Step 1: The first step in this research is to gather information from a variety of Arabic speakers. Speakers must record the Arabic numerals 0 to 9 and say each Arabic number separately in a clear voice with minimal background noise, as shown in **Figure 7**. As a result, data collection was required in order to develop the speech recognition system; this data was collected by various countries around the world, each with its own dialect for pronouncing words (24, 25). Geographical areas influence how speech is delivered, but they aren't always the source of variation; for example, dialects may be influenced by family history. The voice signal is obtained by recording or capturing the entire audible frequency range of a human voice. The sampling frequency is defined as the number of samples obtained in a second.

Step 2: To define where a single utterance begins and ends, the zero-crossing rate (ZCR) and average amplitude thresholds are used. It can be classified as a speech signal segment if the energy in the frame exceeds the energy threshold. However, because unvoiced speech signals are sometimes merged or combined with ambient noises, the marking of start and stop locations may not be precise. Unvoiced speech has a higher ZCR than noise, so it can be used to distinguish between noise and a weak speech signal, allowing for better start and stop point marking, as shown in **Figure 8**.

Step 3: Using CNN to recognize speech: The classification stage is followed by a fully connected layer and a softmax layer, and the convolutional layers and pooling layers are used to learn features. Except for the fully-connected layer, all convolutional and pooling layers used the ReLU activation function. To extract features, have used the following settings: 16,000 sample rate, 512 and 160 sample FFT lengths and hop sizes, as well as the Hamming window function The first CNN layer conducts a convolutional over the input feature vector using 32 ReLU kernels with 3×3 receptive fields and a stride of 1 in both dimensions, as shown in **Table 1**.

The proposed model was tested using an Arabic speech corpus of isolated words. The used corpus is subjected to a variety of modifications, including pitch, speed, dynamic range, noise, and time shifting forward and backward. As shown in **Table 2** and **Figure 9**, the maximum accuracy achieved when using the ReLU activation function with CNN was 84%. The ReLU activation function, a non-linear activation function, has gained prominence in this proposed methodology. When comparing the results of this study to previous research, it is clear that the proposed methodology performed better in the AASR.

Step 4: Text to Braille Conversion: The result, as shown in **Figure 10**, will be processed through the Arabic Text database, which will identify the Arabic text.

Step 5: Postprocessing: The Arabic letter is embossed as Arabic Braille script on the Braille display using solenoid drive (52) as shown in **Figure 11**. The evaluation is based on how it is handled and prioritized including some other performance parameters. The primary reason for employing the device would be decided by determining if the device's benefit outweighs the negative encountered. Following the prototype's implementation, it is evaluated with a small group of visually challenged people, as well as people who are both visually and hearing impaired.

CONCLUSIONS

Braille is a text-based communication system that is solely dependent on touch. People with vision and hearing impairments would use it. We propose a Speech to Braille conversion procedure to provide the visually and hearing-impaired people can easily make notes in Braille using the provided methods (53) by simply speaking or playing a tape. This app will help people with both visual and hearing impairments communicate in real time, and it will be a cost-effective way. This research produces output that is comparable to traditional high-cost braille printers, as well as assisting visually and hearing-impaired people in recognizing the Speech and converting into Braille output. Speech recognition is a bonus feature that allows visually and hearing-impaired people to print braille for personal use without a computer or a mediator by simply speaking the phrases to be printed into a microphone.

Arabic digits six are particularly difficult to recognize when spoken. The complexity of the voiced signals of the spoken digits is the reason. Deep learning requires a large amount of data to achieve better accuracy, the accuracy of CNN model could be greatly improved by using a large amount of training data. More digit voice samples with noise, for example, could give us a more robust classifier. It's worth noting that as the amount of training data grows, so does the amount of time spent training.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author/s.

AUTHOR CONTRIBUTIONS

AD and SB: conceptualization, investigation, and methodology. SB and RA: funding acquisition and resources. AM: project administration and visualization. AD: writing of the original draft. AM and SB: writing of the review and editing. SB: validation. RA: data curation. All authors contributed to the article and approved the submitted version.

FUNDING

This work was supported through the Annual Funding track by the Deanship of Scientific Research, Vice Presidency for Graduate Studies and Scientific Research, King Faisal University, Saudi Arabia (Project No. AN000602).

Age estimation in dental radiographs Orthopantomography (OPG) is a medical imaging technique that physicians and pathologists utilize for disease identification and legal matters. For example, for estimating post-mortem interval, detecting child abuse, drug trafficking, and identifying an unknown body. Recent development in automated image processing models improved the age estimation's limited precision to an approximate range of +/- 1 year. While this estimation is often accepted as accurate measurement, age estimation should be as precise as possible in most serious matters, such as homicide. Current age estimation techniques are highly dependent on manual and time-consuming image processing. Age estimation is often a time-sensitive matter in which the image processing time is vital. Recent development in Machine learning-based data processing methods has decreased the imaging time processing; however, the accuracy of these techniques remains to be further improved. We proposed an ensemble method of image classifiers to enhance the accuracy of age estimation using OPGs from 1 year to a couple of months (1-3-6). This hybrid model is based on convolutional neural networks (CNN) and K nearest neighbors (KNN). The hybrid (HCNN-KNN) model was used to investigate 1,922 panoramic dental radiographs of patients aged 15 to 23. These OPGs were obtained from the various teaching institutes and private dental clinics in Malaysia. To minimize the chance of overfitting in our model, we used the principal component analysis (PCA) algorithm and eliminated the features with high correlation. To further enhance the performance of our hybrid model, we performed systematic image pre-processing. We applied a series of classifications to train our model. We have successfully demonstrated that combining these innovative approaches has improved the classification and segmentation and thus the age-estimation outcome of the model. Our findings suggest that our innovative model, for the first time, to the best of our knowledge, successfully estimated the age in classified studies of 1 year old, 6 months, 3 months and 1-month-old cases with accuracies of 99.98, 99.96, 99.87, and 98.78 respectively.

INTRODUCTION

Age estimation in living and deceased individuals has always been important in pediatric studies, pathological complications, and forensic medicine (1, 2). Human bone age can be estimated from foot, shoulder, ankle, hip, elbow, cervix, ankle, and teeth bones (3–5). The accuracy of the calculated age from a bone specimen depends on genetic and environmental factors such as age, race, smoking, lifestyle, famine and natural disasters (6). While current age estimation methods, for example, Greulich-Pyle or Tanner–Whitehouse method, can accurately estimate age from radiological examination of the left hand in children, age assassination complexities significantly increase when comparing young adults to adolescents. The absence of formal age documentation makes the process even more complicated despite recent discoveries in anthropometric fields demonstrating the importance of other bones, such as the pelvis, in determining bone age (3, 4). OPG or dental radiographs remained to be the primary forensic concern (7).

Orthopantomography, also known as an OPG or dental radiographs, provides a wide panoramic view of the lower face bones (8). OPG displays all the teeth on both jaws. OPG also depicts the jawbone and the temporomandibular joint (TMJ) on the same radiography film. The dental OPG images have been suggested to be more effective when compared to other bones of the body X-ray images. Teeth bones are long-lasting and resistant to high temperatures (2) and organisms which decompose a dead body (9). The Malaysian Institute of Forensic Medicine claimed that the X-ray images of teeth are the primary and the most used method in estimating age (10, 11). However, the traditional image processing approach for OPG age estimation is still relatively expensive, laborious and requires long-term monitoring, increasing potential radiation exposure (12).

Traditional image processing for dental age measurement is a manual method that may include several steps such as segmentation, feature extraction, image pre-processing, classification, or regression. Each of these steps is error-prone and can induce variations in the outcome. For example, in an identical age range, the dry bone image will be different from the wet bone in radiography scan. In recent years, Machine Learning/Deep Learning techniques have been widely used to identify patterns in complex data such as clinical imaging, genomics, bioimaging, and phenotypic data (13–17). Machine learning algorithms for example, NN, SVM, KNN, Decision Tree, displayed promising ability in prediction and classification (18–28) including estimation of bone age (29, 30). The medical and biological datasets are increasing rapidly. To analyse such big and complex data, artificial intelligence and machine learning algorithms become most popular (31–41). Therefore, it is important to implement novel techniques to uncover the medical and biological patterns. In particular machine learning and deep learning techniques have been widely used to analyse imaging data (23, 37, 42).

Deep learning-based methods, also known as end-to-end learning-based methods, such as convolutional neural networks, are either unsupervised that operate directly on the input images and generate the desired output without intermediate steps such as segmentation and extraction or supervised. Supervised learning (SL) models utilize a learning function that requires example input-output pairs for the model validation. The supervised approach runs the comparison between a radiographic image of each subject to an existing reference (i.e., labeled images), including gender and age information (43). Nevertheless, most of these methods require a large amount of labeled data.

Collecting and labeling large datasets are usually expensive, time-consuming, or sometimes impossible. Thus, in recent years, Semi-Supervised Learning (SSL) has emerged. Leveraging both labeled and unlabelled data, SSL has been proved to be a practical approach. Transfer learning (TL), an SSL-based model) aiming to utilize training knowledge gained from one data set to analyse another using a few-shot classification framework (44, 45). Moreover, unprocessed image databases, which usually can be fed to conventional ML or DL models, are prone to inaccurate class recognition. Extracting specific characteristics that accurately represent behavior in different environmental conditions is also a time-consuming task. (11, 46). Hence, choosing a classifier that can differentiate behaviors in terms of diversity within and outside each class is one of the challenges in recognizing behavior. Therefore, converting raw data into attribute vectors systematically and using effective attribute extractors using an engineering approach is required for proper classification (47–49).

Despite these improvements developing and training deep neural networks remained challenging and time-consuming. Thus, Transfer learning (TL) can use the pre-trained deep network to perform data classification, attracting increasing attention (50, 51) this article proposed an innovative automated machine learning model approach to estimate bone age. This approach is based on a deep convolutional neural network (52). We improved the accuracy of age determination in dental panoramic images with approximately 6-month intervals. The proposed method determines the precise age in the range of 15 to 23 years old that is divided into nine age groups. Each age group includes subcategories of images with 1 year, six, three and 1-month(s) intervals. This method combined the methodology of features extraction of the convolutional neural networks with the nearest neighbor feature to analyse and classify information and features in dental images.

More specifically, the architecture of the proposed HCNN-KNN model used in this study consists of four steps (**Figure 1**). Initially, a convolutional neural network (CNN) model was trained on OPG images. Then, a fully connected layer generated from CNN was fed into a principal component analysis (PCA). The PCA performed data transformation and dimension reduction. In the last step, data were classified using the KNN algorithm. The details of the prediction process of the classes in the data set were explained in the following sections.

Related Literature

Age estimation based on dental X-ray images remained a critical field to develop. Tooth bones are immortal and can last more than 20 years through post-mortem decomposition. This made the tooth an essential part of the forensic investigation

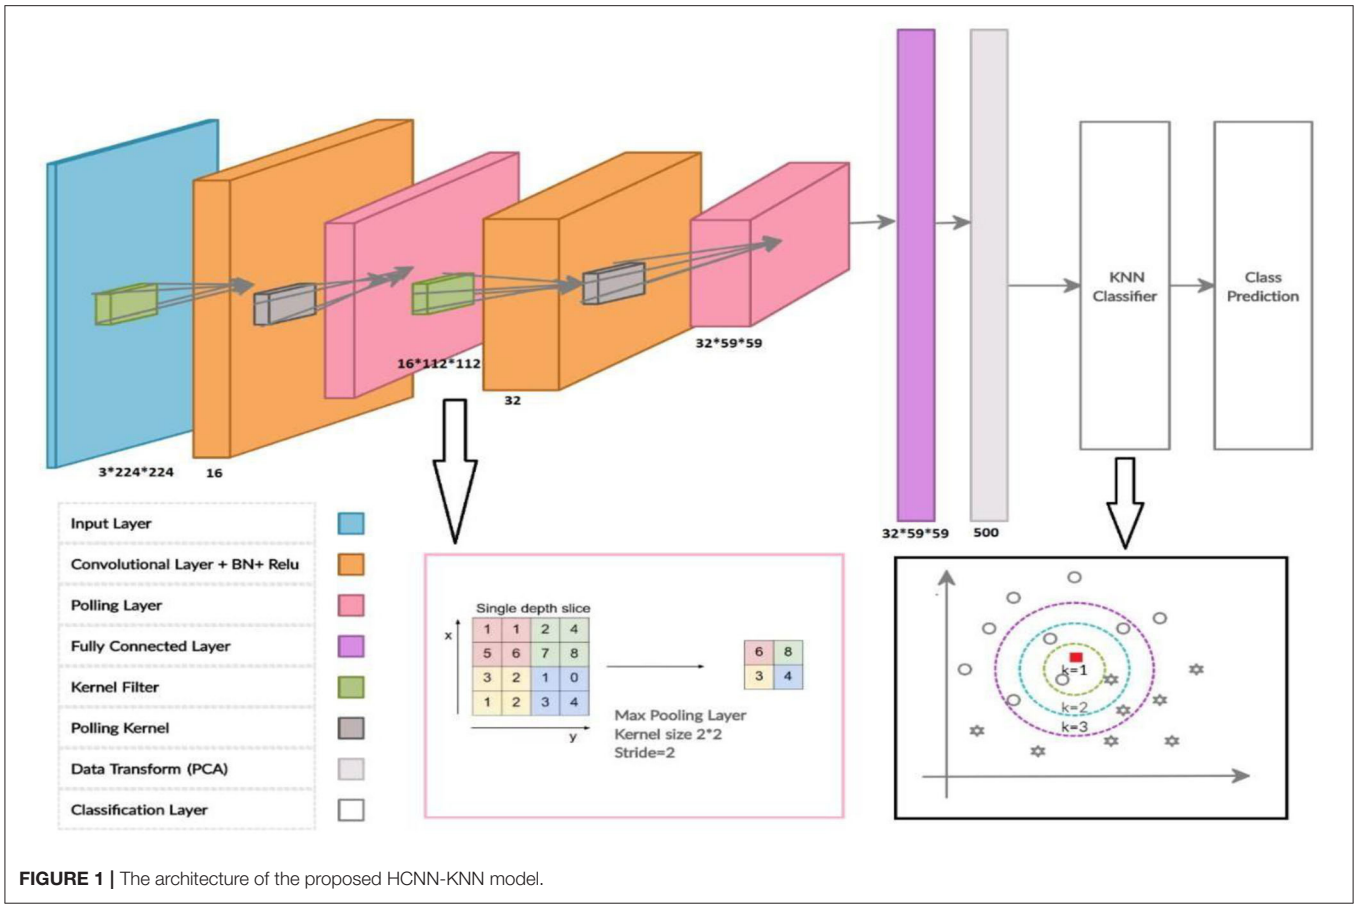

FIGURE 1 | The architecture of the proposed HCNN-KNN model.

