all cohorts **(A)**, training cohort **(B)**, validation cohort **(C)**, and external validation cohort **(D)**.

future. First, this is just a retrospective study. Next, although both the C-index and the calibration curve performed well, validation using a large other external data is still required to further evaluate the predictive accuracy and reliability of our models. Finally, other potential PC-related prognostic factors, such as the family history of PC, obesity, smoking, chronic pancreatitis, history of diabetes, pre-operative nutritional support, and vascular invasion, were not available in the SEER database.

To resolve the above-mentioned limitations, in the future, we aim at implementing the proposed model to determine its real-time applicability and scalability, and we will take other potential PC-related prognostic factors into account during the construction and validation of the model, such as the family history of PC, obesity, smoking, chronic pancreatitis, history of diabetes, and pre-operative nutritional support, lymph node metastasis, and vascular invasion. Besides, methods driven by artificial intelligence (AI) such as deep learning and reinforcement learning will be considered in the formulation of the predictive model, which can help predict specific parameters, hazards, and outcomes (45, 46). Because the blockchain is employed to ensure trust among entities, data immutability, availability, and information security, a predictive model that combines AI and blockchain technology to analyze and integrate clinical characteristics of patients will also be further studied (47, 48). AI and ML could make predictive models smarter and more interesting. Different ML concepts could be added to predictive models to induce a dynamic prediction model. Furthermore, the

feasibility of the models could also be studied by examining the computational complexity (49).

CONCLUSIONS

In conclusion, we analyzed the clinicopathological factors determining OS of elderly patients with PC using a large population-based SEER database. Cancer-specific mortality and competing risk mortality were evaluated. Furthermore, nomograms for predicting 1-, 2- and 3-year OS in elderly patients with PC were established for the first time based on a large study cohort. This constructed nomogram showed good performance and can help doctors and elderly patients with PC to more accurately and conveniently predict individual survival and formulate treatment and follow-up strategies.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://seer.Cancer.gov/.

ETHICS STATEMENT

The data of this study are obtained from the SEER database. The data of patients are public and anonymous, so this study does not require ethical approval and informed consent.

Xue Y, Pyong KH, Oh SS, Tao Y and Liu T (2022) Analysis of the Impacts on the Psychological Changes of Chinese Returning College Students After the Outbreak of the 2019 Coronavirus Disease. Front. Public Health 10:916407. doi: 10.3389/fpubh.2022.916407

This work aims to analyze the impacts on the psychological changes of Chinese returning college students after the outbreak of the 2019 coronavirus disease (COVID-19). A questionnaire survey is used to take 1,482 college students who returned to school after the epidemic as the research objects. The Chinese college students' knowledge of the epidemic, alienation in physical education class, school happiness, and expectations for a healthy life in the future are investigated and analyzed. The research results manifest that Chinese returning college students have relatively poor awareness of COVID-19, and the overall degree of alienation in physical education classes after the epidemic is low, with an average score of 3.55 ± 1.018. The overall level of school happiness is high, with an average score of 4.94 ± 0.883; the overall level of expectation for a healthy life in the future is high, with an average score of 3.50 ± 0.840. It denotes that the epidemic has a great psychological impact on returning college students, and it is necessary to strengthen mental health education for college students after COVID-19. It provides a sustainable theoretical reference for the formulation of psychological intervention measures for returning college students.

Keywords: COVID-19, college students, alienation, school happiness, psychological changes

INTRODUCTION

A major infectious disease broke out in China at the end of 2019, that is, pneumonia caused by a new type of coronavirus, which is called "Corona Virus Disease 2019" by the World Health Organization (WHO) (1, 2). The outbreak of Corona Virus Disease 2019 occurred in December 2019, mainly in Wuhan City, Hubei Province, China. The cause of the disease was unknown. Epidemiological investigations found that they had all been to the Huanan Seafood Market, and were finally diagnosed as acute respiratory disease caused by new coronavirus infection (3). Comrade Tedros of the WHO announced in Geneva, Switzerland on February 11, 2020, that the disease was named as "COVID-19" (4). Meanwhile, the National Health Commission (NHC) issued a notice on February 22 to change its English name to "COVID-19." After that, WHO declared the

current COVID-19 outbreak a global pandemic on March 11 (5, 6). COVID-19 is an infectious disease of the respiratory tract caused by coronavirus type 2 infection, which can induce severe acute respiratory syndrome (7). Since the onset of the disease, all provinces, municipalities, and autonomous regions in China have taken strict prevention and control measures to avoid travel and crowd gathering as much as possible, and have achieved good results. According to the existing case data, the main manifestations of COVID-19 include fever, dry cough, and fatigue. A small number of patients will have symptoms of the upper respiratory and digestive systems, such as nasal congestion, runny nose, and diarrhea. Severely ill patients usually suffer symptoms of dyspnea after 7 days of onset, can be complicated by Acute Respiratory Distress Syndrome (ARDS) in a short period of time, and then develop septic shock and metabolic acidosis (refractory), multiple organ failure, etc. (8–10). COVID-19 is a Class B infectious disease managed at the national level, and a public health emergency. Since the establishment of the People's Republic of China, it has spread the fastest, and it is the most widespread and the most difficult to prevent and control infection among major public health events (11). College students are in an active period of physical and mental development. Faced with the dual pressures of the epidemic and their studies, college students are more likely to have negative emotions, develop bad living and exercise habits, and decline in physical fitness.

So far, measures for the prevention and control of the COVID-19 epidemic taken by Chinese government have developed from the initial emergency state to the current normalization work. Full-scale implementation began, and in the meantime, the resumption of normal work and production has been actively underway (12). The Guidelines for the Prevention and Control of Novel Coronavirus Pneumonia in Colleges and Universities proposed in March 2020 stated that the huge pressure caused by the new coronary pneumonia can easily induce psychological stress such as anxiety, depression, and hypochondriasis. During the period of the epidemic, students were isolated and managed at home. The government and schools encouraged and supervised students to exercise through online physical education teaching and assignment of exercise homework. However, home exercise mainly relies on students' conscious self-exercise, and schools lack effective monitoring methods (13, 14). This has a great impact on college students' self-efficacy, life behavior, mental health, learning adaptability, social responsibility and values (15, 16). With the continuous progress and development of information technology, the research methods in psychology have also undergone great changes since the 1940s (17). In the 1970s, some experts tried to use computers to carry out experiments in psychology, which led to the first revolution in the psychology. In the 1990s, the birth of the online psychological questionnaire was the second revolution in psychology due to the advancement of network technology. At this stage, experts and scholars in the psychology established virtual psychological laboratories on the Internet. The advent of the era of big data has prompted the beginning of the third revolution in psychology. The samples of big data are featured with large amount of data, various types, fast traffic, and great potential significance. They have gradually become valuable resources for researchers to observe the characteristics and laws of human psychological behaviors (18–21).

Compared with previous studies, psychological research based on big data technology has great advantages. This shows that psychological research in the past has focused more on the explanation of a certain psychological response. Big data technology can predict and intervene certain psychological reactions on the basis of interpretation (22). Furthermore, the research method based on big data technology can conduct an overall analysis of all data, avoid the sampling error of previous research methods from the sample to the overall promotion, reduce the experimental error caused by improper control of experimental conditions, and greatly improve the efficiency and scale of data processing. In terms of time validity, real-time collection and analysis of psychological states avoid the deviation of analysis results caused by the lag of data collection in traditional research methods (23, 24). The innovation is the use of regression analysis to examine the status of COVID-19-related knowledge among Chinese returning college students after the COVID-19 pandemic, as well as changes in their alienation in physical education classes, school happiness, and expectations for a healthy life in the future. This study aims to provide a sustainable theoretical reference for the formulation of psychological intervention measures for returning college students. The research framework is to first introduce the research objects, observation indicators and survey methods of the questionnaire; then regression analysis is used to analyze the changes in Chinese returning college students' alienation in physical education classes, school happiness, and expectations for a healthy life in the future after the COVID-19 pandemic.

MATERIALS AND METHODS

Research Objects

The random sampling is adopted to investigate the college students who returned to school after the COVID-19 pandemic in different provinces and cities in China. From June to October 2020, a questionnaire survey was conducted on 1,482 college students who were approved to return to school under the principle of informed consent. The included college students have to meet the following criteria: full-time college students returning to school after the epidemic (undergraduate, master, and above) and returning college students who are informed with this experiment and cooperate with the investigation. If any student meets the below items, it has to be excluded: students who have left or dropped out of school; and students who are on-the-job, self-taught adults, or receiving correspondence education. All respondents have fully understood the situation and signed the informed consent forms, and the Medical Ethics Committee of our hospital has also been informed and agreed to implement it.

Observation Indicators

The general information of included students is investigated, including gender, age, grade, major, and place of origin. Cognition of COVID-19 includes what type of infectious disease is the COVID-19 and its route of transmission, the

main symptoms, the method of transmission, and the personal preventive measures. The situation related to the COVID-19 epidemic includes what information about the epidemic situation is the most concerned about, how much time it takes to pay attention to the epidemic situation every day, how to obtain relevant information about the epidemic situation, and the attention in information about the epidemic situation reported by the media. College student alienation scale (25): there are 52 questions in total, the higher the score, the stronger the alienation. The school happiness scale for college students (26): there are 36 questions, the higher the score, the higher the level of happiness. The expected measure of future healthy life (27): there are 16 questions in total, the higher the score, the higher the expectation.

Investigation Methods

The questionnaire survey is carried out by scanning the questionnaire star QR code with a smartphone. After the consents of the participants are obtained, the mobile phone WeChat is adopted to scan the code to open the general information about returning college students after the COVID-19 pandemic, COVID-19 awareness, epidemic-related situations, alienation in physical education classes, school happiness, and future life expectations. The researcher writes the instruction language uniformly, follows the principle of free and informed consent, and explains the purpose of the questionnaire survey and the confidentiality principle in detail to the participants. In the context of the questionnaire star operation, effective permission settings are carried out, that is, an IP address can only answer the questionnaire online once, and the filling time is not $<$5 min.

Linear Regression Analysis

Linear regression refers to a regression analysis that simulates the relationship between one or more independent variables and dependent variables through the least squares function obtained from the linear regression equation (28). This least squares function is a linear combination of model parameters and one or more regression coefficients. There are also such relationships in our daily life, such as the irrelevant relationship between random numbers, the uncertain relationship between individual height/weight, and the definite relationship between the area/radius of a circle. Regression analysis is one of the mathematical methods that is often used to study the existence or absence of correlations between variables that are not completely determined. When only one independent variable is used for regression analysis, it is called univariate linear regression analysis; when there are multiple variables, it is called multiple linear regression analysis.

I. Univariate linear regression analysis

Univariate linear regression analysis, also known as Simple Linear Regression (SLR), is the simplest regression analysis, and there are regression models that are widely used in various fields of life. Its regression equation is given as follows:

$$A{=}\alpha + \beta B + \varepsilon \tag{1}$$

In general, the least squares method is used to evaluate the minimum errors α and β from the sample (a_i, b_i) (i = 1,2,…,n), ε represents the residual, and the objective is to minimize the residual sum of squares:

$$\sum_{i=1}^{n} \varepsilon_i^2 = \sum_{i=1}^{n} \left(a_i - \alpha - \beta b_i\right)^2 \tag{2}$$

The extreme value can be obtained by using the differential method. In equation (2), the first-order partial differential is made with α and β, respectively, and it is equal to 0 to obtain $\widehat{\alpha}$ and $\widehat{\beta}$:

$$\widehat{\alpha} = \bar{a} - \bar{b}\widehat{\beta} \tag{3}$$

$$\widehat{\beta} = \frac{\sum_{i=1}^{n} \left(b_i - \bar{b}\right)(a_i - \bar{a})}{\sum_{i=1}^{n} \left(b_i - \bar{b}\right)^2} \tag{4}$$

II. Multiple linear regression analysis

The equation for the multiple linear regression prediction model is expressed as follows:

$$\widehat{A}_t = \alpha + \beta_1 b_1 + \beta_2 b_2 + \beta_3 b_3 + ... + \beta_n b_n \tag{5}$$

b_1-b_n represent independent variables; α, β_1-β_n express the parameters of the linear regression equation. The binary linear regression analysis model with only two independent variables is the general form of the multiple linear regression model, which is a method for analyzing the correlation between two independent variables and one dependent variable. Its regression equation is given in equation below:

$$\widehat{A}_t = \alpha + \beta_1 b_1 + \beta_2 b_2 \tag{6}$$

In the above equation, $\widehat{A}_t$ represents the dependent variable, b_1 and b_2 represents the independent variables; α, β_1, and β_2 indicate the parameters of the linear regression equation. α, β1, and β2 can be obtained by solving below equation:

$$\begin{cases} \sum a = n\alpha + \beta_1 \sum b_1 + \beta_2 \sum b_2 \\ \sum b_1 a = \alpha \sum b_1 + \beta_1 \sum b_1^2 + \beta_2 \sum b_1 b_2 \\ \sum b_2 a = \alpha \sum b_2 + \beta_1 \sum b_1 b_2 + \beta_2 \sum b_2^2 \end{cases} \tag{7}$$

Ensemble Learning Method

There is a famous theory of "no free lunch" in machine learning, which states that no algorithm can maintain its accuracy all the time. Therefore, the concept of ensemble learning appears (29). The main idea of ensemble learning is to use a certain strategy to aggregate multiple base classifiers to obtain higher accuracy. Different base classifiers can use different algorithms, parameters, features, training data sets, etc. The basic idea of Bagging, Boosting, and Stacking is to integrate three strategies.

Among them, the basic idea of the Stacking strategy (30) is to train a variety of base classifiers $\{D_1, D_2, ..., D_N\}$. In addition, the Stacking strategy uses the output results $\{q_{i1}, q_{i2}, ..., q_{iN}, a_i\}$ of these base classifiers as input data, retrains to obtain a new model, and obtains the final result. output result.

Boosting tree is a boosting method based on the decision tree function. When it faces the classification task, this decision tree represents a binary decision tree; In the regression problem, the decision tree represents the regression tree, and the boosting tree can be regarded as an additive model of the decision tree:

$$f_N(b) = \sum_{n=1}^{N} T(b; \Theta_n) \tag{8}$$

In equation (8), Θ_n refers to the model parameters, $T(b; \Theta_n)$ denotes the decision tree model, and N is the number of trees.

When binary classification is required, boosting tree is a special case of binary decision trees specified by the base classifier of the AdaBoost algorithm.

Gradient Boosting Decision Tree (GBDT) is an optimization that can be used to solve the optimization problem when the loss function of the boosting tree is a general function (i.e., a non-square loss function or a non-exponential loss function). The GBDT algorithm flow is described as follows. The value of the negative gradient of the loss function in this model plays a key role in the gradient boosting algorithm, which is an algorithm that is very similar to the steepest descent method:

$$-\left[\frac{\partial L(a_i, F(b_i))}{\partial F(b_i)}\right]_{F(b)=F_{k-1}(b)} \tag{9}$$

When faced with a binary classification, the loss function that can be defined is as follows:

$$L(a, F(b)) = \log(1 + \exp(-2aF)), a \in \{+1, -1\} \tag{10}$$

The process of GBDT is as follows:

Input: training dataset $D = \{(b_1, a_1), (b_2, a_2), ..., (b_N, a_N)\}$, a function that is capable of micro-loss is $L(a, F(b))$, and the number of iterations is K.

Output: the GBDT model $F_K(b)$.

The model is initialized as follows:

$$F_0(b) = \arg_\gamma \min \sum_{i=1}^{n} L(a_i, \gamma) \tag{11}$$

k = 1,2,...,K is cycled:

(a) The desired pseudo-residuals are calculated with equation (12) below:

$$r_{ik} = -\left[\frac{\partial L(a_i, F(b_i))}{\partial F(b_i)}\right]_{F(b)=F_{k-1}(b)}, for i = 1, ..., n. \tag{12}$$

(b) The pseudo-residual is fitted to the base classifier $g_k(b)$, that is, the training dataset $\{(b_i, r_{ik})\}_{i=1}^{n}$ is adopted to train the base classifier.

(c) The multiplier γ_k can be calculated by solving a one-dimensional optimization:

$$\gamma_k = \arg_\gamma \min \sum_{i=1}^{n} L(a_i, F_{k-1}(b_i) + \gamma g_k(b_i)) \tag{13}$$

(d) The model is updated:

$$F_k(b) = F_{k-1}(b) + \gamma_k g_k(b) \tag{14}$$

Statistical Analysis

The SPSS 19.0 statistical analysis software package is adopted to enter and analyze the data in this experiment, *t*-test or variance analysis is applied to judge the differences between variables, and the multiple linear regression is selected to analyze the changes on dimensions of alienation and school happiness, expectations for a healthy life in the future. When $P < 0.05$, the difference is statistically significant.

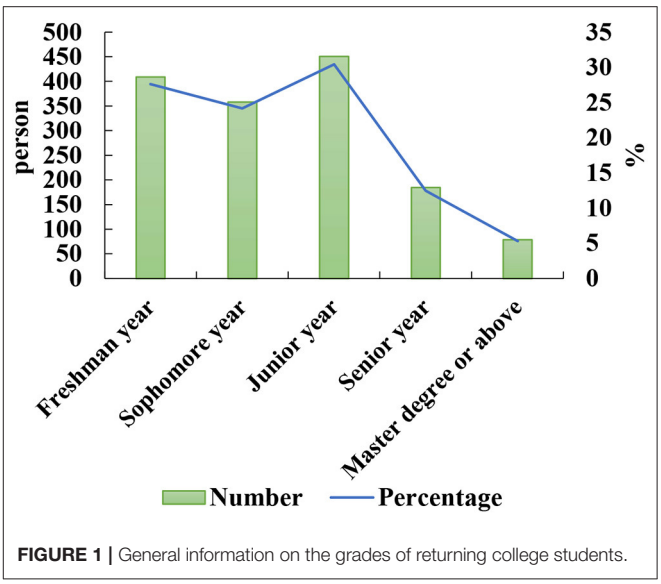

FIGURE 1 | General information on the grades of returning college students.

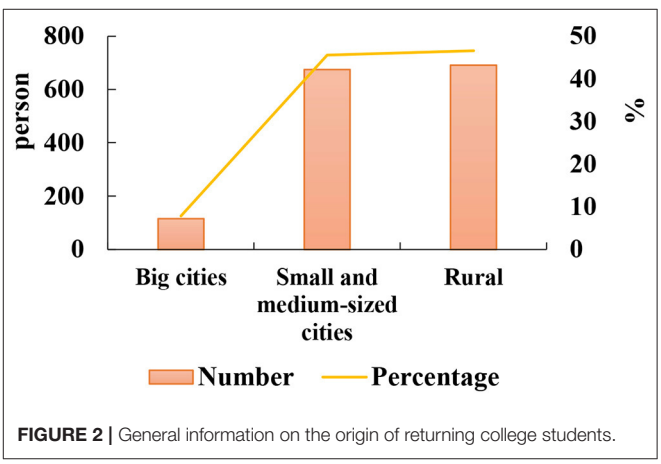

FIGURE 2 | General information on the origin of returning college students.

RESULTS

General Data

After the COVID-19 pandemic, the general information of Chinese returning college students (n = 1,482) is collected, as shown in **Figures 1**, **2**.

Among them, the numbers of males and females are 519 and 963, respectively, aged between 18 and 30 years old, with liberal arts students accounting for 41.26% and science students accounting for 58.74%. In **Figures 1**, **2**, the proportion of freshman students is 27.6%, junior students is 30.43%, and graduate students and above is 5.33%. Among returning college students, 7.83% came from big cities, 45.55% from small and medium cities, and 46.62% from rural areas.

Cognition of COVID-19

After the COVID-19 pandemic, we investigated Chinese returning college students' cognition of the disease and found that 96.7% knew that during the COVID-19 epidemic, the protective measures that people need to do include 6 aspects; and only 10.78% knew that the main manifestations of COVID-19 infection included 3 symptoms. **Figure 3** showed the details.

In the **Figure 3** above, A represents the protective measures that people need to do during the COVID-19 epidemic: washing hands frequently, refusing to eat wild animals, wearing disposable medical masks when entering and leaving public places, trying to avoid entering and leaving crowded places, staying within one meter of people around, opening the window regularly to ventilate, and reduce going out. B represents the main mode of transmission of COVID-19: close contact between people and respiratory droplet transmission. C stands for low case fatality rate of COVID-19; D represents the category B infectious disease of COVID-19 according to the prevention and control management of the category A infectious disease; E represents that if you know that in the absence of effective protective measures, if you have face-to-face communication with infected people, share meals, take public transportation, eat wild animals, or accept express delivery from areas with high epidemic incidence, it will increase the risk of epidemic transmission. F stands for the main clinical manifestations of COVID-19 infection, including fever, dry cough, and fatigue.

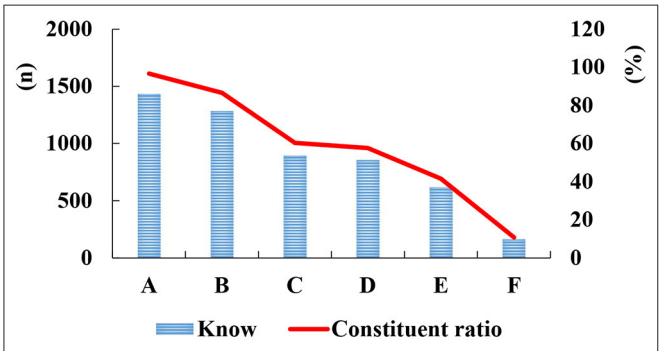

FIGURE 3 | The cognition of Chinese returning college students on the disease after the COVID-19 pandemic.

Situation of COVID-19

After the COVID-19 pandemic, we investigated the three main ways that Chinese returning college students obtain information related to COVID-19: web browsing (91.70%, 1,359/1,482), social tools such as QQ or WeChat (77.68%, 1,151/1,482), television / radio / billboard / billboard (74.8%, 1,108/1,482). The average time spent paying attention to the epidemic every day is 24.50 ± 22.6 min. The most concerned epidemic information includes: epidemic situation (58.86%, 872/1,482), research progress (22.87%, 339/1,482), and prevention and control knowledge (21.04%, 312/1,482). Concern on media reports on epidemic-related information is explained as: very concerned (73.14%, 1,084/1,482), generally concerned (25.48%, 378/1,482), and rarely concerned (4.05%, 600/1,482). The details are given in **Figure 4**.

In the above figure, **Figure 4A** shows the three main ways Chinese returning college students obtain information about COVID-19; **Figure 4B** shows the epidemic information they are

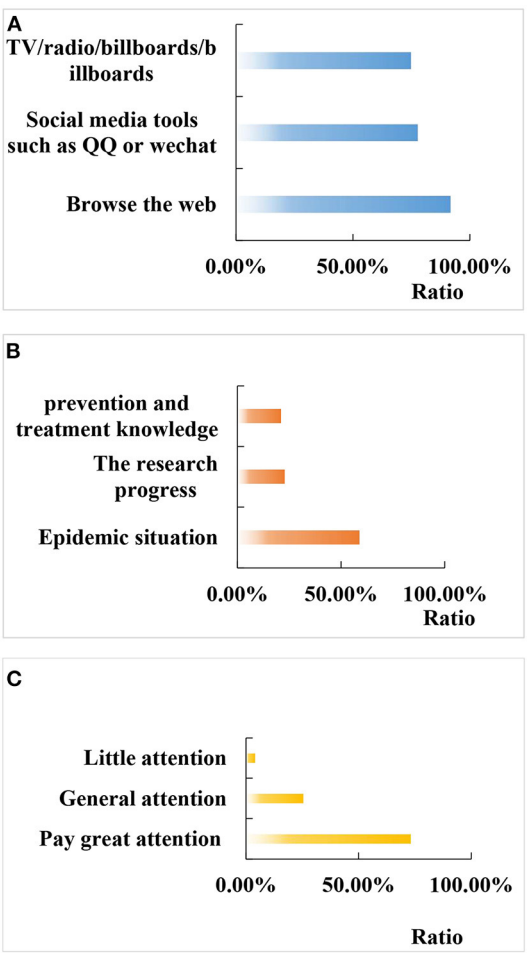

FIGURE 4 | The situation related to the COVID-19. **(A)** Main access way; **(B)** most concerned epidemic information; **(C)** attention to the information related to the epidemic situation reported by the media.

TABLE 1 | Comparison of alienation and school happiness in demographic data.

Alienation and school happiness	Difference in demographic data
Alienation	The score of boys (4.52 points in average) is higher than that of girls (4.31 points).
	The average score of Freshmen (3.98 points) is lower than the score of other grades (4.39 points).
	The average score of non-only children (4.45 points) is higher than that of only children (4.26 points).
	The average score of students living in rural areas (4.38 points) is higher than other places (4.07 points in average).
School happiness	The score of upper class students (average 5.82 points) is higher compared with that of lower class students (5.13 points in average).
	The score of students living in urban areas (with the average of 5.74 points) is slightly higher in contrast to that in rural and urban areas (5.25 points).

most concerned about; and **Figure 4C** shows their attention to media reports on epidemic-related information.