(53). Although the number of bone age estimation models has increased, most remain in the research state with slow or no transition in the industry. Computerized methods for bone age estimation based on OPG images are currently limited to ± 6 months precision (52). Moreover, current Deep neural network algorithms used to estimate the age using dental X-ray images are, for example, AlexNet and ResNet. Training these algorithms requires large imaging datasets. For instance, Houssein et al. used a dataset with 1,429 dental X-ray images to reach acceptable output parameters (11).

In another study, Avuçlu et al. (54) used 1,315 dental images and 162 different dental classes to morphologically predict the age and gender in dental X-ray images with 95% accuracy (54, 55). Farhadian et al. (30) applied Transfer learning to reduce using a neural network that relied on dental data to alter age assessment. The age group of between 14 and 60 was used, and the overall data sample size for the research was 300 images. With an MAE of 4.12 years, the neural network methodology showed a reasonably accurate outcome (30). The neural network errors were smaller than the regression model's estimation errors, with the test data set being RMSE of 10.26 years and MAE of 8.17 years.

Alkaabi et al. (8) examined different Convolutional Neural Networks s AlexNet, VGGNet, and ResNet. Architectures for age estimation. They used common CNN architectures to perform forensic dentistry's automatic age calculation without any modifications. Using Capsule-Net, predicting age estimation from dental images was also performed, which depicted 36% higher accuracy than the CNNs model. The Capsule-Net model based on transfer learning reached a cumulative accuracy of 76% for ± 1-Year-old sample OPG images.

Tao et al. (29) has introduced the Multilayer Perceptron Neural network to estimate dental age. The experiments are carried out on a dataset composed of 1,636 samples. It was also experimentally confirmed that this latest feature set makes the dental age estimation more reliable for sample OPG images of ± 1-Year-old individuals' sample OPG images.

Kim et al. (56) applied a deep learning algorithm, based on CNN neural, to X-ray images of 9,435 cases (4,963 male, 4,472 female). Data in this cohort was sorted into three-age gatherings. Their study suggests that deep learning algorithms based on CNN neural networks show that the proposed approach functions evaluated based on a database of panoramic dental radiographs and worked well for accuracy.

Banar et al. (57) also implemented a fully automatic method leveraging the total capacity of the deep learning approach on their study of a dataset of 400 OPGs x-ray images with 20 OPGs per category and per gender. To overcome the

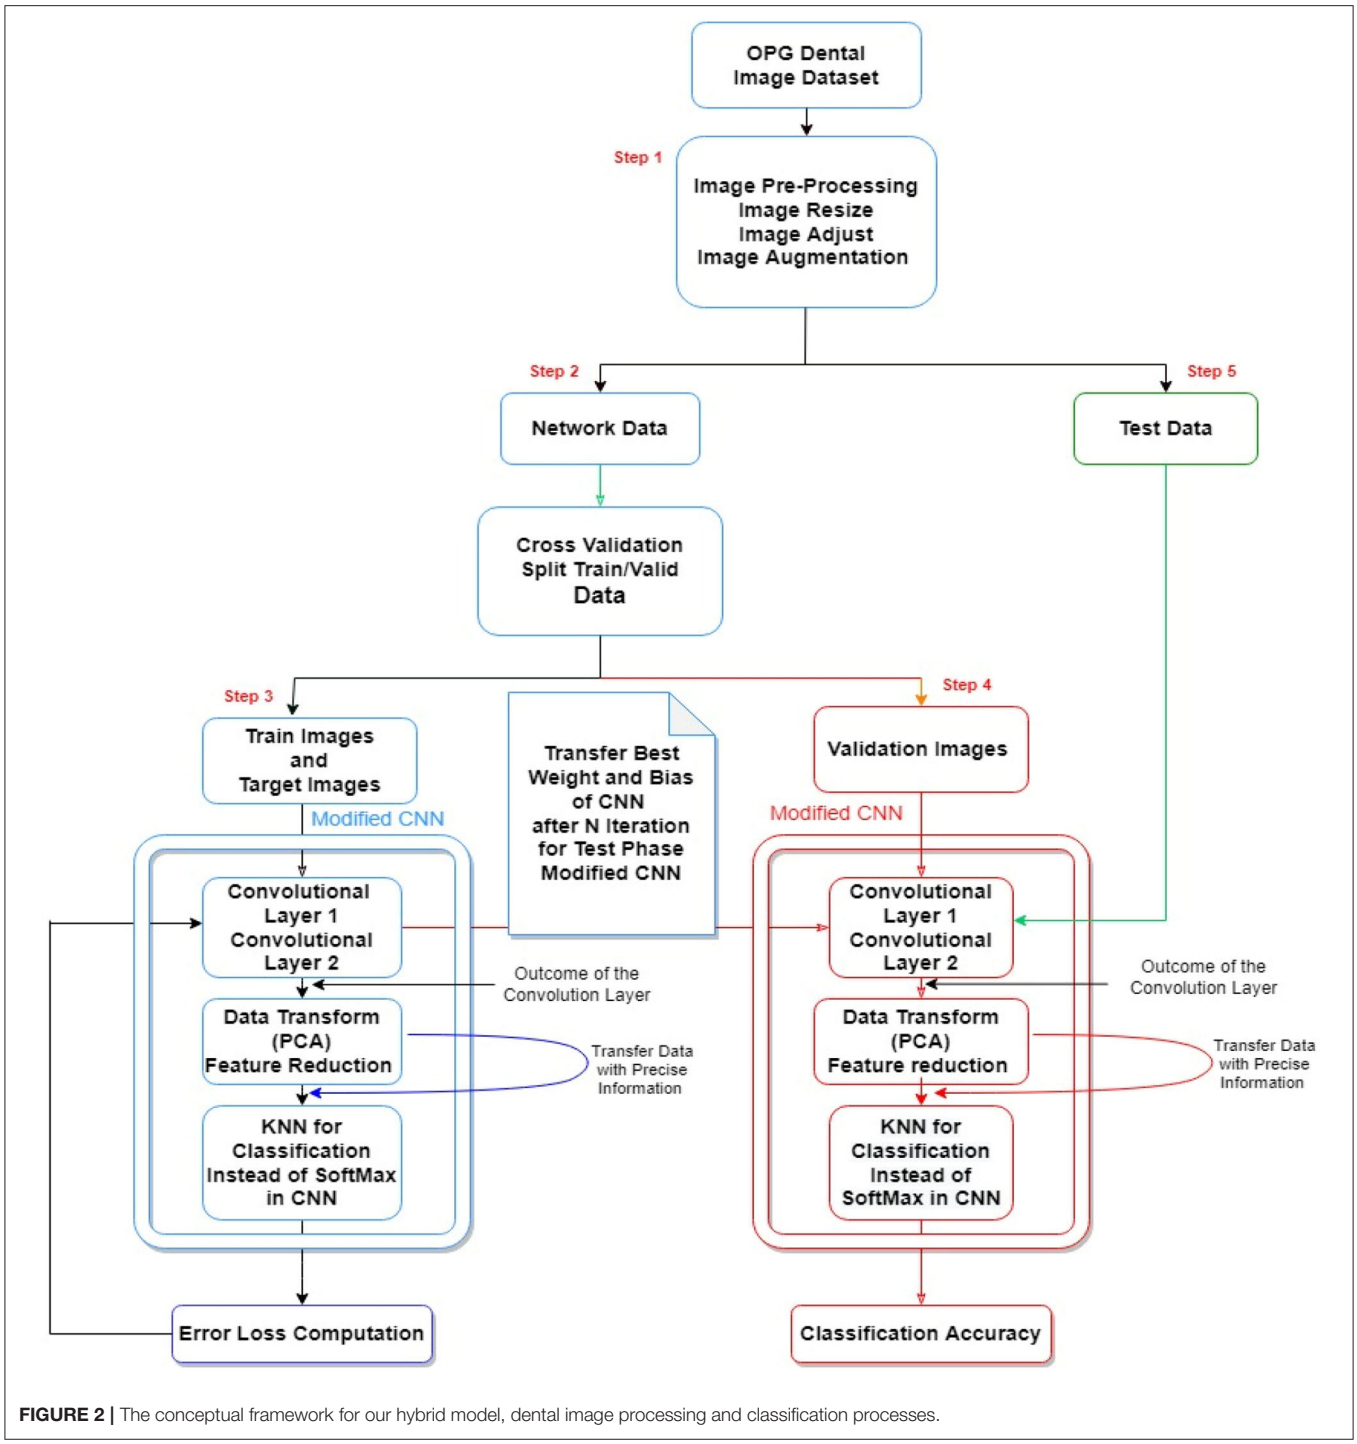

FIGURE 2 | The conceptual framework for our hybrid model, dental image processing and classification processes.

limitations of having a dataset with a limited number of embodiments, the Barnar group employed a transfer learning approach using pre-trained CNNs, and data augmentation. Their study significantly reduced the imaging assessment time over the current conventional method. For example, they have reported that the entire automatic workflow took 2.72 s to compute on average. Given the small size of the dataset, this pilot study indicated the strength of transform learning and suggested a completely automated solution capable of demonstrating outcomes not inferior to manual assessing the images.

Tuan et al. (58) introduced a semi-supervised fuzzy clustering algorithm for pre-image processing and segmentation of dental X-ray images. Their study showed that their recommended work

has superior accuracy than the initial semi-supervised fuzzy clustering and several related approaches.

In the Department of Dentistry and Study of University Sains Islam Malaysia, an age evaluation approach was tested on Malaysian adolescents between the ages of 1 to 17. Initially, the first to the third teeth were segmented, and the invariant deformation characteristics were then collected based on a deep learning method. The designed DCNN model was used to extract a broad range of features in the hierarchical layers, for example, invariance of size, rotation and deformation for sample OPG images of ± 1-Year-old individuals.

MATERIALS AND METHODS

Image Pre-processing and Data Augmentation

Prior to utilizing images in our model, we performed image processing, adjusted the contrast and highlighted the images, removed extra margins (cropping), and normalized the image pixel values at edges from zero to one. In this study, data augmentation was performed by mirroring and data duplication with rotation.

Data were classified before, Splitting for Training the model. To perform the classification, the data in the dataset were divided

into two categories: train data and validation data. The cross-validation was performed with 50–50, 70–30, and 20–80 train and validation split. To take an example, 20–80 split the 20% of the data for validation and 80% for training the model. Obtaining acceptable results on various test data will indicate the correct performance of the proposed model. Thus, to further enhance

the validation of the model, we perform additional validation of the trained model using a data set that the model was seeing for the first time. The additional validation dataset included various features such as OPGs of different races, with different genders and at different ages.

The Architecture of HCNN-KKN Proposed Model

In this study, we proposed a model based on a combination of the HCNN-KKN. Steps in our hybrid model depicted in **Figure 2** for pre-image processing and the dental classification are as follows:

The architecture of the proposed HCNN-KNN model included an inputs layer, two Convolutional layers, a fully connected layer, a PCA transform data layer, and a KNN layer for classification (**Figure 1**). Using RGB images (224 x 224 pixels) as input, each image was fed to a convolutional layer (i.e., the second layer) containing 16 convolutional filters and a kernel size of 5 and 2 paddings. Low-level features like edges, blobs, shapes were obtained. In addition to the 16 convolutional normalization filters, batch normalization (16 layers), followed by a non-linear activation function via rectified linear unit (ReLU) were performed. The convolutional layer is termed "conv1". Maxpooling layer downsampled the model with stride 2 and 2 paddings.

As a result, the Maxpooling layer reduced the dimensions of the images to 112 × 112 pixels, and the final output of this layer is equal to 112 × 112 × 16. These images were fed to the second convolutional block with a similar structure to the first. The later conventional block has 32 filters with 5 and 2 paddings kernel, resulting in the 56 × 56 × 32 images output. In the following step, all the fully connected layers were used to connect all the neurons in different layers (**Table 1**). To reduce the less important features to the next layer in the CNN model, the layers are connected with a 50% dropout between fully connected layers. We then applied a classification approach on a cohort of individuals between 15 to 23 years old and stratified all the cases with intervals of ± 6-months, ± 3-months, and ± 1-month. This resulted in 9 categories for each year (+_ Year), 18 categories for the 6 months intervals (each 6 months), 36 categories for each trimester of each year (each 3 months), 108 for every 12 months from each year (each 1 month). This resulted in the last fully connected layer to modify nine classification tasks with parameters like bias learn rate factor and weight learn rate factor. **Figure 1**: Illustration of the CNN Network elements.

In this step, a combined CNN model with KNN is used as a classifier to evaluate the class event instead of the SoftMax probability layer. Thus, before the data enters a fully connected layer of KNN layers, we proposed that in this model, the data were transferred in the space with more precise information and smaller dimensions using the principal component analysis method so-called "Fully_PCA". Therefore, fully connected layer neurons after PCA data transformation and reductions are considered overlays of the KNN classification layer. In this case, the KNN input is assumed to be 500.

The HCNN-KNN model algorithm pseudo-code proposed in this bone age study is based on dental images. In the KNN network, the distance metric used is the Euclidean Distance metric and the "Ks" are 1, 2, 3. The model is trained using an SGD momentum optimiser with a 0.0001 learning rate. The model is then trained for 10 epochs with a mini-batch size of 16 images. After learning the network and classification operations, the error loss rate is obtained to evaluate the proposed network model in subsequent epochs of network learning.

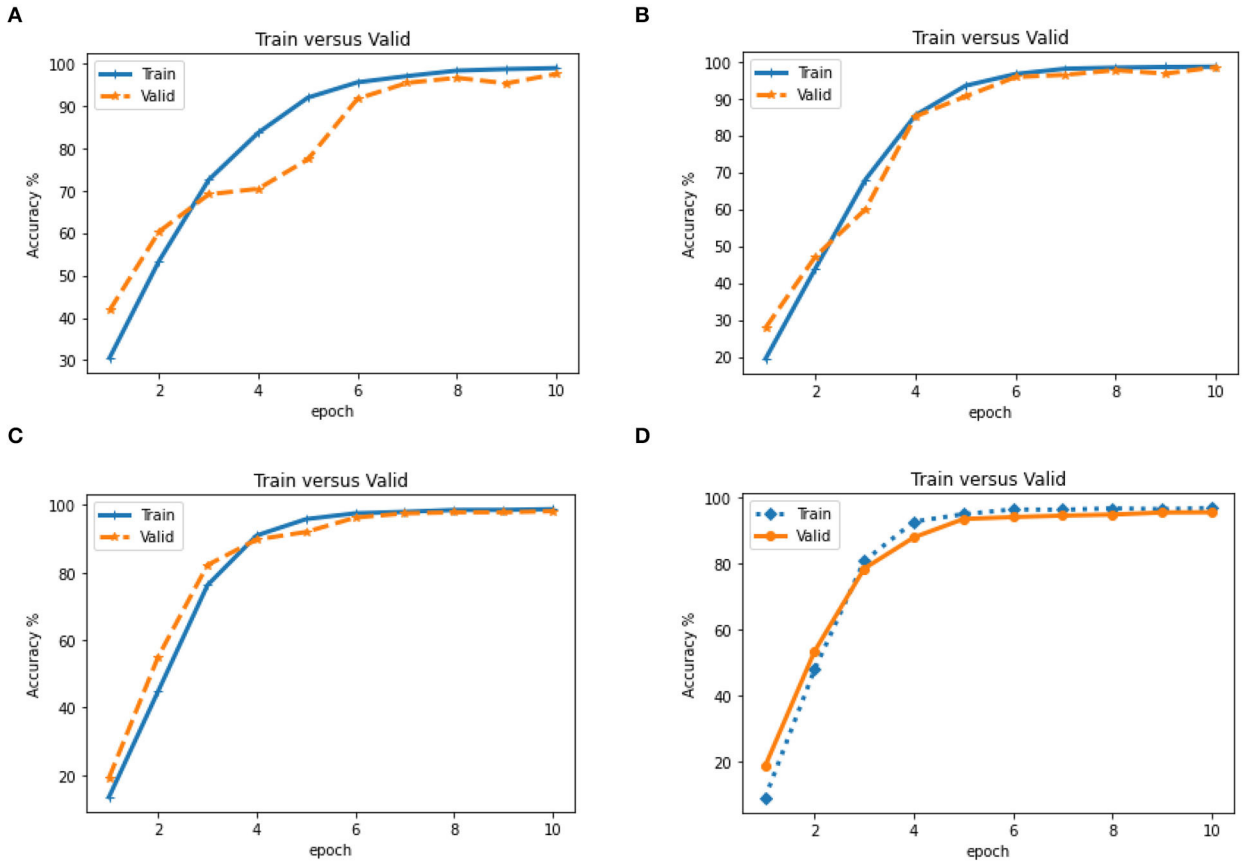

FIGURE 6 | Evaluation of accuracy (Train vs. Valid) in different epoch based on CNN model on four states of the dataset **(A)**. Dataset on Year **(B)**. on ± 6-month **(C)**. on ±3 month and **(D)**. on ± 1 month. **(A)** Train vs. Valid for dataset years. **(B)** Train vs. Valid for the dataset with ± 6 months. **(C)** Train vs. Valid for the dataset with ± 3 months. **(D)** Train vs. Valid for the dataset with ±1 months.

Evaluating the Proposed Model on Validation Data

The network neurons' optimal weight and bias were evaluated following the network training step. The validation data, segmented according to **Figure 2** (step 2), was then categorized on the CNN network with optimal parameters. The components of the classification algorithms were determined according to the training phase process and the criteria that allow the data to pass through the CNN-PCA-KNN layers. Finally, the identification rate was evaluated in which accuracy of the index was selected according to the Confusion Metrics. In brief, the sum of TP + TN (TP: the number of times the class is upbeat and correctly detected, FP: the number of times the class was positive and undiagnosed), divided with the sum of TP + FP + TN + FN. TP is the number of times the class is positive and correctly detected, FP abbreviation for the number of times the class was positive and undiagnosed. The TN, denotes the number of times the class is incorrect (negative) and correctly diagnosed. The FN represents the number of times each class is erroneous (negative) or not correctly recognized.

Validating the Proposed Model on a Test Dataset

To further validate the accuracy of the proposed model, we used test data which the model had not seen before, and was not part of the training dataset. This dataset was collected separately from the trained dataset and had different properties. This data combines X-ray OPG images of other races, with different genders and at different ages. This data enters the CNN network as a validation step and is categorized after passing through conv1, pooling1, conv2, pooling2, fully connected layer, PCA layer, and KNN layer. A vital feature of this step is the validation of the proposed model. Achieving acceptable results on various test data will indicate the satisfactory performance of the proposed model.

Computational Hardware Requirement

For this study, we used an NVIDIA GeForce GTX 1080 8GB, 8GB memory, Intel Core i7, and 3.40GHz. We also used Python libraries NumPy, Matplotlib, Sklearn, Metrics, PyTorch, Torchvision to perform the analyses.

RESULT AND DISCUSSION

We discussed the database used in this article, the tools, and the architecture introduced in the following. Finally, we evaluated our proposed model on the dataset.

Datasets Description

Dental OPG is a panoramic radiograph that scans the upper and lower jaws with a two-dimensional view that shows a semicircle from ear to ear. The used images in this study are dental OPG data, collected from dental teaching institutes and private dental clinics in Malaysia. These collected data with the different image sizes are resized before importing into the proposed model. The original image size for all data has been changed to 600 × 1,024 pixels.

Subjects from this study were randomly selected from 1,922 patients between 15 and 23 years of age, and this age range determines the age of minors which could help the model find more specific features and train the model more accurately, particularly for smaller time intervals. Moreover, to further validate the model, we used a dataset that hasn't been presented to the model during conventional training or the initial validation. Using an additional dataset including 130 random images, we showed that pre-training the model on such a prominent age recognition features (i.e. shorter time intervals, form of age range by year, age range by month, by season (3 months), and 6 months (Dataset on Year, on ± 6 months, on ± 3 months, and ± 1 month), allows us to evaluate our proposed method on a test database to enhance the performance of the proposed method (further details are provided in the experimental Result, **Table 1**, **Figure 3**).

We elucidated the frequency of the dataset generated as the result of data augmentation when augmented more than 150, 68, 32 and 7 images in 1 year, 6 months, 3 months and 1-month categories, respectively (**Figure 4**).

CNN Model Initial Accuracy on Four Different States of the Dataset

As the first experiment, we applied a CNN model on two other dataset states. In stage one, training and validation accuracy were evaluated from the original dataset without any pre-processing and data augmentation. In stage two, training and validation accuracy were assessed post-pre-processing operations on the data augmentation operations (**Table 2**).

We observed that pre-processing and data augmentation operations consistently improved the accuracy by approximately 20% and 40% for training and validation, respectively (**Table 2**).

We then evaluated the loss reduction for each step (i.e., four separate modes) of this data set (1 Year, ± 6 months, ± 3 months, and ± 1 months) with 4,000 repetitions (i.e., epoch equivalent to 10 with about 400 batch size 16). Note that the results are obtained on cross-validation with 80% training and 20% validation and segmentation on dataset images. We observe a sharp decay in loss reduction values for both the 1 year and ± 3 months dataset, while the ± 6 months and ± 1 month dataset showed a more gradual decay (**Figure 5**).

We also evaluated the accuracy of the proposed model on train and validation data in 10 epochs. We observed that the accuracy of train data is generally slightly higher than validation data (**Figure 6**). Therefore, the upward trend inaccuracy at 10 epochs indicates an increase in CNN learning.

Combining HCNN-KNN Enhanced the Accuracy of the Model

We used a combined methodology of convolutional neural networks and the nearest neighbor (classification) to further enhance the model's accuracy. The resulting hybrid model (HCNN-KNN) contained three main CNN, PCA, and KNN layers. Our findings showed that the KNN classification with 500 features selected from "Fully_PCA" (PCA data transform after fully connected in CNN) had increased the accuracy of the original data to approximately the same level of augmented data to 99.98, 99.96, 99.87, and 98.78 for 1 year, ± 6-months, ± 3-months, and on ± 1-month dataset, respectively. Intrinsically, we observed accuracy for train data to be equal to 100% (**Table 3**). This outcome indicated is fully trained using the training dataset. It is noteworthy that the results obtained for k-nearest neighbors value k = 1 in the proposed HCNN-KNN hybrid model. We have also evaluated the KNN method in the proposed HCNN-KNN hybrid model with a "k" value of 2 and 3 (**Table 4**). Model validation is essential for building a model and is susceptible to common pitfalls when splitting the training dataset (59, 60). To evaluate the possibility of overfitting pitfall resulting from splitting the training dataset, particularly for small ks (e.g., $k = 1$–3), we further validate the model using a dataset of dental images separate from the data used for initial training and validation; contained its special features. The unique features of these images are related to different races, different genders and are selected in the age range of 15 to 23. While obtaining acceptable results on these data indicates the proper performance of the KNN classifier even with k = 1.

Evaluation of Different Cross-Validation

Different cross-validation of datasets was applied to evaluate our method (e.g., 50–50, 70–30 and 20–80 train-valid cross-validation, **Table 5**).

Evaluation of Proposed Model on Second Dataset (Test Dataset)

One of this study's innovative and key features is the additional validation step in which a set of images from a diverse cohort has been used to further validate the proposed model. After the initial training and validation, the images are only available to the model. The dataset had a combination of 130 X-Ray OPG images with different races (e.g., Malay, Indian and Chinese), with distinct features, various age ranges and normal distribution of ordinary dentistry, orthodontic and malignant images (**Figure 7**).

As **Table 6** shows, the proposed HCNN-KNN model has obtained better results on the test data. Getting satisfactory results on a new dataset outside the dataset images indicates the performance of the proposed model. Thus, it seems that the proposed HCNN-KNN model has obtained superior results on the tested dataset. Obtaining satisfactory results on a new

neighbors have the same density or classes. Since the classes in our dataset are very near to each other and are pre-processed with noise reduction, the result shows acceptable accuracy at K = 1.

Figure 8 shows the confusion matrix of 97.95 % for the 18-year-old age range which was correctly estimated, and 2.04 % was incorrectly identified for the 19-year-old.

Models Accuracy

The collected data and the proposed model have been tested with other models such as ResNet, CNN, GoogLeNet Inception (**Table 7**). Our finding shows that the hybrid HCNN-KNN model has obtained much higher accuracy than different conventional classification algorithms tested.

The novelty of our study is that to the best of our knowledge, no other study reported measurements of ± 6 months, ± 3 months, and ± 1 month so far, but only compared by the year. However, the results of this proposed model are compared with previous studies by years of accuracy. For example, Avuçlu used the Multilayer Perceptron model with 1,315 dental OPG images, and the highest accuracy was 90% just for accuracy of the years. Also, in 2020, Hussein used the SVM algorithm for a population of 1,429 dental radiographs, and they only achieved 92% accuracy for years. Therefore, based on **Table 7**, the results

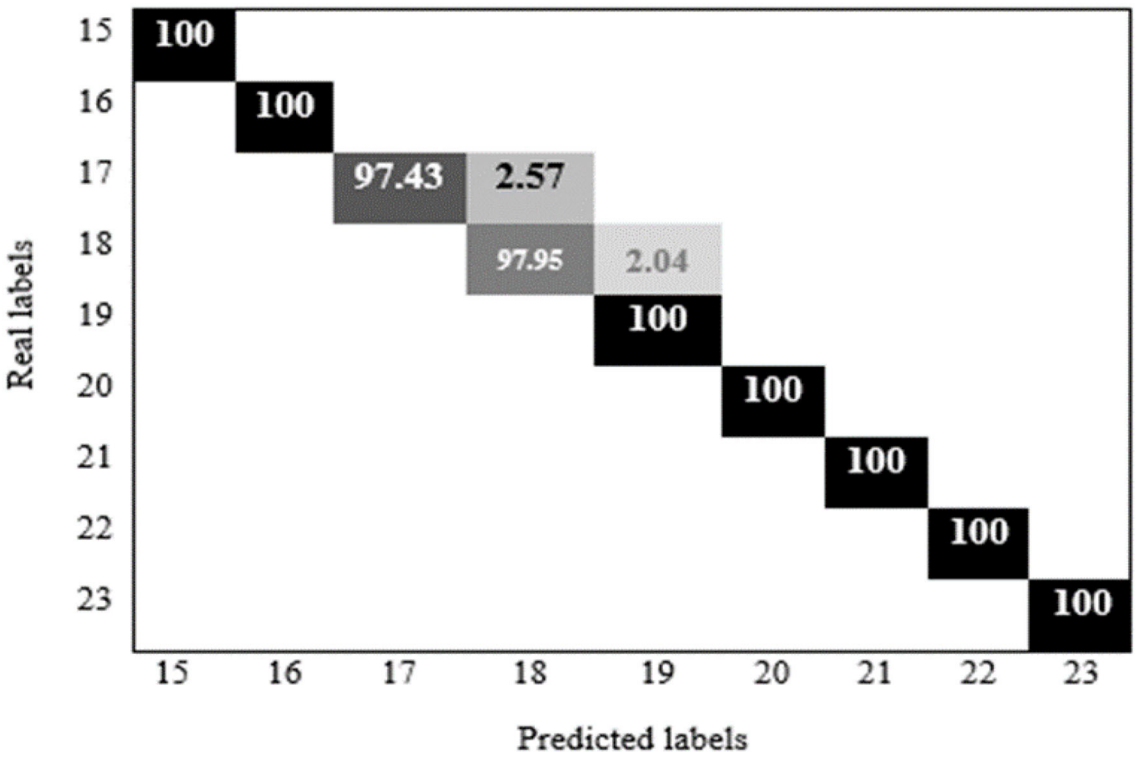

FIGURE 8 | Confusion matrix of hybrid HCNN-KNN proposed model application on enhancement dataset.

of the comparative studies for accuracy by years are still below the accuracy achieved in this study which is 99.98.