Differences in Alienation and School Happiness in Demographic Data

After the COVID-19 pandemic, the alienation in physical education class and school happiness of Chinese returning college students are compared in the term of demographic data. The results are shown in **Table 1**. It demonstrates that that among returning college students, the average alienation in physical education class is higher for boys than for girls. The average of freshmen is lower than that of other grades, the average of non-only children is higher than that of only-children, and the average score of students living in rural areas is higher than in other places. In terms of school happiness, among returning college students, the score of upper class students is higher compared with that of lower class students, and the score of students living in urban areas is slightly higher in contrast to that in rural and urban areas.

Scores of Three Scales for Returning College Students

After the COVID-19 pandemic, the overall degree of alienation in the physical education class of returning college students in China is relatively low, with an average score of 3.55 ± 1.018; the overall level of school happiness is relatively high, with an average score of 4.94 ± 0.883; and the overall level of expectations for a healthy life in the future is high (3.50 ± 0.840 in average). The specific results were shown in **Figure 5**.

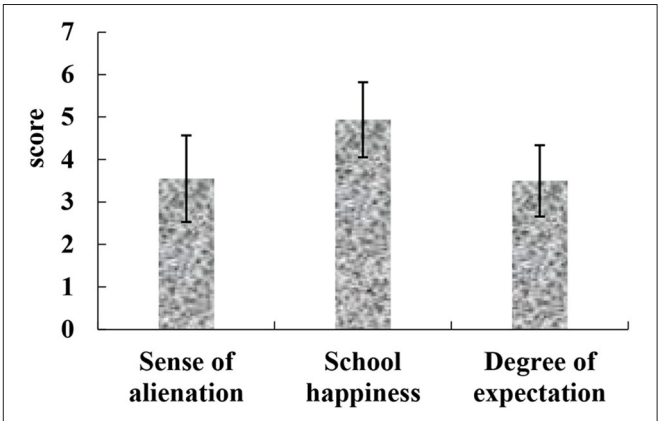

FIGURE 5 | The situation of the three scales of returning college students.

Regression Analysis

After the COVID-19 pandemic, the total score of college students returning to school in the alienation in physical education class is undertaken as the dependent variable and the school happiness and expectations for a healthy life in the future are taken as independent variables for multiple linear regression analysis. Stepwise regression method is used to screen out the optimal combined variable mode. The independent variables included in the model are shown in **Figure 6**.

In the above figure, A represents friendship happiness, B represents academic happiness, C represents freedom happiness, D represents environmental happiness, and E represents expectations for a healthy life in the future.

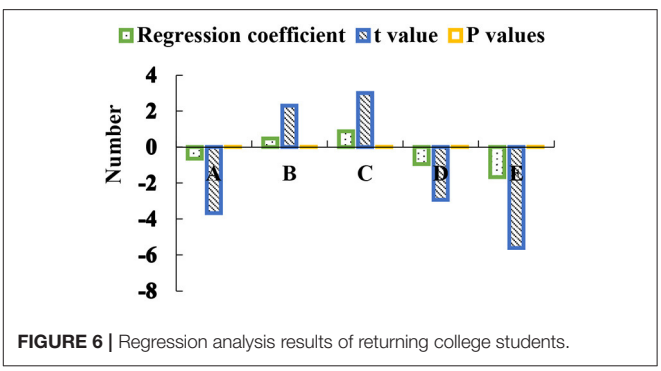

FIGURE 6 | Regression analysis results of returning college students.

Analysis of Mediation Effect

The test procedure of the mediation effect should be followed. The first step: school happiness is selected as the independent variable and alienation is undertaken as the dependent variable to start the regression analysis with the equation of y=-0.723x ($P < 0.05$). The second step: the school happiness is taken as the independent variable, and the expectation degree is used as the dependent variable to start the regression analysis using $m = 0.260x$ ($P < 0.05$). The third step: the school happiness and the expectation degree are determined as independent variables, and the alienation is used as the dependent variable for the

	β value	t value	P value
number	-0.723	-17.24	0.002

FIGURE 7 | The first step of the mediation effect analysis.

	β value	t value	P value
number	0.26	17.87	0.002

FIGURE 8 | The second step of the mediation effect analysis.

	β value	t value	P value
B	-0.374	-9.44	0.002
A	-2.143	-21.85	0.002

FIGURE 9 | The third step of the mediation effect analysis (in the above figures, A indicates that the expectation is the independent variable, and B indicates that the school happiness is the independent variable).

regression analysis using y=-0.374x-2.143m ($P < 0.05$). The specific results are illustrated in **Figures 7–9**.

Figure 7 denotes that the school happiness is selected as the independent variable, and the alienation is selected as the dependent variable for regression analysis, and the *P*-value is 0.002. **Figure 8** refers that the school happiness is selected as the independent variable, and expectation is the dependent variable for regression analysis, and the *P*-value is 0.002. **Figure 9** indicates that the school happiness and the expectation of healthy life in the future are selected as independent variables, and alienation is used as the dependent variable for regression analysis, and the *P*-value is 0.002. It shows a positive correlation when $P < 0.05$.

DISCUSSION

Some experts have pointed out that COVID-19 is an infectious disease of the respiratory tract caused by coronavirus type 2 infection, which can induce severe acute respiratory syndrome. In the world, prevention and control is very difficult (31). Therefore, effective prevention and control publicity and education are needed. The results of this work show that "web browsing" and "social tools (QQ, WeChat, etc.)" are the two most important ways for returning college students to acquire knowledge about the epidemic after the COVID-19 epidemic; in addition, 73.14% of returning college students are very concerned about "the information about the epidemic reported in the media news." The study pointed out that the most trusted source of news is the relevant information released by the official media, and the information stated by the authority has a significant inhibitory effect on the panic of the public (32). There is a positive relationship between the dissemination of information and the risk perception of COVID-19 in the official media (33). It is suggested that schools can use the "school official website, WeChat public account, and QQ group" as well as other platforms to publish publicity and education on the prevention and control of coronavirus disease.

Some documents indicate that alienation is the alienation of the relationship between the individual and the people around him and the society, the natural environment and himself. What's more, it may be controlled and dominated by the object, causing the individual to appear negative emotions such as social isolation, depression, meaninglessness of life, and self-enclosure (34). The average score of returning college students in alienation in physical education class is relatively high. This may be related to everyone's panic about the epidemic, and their lack of knowledge about the epidemic has increased the psychological pressure of returning college students and felt that life is oppressive. Such results are consistent with the findings of Masdrakis et al. (35).

In psychological research, happiness refers to an emotional state that occurs when an individual realizes that his needs are met and his ideals are realized (36). It is a complex and diverse emotional state based on the interaction between psychological factors such as needs (including motivation, desire, and interest), cognition, emotion, and external factors. Happiness indicates the assessor's assessment of the quality of life according to the set standards. The implementation of the overall assessment is a comprehensive indicator to measure the quality of life of an individual (37). In this work, the school happiness of returning college students is relatively high, perhaps because college students have good psychological quality and strong anti-stress ability, can quickly adapt to the environment, and effectively

adjust their negative emotions, so that anxiety can be relieved. The average score of expectations for a healthy life in the future is also relatively high, perhaps because college students live in a relatively simple environment, and their classmates spend a long time with each other and are familiar with each other. In addition, some studies have pointed out that college students have received good higher education, have their own ideas about the future direction, and acquire knowledge relatively quickly, so they have high expectations for future life (38). The disadvantage is that the online questionnaire survey method is used, and the number of respondents is limited and there are regional differences. In future research, a systematic random sampling survey will be conducted according to different regions and different school categories to make the survey results more representative.

CONCLUSIONS

After the COVID-19 pandemic, the cognition on the disease, alienation in physical education class, school happiness, and expectations for a healthy life in the future of Chinese returning college students are investigated and analyzed. It is found that the cognition of college students on COVID-19 is relatively poor. The overall levels of alienation in physical education classes, school happiness, and expectations for a healthy life in the future are relatively high. It can be concluded that the epidemic has a great impact on the psychology of returning college students, and it is necessary to strengthen the mental health education of college students on COVID-19. The disadvantage is that the online questionnaire survey method is used, and the number of respondents is limited and there are regional differences. In future research, a systematic random sampling survey will be conducted according to different regions and different school categories to make the survey results more representative.

Citation:
Zhang S (2022) Application Research of Public Art in the Design of Old People's Rehabilitation Space Based on Virtual Information Interaction Platform From the Perspective of Developing Economies. Front. Public Health 10:917330. doi: 10.3389/fpubh.2022.917330

To solve the problem of the design of the old people's recuperation space, the virtual information interaction platform is used to study the public art application in the design of the old people's recuperation space. Firstly, the principles of interactive design are expounded, and secondly, the existing institutions for the old people are investigated. Under the premise of optimizing the functions of the facilities, the concepts of humanistic care, emotional care and humanization in public art are integrated into the design of the old people's rehabilitation space, to solve the long-term negative impression of the old people's repression and indifference to the old people's care institutions. The construction of the scene allows the old people to experience some operations with the help of the virtual information interaction platform. In the modern elderly rehabilitation space, the attention and application of public art design will inevitably bring spiritual and material help to the old people in their later years, and create a happy, peaceful, and comfortable elderly life for them. The survey results manifest that 65.3% of urban old people and 71.8% of rural old people feel that they cannot keep up with the pace of development. Through the analysis and discussion of the physiological and psychological characteristics of the old people, the whole survey denotes that the physiological functions of the old people are declining, which seriously affects their normal life. Therefore, the design of the rehabilitation space for the old people should not only meet the basic needs of life, but also analyze the space design from the perspective of humanization and emotion. An ecological, natural, and human settlement environment has been established. The recuperation space is designed for the needs of different old people, which helps the old people to eliminate loneliness, enhance their value of the old people, and make life full of joy and meaning for the old people.

Keywords: old-age, recuperation space, virtual information interaction platform, public art, design

INTRODUCTION

The aging of the population is gradually becoming a worldwide topic and an important issue for many countries at this stage. Since the end of the last century, China has entered an aging society. China is a country with a large number of old people population in the world, and also one of the countries with the fastest growing degree of aging (1, 2). How to deal with the needs of many old people and provide more comfortable living conditions for older people is one of China's current national conditions. From the change of social and family roles, the old people are prone to psychological imbalance, which leads to loneliness. In addition to caring for their physical health, the focus of the old people's emotional space is equally critical, so that their later life can be full of happiness and care. In China, with the rapid growth of the elderly population and a large base, little attention has been paid to the old people, and less care has been given to the old people (3). After the old people withdrew from the social role, most of the time they lived at home or in the old-age institutions, and they were more dependent on their living space in their later years. They need to go to public life and communicate with others. Therefore, the living space of the old people should create a living space suitable for health, recreation, emotional communication, social play, and pleasing life (4).

There are many studies on the old people. For example, Lee et al. (5) developed eight personas representing four different user groups in the context of home appliance use: visually impaired, hearing impaired, spinal cord impaired, and the old people. Each has a persona as a tool to understand the target user, a persona card representing their task obstacles, frustrations, needs and references, and a cartoonish persona. In this study, two common accessibility issues and two role-specific issues are addressed in each user group (5). These questions are presented in the language roles of stakeholders to help them understand users. Tsuchiya et al. (6) conducted a study on the evaluation of smart home control systems for the old people with a sample of 10 users in inland cities in Brazil. The control system consisted of a prototype using a web-based mobile application, which was developed taking into account requirements obtained from previous studies and recommendations from the literature The study demonstrated clearly the importance of providing information directly by identifying the user's home location in the application, not hiding information under scrolling, appropriately using images and videos in the system to avoid confusion, limiting the number of open windows to maintain context, avoiding unclear interactive elements to facilitate, and showing the visuals of the room and appliances on the screen (6). The findings could help improve the old people's interactions with smart home systems, especially in rural areas of developing countries. And public art is no longer an unfamiliar word in contemporary China. After the reform and opening up in the 20th century, it became a topic of great concern to Chinese artists in the 1990s (7). The development of contemporary Chinese public art is gradually developed and improved along with the adjustment of national policies, the marketization and internationalization of the economy, the socialization of rapid urban development, and the continuous improvement of citizens' rights. Since the beginning of the 21st century, public art has shifted from intense topic discussion to practical research in China, and is entering the urgent needs and rapid development of contemporary society (8, 9). With the rapid development of China's economy and the urgent need for public art culture, China's contemporary public art and its theories are constantly advancing and exploring, and are influenced by relevant external experience and theoretical research. Combined with the current situation of Chinese society and the needs and problems of public art culture development, corresponding public art practices and theories have gradually been produced (10). The main feature of its theoretical research is to gradually shift from the study of the external form and style of public art and the application of urban public space to the study of public art and sociology. The study of the simple aesthetic value orientation of public art has been transformed into the study of the relationship between public art and urban subject culture and citizens' daily public life. Contemporary Chinese public art no longer exists in only one form of art. Nowadays, the publicity and public participation of public art are emphasized. Various services are provided to the public and diverse forms of social public space, which is the overall social and cultural mission. At present, it pays more attention to various vulnerable groups in the society and realizes social fairness and democratic rights in the form of art (11). Therefore, based on Chinese contemporary public art, the recuperation space for the old people is studied.

With the improvement of people's living standards, its actual functions should be fully considered in the design, to meet the needs of the old people for material life as much as possible. According to the survey, it is found that most of the old people lack communication, have a sense of distance, and lack communication bonds with each other. Through the reasonable planning of public space, it is the main motivation of this research to make the people in the space connect with each other and the environment, and make more contacts. The old people have many needs on the spiritual level, which can be roughly divided into spiritual needs such as emotional, social, entertainment and self-realization. Today, the existing old-age care places in the society can no longer fully meet the spiritual needs of the old people, and the design also needs to be improved. The main innovation is to solve the spiritual needs of the old people. It is designed from three aspects: social, participatory, and service-oriented. Interactivity is applied to the layout of the public space of the old people apartment to solve the needs of the old people. This research explores how to carry out the interactive design in the design of rehabilitation space, enhance the ability of the old people's care services, improve the service level for the old people, and enrich the theory of social elderly care, which has good research value.

METHODOLOGY

The Outdoor Environment Design of the Rehabilitation Space for the Old People

The outdoor environmental space refers to the spatial extent of the specific area except the interior of the building, which is

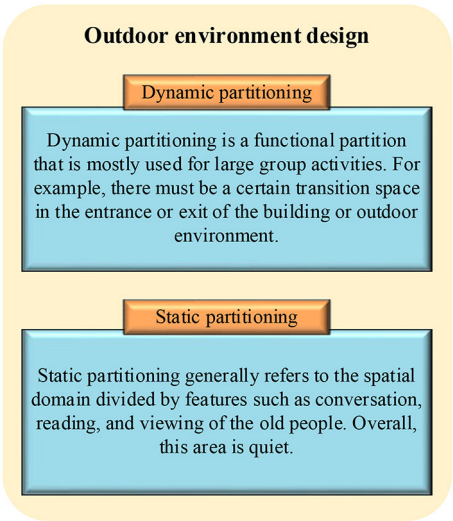

FIGURE 1 | The outdoor environment design of the elderly rehabilitation space.

different from the open space of the city (12). The old people in nursing homes have different cultural levels and different physical qualities. Therefore, in order to meet these different needs of the old people, the way is also ever-changing (13). The overall differences in the activities of different types of elderly groups and the different characteristics of their activities have become the basis for the outdoor environment design in the elderly rehabilitation space.

Necessity, spontaneity, and sociality are several environmental categories in the aged rehabilitation space. The main activities in the entire elderly rehabilitation space are mainly based on essential and spontaneous activities. All activities of the old people are particularly dependent on the quality of the environment and space. When the quality of external activity space is relatively bad, old people mainly focuses on activities that are essential to life, while other interactions are basically not going on. However, when the quality of the activity space environment is good, they will spontaneously generate diverse activities, and social activities will increase.

When setting up the activity space, special consideration is given to the physiological characteristics of the old people. Ventilation and lighting must be very good. However, the outdoor activities of the old people cannot be located at the vents, and the outdoor rest points for the old people should be continuous. The old people have limited physical strength and the outdoor seating should be installed along the road.

The outdoor environment design of the rehabilitation space for the old people is divided into two parts, as shown in **Figure 1**. Outdoor environment design is usually divided into dynamic partitioning and static partitioning. Static partitioning generally refers to the spatial domain divided by features such as conversation, reading, and viewing of the old people. Overall, this area is quiet. Dynamic partitioning is a functional partition that is mostly used for large group activities. For example, there must be a certain transition space in the entrance or exit of the building or outdoor environment. Seats and ornamentals for leisure must be provided. The composition and diversity of space is emphasized when designing outdoor spaces. Light, shadow, and visual effects should be appropriate for older people's life requirements, which avoids the overly shocking picture and space composition.

Functional Composition of the Elderly Rehabilitation Space

The functional composition of the elderly rehabilitation space is shown in **Figure 2**.

Accommodation Function

The accommodation function is the most important requirement of the old people in the rehabilitation space. Old people generally spend most of their time in the living space. Therefore, the accommodation environment for the old people must be taken very seriously. According to the physiological characteristics of the old people and the requirements of life use, the necessary functional facilities, such as the bathroom, storage space, balcony area, emergency equipment, etc., should be considered in the design. At the same time, privacy requirements should also be considered.

Leisure Function

In rehabilitation space, the problem of rest must be involved, whether indoor or outdoor. In the discussion of rehabilitation space, the external environment is the main design object. Therefore, in the environment of external communication activities, reasonable rest places must be set up. Old people often need to sit and rest during outdoor activities for physical reasons. Therefore, in the external landscape area, road walking area, leisure activity area, building periphery and other important occasions, leisure seats should be set up, and the number is higher than the design ratio in the city square. At the same time, the ergonomic requirements of the old people should be met.

Health Care Function

Old people's physical condition is much worse than before, especially the elderly people. Sudden infirmities of age often occur and emergency medical care is needed. Therefore, in the rehabilitation space, the design of the medical function is very important. This guarantees the safety of the old people in the event of an emergency. In the design of the location of the medical space, the road must be smooth and convenient, so the ambulance can arrive as fast as possible, and the rescue time is shortened (14).

Barrier-Free Design Requirements

Barrier-free design is an important factor that must be considered and embodied in rehabilitation space for the elderly. Barrier-free design helps old people perform normal activities. This assists to solve the problems of old people, such as the decline of physiological function and inconvenience of movement. Barrier-free design should be strictly observed in all parts of rehabilitation space for the elderly and in the placement of functional facilities (15).

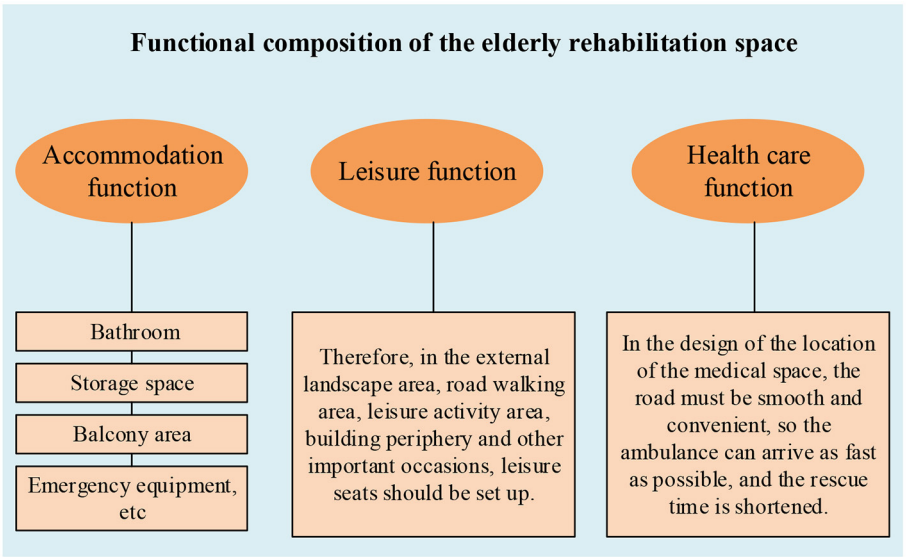

FIGURE 2 | The functional composition of the elderly rehabilitation space.

The Influence of Old People's Physical Decline

Design of the ramp: In the rehabilitation space of the elderly, it is inevitable that there will be road ramps, including stairs with a ground height difference environment. Therefore, the design of the ramp should be based on gentle slopes as much as possible. It is convenient for wheelchairs and other equipment to walk, and must be equipped with safety rails next to it. In addition, there should be reasonable ramps side by side in places where there are steps.

Use of Non-slip Materials

The balance ability of the old people and the flexibility of the limbs are bad, so the floor tiles must be strictly controlled. Floor coverings with high surface smoothness are strictly prohibited, which makes it easy for the elderly to slip. Especially in corridors, stairs, sanitary napkins, etc., these are places where old people are prone to accidents. In outdoor activities, paving should be based on flat and non-slip materials.

The Influence of Hearing and Vision of Old People

After the decline of physiological function, the first manifestation is the change of hearing and vision. Therefore, in the maintenance of the modern elderly, in view of the hearing loss of the old people, there are different amplification devices in different space areas to ensure the normal activities and exchanges of the elderly. For the decline of vision, the following aspects are considered.

Eye-catching signs are set on the road and orientation search, and distinguished by color and shape. Good lighting systems are equipped to assist in lighting. Through voice control and other means, these lighting devices are connected, especially at night. Intelligent devices, some acousto-optic signal devices, such as telephones, doorbells, elevator stop signals, call service facilities, etc. should be strictly observed in the design of the indicator lights. This is brighter than the usual general equipment and is clearly legible for identification. The intelligent guiding device is configured to be carried by the elderly. Whether indoors or outdoors, the location of the elderly can be searched at any time to guide the direction, which helps the visually obsessed old people to live comfortably.

Management Discussion

A sound management system for the elderly rehabilitation space was established. The professional knowledge and skills training of nursing staff was strengthened and the quality of personnel services was improved (16). Moreover, the state should have a strong and sound legal system supervision. The healthy life of the old people is advocated. Self-care ability is improved through the efforts and exercise of the old people themselves. Helping the old people to rebuild their confidence is also one of the important purposes of the construction of the elderly rehabilitation institutions.

Physiological Characteristics of the Elderly and Its Impact on Public Art Design in the Rehabilitation Space of the Elderly

The physiological function of the human body will continue to decline, which is the objective law of human life development. However, the decline of physiological functions will directly affect the lives of the old people and their ability to adapt to the natural environment and living environment. In addition, there will be a significant decline in communication skills. Therefore, in the design of the rehabilitation space for the elderly, the design of the living space and the outdoor environmental landscape should be based on the actual situation of the elderly.

The process of the old people's decline is divided according to the "old people's residential building design guidelines", which

are mainly in four stages: The healthy functioning period of the body function is 60–64 years old. The independent period of self-care is 65–74 years old. The inconvenience of action is 75–84 years old. 85 years of age or older is a serious debilitation and is listed as a key nursing period.

The normal growth and development of the human body will change over time. As the age increases, the overall signs of physiologic weakness are more pronounced. The growing age has gradually degraded the functions of the various parts of the old people's body. Especially after 70 years of age, the signs of this decline are more obvious, which will seriously affect the normal physiological function of the old people. As physiology decreases, the design tools and methods used for the needs of the old people will change. More requirements are also placed on the design of public art in the aged rehabilitation space. According to the special requirements of the old people's physiological functions, public environmental facilities or public works of art that meet the overall requirements are designed.

The degree of self-care of the old people directly determines the degree of privacy of the entire living space and the level of living services and care that the maintenance center needs to provide to the old people. Under normal circumstances, the continuous decline of the old people's self-care ability will directly lead to the weakening of the privacy of the entire old people's living environment. At the same time, the maintenance center will be required to strengthen the care and companionship of the old people who cannot take care of themselves. The entire care phase of an old person consists of the following steps: life self-help period; partial care period; comprehensive care period; termination period. From self-help to termination, the life of the old people is an unchangeable trend. The level of care varies according to the difference in care required at each stage of human normal aging.

In combination with the differences in the physiological characteristics of the older people mentioned above, there is a big difference between adults and old people. The physiology of older elderly people is more fragile. Therefore, more care is needed for older people, considering the particularities of life of older people. Thus, there are several factors that must be considered when designing the old people rehabilitation space.

Auditory System Design

A very prominent feature of the old people group is the sharp deterioration of hearing due to the decline of physiological functions. In the investigation of old people rehabilitation institutions, there have been many cases in which the old people have difficulty communicating due to severe hearing loss. Old people are eager to have sensitive ears to get useful information in life. A sharp decline in hearing can significantly reduce the enthusiasm of older people to participate in activities. Older people will have obvious conversational conflicts in their hearts, and they need tools to help their ears get information.

However, when the old people are alone, they like quiet places and spaces very much. They don't want their quiet state to be disturbed by loud noises. In a survey of nursing homes, it was found that old people were disturbed by noisy external voices because it lived close to the main road. Therefore, for the phenomenon of hearing loss of the old people, the design of the elderly rehabilitation space also brings a lot of challenges.