CONCLUSIONS

For the first time, with precision to the range of +/- 6 months, this novel implementation developed an HCNN-KNN model, used for BAM to increase the existing model's accuracy and prevent CNN overload situations. We considered more specific cases of bone age measurement with the help of Dental X-Ray OPG images to solve the problem of bone age measurement in determining the age range of 15 to 23 years based on the Year, ± 6 months, ± 3 months, and ± 1 month. We integrated the methodology of convolutional neural networks for extraction and analysis of information and features in dental images) and the nearest neighbor (classification method). The primary purpose of this proposed model is to use KNN instead of SoftMax in the fully connected layer to increase the performance of convolutional networks in the classification phase. Using principal component analysis as data transform and feature dimensionality reduction in a fully connected layer before classifying KNN as Fully_PCA. The primary purpose of this method is to transfer data to space with more specific information to increase the performance of the classification phase.

Our proposed model achieved the accuracy of 99.98, 99.96, 99.87, and 98.78 in 1 year, ± 6-month, ± 3-month, and ± 1-month range, respectively. Our proposed method evaluated different cross-validation of the dataset. 50–50 train-valid, 70–30 train-valid and 20–80 train-valid cross-validation on the dataset. Evaluating the proposed model on a new dataset with different races also proved the superior performance of the model. The benchmarking with current existing models also showed that the HCNN-KNN model is the best model for bone age measurement.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

AUTHOR CONTRIBUTIONS

FS and SB designed the study. FS wrote the manuscript, collected the data, carried out the analyses, including statistical analyses and the implementation of machine learning methods and generated all figures and tables. FS, SB, PO, and HA-R edited the manuscript. HA-R and PO were not involved in any analysis. All authors have read and approved the final version of the manuscript.

Analysis of the Impact of Supply Chain Relationship Strategy on Corporate Cash Dividend Policy Based on Chinese Data

*Xingquan Yang and Lingyan Sun**

School of Economics and Management, Shihezi University, Shihezi, China

With the development and application of e-commerce in the process of supply chain integration, the choice of supplier centralized strategy or decentralized mode and how to use supplier financing have become significant contents of supply chain management. This study investigates the effect of competition and cooperation on the corporate cash dividend policy under the influence of the supplier relationship strategy and its mediating mechanism based on Chinese data. The motivation of this study is to provide a basis for enterprises to grasp the dynamic evolution process of the economic consequences of supply chain relationships based on big data and adjust the relationship strategy in time to maximize the positive effects of supplier relationships. This study considers supplier concentration and supplier financing as two dimensions to measure the supplier relationship strategy and selects the balanced panel data of Chinese A-share listed companies from 2007 to 2020 as samples by applying the Logit and Tobit model. The results demonstrate that the supplier relationship is negatively correlated with the cash dividends. The intermediary effect found that the competition effect of the supplier relationship aggravates the agency conflict of enterprises and intensifies the degree of financing constraints, and thus acts on the cash dividends of enterprises. This study expands the economic consequences of relational transactions and provides an explanation of dividend policies from the perspective of a supply chain.

INTRODUCTION

With the development of the supply chain, the influence of supplier relationship strategy formed by enterprise relationships on enterprise financial decisions has gradually attracted the attention of academic circles. There are numerous and extensive nonfinancial studies on the economic consequences of supplier relationship strategy, and the primary research contents include the following components: influence factors of the supplier relationship strategy (1); supplier relationship dimension (2); the influence of the supplier relationship on the enterprise performance (3, 4), supplier relationship integration (5, 6) supplier collaboration (7–9), information sharing (10), and the related incentive and constraint mechanisms (11–13). In recent years, the research with regard to the influence of the supplier relationship on enterprise finance aspects has also attracted the attention of scholars, which primarily involves the influence of the supplier relationship on the

enterprise business credit (14–16), cash holdings (17), capital structure (18–20), transaction costs (21, 22), the choice of corporate governance (23–25), bargaining power (26), earnings management (27), financial distress, and the bankruptcy risk of enterprises (28). However, the influence of the supplier relationship strategy on cash dividend policy is rarely investigated in the extant literature. Existing studies on the impact of supply chain on shareholder wealth only discuss the perspective of customers, ignoring the impact of supplier relationships on dividends (29, 30). Actually, with the development of e-commerce, the business-to-customer model saves the cost of looking for customers and weakens the advantage of buyer's market; In contrast, there is a direct market transaction relationship between suppliers and companies, so suppliers have a greater impact on the transaction costs, investment efficiency and business decisions of enterprises than customers. Therefore, the study on how supplier relationship affects corporate financial decisions not only expands the research on the stakeholder factors of dividend policy but also provides a basis for enterprises to timely judge and adjust relevant business strategies and financial decisions based on the dynamic evolution of supplier relationship observed by big data analysis.

By summarizing the existing empirical research on cash dividend policy, scholars mainly discuss the factors affecting dividend payments from the macro and micro levels: At the micro-level, it mainly includes interest correlation (31), capital structure (32), corporate governance (33, 34), risk (35), ownership structure (36), etc. At the macro level, it mainly involves the legal environment (37), market environment (38), cultural and political factors (37), and external macro-environment (39). These factors are based on the theoretical basis of information asymmetry (40) or agency cost aspect (31, 41, 42) and the financing constraint hypothesis (43, 44). By summarizing empirical research and relevant theoretical findings, although the academic research with regard to the cash dividends has been expanding the explanation of its influencing factors from the theoretical and empirical perspectives, its underlying source can be summarized as the agency theory of enterprises and the perspective of information asymmetry. The early literature on dividend influencing factors only discussed a single aspect, until the dividend tradeoff model proved by Rozeff showed that dividend policy was the result of the joint influence of agency cost and financing constraints under information asymmetry. On the one hand, the information asymmetry between managers and shareholders causes managers to control the cash flow by reducing cash dividends at the expense of shareholders' interests, maximizing their own interests (41). Therefore, increasing cash dividends can restrain agency costs. However, the increase in the cash dividends gives rise to the higher external financing cost while restraining the agency problem, and consequently, the determination of the company's optimal dividend policy requires considering both effects. In addition, in actual corporate governance, enterprises with severe agency costs simultaneously burden financing constraints, and thus, the formulation of optimal financial decisions should be according to both agency costs and financing constraints (43). Therefore, by further expanding the theory of Rozeff (45), Chae et al. (33) conducted an empirical test by using the data of the US-listed companies and proves that the relationship between the dividend payments level and the corporate governance level depends on the relative size of agency costs and external financing costs. Based on the status quo of weak corporate governance and weak investor legal protection in China's listed companies, the problem of financing constraints and agency costs caused by the information asymmetry is serious and longstanding, which curbs corporate governance as well as financial decision making. The scholars gradually began to explore the influence of agency costs and financing constraints on the corporate cash dividend policy from the dual perspectives. Lu and Wang (34) confirmed that when companies faced agency costs and financing constraints simultaneously, companies with good corporate governance would increase the payment of the cash dividend. Subsequently, from the perspective of the cash dividend policy, Zhong and Lu (46) proved that the signal transmission of the cash dividend policy should take into account the dual restriction of financing constraints and agency costs. Yu and Liang (44) proved that China's low dividend is the result of the dual effects of agency cost and financing constraints according to the deviation degree of the actual dividend level.

The relationship between enterprises and suppliers is a dynamic process in which cooperation and competition coexist, and it is internalized into the competition and cooperation relationship. The cooperative effect of suppliers may promote information sharing through relational transactions and constitute an external supervision mechanism to increase enterprises' profitability, thus alleviating the agency cost of enterprises, and consequently, affecting cash dividends. It is also possible to increase cash dividends by easing the financing constraints of enterprises by supplying the commercial credit provided by suppliers. The competitive effect of suppliers on the cash dividend policy of enterprises is primarily manifested in the predatory practices induced by both sides of the transaction to maximize their own interests. On the one hand, the predatory practices of enterprises to suppliers are reflected by opportunism and moral hazard. Thus, the management tends to take advantage of the buyer by inducing suppliers to provide them with on-the-job consumption and personal opportunities or by facilitating participation in the board of directors, and by other covert behaviors, such as transferring corporate wealth, increasing agency costs, and reducing cash dividends. On the other hand, to maximize their own interests, suppliers with bargaining advantages rip off downstream enterprises, reduce the supply of commercial credit, increase the financing constraints of enterprises, and thus reduce cash dividends. In this scenario, this study investigates whether the supplier relationship strategy induces a significant impact on the cash dividend policy of enterprises. If the relationship exists, the central mechanism of action is attributed to the cooperative effect or competition effect.

In this study, the annual reports of companies listed from 2007 to 2020 are used to investigate the two dimensions, namely, supplier concentration and supplier commercial credit financing, and judge their impact on the corporate cash dividend policy. Subsequently, these dimensions are used to explore the mediating mechanism of supplier relationship strategy

affecting cash dividends. The test results show that the supplier concentration is negatively correlated with the cash dividend payments tendency as well as the cash dividend payments level. Supplier commercial credit financing is negatively correlated with the cash dividend payments level and the cash dividend payments intention. The mediation mechanism test supports the competitive effect of the supplier relationship strategy. The supplier relationship strategy increases the agency cost of enterprises and the financing constraint of enterprises, which reduces the dividend payments tendency and the dividend payments level. It provides an explanation of the negative dividend policy based on the perspective of the supply chain.

As the rare empirical study on the impact of supplier relationship strategy on corporate cash dividends, this study explores the cash dividend policy of enterprises from the perspective of the supplier relationship strategy, which not only enriches the relevant literature concerning the influence of the supplier relationship strategy on enterprise behavior but also provides certain enlightenment for enterprises to improve the supplier relationship strategy and optimize the cash dividend policy. This study differs from Wang's (29) study that only discusses the impact of a single level of customer relationship on cash dividends. Wang (29) believes that the financial distress hypothesis and certification hypothesis are the theoretical basis for the effect of economic consequences of customer relationships on corporate cash dividends, and finally proves that the financial distress hypothesis is valid. Different from the research of Wang (29), this article from the perspective of the supplier relationship, summarizes the root causes of its economic consequences as the cooperation effect and competition effect and proves that the supplier relationship affects the agency cost and financing constraints of enterprises through competition effect, thus acting on cash dividends, which is different from the economic consequences of financial distress in customer relationships studied by Wang (29).

The contribution and research motivation of this study can be summarized as follows: First, it can provide a basis for enterprises to grasp the status of cooperation effect and competition effect of supplier relationship in time by using big data analysis, adjust financial strategy in time to improve corporate governance level and anti-risk ability, and maximize the positive effect of supplier relationship. Second, the research conclusion proves the significance of the information effect on supplier relationships, which will promote the comprehensiveness and timeliness of big data construction and provide a reference for the decision-making of regulators and investors at the supply chain level.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

The supplier relationship primarily impacts the cash dividend policy of enterprises by using the "cooperation effect" and the "competition effect," thus generating "positive" and "negative" effects, respectively.

Supplier Relations and the Corporate Cash Dividend Policy: Cooperative Effect

The cooperative relationship is an enterprise relationship based on a long-term written contract, which can play a greater role as compared to the contract and enable both parties to share information, risks, and benefits over a long period of time (47). On the one hand, the cooperation effect of suppliers can constitute the external governance mechanism of enterprises, improve the level of corporate governance, alleviate the agency cost of enterprises, and increase the cash dividends. Specifically, the formation of supplier relationships constitutes a proprietary relationship investment between the buyer and the seller and consequently provides suppliers with access to acquire enterprise proprietary information (19, 20, 48). Accordingly, the supplier can serve as the supervision and certification entity of the enterprise and supervise the opportunistic behavior of the enterprise management, thus reducing the agency cost. In conclusion, the cooperative effect of the supplier relationship alleviates the agency problem while improving the corporate governance environment, and thus it can optimize the enterprise's production and operation activities, generate higher profitability and performance, and increase the company's ability to pay dividends, which is found to be consistent with the conclusion of the "outcome model" of dividend payments of La Porta et al. (42), that is, the company may increase the willingness and the level of the dividend payments.

On the other hand, suppliers can achieve in-depth cooperation by participating in joint research and development of enterprises, offering inventory management for downstream enterprises, or by providing trade discounts and relaxing the term of the commercial credit, which eases the financial constraints of enterprises to some extent, thus enabling enterprises to have more sufficient cash for the dividend payments (40, 49–51). In addition, supplier financing is considered an effective alternative financing instrument that enterprises can use to alleviate financing constraints when the formal system is imperfect. The alleviation of financing constraints implies reducing the cost of external funds and accordingly increasing the cash dividend payments. Based on the above analysis, Hypothesis 1 is proposed.