Vision System Design

A decrease in vision is an important manifestation of the decline in the physiological function of the old people. In previous interviews with several elderly institutions, it was learned that many problems, such as dazzling eyes and difficulty in light perception, will arise because of the impaired vision. The old people went in the wrong direction and even stumbled because they could not see the marker. Therefore, in the design of the elderly rehabilitation space, the visual situation of the old people must be carefully understood. The subject buildings, road-pointing signs, and indexing of important places involve visual observations of the old people, and any environment must be treated with rigorous care. For example, a very prominent reminder sign needs to be placed on the floor building, the stairway, the corner, the slope, and so on.

Tactile System Design

Old people's tactile system is also declining with age. They rely on their physical touch to feel the environment and place very high demands on the environment. For cold and hot, the old people are significantly less able to accept the environment than young people. For example, the old people like to sit around the fire source in winter, or need heating facilities. In summer, they need a cool and ventilated environment. Therefore, there are many requirements for the design of the old people rehabilitation space, which is different from the treatment of young people. At present, the design of old-age maintenance institutions is seriously inadequate. In the future, the elderly rehabilitation institutions have higher requirements.

Barrier Free Design

The concept of barrier-free design must be strictly enforced throughout the design of the elderly rehabilitation space. The old people will continue to decline in their physiological functions, their physical activities will be inconvenient, and the ability to adapt to the environment will show significant decline. Steps, stairs, corridors, handrails, toilets and other very common public facilities, young people usually do not pay much attention to. However, as the physical and mental functions continue to decline, the old people will have inexplicable fears and potential threats to these common public facilities. In the course of practical research, it was found that most of the old people needed crutches and other supporting tools in their activities.

Activity Space Design

As a result of the comprehensive analysis of the physiological characteristics of the old people, as their age increases, the functional organs will also weaken. The overall health status will be significantly lower than in the past. Therefore, the old people will have a very personal health status in their lives, and they are also very concerned about the disease.

From the analysis of physiological characteristics, the old people need a public green space with good environmental quality to breathe fresh air and exercise. In addition, the old people have come out of the life stage of youth and live in

society. However, they have withdrawn from many social things such as social interaction. Second, the dominant role of the old people in society is also changing anyway. From the collective work of the unit to the individual work in the family, the entire social environment and social group relations are also changing. Children lived in other places all the year round and stayed away from the elderly. The lively atmosphere of the family had changed. Therefore, the new living environment, life progress and lifestyle will bring a sense of discomfort. These inevitably lead to the feeling of anxiety and loneliness in the old people. Compared with some families with superior economic conditions, the high-cultural and healthy old people will have great enthusiasm and interest in social, group entertainment and social interaction. This type of old people is hoping that society can provide them with a place that is relatively safe and can satisfy their social interaction activities. Combined with the physical characteristics of the old people, the design of activity venues must include natural health factors, which reflects a kind of care and consideration for old people. The event space for the elderly has a reasonable radius to meet the needs of various entertainment activities. It creates a healthy, comfortable, self-cultivation and physical exercise ecological environment for the old people.

RESULTS AND DISCUSSION

Psychological Characteristics of the Elderly and Their Impact on Public Art Design in the Elderly Rehabilitation Space

Because of changes in the living environment, the social roles and family roles of the old people will also change, which will have a very significant impact on the psychology of the old people. At the same time, the mental state of the old people has changed a lot because of the different nature of the work, the degree of education, the differences in local culture, and the differences in social experience. In the survey, it was found that loneliness, impatience, survival, resentment, attachment, symbiosis, etc. are the common psychological feelings of the old people.

Loneliness

Many old people's spouses may die, the circle of life and activities is smaller, and the number of people who can communicate with themselves is less. In addition, the phenomenon of "empty nest" appears. Old people feel lonely when their children are not around. Therefore, most old people are reluctant to communicate, like to be alone, and not willing to participate in group activities. Lonely feelings can have a very negative impact on the lives of the old people.

Lost Feeling

Lost feeling is also a situation that the old people often encounter. Old people feel left out and abandoned. This psychological pressure caused some of the old people to change from self-care to dependents. The sense of loss seriously affects the normal living conditions of the old people, which can cause mental tension and frustration in the old people.

Inferiority

In the elderly rehabilitation space, the old people will have a feeling of inferiority because of the difference between themselves and others. Especially when the ability is gradually declining and cannot reach a good state, the old people will inevitably have a tendency to feel inferior, and always think in the subconscious that they are no longer able to do so. The inferiority of old people is also a common occurrence. Because of retirement, social status and economic income are gone. At the same time, the physical condition is not as good as before, the elderly need to be taken care of by others. Therefore, they will have a feeling of inferiority.

Isolation

Isolation is the most common phenomenon in the old people group, and it is also a very realistic and serious situation. The very important reason for the emergence of these phenomena is that there is no comfort in the life of the old people. Spiritual comfort cannot be satisfied and cannot make an understanding of the spiritual world. Therefore, ideologically, the elderly will create pressure on themselves, and eager for the care and attention of the people around them, especially their relatives and friends. In view of this, in the design of the rehabilitation space for the elderly, it is necessary to solve the problem of the public art design in the space. At the same time, the accurate grasp of the psychological characteristics of the old people is of great help to design and construction of the old facilities and the public art of the elderly rehabilitation space.

Through investigation on some aspects, such as the urban elderly and the rural elderly cannot keep up with the development of society, the old people are the burden of the society and the family, the society is paying more and more attention to the importance of the old people, the old people like to chat with others and make friends, and the old people often feel lonely. The results are shown in **Table 1**. According to a sample survey, 65.3% of urban old people and 71.8% of rural old people feel that they cannot keep up with the pace of development. 52.5% of urban old people and 61.2% of rural old people consider themselves to be social burdens. It can be seen that the rural old people are far less than the urban old people in their recognition of their own values. Therefore, for the old people in township nursing homes, they will feel that they can't keep up with the pace of development of the times, and they are the burden of family and society. On the emotional issues of the old people, the urban old people who like to chat with others account for 70.9%, and the rural old people account for 76.2%. In terms of making friends, the urban old people who choose to make friends are 63.7%, and the rural old people account for 59.1%. It is also worth noting that the rural old people often feel lonely more often than the urban old people. In short, the old people, especially the rural old people, consider themselves to be the burden of society and cannot keep up with the development of society. Psychological problems are more serious. It is conceivable that this situation will be more serious for the old people of the nursing home, especially in terms of emotional comfort.

Various psychological characteristics were studied. Old people will choose different activities due to different psychological characteristics. Changes in the mental state of the old people

TABLE 1 | Composition of various statements of the elderly in the surveyed cities and rural areas.

	City			Rural		
	Yes	Unclear	No	Yes	Unclear	No
Can't keep up with the development of society	65.3%	13.3%	21.4%	71.8%	14.3%	13.9%
Old people are the burden of society	52.5%	16.4%	31.1%	61.2%	19.8%	19.0%
Old people are the burden of the family	46.9%	15.1%	38.0%	67.3%	15.6%	17.1%
The society is increasingly concerned about the importance of the elderly	82.1%	12.3%	5.6%	86.2%	10.5%	3.3%
Older people like to chat with others	70.9%	10.3%	18.8%	76.2%	9.1%	14.7%
Older people like to make friends	63.7%	12.8%	23.5%	59.1%	15.3%	25.6%
Old people often feel lonely	24.9%	11.4%	63.7%	37.6%	16.1%	46.3%

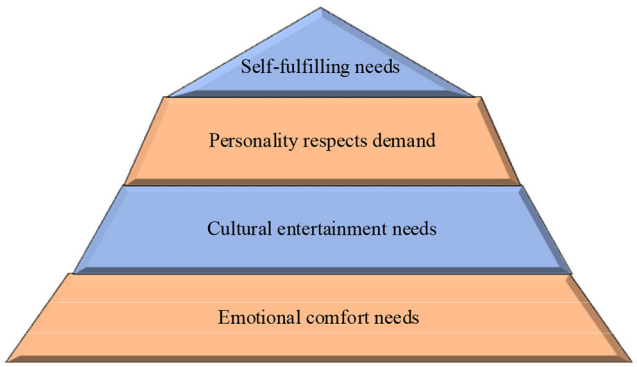

FIGURE 3 | The spiritual needs of the elderly.

will directly affect the design of public art in the old people rehabilitation space. Therefore, the factors influencing this aspect must always be considered in the design. At present, in the elderly rehabilitation space, there are relatively few design studies on the psychological characteristics of the old people. The spiritual needs of the elderly are shown in **Figure 3**.

Safety

The body function of the old people is declining and the movement is inconvenient. The ability to recover from injuries is also weakening. Therefore, security guarantees are important. Environmental design and landscape design in the public space of the elderly must be taken seriously. For example, barrier-free design, emergency call system, emergency system and medical security system are all considerations of old people security requirements.

Sense of Belonging

When entering a new living environment and state, the old people need to be recognized by the people and the environment around them to enhance their self-confidence. In this way, these old people can integrate into the collective, build confidence and be accepted and recognized. A sense of belonging is also a sense of responsibility of the old people to the environment and the people around them. Old people who lack a sense of belonging will have a clear lack of responsibility and vice versa.

TABLE 2 | Analysis of scope of activities.

Scope of activities	Percentage
Home	16%
Community	20%
Square	32%
Elderly activity room	9%
Outdoor	23%

Neighborhood

The neighborhood of the old people is mainly reflected in the social neighborhood and the environmental neighborhood. Social neighborhood means that the old people need to find friends in the new environment who can communicate, exercise and play games with themselves. An environmental neighborhood means that the old people are intimate with the environment of life and are willing to live in this environment. When designing the living space of the old people, the design of the communication environment of the entire event space was improved, and a new neighborhood communication space was created.

Family Sense

In the design of the elderly rehabilitation space, in addition to considering the psychological feelings of the old people, the sense of family also needs to be considered. The family atmosphere is created. The old people in the old-age care institutions have left the familiar life field that has lived for decades, and it takes time to adjust the lever for the new living environment. The sense of family in the whole environment depends on the accumulation of time.

Public Space for the Old People's Convalescence

The public space for elderly rehabilitation is mainly divided by the space range, as shown in **Table 2**. After a survey, it is found that most people aged 50-70 like to live in public spaces such as communities, squares, activity rooms and outdoors. Therefore, the scope of this design is divided into two parts: indoor space and outdoor space. The indoor public space includes a leisure reading area, display area, reading room, fitness room, yoga room and performance hall. In the outdoor public space, there are

rooftop leisure gardens, landscape viewing spaces, and fitness spaces. Indoor public space and outdoor public space together constitute the public space category of this research.

Discussion of Results

Through the analysis and discussion of the physiological and psychological characteristics of the old people, the entire survey shows that the physiological functions of the old people are declining, which seriously affects their normal life. Psychologically, old people are also suffering from a variety of social and family role changes. A healthy mindset can help the old people live a happy life, but most of the old people have a hard time accepting the current situation, from the main role of society to retirement. The main difficulty of the old people is to face a new living environment and establish a new personal relationship and emotional space. Therefore, the design of the old people rehabilitation space should analyze the spatial design from the perspective of humanization and emotionality while meeting the basic needs of life. An ecological, natural and humane living environment has been established. In the old people rehabilitation space, public art is designed to fully consider their needs. In the rehabilitation space, older people can spend their old age in happiness. The quality of the living environment is good. Furthermore, connecting people through shared experiences and emotions focuses on connecting people to artworks and connecting them to specific communities, which is consistent with the work of Zebracki et al. (17).

CONCLUSION

Today, society is facing an increasingly serious phenomenon of aging, and old people are getting more and more attention. The basic starting point of public art, public environment, and public facilities in the elderly rehabilitation space is to meet the physical and psychological needs of the old people, to facilitate their use of the old people, and to provide a comfortable living environment. At the same time, in order to reduce the psychological pressure of the old people, a healthy, harmonious and happy rehabilitation space was established. However, the current main research task for the construction of old-age care institutions should be based on the psychological and behavioral characteristics of the old people. The society is constantly improving, and the concept of life of the old people in each era is constantly changing and continuing. Therefore, the psychological research on the old people is constantly changing, and the design concept of the elderly rehabilitation space will be constantly changing and updating. Taking the elderly as the research object, their physiological, psychological and behavioral characteristics were studied. Existing geriatric care institutions have been investigated on the spot, which provides relatively intuitive research data for exploring conclusions. The results show that the recuperation space design should be built according to the needs of different old people, which helps the old people to eliminate loneliness. At the same time, to enhance the value of the role, the old people can also make life full of joy and meaning. The shortcoming is that it only analyzes the feasibility of the application of public art experience design for the old people. However, the interactive behavior of the old people's care space is related to each other and affects each other. Therefore, a public space that can give the old people a sense of belonging and comfort should be created as much as possible to meet their psychological and physical needs. Creating a public space environment full of communication and interaction in the rehabilitation space for the old people can not only provide new design ideas and research directions for the public space design of elderly apartments, but also enrich other fields of environmental art design in theory and practice.

doi: 10.3389/fpubh.2022.916364

Background: Amino acid metabolism plays a vital role in cancer biology. However, the application of amino acid metabolism in the prognosis of colon adenocarcinoma (COAD) has not yet been explored. Here, we construct an amino acid metabolism-related risk model to predict the survival outcome of COAD and improve clinical decision making.

Methods: The RNA-sequencing-based transcriptome for 524 patients with COAD from The Cancer Genome Atlas (TCGA) was selected as a training set. The integrated Gene Expression Omnibus (GEO) dataset with 1,430 colon cancer samples was used for validation. Differential expression of amino acid metabolism-related genes (AAMRGs) was identified for prognostic gene selection. Univariate cox regression analysis, LASSO-penalized Cox regression analysis, and multivariate Cox regression analysis were applied to construct a prognostic risk model. Moreover, the correlation between risk score and microsatellite instability, immunotherapy response, and drug sensitivity were analyzed.

Results: A prognostic signature was constructed based on 10 AAMRGs, including ASPG, DUOX1, GAMT, GSR, MAT1A, MTAP, PSMD12, RIMKLB, RPL3L, and RPS17. Patients with COAD were divided into high-risk and low-risk group based on the medianrisk score. Univariate and multivariate Cox regression analysis revealed that AAMRG-related signature was an independent risk factor for COAD. Moreover, COAD patients in the low-risk group were more sensitive to immunotherapy targeting PD-1 and CTLA-4.

Conclusion: Our study constructed a prognostic signature based on 10 AAMRGs, which could be used to build a novel prognosis model and identify potential drug candidates for the treatment of COAD.

Keywords: colon adenocarcinoma, amino acid metabolism, prognostic model, immune checkpoint, immune therapy

INTRODUCTION

Colon adenocarcinoma (COAD) is the most common type of colorectal cancer (1). According to the Global Cancer Observatory (GCO) (gco.iarc.fr) in 2020, there were an estimated 1.4 million new cases of colon cancer and 0.5 million deaths worldwide (2). Late diagnosis and lack of reliable biomarkers account for the poor prognosis of COAD (3). Despite many efforts, the attempt to use a single biomarker to predict the outcome of COAD has been unsuccessful (4).

Metabolic reprogramming is a common feature of tumor cells, which is crucial for rapid tumor growth and adaption to tumor microenvironment (5, 6). Apart from the well-known Warburg effect, metabolic alterations in lipid and amino acid metabolism have been observed in a number of tumors, including colorectal cancer, lung cancer, and breast cancer (7). Mounting evidence have indicated that changes in amino acid metabolism contributed to the metastasis, proliferation, angiogenesis, and drug resistance of colorectal cancer (8–11). Recent study has demonstrated that inhibition of ASCT2 (function as a glutamine transporter) exerted a great anti-tumor effect in colorectal cancer (12). Meanwhile, new insights into the metabolic signatures of tumors have revealed the potential of risk prediction model, which is based on the amino acid metabolism-related genes (AAMRG) (13, 14). In addition, amino acid metabolism plays an important role in regulating tumor immunity and targeting amino acid metabolism may help to overcome immunotherapy resistance and improve existing therapies for COAD patients. Therefore, targeting the amino acid metabolism might provide novel ideas for the diagnosis and management of COAD.

MATERIALS AND METHODS

Data Acquisition

The COAD cohort's transcriptional dataset with matching clinical information were downloaded from The Cancer Genome Atlas (TCGA) (https://cancergenome.nih.gov/). Total 524 mRNA expression profiles including 482 COAD tissues and 42 normal colon tissues were enrolled. Three datasets with 1,430 patients with colon cancer from Gene Expression Omnibus (GEO), including GSE39582 (15), GSE29621 (16), and GSE17536 (17) were selected to verify the results of TCGA data analysis (https://www.ncbi.nlm.nih.gov/geo/). The "sva" software package in R version (4.0.2) was devoted to remove the batch effects.

Differentially Expressed AAMRGs in TCGA

Total 374 AAMRGs were extracted from the amino acid metabolism-related genes dataset (REACTOME_METABOLISM_OF_AMINO_ACIDS_AND_DERIVATIVES), which were recorded in Molecular Signatures Database (13, 18). Then, total 327 common expressed AAMRGs in TCGA and GEO were selected. Subsequently, differentially expressed AAMRGs between the COAD and control groups were analyzed using the "limma" software package in R version (4.0.2) (based on $|\log_2 FC| > 1$ and false discovery rate < 0.05).

Construction and Validation of Prognostic Risk Score Model

The univariate Cox regression analysis was conducted for prognosis-related AAMRGs screening. The LASSO algorithm was executed to avoid overfitting the model. The multivariate Cox regression was conducted to get the optimal prognostic genes for the model. Finally, the stable AAMRGs, as the final prognosis model was constructed. We used the following equation to calculate the risk score, which was combined by regression coefficients and expression values of each AAMRG. Risk score = (index gene1 × expression of gene1) + (index gene2 × expression of gene2) + … + (index gene10 × expression of 10). All COAD patients in TCGA were divided into two subgroups (high- risk group and low-risk group) according to the median risk score. Kaplan-Meier curves were used to determine the differences in prognosis between the different groups. Finally, the first, third, fifth-year survival proportions of patients were calculated using the ROC curve. Then, the prognosis model was validated in the above merge GEO dataset.

Establishment of Nomogram Prognosis Prediction Model

We combined age, TNM stage and risk scores to plot a nomogram model using the "rms" software package in R version (4.0.2). The calibration curves were built to show the agreement between the nomogram-predicted survival probabilities and the actual survival probabilities at first-, third-, and fifth-year.

Gene Set Enrichment Analysis Between High-Risk Group and Low-Risk Group

To reveal the effect of differential expression of AAMRGs on biological pathways in COAD, Gene Set Enrichment Analysis (GSEA) was introduced to extract the potential biological function (19). Firstly, "c2.cp.kegg.v7.1.symbols.gmt" set was downloaded from Molecular Signatures Database. Secondly, "GSEA" software was applied to identify the enriched pathways in the two subgroups. The "ggplot2" software package in R version (4.0.2) was employed to visualize the top five significantly enriched biological processes in each subgroup.

Association Between Different Subgroups and Somatic Variation

Mutation data of COAD was downloaded from TCGA. The tumor mutation burden (TMB) value in each COAD patient was calculated the number of mutations in each patient. Then, differences in TMB values were analyzed between high-risk group and the low-risk group. The association between the risk score and TMB level was detected using Spearman correlation coefficient. Finally, the "maftools" software package in R version

Abbreviations: COAD, colon adenocarcinoma; GEO, Gene Expression Omnibus; TCGA, The Cancer Genome Atlas; AAMRGs, amino acid metabolism-related genes; MSI, microsatellite instability; TPM, transcripts per million; LASSO, least absolute shrinkage and selection operator; ROC, receiver operating characteristic; TCIA, The Cancer Immunome Atlas database; OS, overall survival; AUC, area under the curve; HR, Hazard ratio; TMB, tumor mutation burden; GSEA, Gene Set Enrichment Analysis.

(4.0.2) was applied to visualize the top 20 most frequently mutated genes in each group.

Correlations Between Immune Cell Infiltration Between High-Risk Group and Low-Risk Group

The CIBERSORT was performed to analyse the tumor immune microenvironment of COAD. CIBERSORT (https://cibersort.stanford.edu/) is a method of enumeration of 22 immune related cell subsets, which including naïve and memory B cells, seven types of T cell, myeloid cells, NK cells, and plasma cells (20). The "CIBERSORT" software package in R version (4.0.2) was applied to analyse the proportion of 22 immune cells between high-risk group and low-risk group. Bar plot was applied to visualize the differences in immune cells between high-risk group and low-risk group.

Differences in Immunotherapy Sensitivity Between High-Risk Group and Low-Risk Group

The immunotherapy sensitivity data of patients with COAD was obtained from The Cancer Immunome Atlas (TCIA, https://tcia.at/) which included the effectiveness score of patients with PD-1 and CTLA-4 inhibitors. Then, we detected the differences of immunotherapy sensitivity score between two subgroups.

Sensitivity Prediction of Anticancer Drugs

The prediction of the difference in drug sensitivity between high-risk group and low-risk subgroups in COAD was conducted using the "pRRophetic" software package in R version (4.0.2) based on Cancer Genome Project (CGP),which including 138 anticancer drugs (21).

Statistical Analysis

GraphPad 8.0 software and R version (4.0.2) were applied to analyse and visualize the statistical profile. The univariate Cox regression analysis, LASSO algorithm, and the multivariate Cox regression analysis were used to narrow down the number of candidate genes (22, 23). The "survival R" and "surviviner R" software package in R version (4.0.2) were used for Kaplan-Meier analysis. We compared the two groups by student's test or Wilcoxon test. The Pearson or Spearman correlation test was utilized to evaluate the correlations between variables. The $P < 0.05$ was considered statistically significant.

RESULTS AND DISCUSSION

Identifying Differential Expressions of AAMRGs Between COAD and Normal Tissues From the TCGA Dataset

The workflow of the study is displayed in **Figure 1**. Total 263 differentially expressed AAMRGs (180 upregulated genes and 83 downregulated genes) in TCGA dataset were identified. The heatmap exhibited the differentially expressed AAMRGs (**Figure 2A**).

Construction of Prognosis-Risk Signature Based on 10 AAMRGs

Fourteen AAMRGs were identified as prognostic related genes based on the univariate Cox regression analyses (**Figure 2B**). Finally, 10 prognostic related AAMRGs was screened for AAMRGs-risk signature after the LASSO analysis and the multivariate Cox regression analysis (**Figures 2C,D**). The boxplot showed the expression of 10 prognostic related AAMRGs in TCGA including ASPG (asparaginase), DUOX1 (dual oxidase 1), GAMT (guanidinoacetate N-methyltransferase), GSR (glutathione-disulfide reductase), MAT1A (methionine adenosyltransferase 1A), MTAP (methylthioadenosine phosphorylase), PSMD12 (proteasome 26S subunit, non-ATPase 12), RIMKLB (ribosomal modification protein rimK like family member B), RPL3L (ribosomal protein S17), and RPS17 (ribosomal protein L3 like) between COAD and normal samples (**Figure 2E**).

Three AAMRGs including PSMD12, MAT1A and DUOX1 were identified asprotective factors in the prognostic model. Meanwhile, seven AAMRGs including ASPG, GAMT, GSR, MTAP, RIMKLB, RPL3L and RPS17 were identified as risk factors in the prognostic model. The risk score of each COAD patient in TCGA was assessed through the equation: Risk score = $(-0.33 \times$ASPG expression$) + (0.37 \times$DUOX1 expression$) + (0.22 \times$GAMT expression$) + (-0.47 \times$GSR expression$) + (0.15 \times$MAT1A expression$) + (0.48 \times$MTAP expression$) + (-0.81 \times$PSMD12 expression$) + (0.25 \times$RIMKLB expression$) + (0.65 \times$RPL3L expression$) + (0.45 \times$RPS17 expression). Finally, the COAD patients in TCGA were divided into two groups (high-risk and low-risk group) based on the median risk score.

The **Figures 3A,C** conferred a better prognosis and longer survival time in patients with COAD in the low-risk group and worse prognosis with shorter survival time in the low-risk group (**Figure 3B**). In addition, the result of ROC curve analysis showed that the area under the curve (AUC) of first, third, fifth-year survival was 0.715, 0.750, and 0.759, which indicated a good sensitivity and specificity in predicting the prognosis of COAD based on 10 AAMRGs (**Figure 3D**). To further validate the accuracy and sensitivity of the prognosis risk signature, the above merged GEO dataset was used as an external validation dataset. Consistently, a difference in OS between high-risk and low risk group was observed ($P < 0.05$) (**Figures 3E–G**). The AUC of first, third, fifth-year survival was 0.576, 0.596, and 0.599 (**Figure 3H**).