Hypothesis 1: The supplier relationship is positively correlated with the cash dividend payments.

Supplier Relations and Cash Dividend Policies: Competitive Effect

In the competition, both parties will face the possibility of being misappropriated profit by the party with bargaining advantages. The competitive model of the supplier relationship acts on the corporate cash dividend policy by aggravating agency conflicts and financing constraints.

Due to different risk preferences and return functions faced by the management and shareholders, the manager has a strong advantage to retain more free cash flow based on self-serving behaviors, such as on-the-job consumption, which leads to the appropriation of the cash dividend payments level of the company (33). The subtle relationship between enterprises

and suppliers appropriately provides convenient conditions for the management to retain cash. On the one hand, under the competitive effect, the management takes advantage of its buyer's market advantage and seeks to preserve the free cash flow to a greater extent under the pretext of investing in relational proprietary assets in suppliers, and thus, it provides opportunities to them to increase in-service consumption and personal empire construction and increases agency costs, and thus exacerbating the agency problem and expropriating the cash used for the dividend payments (52). In addition, under the influence of competition, suppliers are more inclined to maximize their own interests and use interests as bait to lobby the management of downstream enterprises to facilitate transactions without considering the real capabilities of suppliers. This leads to an increase in inefficient investment due to a lack of high-quality suppliers. Furthermore, the supplier shows opportunistic behavior toward the enterprise for maximizing its own interests, more specifically, exploiting the profits of downstream enterprises by offering low-quality raw materials, thus resulting in an inefficient relational asset investment, which consequently reduces the value of the company and encroaches on the cash used to pay dividends (53).

The supplier concentration degree formed by the supplier relationship reflects the bargaining advantage of suppliers, which easily leads to the competition effect (54), thus reducing the supply of the commercial credit (55). The reason is that under the circumstance of a powerful position possessed by suppliers, even if they reduce the provision of commercial credit to enterprises, they are less likely to face the risk of enterprises changing suppliers. Under the circumstance that suppliers are highly concentrated and have obvious bargaining advantages, they tend to expropriate the cash flow of enterprises by using their bargaining advantage, for instance, decreasing the supply of the commercial credit, increasing the prices of materials, reducing discounts, elevating cash sales, decreasing credit sales, and shortening the payback periods of goods, and thus increasing the degree of financial constraints of enterprises (55). Consequently, it encroaches on the cash quota of cash dividends issued by enterprises and reduces the tendency and the payment intensity of cash dividends (56). Based on the above analysis, Hypothesis 2 is proposed.

Hypothesis 2: The supplier relationship is negatively correlated with the cash dividend payments.

SAMPLE SELECTION AND DATA

Sample Selection

In this study, the data of Chinese A-share listed companies from the period 2007 to 2020 were selected as initial research samples; all details were taken from the "CSMAR" database and WIND database. In addition, for the supplement of missing values, this study searched its annual report through the website of Oriental Fortune and big data and calculated its missing indicators according to the index calculation formula. In this study, the sample companies with excessive outliers and unavailable values are excluded, whereas for the companies with less unavailable values, the annual reports were searched online, and the unavailable values were calculated according to the index calculation formula. To improve the accuracy of the empirical results, the data were analyzed based on the following steps: in view of the current situation of financial anomalies or continuous losses of ST-class and PT-class listed companies, liquidity constraints were very serious. Hence, the samples of such companies were first excluded. Given that the characteristics of capital expenditure in the financial service industries are vastly different from those of other firms, banks, insurance companies, securities, and other types of companies were excluded, simultaneously, companies with incomplete data on relevant indicators, such as corporate governance, were eliminated. To reduce the estimation error caused by statistical errors or abnormal samples and to consider the influence of extreme values, all data were Winsorize processed at 1% and 99% quantiles.

Model Specification

According to the characteristics of the explained variables and sample data, this study uses the Logit model (1) of panel data to study the influence of the supplier concentration/supplier financing on the cash dividend payment tendency of the listed companies. In cases when some enterprises do not pay cash dividends, the ratio of the cash dividend is 0. This makes the cash dividend payment rate a trailing variable with a lower limit of 0. If the regression method of the ordinary OLS is used, it becomes easy to produce deviation. As a consequence, this study refers to the study of Fama and French (57), Brockman and Unlu (31, 32) to develop the Logit model (1) and the Tobit model (2) of the dividend payments. In models (1) and (2), the subscript i represents the company, t represents the year, the explanatory variable top 5 represents the supplier concentration, credit represents the supplier credit financing, and controls represent a group of control variables. The Logit model and the Tobit model are explained as follows.

Logit model: It takes into consideration the supplier concentration, supplier commercial credit financing, and cash dividend payment tendency:

$$\begin{aligned} \text{Logit}(d_payeri, t) &= \alpha_0 + \alpha_1 Top5/credit_{i,t} + \Sigma\alpha_2 control \\ &+ \Sigma Year + \Sigma Ind + \varepsilon_{i,t} \end{aligned} \quad (1)$$

Tobit model: It considers the supplier concentration, supplier commercial credit financing, and cash dividend payment level:

$$\begin{aligned} \text{Tobit}(divi\text{-}ratio, t) &= \beta_0 + \beta_1 Top5/credit_{i,t} + \Sigma\beta_2 control \\ &+ \Sigma Year + \Sigma Ind + \varepsilon_{i,t} \end{aligned} \quad (2)$$

Definition of Variables

Explained Variable

Considering the discrepancy between the cash dividend payment tendency and the cash dividend payment degree, this study refers to the research of Denis and Osobov (58) and uses the cash dividend payment tendency (d_payer) and the payment level

(divi-ratio) to measure the cash dividend policy of the listed companies. Specifically, the cash dividend payment tendency (d_payer) is considered as the dummy variable. If the enterprise pays the cash dividends in the current year, d_payer is considered as 1; otherwise, it is considered as 0. The cash dividend payout level (divi-ratio) is calculated as the ratio of cash dividends to net income.

Explaining Variable

To fully obtain the cooperation and competition status of the supplier relationship strategy, the measurement index of the supplier relationship strategy requires reflecting not only the closeness of the relationship between enterprises and suppliers but also their bargaining advantages. This study refers to the existing literature and applies supplier concentration as one of the indicators to measure the supplier relationship strategy (16, 17, 59, 60). For another dimension of supplier relations, considering the work of Wang and Wang (61), supplier financing that is the net occupation of enterprises, to supplier financing, is selected.

(a) Supplier concentration (Top5): For the measurement of the supplier relationship strategy, most of the earlier studies have used the supplier concentration degree as a proxy. A high proportion of the Top5 implies a close supplier relationship and a high bargaining advantage for suppliers. In this study, the proportion of the purchasing amount of the top five suppliers in the total annual purchasing amount of the listed companies is used as the measure of the supplier concentration.

(b) Supplier commercial credit financing (credit): The existing literature considers that supplier commercial credit financing is the exclusive asset investment existing in the transaction of the supplier relationship strategy, which suggests the higher the proportion of enterprises' commercial credit financing with suppliers, the closer the relationship with suppliers and the stronger the bargaining advantage gained by suppliers. This study refers to the measurement method of the utilization level of supplier financing proposed by Wang and Wang (61), which is measured as the proportion of the enterprise's net occupation of suppliers to the cost of sales. The larger the proportion of the enterprise's net occupation of suppliers, the more the supplier financing, and hence the indicator is calculated as (accounts payable + notes payable – accounts prepaid)/cost of sales.

Other Control Variables

In addition, the model also controls other factors that affect dividend payments. Refer to the studies of Chae et al. (33) and Brockman and Unlu (31), Profit, growth, ROE, age, and state are selected as control variables in this study, and the calculation method is as follows: Profit, that is, the ratio of net profit to total assets. The growth of the company is expressed by the growth rate of the main business income. ROE refers to return on equity, and the company's listing age is the same year —- the company's listing year +1, and the property rights of the company (State). In addition, the control variables also included the industry dummy variable Ind and the annual dummy variable Year.

EMPIRICAL EVIDENCE

Descriptive Statistics

Table 1 presents the descriptive statistical characteristics of the main variables. From the descriptive statistics, it can be observed that the mean value of d_payer for the dividend payments is 0.711, which indicates that more than 70% of the sample listed companies have paid cash dividends. The mean value of supplier concentration is 24.3%, which indicates that China's listed companies show a relatively low degree of supplier concentration. In addition, the average ratio of enterprise supplier financing to the cost of sales (credit) is measured as 26.3%, with a maximum value of 146.1% and a minimum value of −47.9%. It can be concluded that Chinese A-share listed companies have great differences in the capital occupation of suppliers.

Basic Regression Results of the Supplier Relationship Strategy and the Enterprise Cash Dividends

Table 2 presents the regression results of the main effects of models (1) and (2), that is, the regression result of the relationship between supplier concentration/supplier financing, dividend payout tendency, and dividend payout rate. Columns (1) and (2) of the table represent the relationship between the supplier concentration(top5)/supplier financing credit(credit) and the cash dividend payment tendency, respectively. As can be observed from column (1), the coefficient of the supplier concentration Top5 and the dividend payment tendency is −0.749, which is significant at the level of 1%, indicating that the supplier concentration degree is negatively correlated with the dividend payment tendency. From the results of column (2), it can be concluded that the correlation between the supplier financing credit and the dividend payments preference d_payer is negative. Columns (4) and (5) of the table show the Tobit regression results of the model (2), namely, the relation between supplier concentration top5/supplier financing credit and the cash dividend payment level. As can be observed from column (4), the coefficient between the supplier concentration and the dividend payment level is −0.065, which is significant at the level of 1%. From column (5) of the table, it can be concluded that the coefficient of supplier credit financing and dividend

payment intensity is significantly negative at the level of 1%, with a coefficient of −0.074. Therefore, the supplier concentration degree/supplier financing is negatively correlated with the cash dividend payment level, which proves Hypothesis 2.

Robustness Test

The above empirical results may be affected by quantitative problems, such as inverse causality problems, missing variables, and sample selection bias. Therefore, this study performed the following robustness test to ensure the reliability of the above conclusions.

Reverse Causality Problem

The selection of the dividend policy may affect the enterprise's supplier concentration and supplier financing. In other words, there is a potential reverse causality between the supplier relationship strategy and the cash dividend payment level. To test this problem, this study considers the dividend payment tendency of the next phase $dpayer_{t+1}$ and the cash dividend payment level of the next phase $divi\text{-}ratio_{t+1}$ as the explained variables. The regression results are presented in **Table 3**. The results in column (1) prove that there is a significant negative correlation between the supplier concentration (top5) and the cash dividend payment level of the next phase at the level of 1%. In addition, based on the results presented in column (3), the supplier concentration is negatively correlated with the dividend payment tendency of the next phase, which is found to be consistent with the above conclusion. Similarly, based on the results presented in column (2), it is proved that supplier commercial credit financing is significantly negatively correlated with the cash dividend payment level of the next phase, which is found to be consistent with the above conclusion. The results of column (4) also prove the robustness of the results.

Replace Key Variables

To ensure the robustness of the results, this study refers to Kao and Chen (38) and Xu and Xu (62) to replace the measurement index of dividend payment level. As a consequence, this study uses the cash dividend yield divi-ratio2, which is calculated as the ratio of the cumulative cash dividend paid to the closing price of the year substituted for the dividend payment level. The results are presented in columns (5) and (6) of **Table 3**. Column (5) shows the regression results of the relationship between the supplier concentration top5/supplier commercial credit financing and the original variable divi-ratio. Column (6) shows a significant relationship between top5, credit, and the substitution variable divi-ratio2, indicating that the result is still negatively correlated at the level of 1%, which is found to be consistent with the previous conclusion, thus proving the robustness of the results.

Propensity Score Matching (PSM)

Since the model may exist as the endogeneity of missing variables, it may be related to both the dividend payments and the supplier relationship strategy. Specifically, if the control variables in the model fail to well capture the discrepancies between the centralized and decentralized suppliers, as well as the diversities in the characteristics of the supplier financing

scale, the measurement index of the supplier relationship strategy will induce a nonlinear effect. Due to the special types of the Logit and Tobit models, this study uses the propensity score matching method to control the endogeneity of missing variables. This study refers to the research methods proposed by Jiao and Zhang (30) and Meng and Bai (63). The treatment and control groups were divided considering the fact whether the quantile of the Top5 of the enterprise was >60% of the sample (60% quantile of the Top5 and credit variables were used to keep the result unchanged). The propensity score was calculated by using Logit regression. The asset size LNsize, financial leverage Lev, sales revenue Growth rate, property right property State, company Age, market value to the book value ratio Mkt, and industry HHI were used as matching variables. Subsequently, the propensity score matching analysis was performed based on the data of the enterprise in the current year. The model used the most common method of "nearest-neighbor matching" to match the treatment and the control groups. The results are presented in **Table 4**. In column (13) of the table, the *P* values are all >0.05. After matching all variables, no significant difference was observed between the treatment and the control groups, indicating that there is no statistical difference between them. Moreover, the mean difference between the groups is not found to be significant, which basically satisfies the balance test of PSM. In this study, after the PSM test, the results are presented in **Table 5**. Comparing this result with the main effect result presented in **Table 2**, it is found that in column (1) of **Table 5**, for the Tobit model of the dividend payment level, the regression coefficient of Top5 is −0.072. The regression coefficients of the top5 were found to be significantly negatively correlated, which proves the robustness of the results. Similarly, the regression coefficients of credit in column (1) of **Table 5** demonstrate the robustness of the results.

INTERMEDIARY MECHANISM TEST OF THE SUPPLIER RELATIONSHIP STRATEGY AND THE CASH DIVIDEND PAYMENT LEVEL

The intermediary mechanism model can analyze the process and mechanism of the influence of independent variables on dependent variables. This study argues that supplier concentration and supplier financing act on corporate cash dividends through agency costs and financing constraints. The most popular causal steps approach for testing is the Baron and Kenny (64) causal steps approach and the Sobel (65) approach. Therefore, by combining the advantages of the above methods, this study uses the mediating effect analysis method summarized by Baron and Kenny (64) and Wen and Ye (66) to examine the influence mechanism of supplier relationship strategy on cash dividends.

Mediation Variables and Model Specification

Mediation variables: The agent cost AC and financing constraint FC are considered as mediation variables. This study refers to the existing literature. For the measurement of the first type of agency cost, this study refers to the approaches proposed by Singh and Davidson III (36), Li (67) and Jiang et al. (68). In this study, the management expense ratio AC is used to measure the first type of agency cost, and the calculation method is measured as the ratio of the management expense to the main business income. This study exploits the SA index developed by Hadlock and Pierce (69) to measure the degree of the financing constraint (FC) of the listed companies. SA $= -0.737 \times$ company size $+ 0.043$ * square of the total assets $-0.04 \times$ company listing time. The larger the SA index, the smaller the degree of the financing constraint. To test the effect mechanism of the supplier relationship strategy on the corporate cash dividends, this study uses the mediating effect analysis method proposed by Baron and Wen, and this specific model is expressed as follows:

$$AC = \chi_0 + \chi_1 Top5/credit_{i,t} + +\Sigma\chi_2 control + \Sigma Year + \Sigma Ind + \varepsilon_{i,t} \quad (3a)$$

$$FC = \gamma_0 + \gamma_1 Top5/credit_{i,t} + +\Sigma\gamma_2 control + \Sigma Year + \Sigma Ind + \varepsilon_{i,t} \quad (3b)$$

$$\text{Tobit(d}ivi - ratio_{i,t})/\log it(d_\text{payer}) = \varphi_0 + \varphi_1 Top5/credit_{i,t} + \varphi_2 AC + \sum \varphi_3 controls + \Sigma Year + \Sigma Ind + \varepsilon_{i,t} \quad (4a)$$

$$\text{Tobit(d}ivi - ratio_{i,t})/\log it(d_payer) = \delta_0 + \delta_1 Top5/credit_{i,t} + \delta_2 FC + \sum \delta_3 controls + \Sigma Year + \Sigma Ind + \varepsilon_{i,t} \quad (4b)$$

Empirical Results of the Mechanism Test

dividend payment preference d_payer as well as the cash dividend payment level divi-ratio, respectively. The results show that the supplier concentration affects the willingness and the level of the cash dividend payments by increasing the agency cost and the financing constraint. The specific testing steps followed in the intermediary effect mechanism are the following.

Step 1: Implement the regression test for the main effect, namely, models (1) and (2). The regression results are presented in **Table 2**, and the coefficient is found to be significantly negative, which indicates that the supplier concentration is significantly negatively correlated with the cash dividend payment tendency and the cash dividend payment level of enterprises.

Step 2: Regression is performed on models (3a) and (3b), that is, the intermediary variables (agency cost AC and financing constraint FC) were respectively regression with the supplier concentration (top5) of the explanatory variable. The results are presented in columns (1) and (4) of **Table 6**. As can be observed from the table, the higher the concentration of suppliers, the higher the agency cost of the enterprise would be (the coefficient between top5 and AC is measured as 0.023, which is significantly positive). At the same time, the high concentration of suppliers will increase the degree of the financing constraint of enterprises (the coefficient of top5 and FC is measured as −0.600, which is significantly negative, and the dependent variable FC represents the degree of the financing constraint; the higher the FC, the lower the degree of the financing constraint). Therefore, top5 is found to be positively correlated with the degree of financing constraint.

Step 3: For models (4a) and (4b), the explained variable (divi-ratio and d_payer), the explanatory variable (supplier concentration (top5)), and the intermediary variable (agent cost AC and financing constraint FC) were used in the same model for regression to test the significance and the positive or the negative value of the coefficient. The agent cost AC is considered as the first intermediary variable, whose coefficients with the cash dividend payment level and the payment tendency are calculated as −0.446 and −3.507 in columns (2) and (3), respectively. The coefficient is significantly negative, which indicates that the agency cost is negatively correlated with the cash dividends and the cash dividend payment tendency. This finding is consistent with the agency cost theory of dividends. Similarly, for the financing constraint of the second intermediary variable, FC, whose coefficients with the cash dividend payment level and the payment tendency are 0.055 and 0.085 in columns (5) and (6), the significance is positive. Since FC represents the degree of the financing constraint, the lower the FC index, the higher the degree of the enterprise financing constraint would be. Therefore, it can be assumed that the financing constraint is negatively correlated with the cash dividend payment level and the payment tendency, which is found to be consistent with the financing constraint theory of dividends, that is, enterprises with a higher financing constraint level show a lower cash dividend payment level.

Step 4: It presents the validation of the mediating effect according to the significance of the coefficient and its symbol. When the dividend payment level (divi-ratio) and the dividend payment preference (d_payer) are considered as the explained

*is significant at 0.1 level, **is significant at 0.05 level, ***is significant at 0.01 level (the same below).

variables, based on the judgmental criteria of the intermediary effect, the agent cost AC is selected as an example. According to the results that the coefficients β_1, α_1, χ_1, φ_1, and φ_2 are all significant, top5 is found to be significantly negatively correlated with the dividend payment level and the dividend payment tendency, as presented in columns (2) and (3) of **Table 6**, which shows the partial intermediary effect of the agency cost on the relationship between the supplier concentration and the cash dividends. The intermediary effect of the agency cost and the financing constraint on the relationship between the supplier concentration and the cash dividends is explained as follows: combining the results of models (1), (2), (3a), and (4a), the following results can be obtained: the coefficient of the explanatory variable top5 in model (3a) is measured as 0.023, and its product with the coefficient of the agent cost AC in model (4a) is found to be negative, i.e., −0.446, which is the same as the negative sign of the coefficient of the explanatory variable top5 in model (4a), i.e., −0.042. This result indicates that part of the intermediary effect of the agent cost exists, and the total proportion of the intermediary effect is determined as 0.023 * (−0.446)/(−0.042) = −0.24. Similarly, the partial mediating effect of the agency cost on the relationship between top5 and dividend payment tendency can also be proved. The proportion of the agency cost on the mediating effect of the dividend payment tendency is 0.023 * (−3.507)/ −0.573 = 0.14. Similarly, the proportion of the mediating effect of the financing constraint to the total effect of the cash dividend payment level is determined as −0.600 * 0.055/(−0.016) = 2.0625, whereas the total effect of the cash dividend payout tendency is determined as −0.600*0.085/−0.038 = 1.34. To sum up, the increase in supplier concentration leads to an increase in agency costs and financing constraints of enterprises, thus reducing cash dividends.

Similarly, **Table 7** presents the regression results of the mechanism of the supplier commercial credit and cash dividend payment dynamics. In **Table 7**, the supplier commercial credit (credit) is considered as the explanatory variable, and the dividend payment level (divi-ratio) is considered as the explained variable. The steps of the intermediary effect test of the supplier commercial credit financing and cash dividend payment level are also the same as discussed in the previous section, and the corresponding results are presented in **Table 7**. Based on the principle of the intermediary effect test, the mediating effect of agency cost on supplier financing, incentive payment intensity, and dividend payment tendency is 0.404 and 0.77, respectively. In particular, because the sign symbols are different, financing constraint has suppressing effects on supplier financing and dividend payment level and dividend payment tendency, which are 0.065 and 0.138, respectively.

To sum up, the supplier concentration degree/supplier financing primarily affects the cash dividend payment tendency and the cash dividend payment level by increasing the agency cost and the financing constraint degree. To more clearly present the relationship between supplier relationship strategy and cash dividends as well as the intermediary mechanism, the relationship between the above variables is sorted out in **Figure 1**, and the mediating effect of each component is shown in **Table 8**.

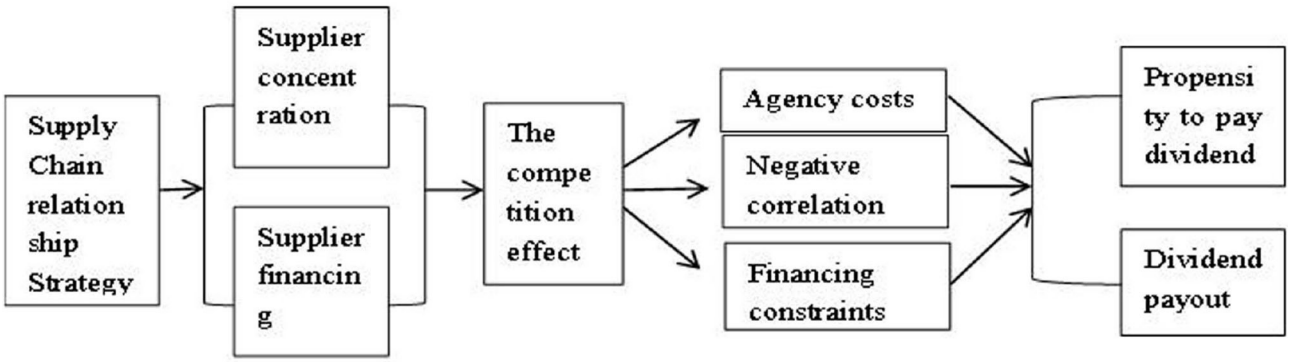

FIGURE 1 | Relationship and mechanism of supplier relationship strategy and cash dividend.

TABLE 8 | Results of intermediary effect between supplier relationship strategy and cash dividend: Intermediary effect of agency cost and financing constraint.

Intermediate effect	Cash dividend payment level				Cash dividend payout tendency			
	Agency cost	Type of intermediate effect	Financing constraints	Type of intermediate effect	Agency cost	Type of intermediate effect	Financing constraints	Type of intermediate effect
Supplier concentration	0.24	Partial intermediate effect	2.0625	Complete mediation effect	0.14	Partial intermediate effect	1.34	Partial intermediate effect
Supplier financing	0.404	Partial intermediate effect	0.065	Suppressing effect	0.77	Partial intermediate effect	0.138	Suppressing effect

CONCLUSION

The relationship transaction is increasingly affecting corporate governance and financial management. Supplier relationship strategy, i.e., choosing a centralized supplier strategy or decentralized supplier strategy and how to leverage the right supplier financing scale, has theoretical and practical significance on whether and how to influence corporate cash dividends. More importantly, the characteristic of the supplier relationship strategy is that the appearance of cooperation and competition alternately results in the various elusive economic consequences or they coexist. Therefore, enterprises need to timely judge the different economic consequences under the state of dynamic supplier relationship based on big data and timely adjust the operation and financial decisions. This study explores how the cooperative effect and competition effect produced by supplier relationship affect corporate cash dividends. It is demonstrated that supplier concentration and supplier financing, are negatively correlated with the cash dividends. Consequently, the competitive effect of the supplier relationship is proved. In the test of the intermediary mechanism of the influence of the supplier relationship strategy on the cash dividends, it is observed that the competitive effect of the supplier relationship strategy aggravates the agency conflict and the financing constraint of enterprises, and thus shows a negative effect on the willingness and level of the cash dividend payments. Based on Chinese data analysis, this study provides a decision-making basis for enterprises to maximize the positive effects of supply chain relationship strategy, and provides information basis for regulators and external investors to make decisions at the supply chain level.

A Study on the Effect of the Pre-Go-Live Training in Anxiety and Depression of Medical Staff Based on the Data of Wuhan Fangcang Shelter Hospital During COVID-19 in the Era of Big Data

Coronavirus disease 2019 (COVID-19) broke out in 2019. In the past 4 years, China has adopted many measures to control the epidemic, including building Fangcang shelter hospitals to isolate confirmed positive cases. Therefore, we aim to explore the mental health status of medical staff in the Wuhan Fangcang shelter hospital and discuss the relevant factors that affect the medical staff's mental status. The subjects of the research were staff from several Fangcang shelter hospitals in Wuhan during the epidemic of COVID-19. Patient Health Questionnaire−9 items Scale (PHQ-9) was used to assess the severity of the participants' depressive symptoms, and Generalized Anxiety Disorder−7 items Scale (GAD-7) was used to evaluate the severity of the participants' anxiety symptoms. The demographic information and health adjustment methods were collected in a self-made questionnaire, and regression analysis on related factors that affect mental health was performed. The three most frequently used methods of psychological adjustment for the staff in the Fangcang shelter hospital are common recreational activities, such as reading, streaming videos, listening to music, and playing games. (93.8%), communicating with colleagues in the Fangcang shelter hospital (92.5%), and communicating with family members and friends (78.3%). Binary logistic regression analysis showed that developing depression symptoms has relation to 2 factors, which are having not participated in medical emergency rescue missions (odds ratio = 2.610; 95% confidence interval 1.398–4.872, $P = 0.003$) and inadequate training before entering the shelter hospital (odds ratio = 2.804, 95% confidence interval 1.293–6.08, $P = 0.009$). Compared with adequate pre-job training, insufficient training increases the risk of anxiety symptoms (odds ratio = 2.692; 95% confidence interval 1.3–5.575, $P = 0.008$). Lack of experience and inadequate training in medical emergency rescue missions exposed the medical staff to a higher risk of developing symptoms of depression and anxiety. Psychological adjustment methods that are helpful to adjust their mental state are most commonly used.

Feng Q, Zhou H, Wang L and Kang C (2022) A Study on the Effect of the Pre-Go-Live Training in Anxiety and Depression of Medical Staff Based on the Data of Wuhan Fangcang Shelter Hospital During COVID-19 in the Era of Big Data. Front. Public Health 10:909241. doi: 10.3389/fpubh.2022.909241

INTRODUCTION

With the development of technology, big data has been more frequently used in people's life. By the end of December 2019, the coronavirus pneumonia (COVID-19) (1) was spreading domestically in Wuhan city of China, which quickly became the epicenter of the COVID-19 pandemic. Under the circumstance of shortage of hospital beds, Wuhan Fangcang shelter hospitals were designed and provided for the first time in China to tackle the COVID-19 outbreak and offer medical care for patients with mild or moderate COVID-19 (2). Within a few months, Wuhan opened a whopping 16 Fangcang shelter hospitals equipped with over 13,000 hospitals beds (3).