Relationship Between the Clinicopathological Characteristics and Risk Score

Compared with the clinicopathological characteristics, the AAMRG-related prognostic risk model showed better capability in predicting one-, three-, and five-year overall survival (OS) (**Figure 4A**). Subsequently, the univariate Cox and multivariate Cox regression analyses revealed that the AAMRG-related prognostic risk model was an independent predictor of COAD prognosis (**Figure 4B**). The expression levels of the 10 screened

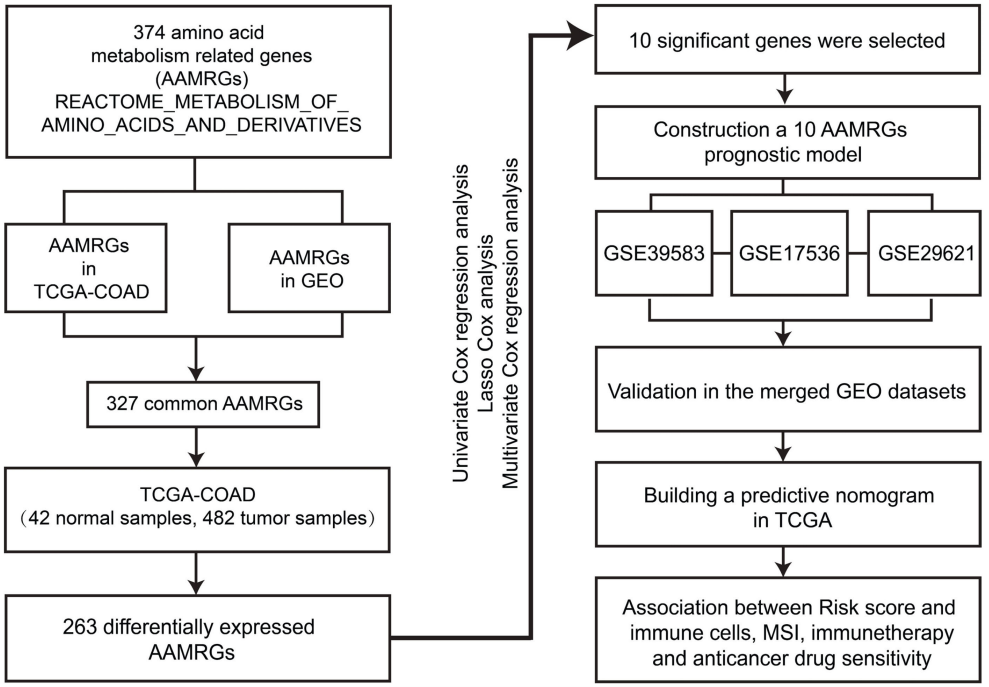

FIGURE 1 | The workflow of the study.

AAMRGs and clinicopathological characteristics between high-risk and low-risk group are depicted by heatmaps. Interestingly, there was a difference in the risk tumor stages, T, N, and M stage between high-risk and low-risk groups (**Figure 4C**). Notably, the COAD female patient in T3–T4 stage, N1–N2 stage, M1 stage, and Stage III–IV in high-risk group showed worse survival (**Supplementary Figures S1A–F**). These results indicated that the risk model may have high sensitivity and specificity for COAD patients.

Development and Evaluation of a Risk-Nomogram Based on the AAMRGs for Predicting OS in COAD Patients

The nomogram of age, stage, and risk score based on 10 AAMRGs was constructed to predict first-, third-, and fifth-year survival (**Figure 5A**). The calibration curve in **Figure 5B** demonstrated that the prediction and actuality of fifth-year survival values were in good agreement.

GSEA With the Prognostic Risk Signature

The GSEA was conducted between the high-risk and low-risk group based on the prognosis-risk scores. As displayed in **Supplementary Figure S2A**, the melanoma related signal pathway, ECM receptor interaction, WNT signaling pathway, mTOR signaling pathway and *TGF-β* signaling pathway might be positively correlated with the higher risk scores in COAD patients. In addition, the porphyrin and chlorophyll metabolism, proteasome, pentose and glucuronate interconversions, citrate cycle, TCA cycle, and drug metabolism related signal pathway were negatively correlated with COAD patients in high-risk group.

The Correlations Between Tumor Microenvironment Cell Infiltration Characteristics and Risk Score

The CIBERSORT results showed that activated NK cells, eosinophils, and neutrophils were more abundant in patients in the low-risk group ($P < 0.05$) (**Figure 6**). On the other hand, the infiltration of monocytes increased significantly in the high-risk group.

Correlations Between the Risk Score Model and Somatic Variants

The TMB levels were calculated between high-risk and low-risk groups. However, there was no significant difference in TMB between the two groups (**Supplementary Figure S2B**). However, the somatic mutations of TTN, SYNE1, PIK3CA, MUC16, FAT4, ZFHX4, RYR2, OBSCN, DNAH5, PLCO were more common in the low-risk group, whereas the mutation frequency of APC, TP53, and KRAS mutations was higher in the high-risk group (**Supplementary Figures S2C,D**).

Risk Score Predicts Resistance to Immunotherapy

The COAD Patients from TCIA database were divided into three groups based on the MSI status: high microsatellite instability (MSI-H), microsatellite-stable (MSS), and low microsatellite instability (MSI-L). As shown in **Figure 7A**, the proportion of

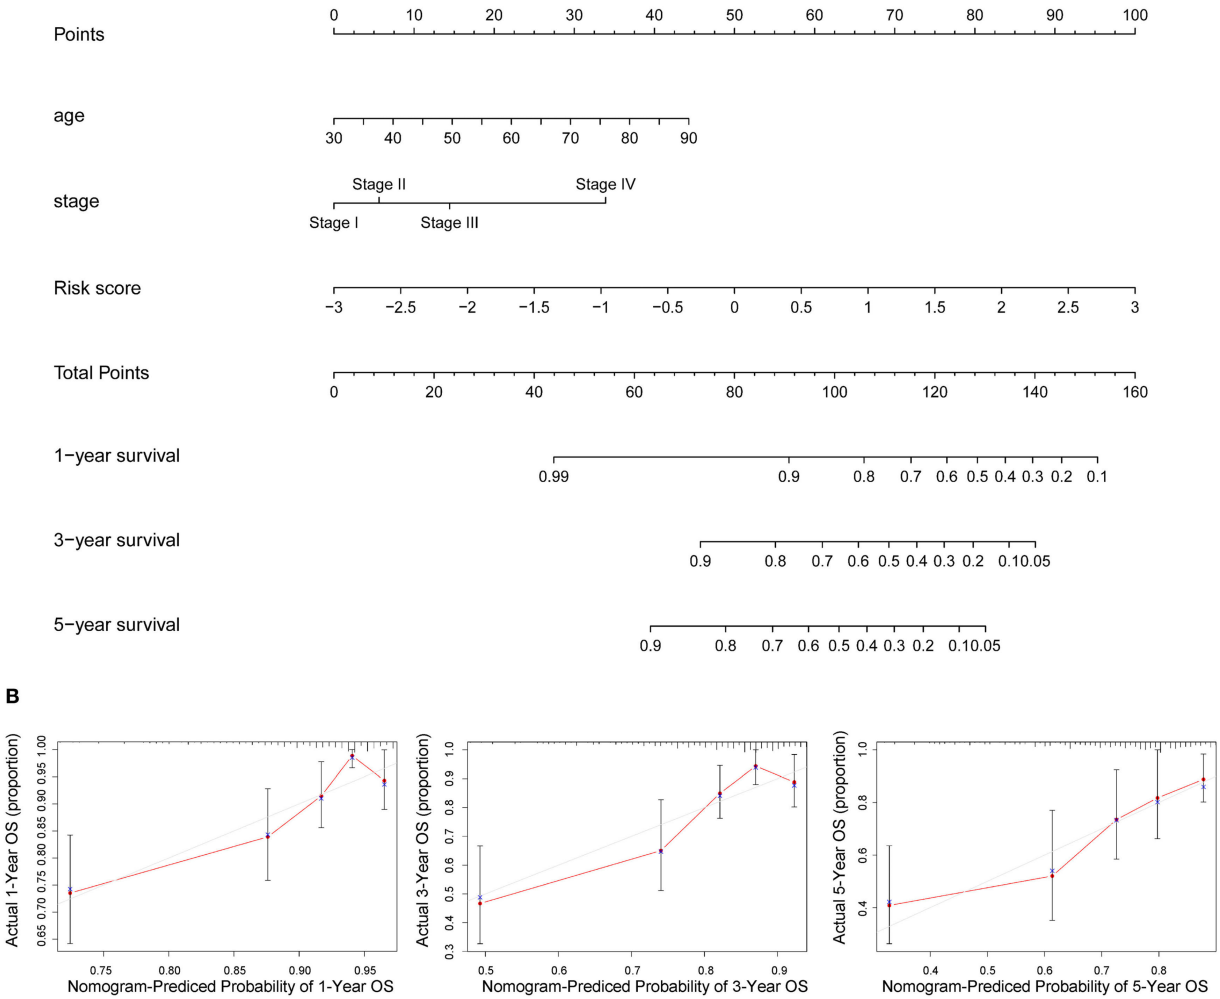

FIGURE 5 | Prognostic nomogram incorporating the risk score model and clinicopathological characteristics. **(A)** The nomogram of age, stage, and risk score for predicting 1-, 3-, and 5-year survival. **(B)** The 1-, 3-, and 5-year calibration curves of TCGA dataset.

MSI-H patients in low-risk group (26%) was higher than the high-risk group (12%). The results showed that patients in the MSI-L and MSS groups had higher risk scores, compared with MSI-H group ($P < 0.05$) (**Figure 7B**). This indicated that patients with lower risk scores were more sensitive to immunotherapy. Notably, the COAD patients in low-risk group were more sensitive to the combination of PD-1 and CTLA-4 inhibitors ($P < 0.05$) or CTLA-4 inhibitors alone ($P < 0.05$) than in the high-risk group (**Figures 7C,D**). However, there was no difference observed in the sensitivity PD-1 inhibitors alone between the two subgroups (**Figures 7E,F**). These data suggest that the risk score of COAD patients may affect the immunotherapy selection in COAD patients.

Results of Risk Score Model and Drug Sensitivity

Four drugs including imatinib ($P = 6.8e{-}09$, **Figure 8A**), midostaurin ($P = 1.2e{-}06$, **Figure 8B**), pazopanib ($P = 3.7e{-}04$, **Figure 8C**), and elesclomol ($P = 8.2e{-}03$, **Figure 8D**) were identified with lower IC50 level in high-risk group of COAD patients, which are suggestive of better efficacy. Besides, we found that COAD patients in the low-risk group were more sensitive to drugs including paclitaxel, metformin, rapamycin, bortezomib, sorafenib, and gemcitabine (**Supplementary Figures S3A–F**).

DISCUSSION

Colorectal cancer is one of the most common types of malignant tumors. The majority of COAD patients in high-risk stage II and stage III were recommended to receive surgery combined with adjuvant chemotherapy to reduce the risk of recurrence. However, approximately half of the patients in the early stage received radical surgery developed recurrence and metastasis (24). Therefore, there is still an urgent need for constructing a prognostic model that

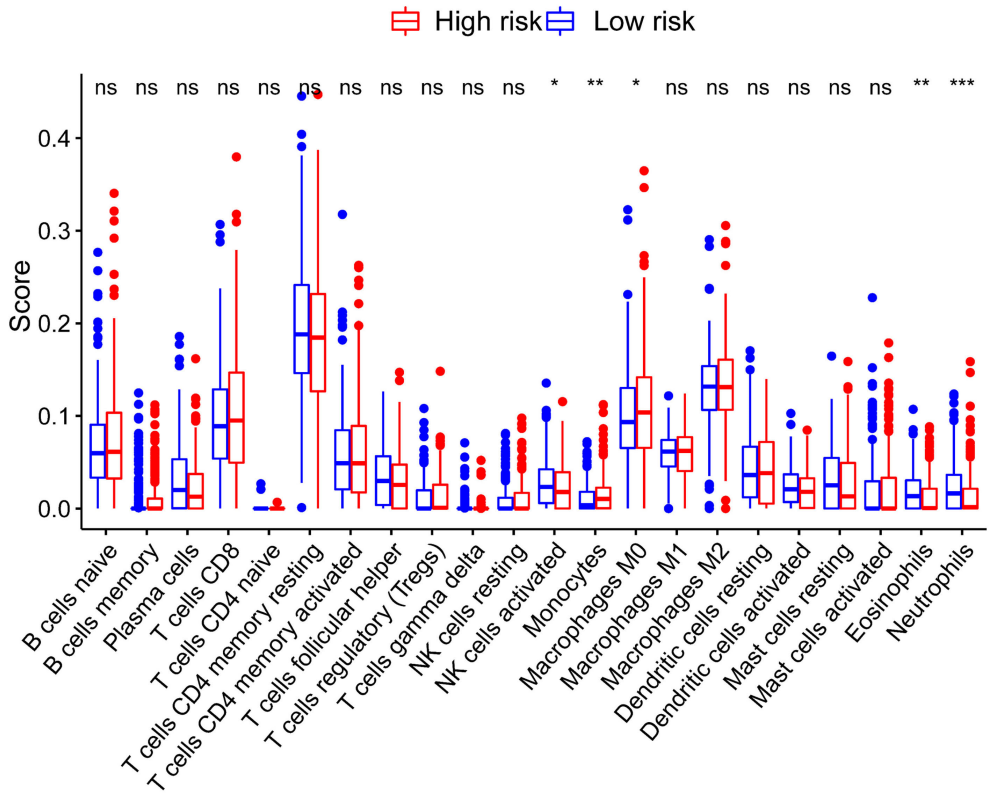

FIGURE 6 | Correlations between the risk score model and tumor-infiltrating immune cells. *$P < 0.05$; **$P < 0.01$; ***$P < 0.001$.

provides personalized prognosis and precision medicine for COAD patients.

Characteristic metabolic changes in malignant cells were observed including abnormalities in amino acid metabolism, increased fatty acid synthesis and glucose uptake (25). The reprogramming of amino acids played an essential role in the tumorigenesis and tumor progression. The abnormalities in amino acid metabolism also deeply reshaped the tumor microenvironment, especially the function of immune cells (26). Several studies have demonstrated that amino acid metabolism could be a therapeutic target in multiple solid tumors (27–33). Therefore, we constructed and validated a predictive model based on AAMRGs to predict the prognosis of COAD patients.

In this study, we analyzed the differentially expressed genes related to amino acid metabolism in TCGA by performing the univariate Cox regression analysis, LASSO algorithm, and multivariate Cox regression analysis. Ten AAMRGs (ASPG, DUOX1, GAMT, GSR, MAT1A, MTAP, PSMD12, RIMKLB, RPL3L, and RPS17) were screened to construct a prognosis risk model for prediction. GSR was downregulated in COAD and inhibited the metastasis of colon cancer cell (34). In addition, GSR plays an important role in the conversion of GSSG to GSH in COAD (35). MTAP was upregulated in COAD and could accelerate the proliferation, invasion and migration of COAD (36, 37). However, the functional role of PSMD12, MAT1A, ASPG, GAMT, RIMKLB, RPL3L, and RPS17 in COAD remains unknown. The accuracy and sensitivity of the model were further validated with a merged GEO dataset. Our results indicated that high-risk is linked to worse prognosis.

To explore the correlations between immune cell infiltration and risk score, we use CIBERSORT algorithm and estimate the difference in immune infiltration between two subgroups. We found that the levels of monocytes, activated NK cells, eosinophils, and neutrophils were significantly increased in the low-risk group. These results suggested that the amino acid metabolism-related gene signature may affect the infiltration of immune cells and potentially the response of immunotherapy.

It was known that TMB is associated with the production of neoantigens and the response of immunotherapy in various tumors (38). There was only a small population of COAD patients who benefited from immunotherapy (39–42). Currently, TMB and MSI are the best predictors of the therapeutic effects of immune checkpoint inhibitors (ICIs) in COAD patients (43, 44). We further analyzed the relationship between the risk score and MSI. The low-risk group was found to have higher MSI level and increased sensitivity to immunotherapy. Data in the TCIA database showed that patients with low risk score might show greater sensitivity to the combination of PD-1 and CTLA-4 inhibitors and

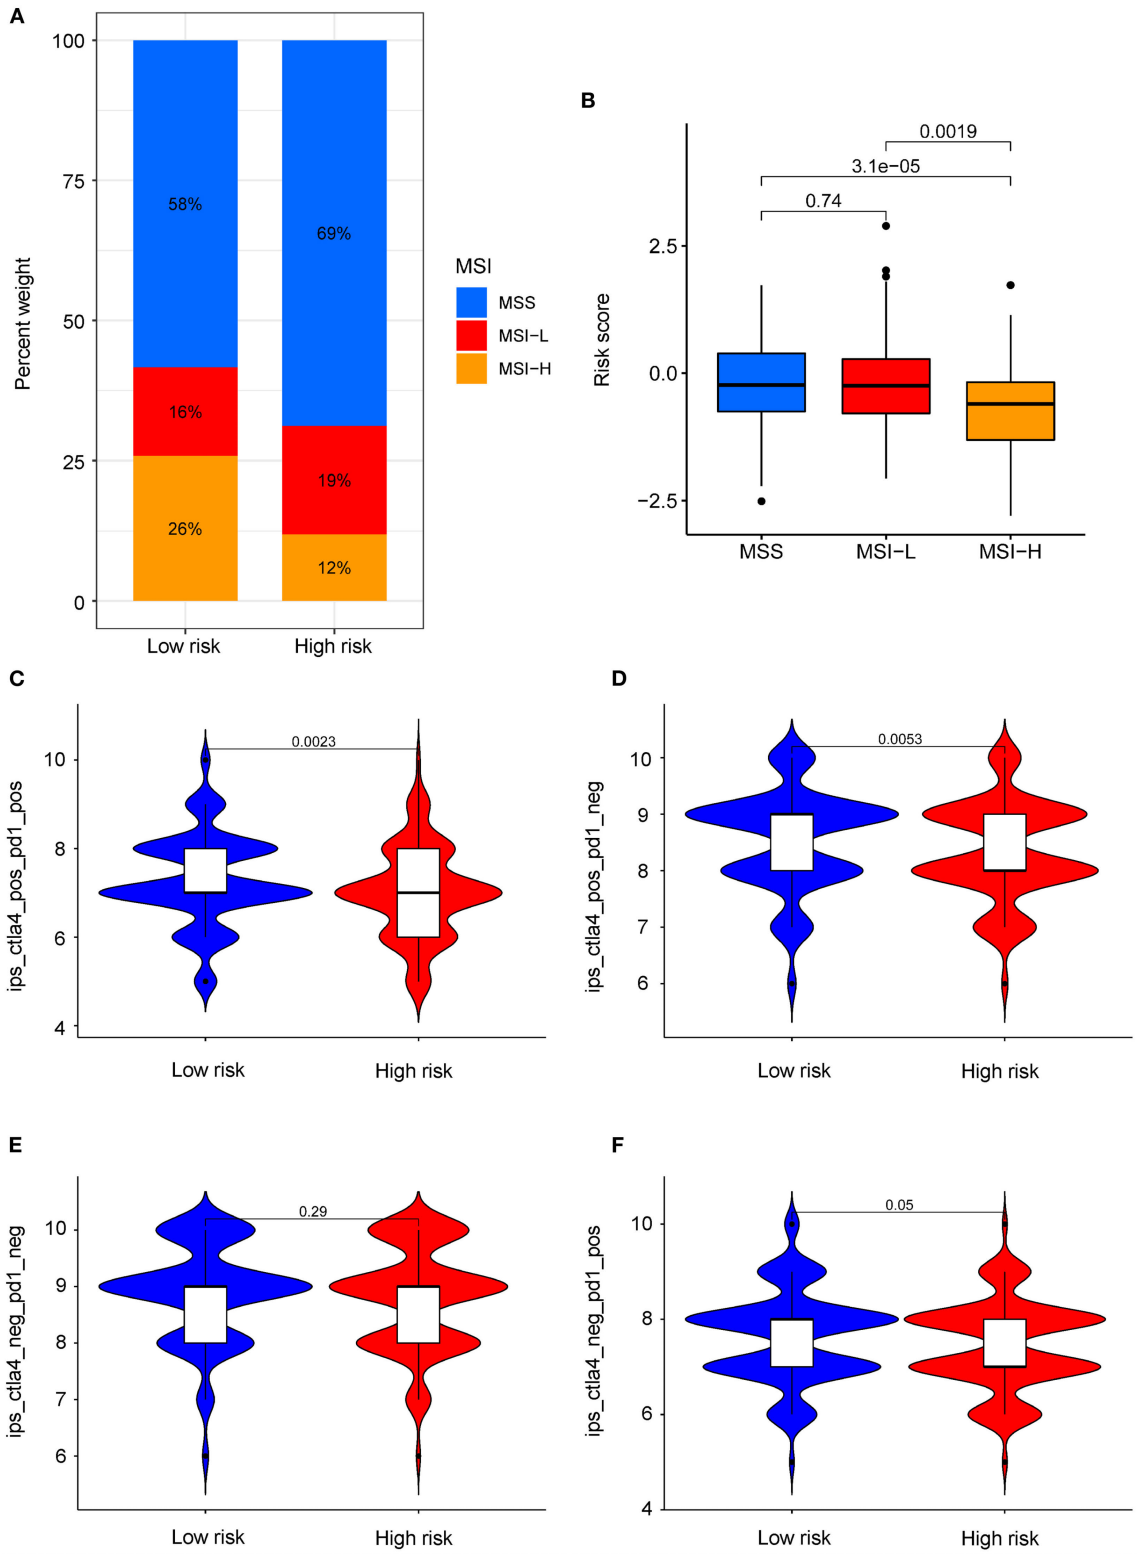

FIGURE 7 | Role of risk score in predicting MSI and immunotherapy benefits. **(A)** The proportion of different MSI levels in the subgroups with high and low risk score. **(B)** Differences in risk score among groups with different MSI levels. **(C–F)** Sensitivity of patients with high and low risk score subgroups to four treatments. **(C)** PD-1 inhibitor in combination with CTLA-4 inhibitor. **(D)** CTLA-4 inhibitor alone. **(E)** Without immune checkpoint inhibitors. **(F)** PD-1 inhibitor alone.

CTLA-4 inhibitors alone. In conclusion, dual CTLA-4/PD-1 blockade might be considered as suitable drug for patients with low-risk scores.

The combination of traditional chemotherapy drugs and targeted therapy has been widely used in the treatment of advanced colon cancer. We found that patients in the high-risk group had a higher sensitivity to elesclomol, midostaurin, pazopanib, and imatinib than in the low-risk group. Elesclomol, a reactive oxygen species (ROS) inducer, plays an important role in mediating cuproptosis (45). Pazopanib is a multi-targeted receptor tyrosine kinase inhibitor that selectively restraining the autophosphorylation of receptors such as VEGFR-2, Kit, and PDGFR-β in renal cell carcinoma (46). In our study, we may provide a new complementary for the treatment of advanced colon cancer. However, the results of this drug screening still need further validation in clinical trials.

CONCLUSIONS

In summary, we constructed a prognostic signature based on 10 AAMRGs with strong predictive value. This study paved the way for personalized treatment of COAD patients.

DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: https://www.ncbi.nlm.nih.gov/geo/, GSE39582, GSE29621, and GSE17536.

AUTHOR CONTRIBUTIONS

YR and WY conceived and designed the study. YR and SF performed the experiments and analyzed the data. YR and

SH wrote the manuscript. WY contributed to manuscript revision. All authors contributed to the article and approved the submitted version.

FUNDING

This study was supported by the Guangdong Natural Science Funds for Distinguished Young Scholar (No. 2017A030306030 to WY).

ACKNOWLEDGMENTS

The authors express their gratitude to the editor and the reviewers for their useful comments and suggestions that helped improve the quality of this study.

SUPPLEMENTARY MATERIAL

The Supplementary Material for this article can be found online at: https://www.frontiersin.org/articles/10.3389/fpubh.2022.916364/full#supplementary-material

Supplementary Figure S1 | Kaplan-Meier survival subgroup analysis according to the signature stratified by clinical characteristics. **(A)** Age ≤ 70 years and age > 70 years. **(B)** Female and male. **(C)** T1-2 and T3-4. **(D)** N0 and N1-2. **(E)** M0 and M1. **(F)** Stage I–II and stage III–IV.

Supplementary Figure S2 | Correlation between risk score and GSEA, somatic variation. **(A)** Enriched gene sets annotated by the KEGG collection between the high- and low-AAMRGs-risk groups in the cohort. **(B)** TMB levels between the high- and low-risk groups. **(C)** Correlation analysis between risk score and mutation load. **(D,E)** The mutation rates of reported prognostic-related genes in low- and high-risk groups.

Supplementary Figure S3 | Differential chemotherapeutic response based on IC50 available between the high- and low-risk groups. **(A–F)** The half-maximal inhibitory concentration (IC50) of six chemotherapeutic agents (Paclitaxel, Metformin, Rapamycin, Bortezomib, Sorafenib, Gemcitabine).

Although peripheral venous blood biomarkers are related to respiratory function in Amyotrophic lateral sclerosis (ALS) patients, there are still few prediction models that predict pulmonary function. This study aimed to investigate the venous blood biomarkers associated with respiratory function in patients with ALS from southwest China and to create prediction models based on those clinical biomarkers using logistic regression. A total of 319 patients with ALS from the retrospective cohort and 97 patients with ALS from the prospective cohort were enrolled in this study. A multivariable prediction model for the correlation between peak expiratory flow (PEF) and hematologic, biochemical laboratory parameters, and clinical factors in patients with ALS was created. Along with female patients, bulbar-onset, lower body mass index (BMI), later age of onset, lower level of creatinine, uric acid, triglyceride, and a higher level of high-density lipoprotein cholesterol (HDL_C) were related to reduced PEF. The area under the receiver operating characteristics (ROC) curve is.802 for the test set and.775 for the validation set. The study constructed a multivariable prediction model for PEF in patients with ALS. The results can be helpful for clinical practice to predict respiratory impairment.

Keywords: Amyotrophic lateral sclerosis, peak expiratory flow, prediction model, respiratory function, venous blood parameters

INTRODUCTION

Amyotrophic lateral sclerosis (ALS) is a rapidly progressive neurodegenerative disease clinically characterized by loss of bulbar and limb function (1). Recent studies have shown that the average onset age of ALS is 51–66 years (2). Men have a higher risk of developing ALS than women. Studies reported a male to female ratio of 1:2 (2). Patients with ALS usually die from respiratory failure 3–5 years after the symptom onset (3).

To monitor the health status of patients with ALS, close clinical and functional follow-up with particular care for respiratory monitoring was recommended for patients with ALS (4).

Peak expiratory flow (PEF) can assess the strength of respiratory muscles and can evaluate the efficacy of clearing the bronchial tree (5). The study reported that 85% of patients with ALS would develop dysphagia and impaired secretion management, leading to impairment of mucociliary clearing and airway protection (6), which resulted in malnutrition, dehydration, and aspiration pneumonia (7). PEF can be used as a tool for assessing cough ability for patients who underwent lung surgery (8), pulmonary function assessment before lung surgery (9, 10), and airway clearance in neurodegenerative disease (11). Recent studies reported that respiratory impairments in patients with ALS demonstrated reduced peak expiratory flow (PEF) rates compared to healthy controls (12, 13), implying that PEF may be a good screen tool for identifying patients with ALS at risk for aspiration (13). Moreover, the authors found that PEF was an independent factor for survival (14) and positively correlated with the revised functional rating scale score (ALSFRS-R), indicating a predictive value for survival and disease severity in patients with ALS (15).

For patients in the final stages of ALS, the pulmonary function tests were hardly carried out due to their inability to perform the tests. Thus, it is necessary to explore more easily accessible and low-cost parameters for the prediction of respiratory function. Venous blood parameters have been related to respiratory impairment and disease severity in patients with ALS in several studies (16–20). To the best of our knowledge, no studies of venous blood biomarkers associated with PEF in patients with ALS were seen.

We aimed to develop and validate a predictive model based on a new panel of eleven variables analyzed in venous blood parameters of patients with ALS, along with their clinical characteristics. The multivariable logistic regression model created in this study can predict the impairment of PEF in patients with ALS.

MATERIALS AND METHODS

Patients

This is a retrospective and prospective study. Patients from a large, regional, and referral ALS clinic in Southwest China, were enrolled in the study. In the retrospective cohort, 319 patients with ALS were registered from 1 January 2015 to 30 December 2020. In the prospective cohort, 97 participants from 1 March 2017 to 30 October 2021 were enrolled. All the participants fulfilled the revised El Escorial criteria for probable or definite ALS (21, 22). We excluded patients with other medical or neurological diseases and patients with missing baseline hematologic and biochemical values. Patients with manifestations of neoplastic disorders were also excluded. This study was approved by the Ethical Committee of West China Hospital of Sichuan University.

Clinical Variables

In this study, the relevant demographic and clinical data were collected, including age, age at ALS onset and diagnosis, sex, onset body region, and blood pressure. BMI was calculated at

SBP, systolic blood pressure; DBP, diastolic blood pressure; BMI, body mass index; PLT, platelet count; NEUT#, neutrophil count; LYMPH#, lymphocyte count; PLR, the ratio of PLT to LYMPH#; MONO#, monocyte count; BASO#, basophil count; ALB, albumin; GLU, glucose; UREA, urea; CREA, creatinine; URIC, uric acid; TG, triglyceride; CHOL, cholesterol; HDL_C, high-density lipoprotein cholesterol.

the time of pulmonary function tests. High blood pressure was defined as systolic blood pressure (SBP) of ≥140 mmHg and/or diastolic blood pressure (DBP) of ≥90 mmHg in this study.

Hematologic and biochemical laboratory parameters were obtained using an automated hematology analyzer (KX-21 N, Sysmex America, Lincolnshire, IL, USA), and data on platelet count (PLT), neutrophil count (NEUT#), lymphocyte count (LYMPH#), monocyte count (MONO#), eosinophil count (EO#), basophil count (BASO#), albumin (ALB), glucose (GLU), triglyceride (TG), urea (UREA), cholesterol (CHOL), uric acid (URIC), high-density lipoprotein cholesterol (HDL_C), creatinine (CREA), and creatine kinase (CK) were obtained. PLR was defined as the ratio of PLT to LYMPH#. Using electronic spirometry, PEF was measured with the patient in a standing position.

Statistical Analysis

Correlation Analysis

Continuous variables with normal distribution were reported as mean (standard deviation [SD]); non-normal variables were presented as median (interquartile range (IQR), 25 to 75%). The linear correlations of these variables and the respiratory function index (PEF) were calculated by Spearman. For categorical variables, the correlations were performed by the nonparametric test (Wilcoxon rank-sum test). For normal distribution data, differences between the groups who had a PEF of <5.50 or

not were performed by the Independent Samples *t*-test. For non-normal distribution, differences were estimated using the Mann-Whitney test or chi-squared tests.

The Training Set and the Test Set

The retrospective cohort was divided into two independent sets: the training set and the test set. The training set included 70% (220/319) of the retrospective cohort, randomly selected from the cohort. The test set included 30% (95/319) of the retrospective cohort. Models were developed based on the characteristics of the training set. The test set was used to validate the models (**Figure 1**). Partition of the data set was realized by the sample() function in R. In the partitioning, the set.seed() function was used to generate a sequence of random numbers.

Logistic Regression

A total of 23 variables, namely, gender, onset age, site of onset, diagnostic level, height, BMI, Blood pressure, PLT, PLR, NEUT#, LYMPH#, MONO#, EO#, BASO#, ALB, GLU, UREA, CREA, URIC, TG, CHOL, HDL_C, and CK, were included to construct

the model. Based on the results of the backward stepwise regression method, combined the with Akaike information criterion (AIC), the heatmap of PEF for predicting peak expiratory flow impairment in patients with ALS was established. Receiver operating characteristic (ROC) curves and calibration curves were drawn to evaluate the predictive accuracy. Then, we tested the model in the validation set. All statistical analyses were performed using SPSS 24.0 (IBM, Chicago, IL, USA) and R 4.1.0 (www.rproject.org).

RESULTS

Of the 416 patients with Amyotrophic lateral sclerosis included in the study, there were 57 males (51.35%) in the retrospective cohort and 16 males (47.06%) in the prospective cohort with PEF of <5.5 L/s, while 54 females (48.65%) in the retrospective cohort and 18 females (52.94%) in the prospective cohort with PEF of <5.5L/s (**Table 1**). Similarly, there were significant age differences in onset age, BMI, level of PLR, CREA, TG, and HDL_C (all $P < 0.05$) when stratified by PEF either in the retrospective cohort or in the prospective cohort (**Table 1**).

We developed a multivariable logistic regression model for the association between the hematologic, biochemical laboratory parameters, clinical factors, and PEF in patients with ALS in the test set. The regression equation was developed from the estimate values obtained by z-value and is reported in **Table 2**. Moreover, we constructed a heatmap to show the relation between these variables in the equation and PEF (**Figure 2**).

Model PEF = −3.483+1.601 Gender (Female) + 1.373 Site.of.onset 2 (bulbar onset) or.695 Site.of.onset 3 (except for limb onset and bulbar onset) −0.106 BMI +0.005 PLT −14.968 'BASO#' −0.041 CREA level +0.004 URIC level +0.366 TG level −0.483 CHOL level + 1.363 HDL_C level +0.088 Onset.age (**Table 2**).

The ROC curve, with 11 predictive factors, revealed that the area under the curve was 80.2% in the test set (**Table 3**; **Figure 3**). And the ROC curve has a standard error of.049 with a 95% confidence interval (CI) of.707–0.898 in the test set. Furthermore, the calibration curve was also constructed (**Figure 4**). The calibration curves further indicated good calibration power.

TABLE 3 | ROC curve for the test set and the validation set.

	The test set	The validation set
The area under the ROC curve (AUC)	0.802	0.775
Standard error	0.049	0.052
95% Confidence interval	0.707–0.898	0.674–0.877
Z-statistic	6.197	5.326
Significance level P (Area=0.5)	5.77E−10	1.01E−07

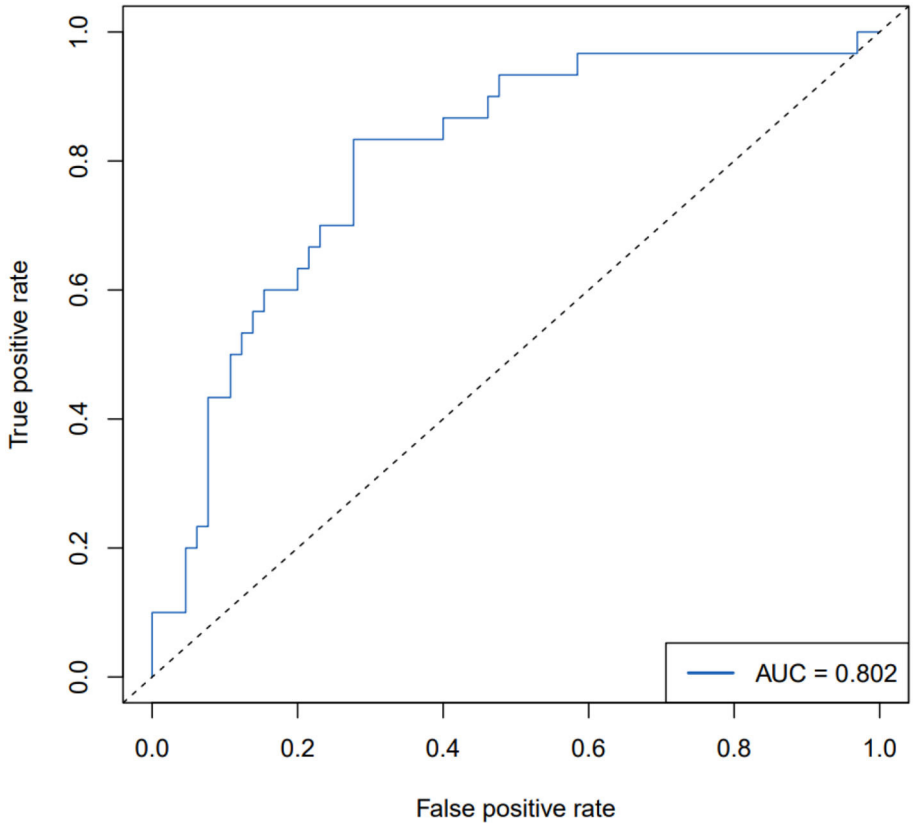

FIGURE 3 | ROC curve for the backward stepwise regression method combined with the AIC model for predicting PEF impairment in patients with ALS in the test set.

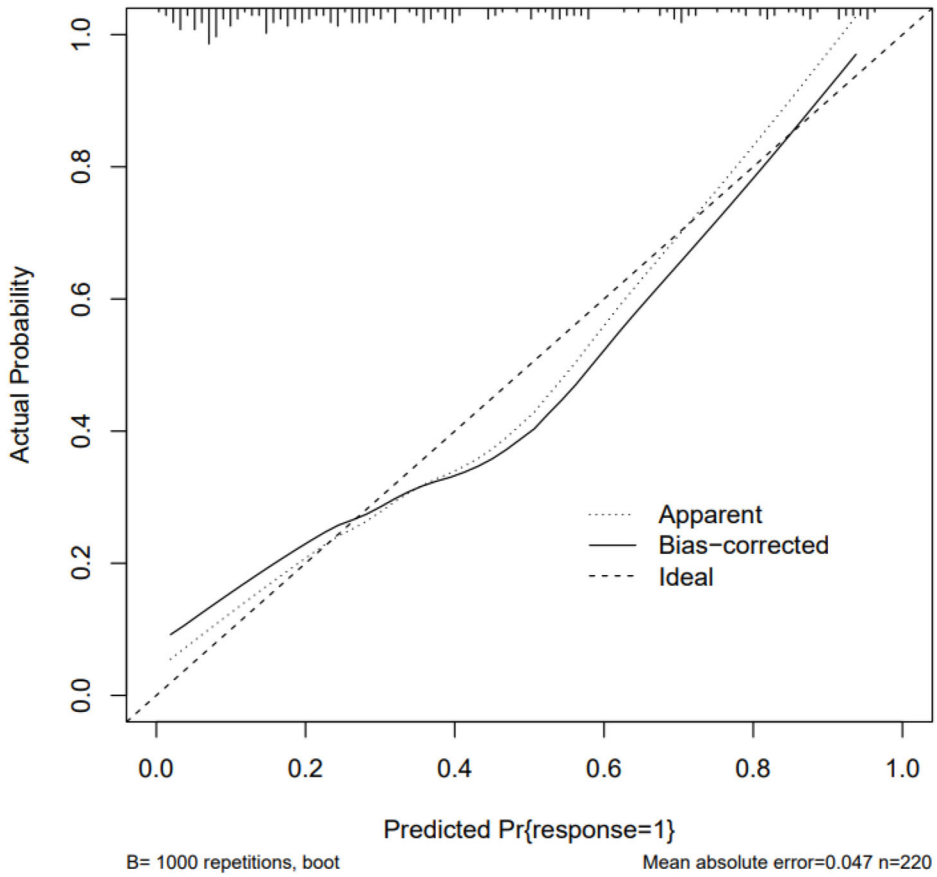

FIGURE 4 | The calibration curve for the model in the training set.

To validate the model, we tried to predict the data from the prospective cohort and calculated the ROC curve, which yielded a concordance statistic of.775 (95% CI,0.674–0.877) (**Figure 5**).

DISCUSSION

Since most patients with ALS in their advanced phase would develop respiratory impairment, it is important for clinicians to evaluate the respiratory function status. To date, there are few studies about models predicting respiratory function in patients with ALS (16, 23). Our study created and validated a multivariable logistic model for the association between PEF and the venous blood biomarkers and clinical factors in patients with ALS. Our single-site study revealed that PEF is related to ALS characteristics, as well as hematologic and biochemical laboratory parameters, and further verification is needed in external data sets with a large sample. To the best of our knowledge, this is the first study of a prediction model for PEF in ALS.

The PEF decreases in neuromuscular diseases (24) and showed excellent discriminant ability to evaluate the presence of aspiration pneumonia (13). Furthermore, the peak cough expiratory significantly correlates with bulbar impairment in patients with ALS (25) and maybe a good indicator to discriminate between ALS with "non-invasive ventilation (NIV) indication" and those with "no NIV indication yet" (26). The prediction model in our study consists of variables that are easy to get. Therefore, it can be a preliminary screening tool for the severity of the disease quickly and be used to evaluate the cough ability of patients with ALS in the outpatient department. The PEF prediction model may be a good screen tool for clinical utility.

In our study, patients with ALS with a lower level of TG, and a higher level of HDL_C showed a trend of reduced PEF. Also, in the prospective cohort, PEF was inversely associated with cholesterol. This study has not confirmed previous research, which found that lower serum lipid levels are related to reduced functional vital capacity (16). Another study from Japan reported that forced vital capacity (FVC) was inversely correlated with serum total cholesterol (17). Prospective cohort studies with a larger sample size are warranted to clarify the relationship between serum lipid and respiratory function.

In contradiction to previous research (23), we found that lower levels of creatinine and uric acid were associated with decreased PEF, but not independent predictors of PEF. Several

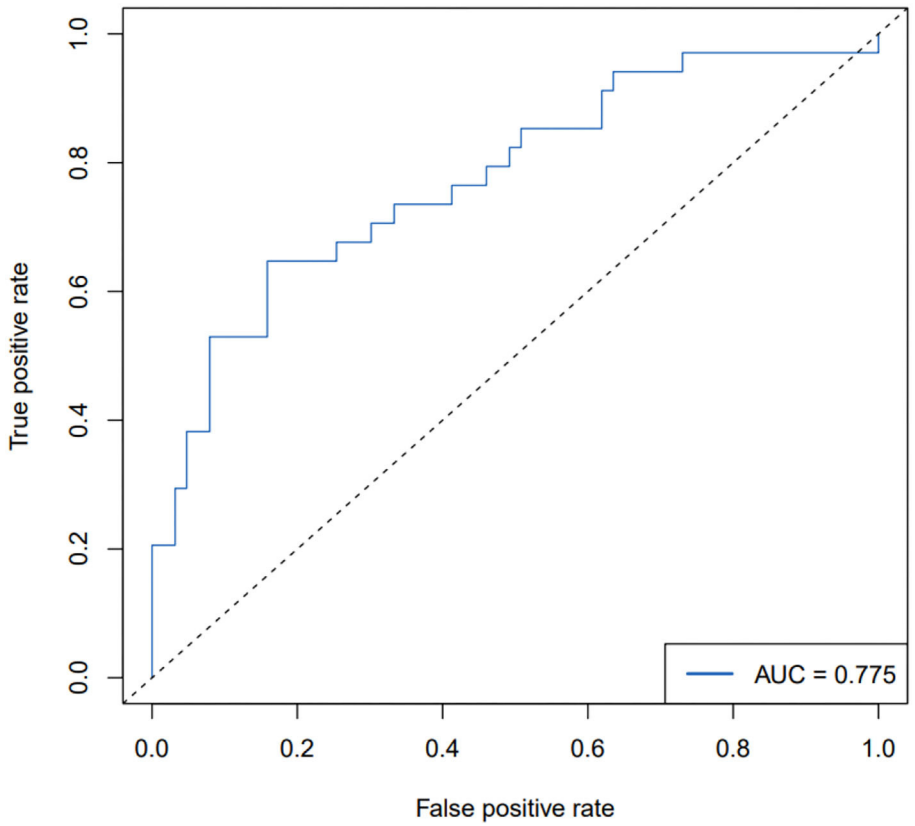

FIGURE 5 | Receiver operating characteristic (ROC) curve of PEF in the validation set.

studies have shown that low levels of serum creatinine and uric acid have been associated with poor survival, and faster functional decline (18–20, 27). One possibility is that patients with ALS with short survival have a faster respiratory decline. These patients have decreased levels of creatinine and uric acid at the same time, ultimately resulting in a low level of creatinine and uric acid-related to impaired respiratory.

Dysphagia in patients with ALS had a close relationship with respiratory impairment (13). A prospective study demonstrated that not only bulbar-onset but also most limb-onset patients with ALS had problems with dysphagia (6). Moreover, about 20% of spinal-onset patients with ALS, who did not show dysphagia at diagnosis, had initial respiratory impairment (28), highlighting the importance of evaluating PEF at the beginning of enrollment. In this study, female patients with ALS with bulbar-onset, later age at onset, and lower BMI tended to have reduced PEF in our study. Age at onset, onset region, and weight loss were factors independently influencing survival in patients with ALS (28–30). Further studies are needed to investigate the relationship between bulbar-onset, age at onset, BMI, and PEF.

Our results should be interpreted with caution due to several limitations. Firstly, our retrospective cohort could not analyze biomarkers potentially significant to the risk of PEF. For example, lipid and uric acid values collected at admission might be affected by the other conditions that coexisted with ALS, which we did not analyze. Secondly, the validation data set in our study was not technically an external data set, thus, external validation is needed. Thirdly, the prediction model is only suitable for probable and definite patients with ALS. Additionally, since the model is derived from the retrospective cohort and a single medical center, it should be tested and verified on larger prospective cohorts to evaluate the validity and predictability.

In conclusion, our study constructed a multivariable logistic regression equation of PEF derived from venous blood biomarkers and clinical factors in patients with ALS. The finding needs to be verified in prospective and multi-site studies.

Climate change is unexpected weather patterns that can create an alarming situation. Due to climate change, various sectors are affected, and one of the sectors is healthcare. As a result of climate change, the geographic range of several vector-borne human infectious diseases will expand. Currently, dengue is taking its toll, and climate change is one of the key reasons contributing to the intensification of dengue disease transmission. The most important climatic factors linked to dengue transmission are temperature, rainfall, and relative humidity. The present study carries out a systematic literature review on the surveillance system to predict dengue outbreaks based on Machine Learning modeling techniques. The systematic literature review discusses the methodology and objectives, the number of studies carried out in different regions and periods, the association between climatic factors and the increase in positive dengue cases. This study also includes a detailed investigation of meteorological data, the dengue positive patient data, and the pre-processing techniques used for data cleaning. Furthermore, correlation techniques in several studies to determine the relationship between dengue incidence and meteorological parameters and machine learning models for predictive analysis are discussed. In the future direction for creating a dengue surveillance system, several research challenges and limitations of current work are discussed.

Keywords: predictive models, machine learning, surveillance system, dengue, climatic factors

1. INTRODUCTION

Artificial Intelligence is a field in which a machine exhibits intelligence by learning about itself. Artificial Intelligence may employ various approaches and algorithms to comprehend human intellect, but it is not limited. Machine Learning is a branch of AI that deals with techniques that can learn from experience on their own (1). In automated decision-making and predictive analytics, AI plays a crucial role (2). Methods based on various kinds of AI are already being used in a variety of climate change and environmental monitoring research sectors (3). Machine Learning and Deep Learning

are used in education, finance, healthcare, agriculture, and many more. The application of Machine Learning in healthcare demonstrated encouraging results, instilling trust in the sector (4). There are varied reasons for using artificial intelligence in healthcare. Primarily, it helps to manage the clinical records of patients and aids in providing personalized treatment and medicines, early identification of disease, providing predictive analytics, which could help health officials take preventive measures in advance before the outbreak of any disease (5). Artificial Intelligence goes back to the too early 1990s and today has evolved into a burgeoning field with a significant contribution in healthcare (6) through various modes like drug and discovery, personalized treatment and medicine, preventive measures, a health assistant chatbot, clinical trial and researches, diagnosing and pathology, analytics, image processing and prediction of an outbreak. Artificial Intelligence is a boon, and **Figure 1** demonstrates the evolution of AI in healthcare throughout 1950–2020. Climate change is long-term changes in temperature and weather patterns.These variations might be attributed to natural causes such as solar cycle oscillations. Due to the use of fossil fuels such as coal, oil, and gas, human activities have been the leading cause of climate change since the 1800s (7). Greenhouse gas emissions from fossil fuel combustion act as a blanket, trapping the sun's heat and boosting global temperatures. The amount of greenhouse gases in the atmosphere is at its highest level in 2 million years. Artificial Intelligence is a field in which a machine exhibits intelligence by learning about itself. Artificial Intelligence may employ various approaches and algorithms to comprehend human intellect, but it is not limited. Machine Learning is a branch of AI that deals with techniques that can learn from experience on their own. In automated decision-making and predictive analytics, AI plays a crucial role. Methods

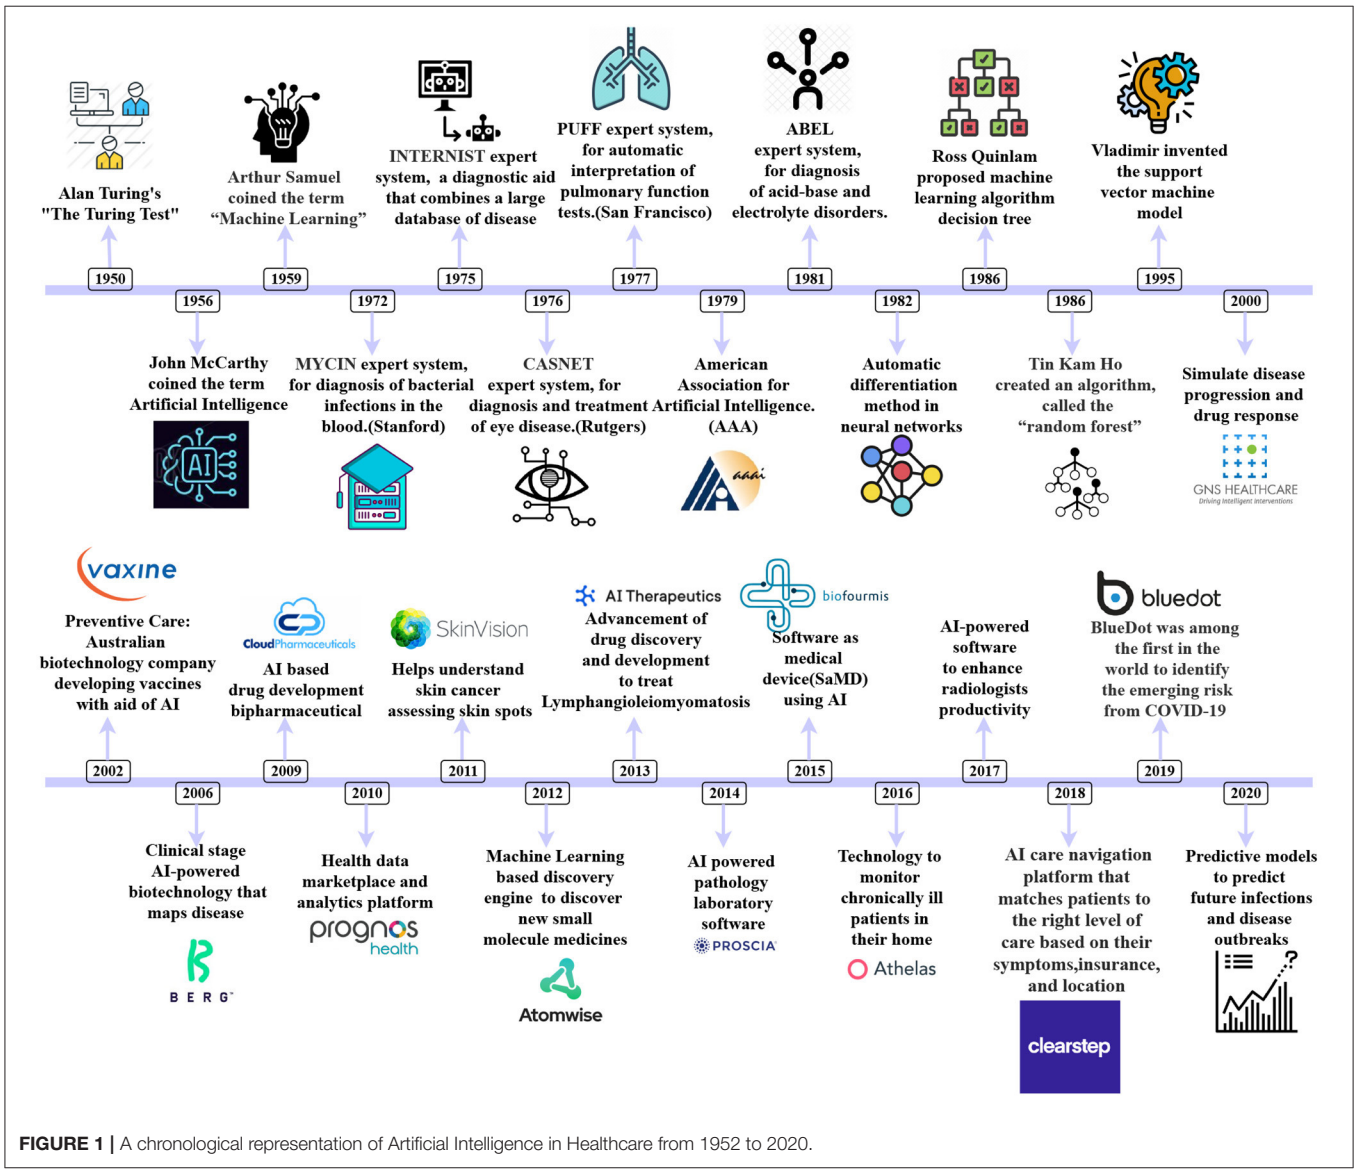

FIGURE 1 | A chronological representation of Artificial Intelligence in Healthcare from 1952 to 2020.