Under such a crisis situation, healthcare providers on the frontline caring for patients positive for COVID-19 were prone to developing psychological distress and mental symptoms. Recent research shows that medical workers caring for patients with COVID-19, especially nurses and women, in fever clinics and wards in Wuhan and other regions in China reported experiencing more psychological stress (4), and that they experienced the challenges of daily clinical work in COVID-19 wards (5–7). As the epidemic of COVID-19 progressed, local healthcare workers in Wuhan became overworked under the situation of the accumulative number of suspected and confirmed clinical cases in the process of the outbreak. In response to the medical crisis, 42,000 healthcare workers (including 28,600 nurses) across pan-China came to Wuhan's aid, including neighboring cities within Hubei province (8). Although it was a joint effort in an unfamiliar environment full of challenges, medical team members from their respective hospitals are kept intact during the Fangcang shelter tenure (9, 10). In addition, professional support from psychiatrists who consistently conducted face-to-face group psychological interventions and online psychological services for medical staff have a positive impact on maintaining mental health (11).

Therefore, we explored the mental health outcomes of healthcare workers caring for patients with COVID-19 in Fangcang shelter hospitals in Wuhan. To improve the validity of our research, we made a questionnaire to investigate 240 patients from the Wuhan hospital. We also provided additional evidence with respect to the mental wellbeing of healthcare workers. In addition, we used Patient Health Questionnaire-9 items Scale (PHQ-9) to evaluate the severity of the participants' depressive symptoms and Generalized Anxiety Disorder-7 items Scale (GAD-7) to assess the severity of the participants' anxiety symptoms.

METHOD

Participants and Sampling

This study was cross-sectional designed and conducted between February and March 2020, ∼1.5 months after the novel coronavirus disease 2019 (COVID-19) outbreak. A total of 240 participants recruited were medical workers from Fangcang shelter hospitals located in Wuhan city in China. The participants were allowed to finish the survey after the closure of Fangcang shelter hospitals. A total of 240 medical staff members completed the questionnaires voluntarily. The average working time of the participants in the Fangcang shelter hospital was 21.73 ± 10.69 days, 189 people (78.8%) were from Wuhan Living Room Fangcang Shelter Hospital, and 51 (21.2%) were from other Fangcang shelter hospitals. The average age of the participants was 35.27 ± 7.31 years old, including 159 women (66.3%), 81 men (33.8%), 82 doctors (34.2%), 143 nurses (59.6%), and 15 other staff (6.3%). Of 189 people, 58 individuals (24.2%) have previously participated in medical emergency rescue missions. In terms of mental health, 83 people (34.6%) had depression symptoms, and 93 people (38.8%) had anxiety symptoms. Univariate analysis showed that people who had not participated in medical emergency rescue missions before were more prone to depression symptoms ($\chi^2 = 8.035$, $P < 0.05$). The healthcare workers with insufficient training before entering Fangcang shelter hospitals had a greater proportion of depression and anxiety symptoms ($P < 0.05$).

In accordance with the Declaration of Helsinki, the ethics panel of the Medical Association of Shanghai East Hospital approved this study (No. 2020007). All the participants provided informed consent for research details and anonymized responses to be published. They were clearly informed that they had the right to refuse or withdraw from the research at any time. In the light of standardized instructions, we introduced the research purpose, questionnaire content, study process, and principle of confidentiality to the potential participants. The survey was anonymous, and because of the requirements of epidemic prevention, informed consent was provided electronically by all the survey participants after participating in the study.

Assessment Procedure

The survey participants used a mobile phone or a tablet to scan a WeChat QR code to access the mobile questionnaire survey system. All the participants filled in the questionnaires and scales online, which consisted of a general information questionnaire, a questionnaire on Fangcang shelter hospital work, the 9-item Patient Health Questionnaire Scale (PHQ-9), and the 7-item Generalized Anxiety Disorder Scale (GAD-7).

Questionnaire

This questionnaire included age, gender, occupational role (physician, nurse, or other), marital status, educational level (<undergraduate, bachelor or >graduate), types of personality traits, and past history of mental illness. This questionnaire was self-reported by the participants, including items related to the Fangcang shelter hospitals' scope of work, such as training and mental preparation prior to entering hospital, stress factors before work, past experience in emergency rescue, and coping methods.

Depression and Anxiety Assessment

With Chinese versions of validated measurement tools, symptoms of depression and anxiety among all the participants are investigated. As such, PHQ-9 and GAD-7 were used to assess the degree of severity of depression and anxiety symptoms, respectively. The outcome scores of measurement tools were interpreted as follows: the two scales' categories were both based

on established values in the literature, and items were rated on a 4-point Likert-type scale, ranging from 0 (not at all) to 3 (nearly every day). Total scores of PHQ-9 range from 0 to 27, with high scores meaning more depression symptoms. Based on existing original validation studies, the outcome of total scores was interpreted as four symptom levels suggesting no depression (0–4), mild (5–9), moderate (10–14), and severe (15–27), separately. Total scores of GAD-7 range from 0 to 21, with high scores meaning more anxiety symptoms of four levels of classification, which suggest no anxiety (0–4), mild (5–9), moderate (10–14), and severe (15–21), separately.

Investigation on Psychological Adjustment Methods

Nine self-help psychological adjustment methods were investigated for the participants, including communication with family members and friends, communication with colleagues in the Fangcang shelter hospital, physical exercise, typical recreational activities (such as reading, watching videos, listening to music, and playing games), reading books that guide psychological adjustment (either paper or Ebook), listening to an audio guide to psychological adjustment, self-learning self-relaxation techniques (such as breathing adjustments and progressive muscle relaxation exercises) through the Internet, calling the psychological assistance hotline, and seeking help from a psychological specialist (online or offline).

Statistical Analysis

SPSS 22.0 (IBM, Chicago) was used for statistical analysis. The significance level was set at $\alpha = 0.05$, and all tests were 2-tailed. Descriptive statistics were computed for categorical variables, and a Chi-squared test compared their respective rate variation. The continuous data of this questionnaire were not normally distributed and therefore presented as medians with interquartile ranges (IQRs). The non-parametric Mann-Whitney U test and the Kruskal-Wallis test were conducted to compare the severity of symptoms between two or more groups. To explore potential risk factors for symptoms of depression and anxiety in the participants, a logistic regression analysis was performed, and the risk factors are presented as odds ratios (ORs) and 95% confidence intervals (CIs), with adjustment for confounders, namely, age, gender, marital status, educational level, emergency rescue experience, and degree of training.

RESULT

In the study, 240 participants volunteered to complete the survey, 82 were physicians, 143 were nurses, and 15 were miscellaneous staff (such as laboratory personnel). Majority of the participants were women (159) aged 30–40 years (134), were married (180), had an educational level of undergraduate (153), and worked for 2–4 weeks in the Fangcang shelter hospital (**Table 1**).

Physicians vs. Nurses and Subgroup Analysis

Differences between the physicians and the nurses in terms of demographic characteristics, namely, gender, age, education level, marriage, and length of work, were statistically significant ($P < 0.05$). Most of the doctors are male, older, married, and have higher education levels and longer working years.

According to this study, the physicians and nurses working in Fangcang shelter hospitals vary in terms of personal background. The physicians (31.7 vs. 17.5%) had more experience in rescue missions than the nurses ($P < 0.05$). However, the nurses trumped the physicians in terms of support from family members (66.4 vs. 48.8%) to work in Fangcang shelter hospitals. Among the physicians, highly educated physicians were more likely to worry about being infected (85.4 vs. 61%); young physicians are more worried about being incapable of working in the Fangcang shelter hospital and having a heavy workload ($P < 0.05$).

Among physicians, those who had an above bachelor's degree were more likely to be stressed for the probability to be infected. Speaking to family was the method of choice of more educated doctors for psychological self-adjustment compared with the counterpart with less academic education. Physicians with above bachelor's degrees showed higher rates of depression and anxiety symptoms (**Table 2**). There were no similar results among the nurses.

With Past Emergency Rescue Experience vs. Without Past Emergency Rescue Experience

Compared with those who had emergency rescue experience, participants with no emergency rescue experience were more nervous about overload (before they went to Fangcang shelter hospital [38 (20.9%) vs. 5 (8.6%), $p = 0.03$]. Those with emergency rescue experience were more worried about being infected ($Z = -3.557$, $p < 0.05$ and the health of their families ($Z = -3.056$, $p < 0.05$) during their Fangcang shelter hospital tenure. The difference between PHQ-9 and GAD-7 scores was not statistically significant.

Risk Factors of Depression and Anxiety

The logistic regression analysis identified the following two groups to be at a higher risk of developing depression symptoms: no emergency rescue experience and inadequate training. In addition, the logistic regression analysis showed that the individuals with inadequate training were at higher risk of experiencing anxiety symptoms (**Table 3**).

Psychological Adjustment Methods and Self-Evaluation Effectiveness

The top three frequently used methods of psychological adjustment for the staff in the Fangcang shelter hospitals are usual entertainment (such as reading, watching videos, listening to music, and playing games) (93.8%), communicating with colleagues in the Fangcang shelter hospital (92.5%), and communicating with family members and friends (78.3%), and the three most effective methods of psychological adjustment were calling the psychological assistance hotline (81.8%), seeking help from a psychological specialist (64.3%), communicating with colleagues in the Fangcang shelter hospital 120 (54.1%) (**Table 4**).

TABLE 1 | Demographic characteristics of participants.

Variable N	Total (%)	Physicians (%)	Nurses (%)	Other staffs (%)
Overall	240 (100)	82 (34.2)	143 (59.6)	15 (6.3)

DISCUSSION

This study found that there was no variance in anxiety and depression levels between the physicians and the nurses. Previous research shows that women, nurses, frontline healthcare workers, and those working in Wuhan reported significantly higher severity of mental health symptoms than all other healthcare workers. The frontline healthcare workers who engaged in the daily work of diagnosis, treatment, and nursing of patients with COVID-19 had a higher risk of experiencing symptoms of insomnia, anxiety, depression, and distress (4). Other research shows that being at risk of contact with patients with COVID-19, living in rural areas, and being female were the most common risk factors for people developing insomnia, anxiety, depression, and obsessive-compulsive symptoms (5). The possible rationale might be fear of infection, prolonged working hours, lack of protective medical apparatus, infected patient load, less effective COVID-19 medication, loss and death of medical colleagues after exposure to COVID-19, social distancing, or isolation from family and friends, and the deteriorating situation of patients may have a negative impact on the mental health of medical workers (12).

TABLE 4 | Psychological adjustment method and Self-evaluation effectiveness.

Psychological adjustment method	Number of options *n* (%)	Self-evaluation effectiveness *n* (%)			
		Very helpful	Helpful	Help a bit	Helpless
1. Communicating with family members and friends	188 (78.3)	99 (52.7)	71 (37.8)	15 (8.0)	3 (1.6)
2. Communicate with colleagues in the Fangcang shelter hospital	222(92.5)	120 (54.1)	82 (36.9)	14 (6.3)	6 (2.7)
3. Physical exercise	168 (70.0)	78 (46.4)	71 (42.3)	12 (7.1)	7 (4.2)
4. Usual entertainment	225 (93.8)	105 (46.7)	103 (45.8)	12 (5.3)	5 (2.2)
5. Read books that guide psychological adjustment	132 (55.0)	63 (47.7)	58 (43.9)	8 (6.1)	3 (2.3)
6. Listen to an audio guide to psychological adjustment	92 (38.3)	46 (50.0)	36 (39.1)	9 (9.8)	1 (1.1)
7. Self-learning self -relaxation techniques	110 (45.8)	53 (48.2)	45 (40.9)	9 (8.2)	3 (2.7)
8. Call the psychological assistance hotline	11 (4.6)	9 (81.8)	0	1 (9.1)	1 (9.1)
9. Seek help from a psychological specialist	14 (5.8)	9 (64.3)	4 (28.6)	0	1 (7.1)

Compared with those of the physicians, the nurses' families were more supportive of their work in the Fangcang shelter hospital [40 (48.8%) vs. 95 (66.4%), $p = 0.03$]. There were no differences in scores measuring symptoms of depression and anxiety between the two groups. Those who had experiences of previous rescue missions were more worried about getting infected and the health status of their family members. By regression analysis, it was found that depression and anxiety symptoms were related to whether they had participated in rescue training and sufficient pre-go-live training.

Research shows receiving negative information about COVID-19 and participating in frontline work against COVID-19 appear to be vital risk factors for mental health problems (13–15). In terms of psychological adjustment, this study demonstrated that doctors with higher education levels had more contacts with their family members (87.8 vs. 63.4%); older doctors were more inclined to adjust their psychological pressure by reading ($Z = -1.99$, $P < 0.05$). Among the nurses, even the older nurses were more worried about being infected ($Z = -2.076$, $P < 0.05$), but they were more inclined to adjust their psychological stress through physical exercise ($Z = -3.001$, $P < 0.05$). Based on these investigation results, healthcare workers have sufficient resources at their disposal to overcome the stress related to their daily work in the Fangcang shelter hospital (16).

This result shows that within a centralized isolation treatment environment of the Fangcang shelter hospital, stress is widely existent, and depression and anxiety symptoms are common. For the medical staff in Fangcang shelter hospitals, training before on-boarding, appropriate recreational activities, and strengthening interpersonal communication and support can help reduce the stress, anxiety, and depression levels.

CONCLUSION

In conclusion, we found that, for the mental health of medical personnel fighting COVID-19, it is very important for them to have medical rescue experience and undergo pre-go-live training. With the psychological adjustment methods of improving interpersonal contact and professional help and peer support, medical workers can regain their psychological strength against stress from COVID-19.