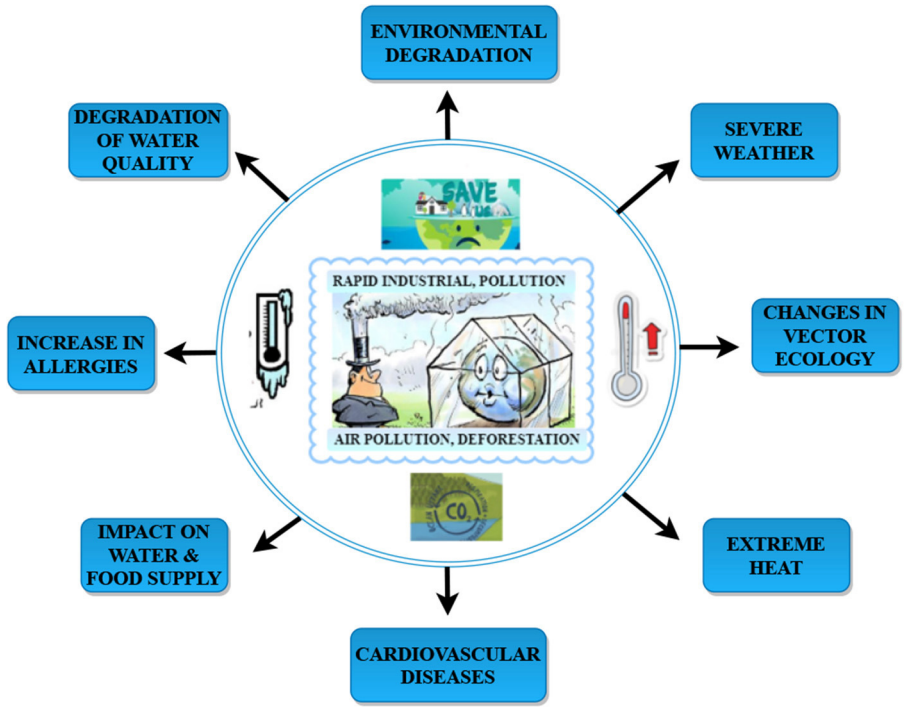

FIGURE 2 | Causes and consequences of climate change.

based on various kinds of AI are already being used in a variety of climate change and environmental monitoring research sectors. Machine Learning and Deep Learning are used in education, finance, healthcare, agriculture, and many more. The application of Machine Learning in healthcare demonstrated encouraging results, instilling trust in the sector (8). There are varied reasons for using artificial intelligence in healthcare. Primarily, it helps to manage the clinical records of patients and aids in providing personalized treatment and medicines, early identification of disease, providing predictive analytics, which could help health officials take preventive measures in advance before the outbreak of any disease. Artificial Intelligence goes back to the too early 1990s and today has evolved into a burgeoning field with a significant contribution in healthcare through various modes like drug and discovery, personalized treatment and medicine, preventive measures, a health assistant chatbot, clinical trial and researches, diagnosing and pathology, analytics, image processing and prediction of an outbreak. Artificial Intelligence is a boon, and **Figure 1** demonstrates the evolution of AI in healthcare throughout 1950–2020. Climate change is long-term changes in temperature and weather patterns.These variations might be attributed to natural causes such as solar cycle oscillations. Due to the use of fossil fuels such as coal, oil, and gas, human activities have been the leading cause of climate change since the 1800s. Greenhouse gas emissions from fossil fuel combustion act as a blanket, trapping the sun's heat and boosting global temperatures. The amount of greenhouse gases in the atmosphere is at its highest level in 2 million years. Emissions are steadily increasing. Since the late 1800s, the Earth has warmed by around 1.1°C. The previous 10 years (2011–2020) have been the hottest on record. **Figure 2** explains the causes of climate change and the effects due to those variations. Vector-borne illness is a severe public health threat in underdeveloped nations that is only becoming worse. Temperatures in the air and water, precipitation patterns, severe rainfall events, and seasonal changes are all known to impact disease transmission (9). At the moment, dengue (10) is spreading widely after COVID-19; dengue is a vector-borne disease that spreads through an infected female mosquito of species Aedes aegypti (11) and is one of the most common diseases in more than 100 countries (12). Aedes aegypti can be found in urban and suburban settings with high human population density and housing density. This species is endophilic, which means it seeks shelter inside structures. As a result, the intradomicile is more typically seen than the peridomicile. Tires, cans, bottles, pots, vats, brass, swimming pools, and abandoned aquariums are frequent breeding habitats filled with rainwater or household water.

These mosquitos carry the Chikungunya, yellow fever, and Zika viruses. Dengue fever is widespread in the tropics, with different risk levels based on rainfall, temperature, relative humidity, and unplanned fast urbanization. Dengue fever may be fatal if it is not treated appropriately. It was first discovered during dengue epidemics in the Philippines and Thailand in

the 1950s. Most Asian and Latin American nations now have severe dengue fever, a leading cause of hospitalization and mortality among children and adults. A Flaviviridae virus causes dengue with four unique but closely related serotypes (DENV-1, DENV-2, DENV-3, DENV-4), and the fifth serotype of dengue has been detected in the Malaysian state of Sarawak (13). Dengue fever is caused by DENV infection in our bodies. **Figure 3** depicts the common symptoms of dengue. Dengue fever causes severe joint and muscle pain, enlarged lymph nodes, headaches, fever, exhaustion, and a rash. Dengue fever is characterized by non-specific flu-like symptoms such as chills, appetite loss, lethargy, and low backache. According to a recent WHO research, dengue fever grew in several countries in 2020, including Bangladesh, Brazil, the Cook Islands, Ecuador, India, Indonesia, the Maldives, Mauritania, Mayotte, Nepal, Singapore, Sri Lanka, Sudan, Thailand, Timor-Leste, and Yemen. In 2019,

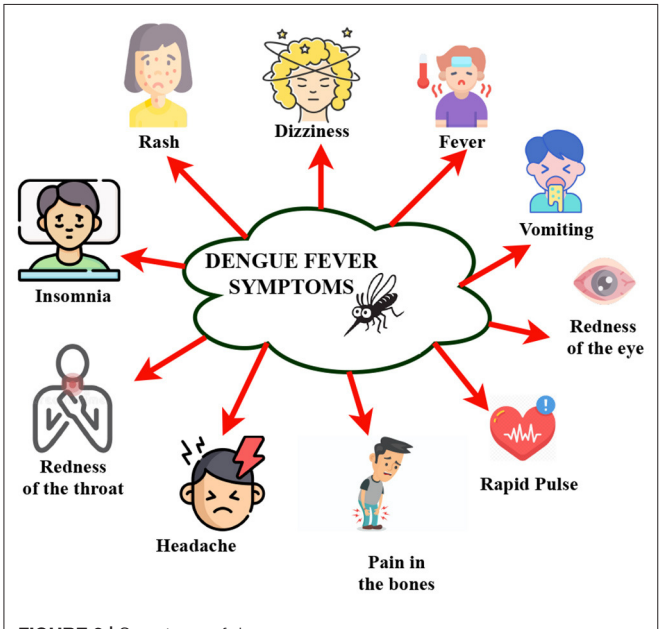

FIGURE 3 | Symptoms of dengue.

dengue fever cases reached an all-time high in the world. Dengue fever is slowly gaining ground in 2021, with instances documented in several nations. Around 40 per cent of the world's population lives in areas with a high risk of dengue fever, such as tropical and subtropical climates. Dengue fever has become much more common in recent decades worldwide. According to one estimate, 390 million dengue virus infections occur each year (12). Emissions are steadily increasing. Since the late 1800s, the Earth has warmed by around 1.1°C. The previous 10 years (2011–2020) have been the hottest on record (9). **Figure 2** explains the causes of climate change and the effects due to those variations. Vector-borne illness is a severe public health threat in underdeveloped nations that is only becoming worse. Temperatures in the air and water, precipitation patterns, severe rainfall events, and seasonal changes are all known to impact disease transmission (10). At the moment, dengue (11) is spreading widely after COVID-19; dengue is a vector-borne disease that spreads through an infected female mosquito of species Aedes aegypti (12) and is one of the most common diseases in more than 100 countries (14). Aedes aegypti can be found in urban and suburban settings with high human population density and housing density. This species is endophilic, which means it seeks shelter inside structures. As a result, the intradomicile is more typically seen than the peridomicile. Tires, cans, bottles, pots, vats, brass, swimming pools, and abandoned aquariums are frequent breeding habitats filled with rainwater or household water (13). FIGURE 4 | Roadmap of the conducted review.

DENV infection in our bodies. Dengue fever causes severe joint and muscle pain, enlarged lymph nodes, headaches, fever, exhaustion, and a rash. Dengue fever is characterized by non-specific flu-like symptoms such as chills, appetite loss, lethargy, and low backache. According to a recent WHO research, dengue fever grew in several countries in 2020, including Bangladesh, Brazil (16), the Cook Islands, Ecuador, India (17), Indonesia (18), the Maldives, Mauritania, Mayotte, Nepal, Singapore (19), Sri Lanka, Sudan, Thailand (20), Timor-Leste, and Yemen. In 2019, dengue fever cases reached an all-time high in the world. Dengue fever is slowly gaining ground in 2021, with instances documented in several nations (14). Around 40 per cent of the world's population lives in areas with a high risk of dengue fever, such as tropical and sub-tropical climates. Dengue fever has become much more common in recent decades worldwide. According to one estimate, 390 million dengue virus infections occur each year (14). Dengue fever will affect 60 per cent of the world's population by 2080, according to researchers who blame climate change for the disease's spread. Climate change is widely cited as a contributing factor in the rapid spread of pandemic disease (21). Climate change is frequently identified by WHO, national, and international health authorities as one of the primary causes of the global spread of dengue fever and other Aedes-transmitted viral infections. According to the World Health Organization, dengue fever has become increasingly widespread internationally in recent decades (WHO). According to the World Health Organization, dengue fever affects 50–100 million people globally each year. As a result, it is vital to anticipate dengue epidemics. The accuracy of dengue epidemic prediction is currently a problem that must be addressed. The role of climate variables in predicting dengue outbreaks has been studied in a small number of studies. Tropical countries are the hardest hit because of their environmental, climatic, and socioeconomic characteristics (22). The weather has an impact on the vector-borne illness dengue's temporal and geographical spread. As a result, rainfall and ambient temperature are referred to as macro factors that influence dengue since they directly impact Aedes aegypti population density, which varies seasonally based on these important variables. Its population density tends to decline drastically during less precipitation and lower average temperatures in regions with a tropical or subtropical climate. Still, it grows consistently in locations with a tropical or subtropical environment (23). As the vector-weather association is as significant as the vector-human interaction, studies of climatic variables can have a better understanding of epidemic seasonality and the ability to anticipate it (24). In recent years, epidemiological research has focused on developing mathematical and statistical models based on weather parameters to explain the dynamics of dengue fever incidence. Its main goal was to find models with promising future predicting the potential of dengue incidence to help public health officials. Several researchers investigate the link between climate variables and dengue fever, frequently employing time-series analyses to characterize temporal trends, uncover patterns, and even make forecasts. Bhatt et al. (21) Many parameters, such as entomological, epidemiological, and geographic characteristics, can help predict the dengue outbreak effectively. Artificial intelligence has been employed in healthcare for a long time. This review study discusses the studies undertaken until now. **Figure 4** represents road-map of the present study. It investigates several other vulnerable groups that will be useful in predicting positive dengue cases and eventually help prevent the outbreak and take preventive measures at an early stage. The present study is structured as follows: Section 2 describes the methodology and objectives of the survey carried out; Section 3 provides a detailed analytical review of the papers; Section 4 discusses the challenges and future work, and Section 5 concludes the present study.

2. METHODOLOGY AND OBJECTIVES

To carry out the systematic literature review of dengue prediction models, process was followed which included i) establishing research questions, ii) developing a search strategy to narrow down the results, iii) selecting papers using eligibility criteria and iv) analyzing to extract strengths, weaknesses, and difficulties to overcome from articles. The main objectives of this systematic literature review are i) To gather and describe dengue machine learning models for dengue surveillance systems and ii) To illustrate the obstacles that future dengue modeling studies will face.

2.1. Search Strategy

Various digital libraries like Taylor and Francis, Google Scholar, MDPI, IEEE Xplorer, ScienceDirect, Pubmed, BMC and PLOS were used. The inclusion criteria were articles from January 2017 to August 2021 related to various dengue prediction models based on explanatory variables. The requirements for discarding the publications were personal opinions, unpublished works, posters, short articles and conference papers. The selection procedure included choosing themes by scrutinizing their title, keywords and abstract to eliminate the results that were not related. Further, to investigate more relevant papers, we examined summaries to determine if we could select the article or not.

2.2. Preliminary Analysis

To analyze the amount of research carried out, we analyzed Scopus data using keywords dengue, predicting, climatic factors, age and gender. **Figure 5A** were graphically represented using the query "[(predicting dengue) and (climatic factors and dengue)]" which fetched 1,315 documents, and **Figure 5B** were graphically represented using the query [(predicting dengue) AND (climatic factors and dengue) and (age group and gender)] which fetched only 38 documents. Therefore, we can deduce that studies on dengue prediction based on climatic factors, age group and gender has not been done by many researchers, and we can explore this field. As it is not carried out in many regions, there is a scope to examine countries/territories where this study has not been carried out. The analytic review that we carried out had the highest number of studies were from India, Brazil and Malaysia. **Figure 6** displays the number of studies done in different countries and republics. As stated by the WHO report, these countries belong to tropical and sub-tropical regions that are more prone to

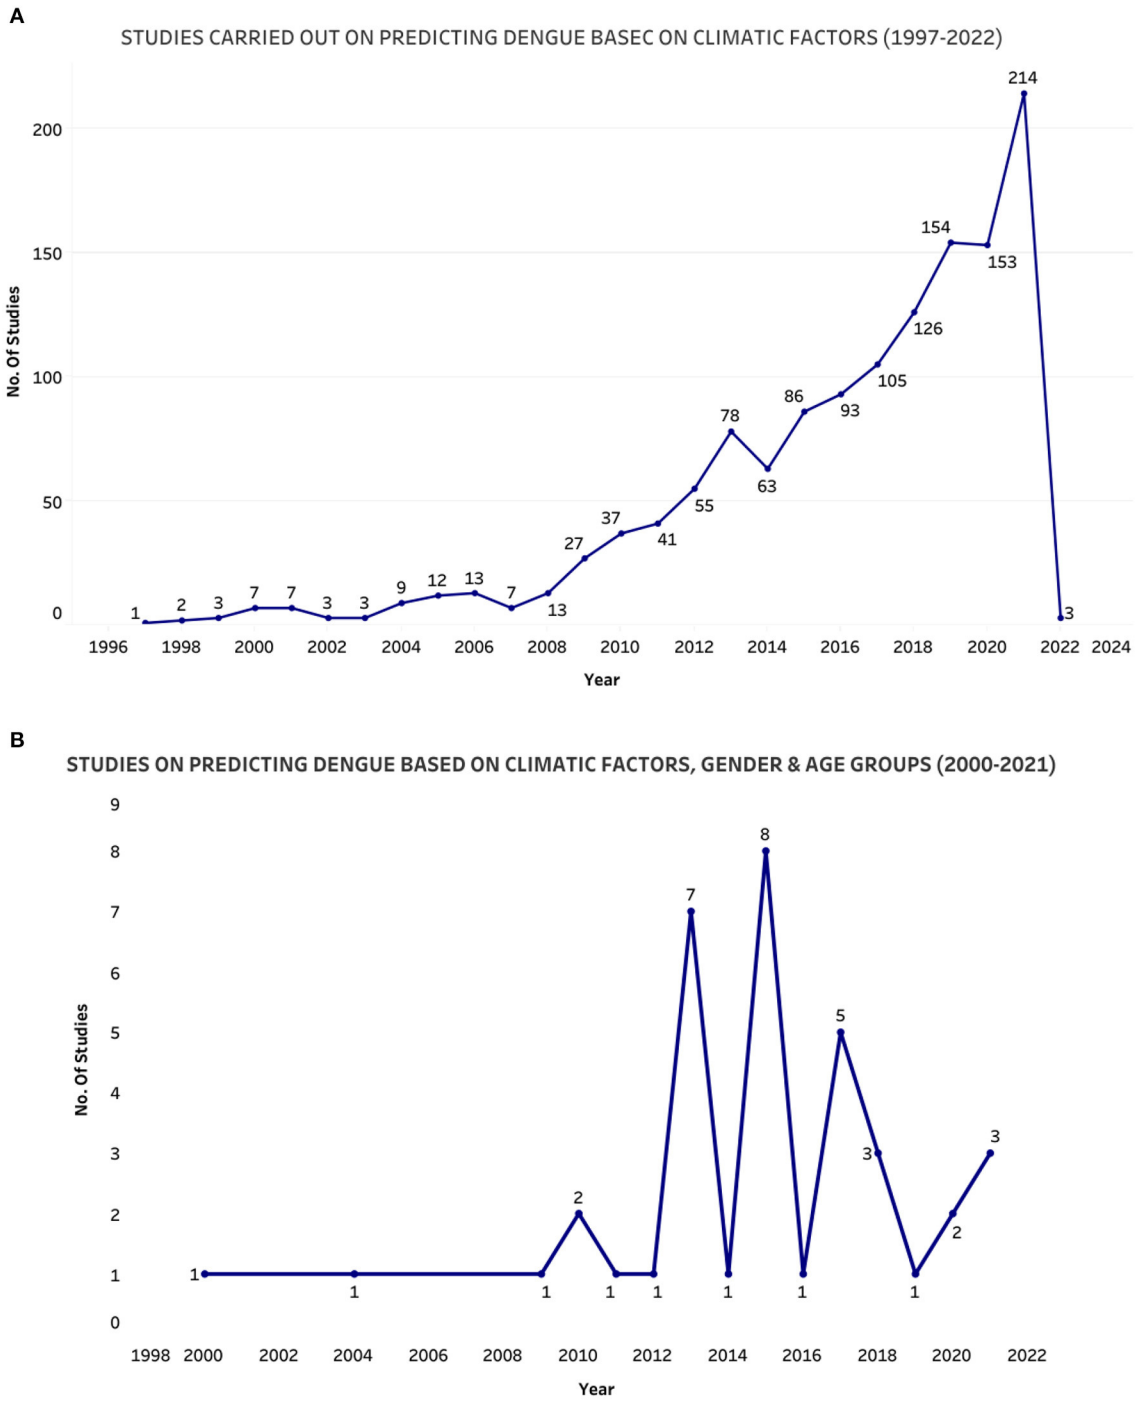

FIGURE 5 | No. of studies in different regions and time-period of scopus database: **(A)** No. of studies carried out on predicting dengue based on climatic factors for the time period 1997–2022 and **(B)** No. of studies carried out on predicting dengue based on climatic factors, age group and gender for the time-period 2000–2021.

dengue. Various explanatory variables are presently used for dengue modeling, categorized according to their characteristics and method of collection. The variables used were clinical, economic, laboratory and climatic factors. In general, climatic factors mainly were used. According to this review, vulnerable groups like age group and gender were least for dengue outbreak prediction as data about patients is not that easily available.

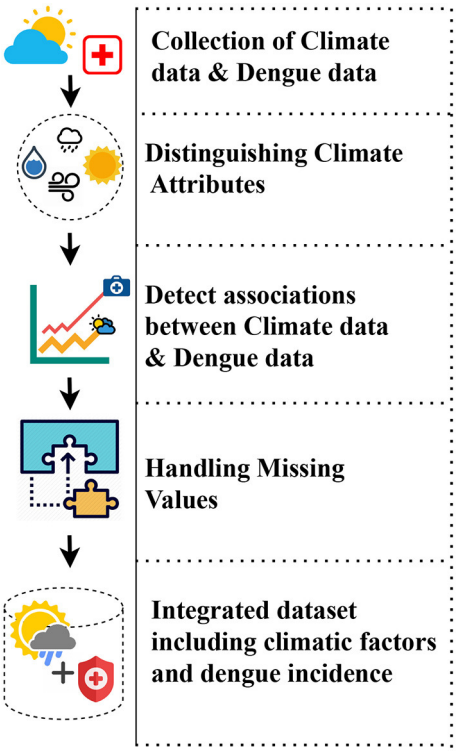

FIGURE 6 | Data pre-processing stages.

3. ANALYTICAL REVIEW OF PREDICTING DENGUE OUTBREAK

Forty articles of period 2019–2021 were reviewed and analyzed to understand the dengue prediction models and how different factors like meteorological conditions, laboratory tests, symptoms, demographic features were dependent variables for the rise of dengue cases.

3.1. Diagnosing Dengue

Identifying the dengue infection, viral antigens, viral RNA, and antibodies against the virus in the patient's blood or tissues are among the laboratory procedures used to diagnose dengue. Only 4–5 days after symptoms can the virus be discovered in the blood (25). Dengue can be diagnosed by isolating the virus, viral RNA, and viral protein during the early stages of the disease. Identifying antibodies IgM and IgG in an infected person's blood is an indirect approach to diagnosing dengue fever. This approach is widely used to identify dengue fever in its latter stages after virus levels have dropped. Doctors can discover antibodies to dengue 5 days after the onset of symptoms in most individuals, and IgG can be detected for months or even years after infection. IgM levels are very high after a primary (initial) dengue infection, but they are decreased with subsequent infection. During a subsequent infection, IgG levels increase. As a result, doctors can use IgM and IgG concentrations to determine whether a patient has a primary or secondary dengue infection (26). Therefore, in most of the data, IgG and IgM and levels are specified for easy detection and also it can aid in creating the laboratory dengue surveillance system (27).

3.2. Meteorological Data and Data Pre-processing

Meteorological data represents the weather conditions like relative humidity, precipitation, minimum temperature, maximum temperature, air pressure, wind speed and many other parameters for location and time. These are massive data collected and later utilized to record the highest and lowest climatic events for various reasons like weather forecasting to identify seasonal change and public health. There are various sources through which we can obtain data. A brief description of the explanatory variables, data source, region and period is presented in the **Table 1** used in different studies. Data Pre-processing is a crucial stage after data collection. This step enhances the model's performance, to which they will further provide the data for training and testing. Dengue incidence data collected contains information that might not be required, and there might be missing values. To handle these shortcomings, data pre-processing is a significant step. **Figure 6** shows the steps followed in information pre-processing. The major concern for reviewers is missing data and data not being available completely (28). Jorge et al. (29) developed a three-stage to take the missing values in the dataset wherein first stage parameters with more than 20 per cent of missing values were eliminated. At the next stage, they discarded cases with a non-response rate higher than 80 per cent. There are no particular rules for selecting the proper imputation of missing variables. It relies on the dataset type, non-response type, pattern of loss of response, research aims, specific population features, general study organization characteristics, or available software. Given the data entry procedure's features and the dataset's epidemiological nature, they concluded that imputing the mean of the valid neighboring data to the missing values was the best option at the third stage (30).

3.3. Climate Factors That Played a Major Role in Predicting Dengue

According to many studies, certain meteorological factors like temperature, rainfall, humidity, wind speed, air pressure and vegetation index displayed a positive correlation with the rise in dengue incidence. Hence, it helps us narrow down to a few concrete factors that can be used in further research to create dengue surveillance systems for different vulnerable groups. **Figure 7** displays the percentage and combination of climatic factors that have been used in review papers, where temperature, rainfall and humidity account for 49 per cent. Therefore, other least used elements that show some relation with dengue incidence can be used for efficient prediction.

3.3.1. Temperature

The most critical weather component affecting mosquito vector growth and dispersion and a potential predictor of dengue outbreak is temperature (31). The density of the mosquito population, biting rates, gonotrophic cycle lengths, and vector

size are all affected by temperature during the mosquito's incubation life cycle and behavior. The findings of Teerawad Sriklin et al. study.'s back with prior research suggest that severe temperatures alter the development of dengue vectors. As a result, the temperature has an impact on vectorial efficiency as well as the probability of an epidemic. Given the link between temperature and dengue cases, the predicted temperature change could worsen dengue transmission (28, 32).

3.3.2. Rainfall

Dengue transmission was found to be linked to rain and wet days. Rainfall has been identified as a role in the spread of dengue fever. Mosquitoes spend their whole life cycle in water before hatching into adult mosquitoes. Increased rainfall may create new habitat for larvae and vectors and boost adult survival (33).

3.3.3. Humidity

Despite widespread interest in the relationship among climatic conditions and positive dengue cases prevalence among researchers, research on relative humidity as a critical climatic component has been limited. Furthermore, the findings of the few study were equivocal and contradictory. They showed relative humidity as the most crucial predictor in an Indonesian investigation of dengue outbreaks in that nation, with a 3–4-month lag time. According to this study, low humidity in September and October is generally followed by a dengue

outbreak early the following year. As a result, it's highly likely that if seasonal circumstances vary as a result of climate change, seasonal dengue outbreaks will shift as well (34).

3.3.4. Geographic Factors

The influence of residential regions on mosquito incidence became more evident under certain environmental circumstances, such as lower precipitation. According to research, mosquito incidence is very susceptible to high residential sites with a more significant density of residential streets. Roads feature drainage components that collect surface water runoff and release it in appropriate areas to avoid inland floods. However, concrete structures encroaching on channels or garbage filling them can often undermine adequate drainage in residential areas. These obstructions can prevent complete water flow, resulting in water accumulation places that can provide favorable habitat for Aedes aegypti. A growing body of research suggests a link between drainage and the presence of Aedes aegypti (28).

3.4. Determining Correlation Between Climatic Factors and Dengue Positive Cases

Correlation is a statistical method for deciding the degree to which two parameters are related, using correlation coefficients. Correlation coefficients are used to determine the strength of a linear relationship between two parameters. Correlation coefficient can be used to determine if a climatic element is positively or adversely associated with the increase of dengue fever cases (35). Various correlation strategies have been utilized in various research, and they have proven to help remove the climatic factors that were not very significant. The Pearson's correlation coefficient determines the statistical relationship between two variables. It is based on the covariance method. It is widely acknowledged as the most effective approach for determining the connection between two variables of interest. It offers information on the amount and direction of the link, or correlation, between the two variables. A non-parametric test called Spearman rank correlation predicts the degree of relationship among two variables. Pearson Correlation Coefficient (36) and Spearman's Rank Correlation Test (37) have been widely used. Sourabh Bal et al. carried out their study of dengue occurrence based on climatic factors for the region Kolkata, India, using auto-correlation coefficient and partial auto-correlation coefficient values. An auto-correlation analysis is used to examine dengue cases affected by prior instances. In addition, the Pearson correlation was used to assess for collinearity between the various climate variables (38). In the study carried out by Daniel Sánchez-Hernández et al. carried out correlation analysis to inspect they built the relationships of proximity, environmental, social factors and location about the occurrence of dengue, a multivariable logistic regression model. A logistic curve may be produced by graphing the connection between the explanatory and predicted variables, which will help us evaluate the correlation strength (39). Various correlation techniques have been according to the review Pearson, and spearman's correlation test were widely used and effective in most of the studies.

3.5. Dengue Prediction Modeling Techniques

Various models can predict dengue incidence based on climatic variables (40). Several studies carried out have used different models are described along with the results. **Figure 8** depicts the steps and techniques that will required and are essential to develop an early monitoring dengue surveillance system.

3.5.1. Support Vector Regression

SVMs and Support Vector Regression are both based on similar concepts. SVR's main goal is to find the best-fitting line. The hyperplane with the greatest number of points is the best fit line in SVR. In SVR, unlike other regression models, the goal is to fit the best line inside a threshold value. The complexity of SVR's reasonable time grows more than quadratically with the number of samples, making it difficult to scale to datasets with more than a few tens of thousands of samples. Linear SVR is faster than SVR; however, it solely considers the linear kernel. As the cost function ignores samples whose prediction is close to their goal. Based on the evaluation metrics like RMSE and MAE, SVR with linear kernel proved to be quite good at forecasting the number of dengue incidents in Jakarta. Their experiments with various penalty parameters for SVR with linear kernel yielded quite accurate outcomes. When cross-correlation between variables,

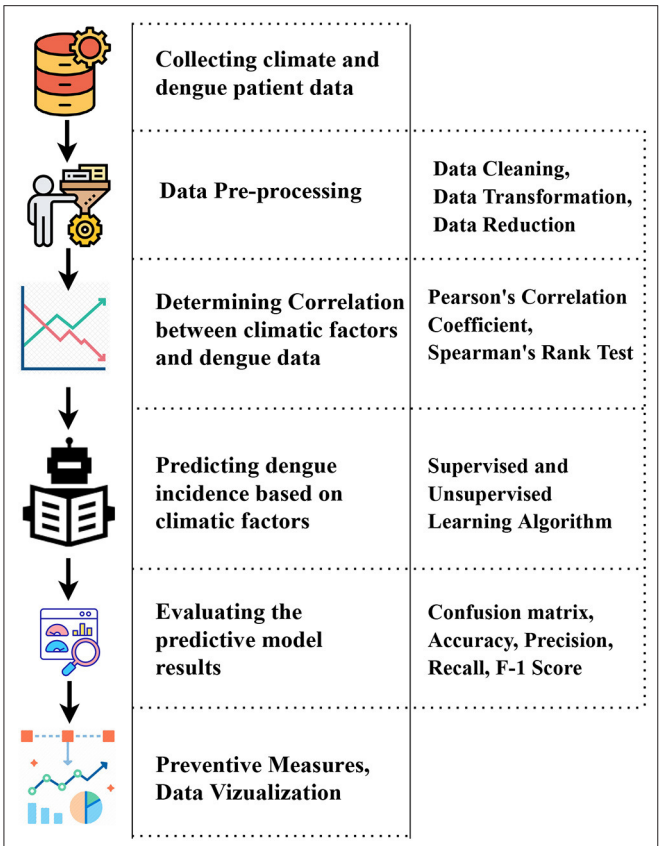

FIGURE 8 | Process of developing a dengue surveillance system.

the linear kernel has a higher prediction accuracy than the radial kernel (41).

3.5.2. Random Forest

Random Forest (42) is an ensemble technique that builds many separate bootstrapped trees from random small subsets of the data using bootstrap aggregation (bagging) (43). As it can handle large numbers of target variables even in complicated interactions, RF is utilized to tackle issues in classification and regression (44). Every tree in the random forest produces a class prediction, and the class with the most votes becomes the prediction of our model. Before training, three hyperparameters of random forest algorithms have to be established. The factors to be considered are the size of nodes, the number of trees and the number of characteristics sampled. This technique is used by Micanaldo et al. (45) in predicting dengue based on various explanatory variables.

3.5.3. Model-Based Recursive Partitioning

The combined effects of the chosen explanatory variables on OI and Dengue fever incidence, Micanaldo et al. (45) used a Model-Based (MOB) recursive partitioning. MOB is similar to CART (classification and regression tree) methods, which recursively partition datasets into subsets depending on independent variables at each step (46). The following steps are repeated iteratively by the MOB algorithm: (1) fit the data to a user-defined linear regression equation; (2) determine if other variables have an impact on model parameters.; (3) if so, using a threshold that results in the most significant changes in the linear model parameters based on the M-fluctuation test, split the model and data into two groups concerning the covariate.; and (4) In each of the subsamples, repeat steps 1–3. Until a specific stop condition is satisfied, the steps are repeated.

3.5.4. Distributed Lag Non-linear Models

Distributed Lag Non-Linear Model is modeling framework for representing links in time series data with non-linear and delayed effects flexibly. The establishment of cross basis, bi-dimensional functional space created by the combination of 2 sets of basis functions that characterize the relationships in the predictor and lag dimensions, respectively, is the cornerstone of this technique.

3.5.5. Generalized Linear Model

Generalized Linear Model is a sophisticated statistical modeling technique that enables us to construct a linear relationship between the answer and the predictors, even though their underlying relationship is not linear. This is possible because of the employment of a link function, which connects the response variable to a linear model. Here, the error distribution of the response variable does not have to be regular.

3.5.6. Generalized Additive Model

Generalized Additive Models are a sort of statistical model. Many nonlinear smooth functions replace the typical linear relationship between the response and targets to represent and capture data non-linearities. These flexible and soft approaches allow us to fit linear models that are either linearly or non-linearly dependent on many predictors to capture nonlinear correlations between response and predictors.

3.5.7. Multilayer Perceptron

A feed-forward ANN called a Multilayer Perceptron is a feed-forward artificial neural network. A hidden layer, an input layer, and an output layer are at least three levels of nodes. For a long time, ANN has been a reliable perceptive classifier for various applications, including medical diagnosis and disease early detection. MLP adapts the classic linear perceptron and employs a supervised learning technique to propagate the network. As a result, it can distinguish facts that cannot be separated. A perceptron forms a linear combination using input weights to produce a single output based on numerous real-valued inputs. They train on a collection of input-output pairs to learn how to express the correlation between inputs and outputs. The model's parameters, or weights and biases, are adjusted throughout training to minimize inaccuracy. Back-propagation is used to change the consequences and preferences about the error, which can be quantified in various ways (47).

3.5.8. K Nearest Neighbor Regression

Scavuzzo et al. (48) used the K-Neighbors Regressor module. Based on k-nearest neighbors, this technique infers a regression. Local interpolation of the training set's targets

in the neighborhood is used to forecast the target. Only the first five principal components are used to deconstruct the original data. Four neighbors, Chebyshev metric, brute force and uniform weight, were the tuning settings available. Out of all the tested models, this model gave beast results for modeling the dengue vector population.

3.5.9. Auto-Regressive Integrated Moving Average Model

Xavier et al. (15) chose the ARIMA model, a family of autoregressive moving averages, to describe the relationship among the count of positive dengue cases (dependent variable) and meteorological parameters (explanatory variables). The ARIMA model's primary goal is to directly simulate the autocorrelation in a time series to capture it. Solid underlying mathematics and statistical theory are commonly used to predict time series data, making it easier to construct expected ranges. The ARIMA model is very adaptable, capturing a wide range of patterns. Choosing order and differencing are two fundamental principles in the ARIMA model.

3.5.10. Time Series Poisson Regression Model

Sang et al. (56) to determine the relationship between meteorological conditions and local dengue count, researchers developed this model called Time Series Poisson Regression. According to this model, dengue count was positively related to dengue count in the preceding month, imported cases in the previous month, the minimum temperature during the last month, and accumulative precipitation with 3-month lags.

Table 2 illustrates the detailed representation of latest research papers which has undertaken the study to understand the relation between dengue and meteorological patterns and the need to develop a dengue surveillance system.

4. DISCUSSION

According to the number of people infected, dengue fever is the most common arboviral disease in the world. Understanding the precise relationship between meteorology and dengue transmission is not a simple process because dengue transmission involves dengue viruses, vectors, and susceptible people. Furthermore, forecasting the future of dengue under various climate change scenarios involves a complete understanding of the association between climate and dengue and future climate and other variables. Despite this, a lot of progress has been achieved in this area. Despite the advances achieved in forecasting dengue's future, numerous uncertainties remain (59). To begin with, socio-demographic factors play a significant influence in dengue transmission, and including socio-demographic components into future dengue, projections remains a challenge. Second, in previous studies estimating the future of dengue, the increasing temperature has been commonly employed as a climate change indicator, with rainfall and humidity being under-researched. According to Hales et al., the climate indicator that most correctly predicts the occurrence of dengue fever is vapor pressure, which is a temperature and humidity measurements. However, the relationships between numerous environmental conditions and dengue transmission are complex and sometimes non-linear. Dengue modeling is an essential technique for early detection of dengue outbreaks, assessing risk factors for Severe Dengue, and possibly controlling the disease's vectors. Although much research has been done on these topics, it is critical to understand what areas of dengue modeling still have to be explored to build future research that will significantly reduce disease morbidity rates. The primary goal of this study was to provide an overview of dengue modeling and identify critical issues for future research. This section focuses on the limitations of the studies that have been reviewed. Some research problems or opportunities are described based on those restrictions.

4.1. Limitations, Research Challenges and Future Work Directions

4.1.1. Inclusion of Micro Climatic Factors

Researchers have widely used temperature, humidity, and rainfall are macro climatic factors. But to bring in more explanatory variables that can explain the rise in dengue incidence rise can aid in building a better dengue surveillance system (32, 55, 60, 61).

SOLUTION: There are many climatic variables like wind speed, air pressure, vegetation index, and we can add many other microclimatic factors to the model for better dengue incidence.

4.1.2. Exploring Different Geographic Locations

Many types of research stated the limitation that how dengue outbreak prediction model developed for one region cannot be used accurately for different areas as dengue incidence may or may not be related to the same climatic factors of one place and due to weather fluctuations and pattern of coastal regions might not give excellent predictive results from the model that was developed for non-coastal regions (55, 62–64).

SOLUTION: Exploring different regions other than that have already been investigated or studying the weather patterns of the country where more minor number studies have been carried out in predicting dengue incidence based on the weather forecast can help in understanding the relationship between different patterns of weather for various regions and dengue rise and eventually would help build a dengue surveillance system.

4.1.3. Data Limitations

Obtaining a dengue dataset that is completely fit for the model and has all characteristics is difficult to find. There are many issues faced by the researchers in this area like i) data being incomplete, ii) data being not available in required time lag like weekly or monthly and for a specific time-period and iii) data that is available only on a macro level like country-level or state-level and not on micro-level like city-level (15, 28, 45, 54, 63, 65).

SOLUTION: Data cleaning can be handled by using various data pre-processing techniques based on the data type. When data is not completed available, taking the average or mean of the available information can be helpful. To obtain data at the micro-level can be a tedious task, but with all the proper procedures, the patient's data can be obtained from the Health Department of the respective region.

TABLE 2 | Detailed representations of different models and feature engineering techniques used in different studies.

References	Year	Region	Techniques	Contributions
Leandro et al. (15)	2021	Brazil	Feature Engineering: ARMAX model	ARMAX model best fits the data used in this study and produced the dengue incidence count with good precision for future.
Joseph et al. (27)	2021	Philippines	Feature Engineering: Pearson's Coefficient Predictive Model: Linear Regression, Exponential Regression	Regression modeling estimated the annual dengue force of infection across urban centers from the age of those with infections and the transmission intensity showed significant spatiotemporal variation.
Daniel et al. (39)	2019	Mexico	Feature Engineering: Multivariate Analysis Predictive Model: Multivariable Logistic Regression Model-MLRM	The connection between dengue and explanatory factors was evaluated via MLRM. A high spatial resolution map was created to highlight the most likely patterns of dengue risk.
Sourabh et al. (38)	2020	India	Feature Engineering: AutoCorrelation Coefficient, Partial Correlation Coefficient and Cross-correlation coefficient Predictive Model: Poisson Distribution Regression Model and Zero Inflated Poisson Regression Model-ZIP	Based on the numerous explanatory factors, the ZIP Model was used to predict the severity of dengue fever in Kolkata.
Oladimeji et al. (34)	2021	Brazil	Feature Engineering: Statistical Analysis Predictive Model: LSTM, RNN	This study used RNN to forecast dengue count and it also uses clustering before modeling which aggregates dengue count with similar temporal patterns.
Micanaldo et al. (45)	2021	Phillipines	Feature Engineering: Cross-correlation Analysis, Variable selection using Random Forest algorithm Predictive Model: Model-based recursive partitioning	MOB recursive partitioning displayed high correlation between dengue transmission and climatic factors and gave accurate predictions.
Sandali et al. (57)	2021	India	Feature Engineering: Data Imputation and Normalization, filling missing values with mean Predictive Model: Artificial Neural Network	A new ANN based multimodal outbreak prediction algorithm is used to predict dengue with the accuracy of 86 percent.
Ivan et al. (41)	2020	Indonesia	Feature Engineering: Cross-correlation, Augmented Dickey Fuller Test Predictive Model: Support Vector Regression	SVR with a linear kernel was applied to climate and dengue incidence data for predicting dengue count and this study also provides a comparative analysis of linear and radial kernel.
Mohd et al. (58)	2019	Malaysia	Feature Engineering: Average Nearest Neighbor (ANN) Predictive Modeling: Spatial Clustering	The hotspot locations were detected using ANN and Kernel density estimation. Based on past data, this study found that it is feasible to estimate dengue risk.
Sabrina et al. (28)	2021	Bangladesh	Feature Engineering: Statistical Analysis Predictive Model: Generalized Additive Model, Generalized Linear Model	The GLM and GAM models were used to show the link between dengue and environmental variables.
Teerawad et al. (32)	2021	Thailand	Feature Engineering: Spearman's Rank Correlation Test Predictive Model: Poisson Regression Model and ARIMA model	Spatial and Temporal modeling of dengue fever transmission was presented and Poisson regression model was used for prediction of dengue based on various climatic factors
Gayan et al. (54)	2018	Sri Lanka	Feature Engineering: Pearson Correlation Coefficient, AutoCorrelation Coefficient, Partial Correlation Coefficient Predictive Model: Time Series Regression Model	The suggested weather-based forecasting algorithm provides high-precision warnings of oncoming dengue outbreaks and epidemics up to one month ahead of time.
Felestin et al. (55)	2021	Malaysia	Feature Engineering: Pearson Correlation Coefficient Predictive Model: Bayes network (BN) models, support vector machine (SVM), RBF tree, decision table and Naive Bayes	The TempeRain factor (TRF), a novel risk factor, was discovered and employed as an input parameter for a dengue epidemic prediction model. The Bayes network produced reliable findings.
Rachel et al. (33)	2021	Brazil	Feature Engineering: Pearson Correlation Test Predictive Model: Spatiotemporal Bayesian Hierarchical Model, Distributed Lag Non-Liner Model	Space-varying, non-linear, and delayed connections between hydrometeorological parameters and dengue incidence are described using coupled spatiotemporal Bayesian hierarchical models with distributed lag non-linear models.
Wu et al. (53)	2021	China	Feature Engineering: Spearman's Correlation Coefficient Predictive Model: Ecological Niche Models(ENM)	ENMs determined the non-random association between dengue count and meteorological factors. Maxnet model was used to predict dengue incidence.

4.1.4. Considering Vector Density and Mosquito Larvae Data

The main issue highlighted in most of the studies was the correlation between climatic factors and dengue incidence; whereas those are not the only factors that contribute to increased disease transmission of dengue, the main factor is the vector that carries the transmission (32, 33, 49).

SOLUTION: Considering the vector density, mosquito larvae data or land use would aid in gaining a better understanding of the main factor behind the rise in dengue cases. Considering

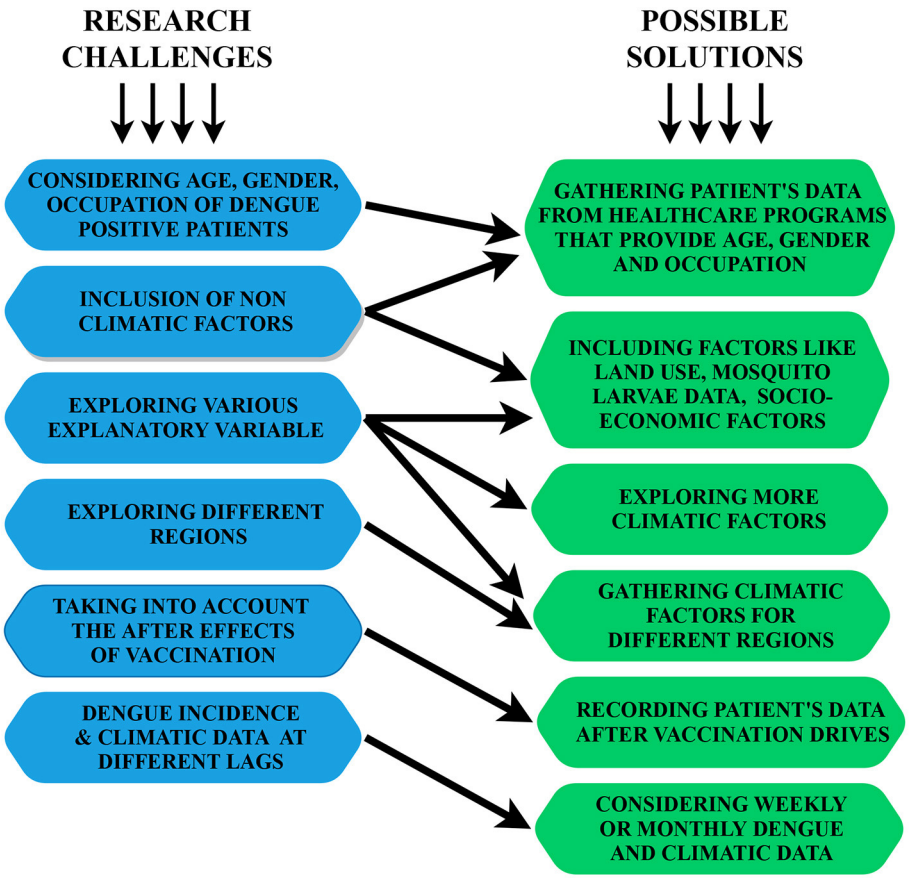

FIGURE 9 | A logical mapping of research challenges and possible solutions.

TABLE 3 | Research challenges.

Reference	Year	Research challenge	Discussion
Nuraini et al. (64)	2021	Stratifying dengue incidences based on age, gender and occupation	Classifying the population based on different vulnerable groups can help understand which crowd has been affected the most and make future predictions accordingly
Nuraini et al. (64)	2021	Different Regions	Climatic and non-climatic factors vary in different regions. Hence, it is important to understand the geographic and weather patterns to predict dengue accurately for a particular region.
Sriklin et al. (32)	2021	Stratifying dengue incidences based on age, gender and occupation	Non atmospheric data can help understand the factors contributing to dengue and help prevent dengue at an early stage.
Nuraini et al. (64)	2021	Climatic Factors	Rise in dengue incidences became correlated to the temperature and rainfall which would help make dengue outbreak predictions based on weather forecast.
Sriklin et al. (32)	2021	Dataset	Available datasets of dengue incidence were mostly yearly or monthly, hence weekly data could help make accurate predictions. And also the dengue incidences dataset were not accurate and had some missing data regarding patients.

these parameters would help predict the outbreak better and take preventive measures well in advance.

4.1.5. Taking Into Account the Effect of Vaccination After the Outbreak

The studies carried until now focus on determining the correlation between the climatic factor and dengue incidence and then using weather forecast of coming time to predict the dengue incidence and taking preventive measures. Still, the shortcoming that few researchers found is that there might be a fluctuation in predicting dengue incidence when every infected person might be vaccinated (66–68).

SOLUTION: As and when the vaccination of patients is done, the data of the patient's immune can be determined and kept a

record of. Further, that data can be used whenever the prediction for other outbreaks is being carried out. **Figure 9** represents the logical mapping of limitations and their possible solutions.

4.2. Contributions

Dengue Surveillance system can aid the health sector in taking preventive measures for dengue outbreaks in advance. Also, it can help to be prepared for the worst of situations and reduce the vulnerability of epidemics. Several research studies have predicted the epidemic using machine learning approaches, including climatic factors. The present review discusses the most common data sources, data pre-processing stages, most common correlation techniques for dengue incidence and climatic factors, machine learning techniques, limitations, and future research directions. **Table 3** represents the research challenges of the current study. The contribution of the presented student are:

- The present study gives a detailed insight into the amount of work done in predicting dengue incidence using different machine learning techniques based on various explanatory variables.
- To assist readers, we have discussed several data sources for dengue incidence count and weather variables.
- different approaches for determining the relation between dengue incidence and explanatory variables and various explanatory variables (climatic factors, demographic variables, vulnerable groups).
- Furthermore, we have discussed various dengue modeling techniques for predicting outbreaks.
- This work's main contribution is to outline open research concerns and limitations of various studies.

5. CONCLUSION AND FUTURE ENHANCEMENTS

A systematic literature review was conducted on predicting dengue based on climatic change using machine learning techniques. The main objective was to understand the research and studies that have been carried in building a dengue outbreak prediction model. Forty articles were chosen and analyzed to determine the state-of-the-art from many scientific libraries. The results of the review represent that dengue modeling is continuously growing. Logistic Regression, LASSO Regression, and Support Vector Machine approaches were the most commonly used diagnostic models. Because of their ease of implementation and interpretation, they are the most widely used modeling techniques. Although alternative strategies, such as decision trees, are simple to understand, they have a large number of nodes and take a significant amount of mental work to comprehend a specific forecast. These models, on the other hand, are just a set of coefficients, which makes it appealing to learn about the impact of attributes on the predictor variable. Furthermore, continuous independent variables do not have a normal distribution, and continuous and discrete predictors can be used in the regression. In terms of feature types, climate data was the most commonly used in these models. Dengue incidence data of patients is not readily available through APIs, which has been a restriction in many studies and should be considered for future work by forecasting dengue incidence for sensitive groups such as the age and gender of patients. The examined articles had several flaws, including the lack of documentation of the pre-processing procedures employed, the unavailability of patient data, and incomplete data. Following the review of the papers' strengths and shortcomings, future research projects were identified: i) using microclimatic parameters such as wind speed, air pressure, or vegetation index, ii) using demographic and socioeconomic aspects, iii) exploring climatic conditions in different places, iv) using vector density data, and v) taking vaccination drives into account when building a prediction model. Forecasting the future of dengue fever in the context of climate change can assist governments and public health professionals in implementing timely and preventative steps to protect people from dengue in the future. To sum up, climate change is creating an alarming situation affecting many sectors. Dengue has been a reason of concern for a long time. Hence, monitoring the fluctuations of weather patterns can aid in creating a dengue surveillance system that would be of great help to the health sector in taking preventive measures well in advance.

Natural Language Processing (NLP) is a group of theoretically inspired computer structures for analyzing and modeling clearly going on texts at one or extra degrees of linguistic evaluation to acquire human-like language processing for quite a few activities and applications. Hearing and visually impaired people are unable to see entirely or have very low vision, as well as being unable to hear completely or having a hard time hearing. It is difficult to get information since both hearing and vision, which are crucial organs for receiving information, are harmed. Hearing and visually impaired people are considered to have a substantial information deficit, as opposed to people who just have one handicap, such as blindness or deafness. Visually and hearing-impaired people who are unable to communicate with the outside world may experience emotional loneliness, which can lead to stress and, in extreme cases, serious mental illness. As a result, overcoming information handicap is a critical issue for visually and hearing-impaired people who want to live active, independent lives in society. The major objective of this study is to recognize Arabic speech in real time and convert it to Arabic text using Convolutional Neural Network-based algorithms before saving it to an SD card. The Arabic text is then translated into Arabic Braille characters, which are then used to control the Braille pattern via a Braille display with a solenoid drive. The Braille lettering triggered on the finger was deciphered by visually and hearing challenged participants who were proficient in Braille reading. The CNN, in combination with the ReLU model learning parameters, is fine-tuned for optimization, resulting in a model training accuracy of 90%. The tuned parameters model's testing results show that adding the ReLU activation function to the CNN model improves recognition accuracy by 84 % when speaking Arabic digits.

Keywords: braille, Speech to Text, speech to Braille, speech recognition, text to braille, Arabic digit

INTRODUCTION

Louis Braille invented Braille, a worldwide method of reading and writing for visually impaired people, in 1821. The Braille cell is the system's smallest unit. Because of the prosody (intonation) of the system, visually and hearing-impaired individuals who are skilled in Finger Braille can communicate words and express a variety of emotions (1). Because there are so few people who

can read Finger Braille, visually and hearing-impaired people can only communicate through an interpreter. As a result, those who are visually and hearing impaired are severely limited in their participation. Finger Braille input techniques, including a wearable device, have been developed (2). Created a wearable input device employing accelerometers affixed on the tops of rings and invented finger Braille gloves with accelerometers integrated in the fingers (3). In addition (4), created a wristband with an eighteen-accelerometer Finger Braille input device.

Visually and hearing-impaired people must wear gloves, rings, or bracelets to input Finger Braille (5) into these devices. People who use these assistive devices (6) who are blind and deaf must not only wear the sensors, but also learn a new communication system. Children who have both hearing and vision impairments require different teaching strategies than children who only have one impairment. Although different countries define hearing and vision impairments differently, the negative effects of dual sensory impairments on access to environmental information are universally acknowledged, as is the fact that this unique disability necessitates specific teaching strategies to aid and support learning.

Because they cannot read text written on regular paper, visually impaired people use the Braille system in their writing and reading. However, Visual and hearing individuals in UAE are deprived of education and information due to a lack of basic reading materials, such as books and notes in Braille written format. As a result, we created an automatic Arabic speech to Braille translation system to address this issue by converting electronic Arabic books to Arabic Braille books.

Braille System

The Braille system (7) is a reading and writing system used worldwide by visually impaired people. Passing fingers across Braille characters or Braille cells is how it's read. In a Braille cell, six dots are arranged in a rectangle grid of two dots horizontally in a row and three dots vertically in a column, yielding four different patterns. Each dot arrangement is known as a cell (1), and each cell will have at least one elevated dot and a maximum of six.

Each of the twenty-five rows of text on a standard Braille printed page has forty cells. The size of a standard Braille page is about 11 inches by 11 inches. A Braille cell's size is also specified, though it varies greatly depending on the country. The dimensions of a Braille cell as printed on an embosser are shown in **Figure 1**.

The inventor of the Braille system anticipated the need to convey information in a compact format so that a group of cells could convey a lot more information in the string of letters that make up the cells. The cell's six dots (7) can be combined to make 63 different dot patterns. Despite the fact that there are a total of 64 patterns, the final one is a cell with no dots, which serves as a gap. When viewed through the lens of text representation in a computer, a Braille cell is thus analogous to a 6-bit character code. Almost all information can now be created electronically, and computer use in daily activities (typing and printing) has increased significantly. As a result, more specialized technologies that are accessible to visually impaired individuals are critical, allowing them to use computers for everyday transactions and contribute as much to society and the evolution of IT as others.

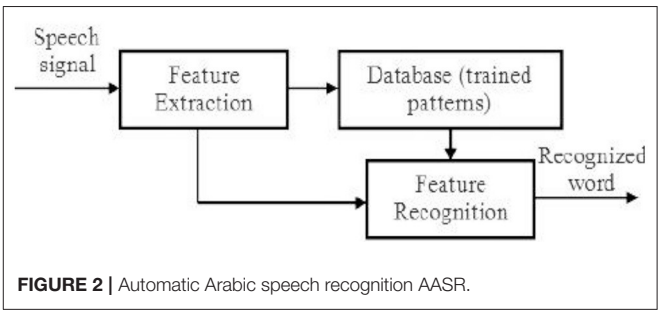

FIGURE 2 | Automatic Arabic speech recognition AASR.

Automatic Arabic Speech Recognition—AASR

Automatic Arabic Speech Recognition (AASR) (8) is a system that converts human speech into text. It's a difficult task because human speech signals are highly unpredictable due to a variety of speaker characteristics, speaking styles, and imprecise background noises (9). Variable-length voice signals must also be translated into variable-length word or label sequences by AASR. An AASR system is made up of many components, as shown in **Figure 2**. A microphone captures the speech signal first and foremost, which is then saved in digital format (10). The voice signal is non-stationary and fluctuates a great deal. As a result, the signal is divided into small chunks known as frames, with each frame's signal becoming more stationary and its features represented by a fixed length feature vector (11, 12). The procedure is referred to as feature extraction (13, 14), and the component that performs it is referred to as the front end. The front end's output is the observation sequence X, with each observation being a feature vector representing a single frame.

The acoustic model's goal is to simulate the acoustic characteristics of various speech units, as well as the relationship between the acoustic aspects of the entire voice utterance and the utterance label sequence or text. For spoken acoustic signals, the hidden Markov model (HMM) (15) is a popular and successful model. The HMM is very versatile when it comes to modeling variable length sequences, and it tolerates changes in speaking speeds.

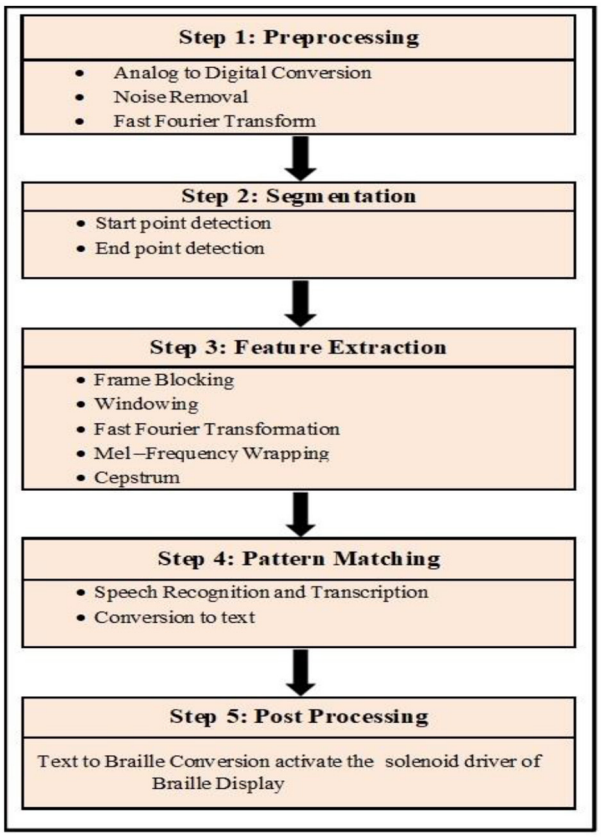

FIGURE 3 | Flow of Proposed Methodology.

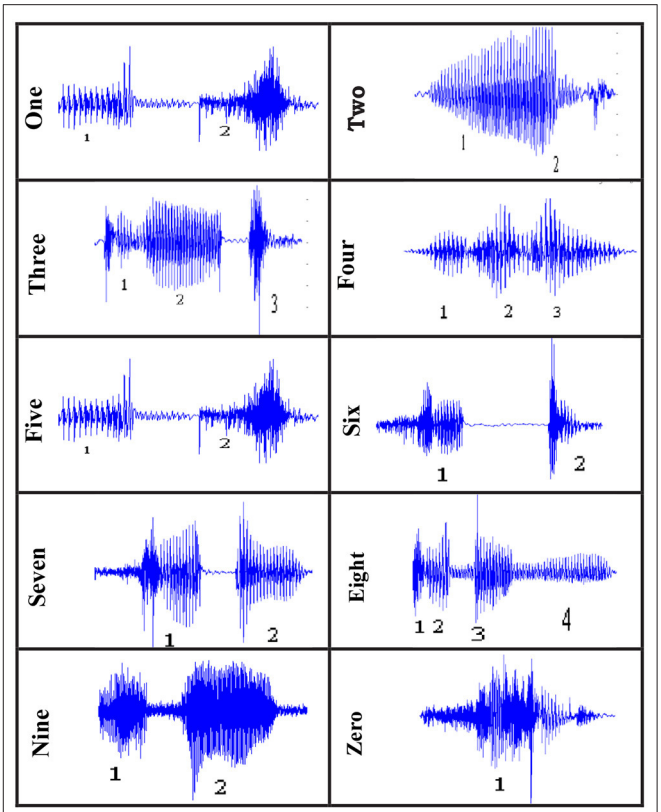

FIGURE 4 | Wave of Arabic Digit.

It models the likelihood of getting the speech observation sequence given a set of latent (hidden) discrete states. A decoder is used to recognize speech based on the acoustic and language models to model the relationship between an HMM state and the speech observations that pertain to this state. The decoder component searches for the best label sequence for a given voice utterance that maximizes the scores computed by the acoustic (16) and linguistic models. Because the number of viable label sequences grows exponentially with the length of the input feature sequence, the efficiency and speed of the decoder are critical elements of a successful ASR system (17).

Feature Extraction on ASR

The initial stage in speech recognition is the extraction (13, 14) of a sequence of feature vectors X that reflects the input voice signal. Feature vectors (18) are available in a wide range of sizes and shapes. In an acoustic model-based system, a good feature vector should include all relevant information for classification of the input signal (19). It's also a good idea to get rid of any data that isn't absolutely necessary. Mel frequency spectral coefficients (MFSC) and Mel-frequency cepstral coefficients (MFCC) are two feature vectors commonly used in academic and commercial ASR systems (20).

The first step is to take short overlapping windows of the speech signal, making it quasi-stationary and incorporating properties unique to single speech units. A Hamming window (or similar bell-shaped functions) is multiplied by this speech window to reduce the effect of discontinuity at the window's two edges. Because distinct speech units and sounds differ primarily in the distribution of energy along different frequencies, it is common practice to convert the speech time domain data into a frequency domain signal using Fast Fourier Transform (FFT) analysis (21). Filter bank analysis is then used to measure the energy in a small number of frequency ranges. These filters are dispersed along the Mel scale frequency to imitate human ear's sensitivity to frequency variances (22). Mel frequency filter bank analysis employs triangular filters. The energy in each filter is estimated to estimate the MFSC feature.

In practice, the log is used to calculate log-MFSC characteristics, which are closer to the sensitivity of the human ear and allow for better discrimination. In fact, neural network models, particularly convolutional neural networks, benefit from the log-MFSC feature. The log-MFSC features are closely correlated because the spectral envelop changes smoothly with frequency and neighboring filters overlap. The discrete cosine transform is used to minimize correlation in order to generate MFCC features (23). When using Gaussian Mixture Models (GMMs), this is especially important when using a diagonal covariance matrix.

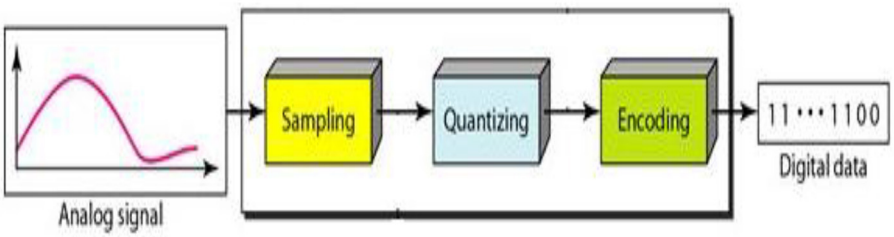

FIGURE 7 | Speech signal Capture.

HMM Based ASR System

An HMM can be used in a variety of ways to recognize speech. Isolated speech recognition is the most basic type, in which the system's goal is to classify individual words. In this scenario, each word is modeled using a different HMM model. The number of distinct acoustic portions of the word corresponds to the number of states in each HMM model. To classify the segment, the term associated with the model with the highest likelihood is used. The likelihood is calculated either exactly using the forward probability or roughly using the Viterbi algorithm's likelihood of the optimum state sequence in this scenario.

Speech recognition that is connected (continuous) is a more advanced technology that allows the speaker to continuously utter a large number of words. In this scenario, different word models are combined to create a large composite HMM. The types of transitions that are allowed between words are defined by a grammar. Furthermore, a language model is frequently used to assign different weights to different word transitions. Speech recognition is accomplished by determining the most likely state sequence and mapping that sequence into a word sequence that represents the uttered sentence. The disadvantage of this model is that learning a good model for each word necessitates a large

amount of training data. Furthermore, the model is incapable of recognizing terms not found in the training data.

To overcome these difficulties, models that represent sub-word units such as phonemes can be used. In these models, each phoneme is represented by a three-state sequence that includes the phoneme's transitional beginning and end, as well as the middle stationary state. To represent a word, a series of phoneme models are combined to form a word model. A dictionary is used to specify the phoneme models that represent a word. This method has the advantage of sharing each phoneme's training data across multiple words, reducing the amount of data needed for training. It can also recognize unseen words if they have equivalent entries in the dictionary.

Neural Network (NN) Based ASR

As a result of improved performance on a variety of speech recognition tasks, deep neural network models (DNNs) have recently resurfaced (26). Previous attempts to use NNs in acoustic modeling attempted to use the NN as a separate model for detecting simple speech units. To replicate the Viterbi algorithm's work in Lippmann (27), devised a recurrent neural architecture dubbed Viterbi net. As a result, it can recognize speech almost instantly. However, it lacked a training algorithm. The weights of the Recurrent Neural Network (RNN) were calculated using a trained HMM model. As a neural network architecture, the Time Delay Neural Network (TDNN) was proposed in Waibel et al. (28). The TDNN combines longer input contexts by using a series of consecutive input frames and hidden activations in the top layers. The model was used to classify a small number of phonemes. To successfully use NNs for ASR, a hybrid NN-HMM model was used. In one version of the model that has recently gained popularity, the NN replaces the GMM in scoring speech frames, while the HMM is used to model the speech signal's sequential temporal behavior.

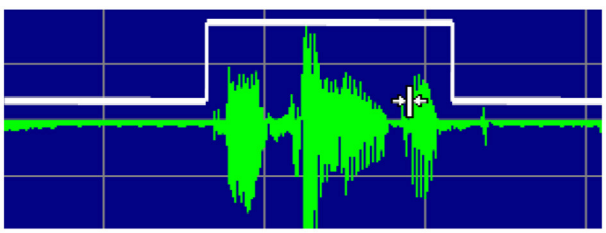

FIGURE 8 | Endpoint Identification.

RESEARCH METHODOLOGY

The Arabic language is the world's largest and most experienced Semitic language (26), and it differs from other European dialects such as English in several ways. Arabic is the Arab world's official language. Arabic is the world's sixth most communicated language, based on the number of people who speak it as their first language. Furthermore, ∼250 million people speak Arabic as their first language. Arabic sentences are written from right to left, and some letters may change shape depending on their position within a word (29).

Speech to-Braille STB (30) is a branch of computer science that focuses on developing computer frameworks that can recognize expressed words from an amplifier and convert them to messages. Speech to Text is the process of converting or deciphering an audible signal obtained by a receiver or a phone into a string

TABLE 1 | Performance Table.

of words. Extraction of highlights from a gathered signal and matching them to a voice test in an information base is used to perceive a word (31, 32).

The goal of the procedure is to create a Digit speech recognition refers to the recognition of utterances in which the user can speak normally without pausing between words, which is similar to how humans speak. Subword sounds, such as phonemes (alphabets in Indian languages) (29), are commonly used as the basic unit of recognition in continuous speech recognition systems. The sequence of phonetic models forms the larger linguistic unit, such as words/sentences, during recognition. Because the number of sub-word units is limited, collecting enough data to train each of these basic sounds in a variety of acoustic environments is not difficult. Adding a new word is simple because all that is required is a description of the new word in terms of previously learned speech sounds. Among the features are speech analysis, training tools, recognition tools, outcome analysis, and labeling tools. It can recognize both single and related words. It is capable of modeling both full words and sub-word units.

The system's post-processing involves retrieving the exact data associated with the recognized speech. As shown in **Figure 3**, the fetched Arabic data corresponding to the Arabic Corpus dataset is converted into Arabic Braille script and delivered to the user in the form of Braille Display.

CONVOLUTIONAL NEURAL NETWORKS FOR ASR

Speech signals can take many different forms that have little to do with the speech's grammatical content. For example, different speakers may have different voice qualities. There can be a lot of differences between speakers, even if they are the same person. Variations in speaking speed, pitch, and formant frequencies due to changes in vocal tract length, as well as background noise, are examples.

A variety of strategies have been proposed to deal with these differences. In this case, there are two approaches: passive and active. The goal of passive strategies is to standardize speech variances. This can be accomplished by employing special features such as MFCCs, which filter out information that is unrelated to the speech's linguistic content. The HMM normalizes rate variations because it is tolerant of variations in speaking pace.

Active approaches aim to estimate some parameters that transform the speech signal or to fine-tune the trained speech models to perform better in new situations. Some speaker adaptation strategies, for example, change the HMM model parameters to reflect the new speaker's characteristics. Other speaker adaptation strategies convert a new speaker's speech signal into a canonical speaker that the acoustic model can learn from. The new model or transformation parameters are calculated from some speech adaption data collected from the new speaker in both situations before performing speech recognition on this speaker.

The Convolutional Neural Network (33) (CNN) is a type of artificial neural network that processes data in the form of patterns. CNN is an effective method for building deep learning models that have been used in object recognition applications. CNN (34) was proposed as a method of reducing the amount of data required for traditional artificial neural networks. Three layers make up a traditional Convolutional Neural Network: convolution, pooling, and fully connected layers (35). The pooling layer is used to reduce the number of values in feature maps, while the convolution layer is used to extract features. The best feature maps are passed into the classifier using a fully linked layer (35, 36). CNN is scalable in general and the training procedure takes less time.

The main advantage of the CNN is that domain knowledge can be used to create the CNN structure in order to manage

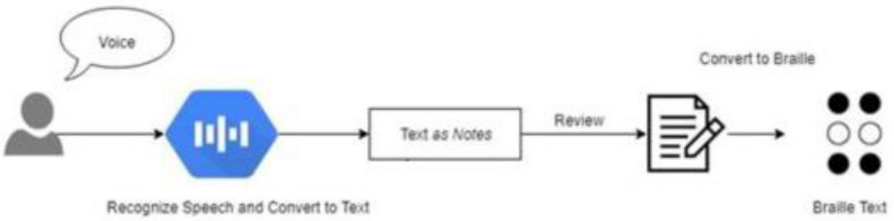

FIGURE 11 | Spoken Arabic Digit to Braille.

application-specific variances. In these applications, CNNs are used to take advantage of translation invariance and to tolerate small changes in visual patterns in multiple directions. Weight sharing, local connectedness, and pooling are some of the network topologies used by CNNs, as opposed to standard NNs. As a result, minor image deformations and noise, as well as small rotations and scaling, are less noticeable to the CNN. These invariances are difficult to learn automatically in typical NNs. In a similar way, CNN ideas have recently been applied to voice processing.

Unsupervised learning of acoustic features was achieved using the CNN structure (37). Convolution over time is used in these studies to manage small temporal shifts for better speaker, gender, and phonetic classification representations, but not for audio recognition.

The CNN structure allows us to acquire frequency invariant features when applied along the frequency axis (38, 39). A CNN can also accommodate temporal changes and thus better handle speaking speed variances when applied along the time axis (40). However, the HMM can handle these variances inside the hybrid NN-HMM model, reducing the benefit of applying convolution and pooling over time.

Description of Arabic Digits

Due to background noise interference, speech is harmed in voice applications. As a result, we can't tell whether a signal contains valid data just by looking at it (41). Many efforts have been made in speaker system independent, automatic Arabic speech recognition for an isolated digit or continuous digit speech for many languages. There is still a scarcity of research on speech recognition in the Arabic language. All speech recognition applications, including those described here, are, however, available in English. Despite the fact that our study focused on Arabic speech recognition in digit contexts (**Figure 4**).

Feature Extraction and Classification Using CNN

The feature extraction technique for audio data is depicted in **Figure 5** (42–46). It shows the spectrum of audio data before and after feature extraction using the Python'sklearn' module. The data was split 80:20, with 80% going into the training dataset and 20% into the test dataset, with 20% of the training dataset being used as a validation set for this Speech recognition processing (47). The model processes the training, test, and validation datasets, which will be used in the trained model's test dataset prediction analysis.

- In the convolution layers, we created two separate models, each with its own set of parameters.
- In both models, the first 2D-convolutional layer (conv2D) was used to analyze train data, and it has a 128-bit resolution (Model-1).
- A RELU activation function with a filter size of 64 (model-2).
- The output of the first Conv2D layer was sent to the first batch normalization layer.
- For each model, this procedure is repeated twice using the second and third conv2D.
- The first model employs 48 filters with a normalization pool size of (3, 3), whereas the second employs 32 filters with the remaining two parameters unchanged.

After the feature learning stage, the classification technique starts by flattening the resulting vector into a one-dimensional vector. The data was flattened because categorization is easier with a one-dimensional vector. The 1D vector of the flatten layer is then passed through a series of layers.

Finally, the output vector is sent to a 20-unit dense layer, which corresponds to the number of key words in the Arabic dataset. After that, the final result was obtained. The optimizer in this model is 'Adam,' and the loss function is 'Sparse-Categorical Cross-entropy.' **Figure 5** depicts the basic architecture of our proposed model.

TEXT TO BRAILLE

Figure 6 depicts the steps involved in converting text to braille.

- Enter Arabic Text: Entering Arabic text in the provided area or by browsing and attaching a text file (48).
- Validation and data verification of Arabic text: The primary function of this block is to validate and verify the Arabic content extracted from the speech. Validating a meaningful text and verifying the converted word in a database (Text Database) (48) is part of the validation procedure.
- Braille conversion process: The Braille Process converts each character into an equivalent Braille character. The symbols for each and every Arabic digit character can be found in the currently available database (Braille Database) (49–51).

- Arabic Braille Output: After the conversion has been replaced appropriately, the final output, as shown in **Figure 6**, can be handled through the output interface to reach the end user.

EXPERIMENTAL ANALYSIS

The Methodology of Speech recognition and Conversion to Braille system (30) has following steps.