However, this research is limited in time frame and because of the cross-sectional design. The psychological assessment was based on a voluntary online survey and self-report tools and had a small sample size. Future longitudinal studies are required for follow-up of the mental wellbeing of medical workers. Qualitative research interviews are also encouraged in future studies to generate a more comprehensive understanding of follow-up mental wellbeing adjustment (e.g., Balint group).

The Effect of Big Data-Based Digital Payments on Household Healthcare Expenditure

Chengming Li[1], *Daming Li*[1], *Si He*[1], *Shiqi Sun*[2], *Yuan Tian*[3] *and Zeyu Wang*[4]*

[1] School of Economics, Minzu University of China, Beijing, China, [2] School of Software & Microelectronics, Peking University, Beijing, China, [3] Center for Enterprise Growth and National Economic Security Research, Tsinghua University, Beijing, China, [4] School of Public Administration, Guangzhou University, Guangzhou, China

Whether families using big data-based digital payments will increase household healthcare expenditure is a subject that needs to be investigated in the era of big data. Based on the data from China Family Panel Studies (CFPS), 24,126 samples from 2014 to 2018 are used to examine the impact and mechanism of big data-based digital payments on household healthcare expenditure. The empirical results of this paper show that the use of digital payments by households can significantly increase household healthcare expenditure with the empowerment of big data. This research employs the instrumental variable method to verify and produce consistent estimation results in order to address potential endogeneity issues such as measurement error and missing variables. We learn via mechanism analysis that household adoption of big data-driven digital payments can remove credit limitations and build social capital, resulting in higher household health-care spending. We also perform a heterogeneity analysis. The findings reveal that when a family's traditional financial accessibility is high, the head of the household is young or middle-aged, and the head of the household has a higher level of education, digital payment will play a larger role in encouraging household healthcare expenditure. The conclusions of this paper are still solid after changing the indicators of household healthcare expenditure substituting the indicators of digital payment, and adjusting the variables. As a result, this article provides micro-evidence for the usage of digital payments by households to enhance healthcare spending.

Li C, Li D, He S, Sun S, Tian Y and Wang Z (2022) The Effect of Big Data-Based Digital Payments on Household Healthcare Expenditure. Front. Public Health 10:922574. doi: 10.3389/fpubh.2022.922574

INTRODUCTION

Household healthcare expenditure have risen to become the third greatest family expense after housing and education, and the phenomenon has been attracting the attention of many academics. Economic strife (1), family income (2–6), age and gender (7, 8), microfinance (9, 10), and other factors have been identified to influence household healthcare expenditure in previous studies.

Health problems are growing more serious as China's economy grows, and households are paying greater attention to medical treatment. The share of families working overtime and staying up late in Beijing is substantially higher than the general average level, according to the survey results of 2021 Chinese Urban Family Health Life Power White Paper. Families in

Beijing and Shanghai are burdened by a greater economic load, while families in Zhengzhou are plagued by mental illness and financial strain. Families are increasingly confronted with acute mental sub-health and intense pressure in an era when individuals are more concerned about their health. Health security is becoming an increasingly significant aspect of family health management. For example, 65 percent of families agree that customizing commercial health insurance is vital. When compared to traditional payment methods, digital payment based on big data is more favorable to breaking down time and space barriers and lowering the threshold for consumers to enjoy financial services, allowing them to do so more conveniently and swiftly. Digital medicine has become an active choice to alleviate the shortage of medical resources and limited medical conditions, thanks to the empowerment of digital technologies like big data, cloud computing, and blockchain. Digital payment has a bigger role to play in the growth of digital healthcare. As a result, from the standpoint of big data, this research investigates the effect of big data-based digital payments on household healthcare expenditure.

On the one hand, households' use of digital payment based on big data can broaden available financial services, increase sources of income, and alleviate credit constraints; on the other hand, we can accumulate social capital, broaden information channels, and reduce transaction costs, which may lead to an increase in household healthcare expenditure. However, existing research does not provide a clear response to the question of how digital payments based on big data affect household health care spending. The majority of studies look at the impact of family income (6), age and gender (8), and microfinance (9) on family healthcare expenditure, or address the potential benefits and risks of digital payment (11) and the impact of digital payment on rural household consumption in China (12, 13). Of course, some articles focus specifically on the impact of mobile money on household medical spending (14). However, there are few papers that look at the influence of digital payments on household health care spending from a big data viewpoint.

As a result, utilizing the China Family Panel Studies (CFPS) database and 24,126 family sample data from 2014 to 2018, this research investigates the influence of digital payment on household healthcare expenditure from a big data viewpoint, yielding the following findings. First, this research shows that digital payment enabled by big data can boost household health care expenditures using OLS estimation. Second, we use the instrumental variable technique to verify and get consistent estimation results in order to address potential endogenous issues such as measurement errors and missing data. Third, the mechanism analysis reveals that digital payments enabled by household big data applications can reduce credit limitations and build social capital, resulting in an increase in household health-care spending. Fourth, the heterogeneity analysis reveals that the use of digital payment based on big data is more effective in encouraging household healthcare expenditure in families headed by middle-aged and young individuals with a high level of education and financial accessibility. The conclusions of this research are still solid after replacing the indicators of household healthcare expenditure, replacing the indicators of digital payment, and tail reduction. As a result, this article presents micro evidence encouraging families to adopt digital payment to boost their household healthcare expenditure.

The following are the contributions of this paper. First, this paper adds to the body of knowledge about the factors that influence household healthcare expenditure (5, 6, 8, 9). The existing literature focuses mostly on home consumption studies and does not consider the influence of household health care spending. Song et al. (15) and Li et al. (16), for example, looked at the relationship between digital finance and household consumption from a digital finance perspective; Hou et al. (17) believed that liquidity constraints would affect household consumption; Kang (18) believed that social networks would increase household consumption. Furthermore, a few studies have looked into the characteristics that influence household healthcare expenditure. Microfinance (9), family income (5, 6), and age and gender (8) all have an impact on household healthcare expenditure. This study investigates the influence of digital payment based on big data on household healthcare expenditure and clarifies the impact of payment mode shift on household healthcare expenditure in the digital era through empirical analysis.

Second, this research adds to the body of knowledge about the influence of digital payments on household spending. The majority of existing work focuses on the possible benefits and risks of digital payment (11), the influence of digital payment on Chinese households' overall spending (12, 13), etc. There are, of course, certain studies that look specifically at the influence of mobile money on household health-care spending (14). However, there is limited literature on the influence of digital payment on household healthcare expenditure under the empowerment of big data from a big data perspective. As a result, this work adds to the body of knowledge about the influence of digital payments on household consumption, as well as offering new perspectives and research ideas in this area.

Third, this study adds to the body of knowledge about the impact of Fintech on family economic behavior. The impact of consumer finance (19, 20) and technology finance (21–23) on family economic behavior is the subject of most existing studies. Digital payment is an important financial technology tool, but there is little research on its impact on family healthcare behavior. This research provides new evidence regarding the impact of Fintech on family economic behavior based on this, from the standpoint of digital payment, along with the enabling function of big data.

This paper's structure is as follows: The theoretical analysis of digital payment on household healthcare expenditure under big data empowerment is summarized in Section Theoretical Analysis and Research Hypotheses; Section Data and Methods provides the data, variables, and models used in empirical analysis; Section Results presents the major result, which includes a mechanism and robustness analysis; Section Further Discussion: The Heterogeneity of Household Healthcare Expenditures presents the paper's further analysis; and Section Conclusion presents the conclusion.

THEORETICAL ANALYSIS AND RESEARCH HYPOTHESES

Household Use Big Data-Based Digital Payments Can Ease Credit Constraints and Thus Increase Household Healthcare Expenditure

Financial institutions gain access to a large amount of household data after households use big data-based digital payments. On the one hand, financial institutions can use big data from households to understand households' consumption preferences and accurately deliver personalized information by mining households' consumption data in order to increase households' demand for financial services (24); on the other hand, financial institutions can use big data analytics (BDA) to build decentralized and distributed models to predict households' credit default probabilities (25). As a result, big data-driven digital payments can affect both the supply and demand sides of financial services to ease household credit constraints encouraging households to use healthcare services (26).

On the demand side of financial services, households' use of big data-based digital payments helps them increase their financial and entrepreneurial incomes (12), while higher incomes increase the likelihood of successful credit access and help alleviate credit constraints. On the one hand, financial institutions use big data to push appropriate financial products to households based on their characteristics and needs in order to increase household financial income. Households can better manage their finances with the help of big data-based digital payments, such as purchasing money funds and investing in equity funds, thereby increasing their financial income. On the other hand, big data based-digital payments can stimulate households' entrepreneurial enthusiasm and thus increase their entrepreneurial income by providing functions such as information transfer, credit, and social interaction (27, 28).

On the supply side of financial services, on the one hand, financial institutions analyze households' credit, consumption, social, and other behaviors based on big data generated by digital payments (29) to accurately grasp households' credit status (30, 31) and include creditworthy but without collateral households into the scope of credit allocation and expand the coverage of financial service supply. Financial institutions, on the other hand, can use big data to better control the risk of credit disbursement, lower the cost of credit risk, and exit more low-threshold credit services. As a result, households can use microfinance services provided by digital platforms like WeChat and Alipay to gain access to more flexible, convenient, and low-threshold credit, easing their credit constraints (32). Traditional payment tools can achieve microfinance mobilization in the short term, but some households will face problems such as financial exclusion due to high barriers erected by financial institutions and a lack of awareness among some rural households, which will not be able to alleviate credit constraints (33–35).

In conclusion, households' use of big data-based digital payments can boost household healthcare expenditure by increasing income sources from both the demand and supply sides. As a result, this paper proposes hypothesis below.

H1: Households use big data-based digital payments to alleviate credit constraints and thus boost household healthcare expenditure.

Household Use Digital Payments Based on Big Data Can Increase Social Capital and Thus Increase Household Healthcare Expenditure

Digital platforms in China, such as WeChat and Alipay, offer not only digital payment services but also virtual social features. When households use big data-based digital payments, these digital platforms tend to use big data, based on a MapReduce-based paradigm, to perform social data analysis through the most popular framework, Apache Hadoop, to drive the creation and strengthening of social networks among different households on digital platforms to increase the viscosity of households' use of digital platforms to increase the viscosity of households' use of digital platforms to increase the viscosity of households' use of digital platforms (36). The formation and strengthening of social networks increase not only the viscosity of families' use of digital platforms, but also their social capital. In other words, households' use of big data-based digital payments on increases the frequency of communication with friends, relatives, and other subjects, thereby expanding and strengthening household social networks and contributing to the accumulation of social capital (37). As a result, increasing household social capital facilitates the expansion of information channels and the reduction of transaction costs, which increases household healthcare expenditure.

Households' use of big data-based digital payments expands access to information. Households are connected to digital platforms and their social capital grows when they use big data-based digital payments. Following that, digital platforms like WeChat and Alipay can push more healthcare-related information to households, increasing their access to information. Households can purchase products such as health insurance and health consultation based on information pushed to the Internet by big data. Furthermore, digital payments make it easier for households to buy healthcare-related products and services by streamlining the transaction process by allowing payments and transfers to be made via the Internet (22, 38).

Furthermore, households can reduce transaction costs in healthcare visits by using big data-based digital payments. When households build social capital through big data-based digital payments, they become more connected to subjects like family and friends, other households, and hospitals, giving them more opportunities and resources while lowering transaction costs (19, 39). Hospitals can use big data from households to analyze the health needs of households in real time and provide remote registration and online medical services as needed, establishing triage mechanisms and personal medical databases for patients and adjusting resource allocation, making it more efficient and convenient for patients to see a doctor and, to some extent, reducing the transaction costs of household healthcare (40). It is also easy for banks to assess the creditworthiness of potential borrowers using big data from households, allowing

them to provide more accurate and cheaper credit to households (41), lowering the transaction costs of credit between banks and households.

In conclusion, households' use of big data-based digital payments can reduce widening information channels, lower transaction costs, increase social capital, and thus boost household healthcare expenditure. Thus, this paper proposes hypothesis below.

H2: households' use of big data-based digital payments can accumulate social capital, boosting household healthcare expenditure.

Different Types of Household Applications of Big Data-Based Digital Payments Have Heterogeneous Impact on Household Health Care Expenditure

Furthermore, the use of big data-based digital payments by households has a heterogeneous effect on household health care expenditures, according to our study. Financial literacy is influenced by socio-demographic characteristics (e.g., age, education) in households (42), and because big data-based digital payments are a key component of digital finance, financial literacy influences households' use of big data-based digital payments. In terms of age differences, young and middle-aged people typically have higher cognitive levels, and higher cognitive levels significantly increase wage income (43, 44). Increased income allows this group to use big data-based digital payments more frequently, which boosts household income (26). Due to physical aging, the cognitive level of household heads declines as they grow older. As a result, young and middle-aged heads of households typically have a higher level of cognition than older heads of households, and are able to use and enjoy the benefits of big data-based digital payments more quickly, resulting in higher household healthcare expenditure. When it comes to education, the more educated group typically has better learning abilities and a larger knowledge base (45). Big data-based digital payments are novel and distinct from traditional payments, and they operate at a certain threshold, requiring users' ability to learn. Without assistance, the less educated may not be able to use or comprehend the features of big data-based digital payments, and may be hesitant to use them. As a result, higher education lowers the barrier to household heads using big data-based digital payments (46).

The use of big data-based digital payments is more prevalent in promoting household health care expenditures among households living in areas with greater financial accessibility on a regional level. Financial exclusion has long been a problem in rural areas of the country with distinct geographic characteristics (47), and the presence of financial institution outlets can effectively mitigate financial exclusion (47, 48). In other words, if households live in areas with limited access to traditional financial services, they are more likely to be financially excluded due to their remote location. Households can enjoy traditional financial services more conveniently and have good habits of participating in financial services in places with convenient transportation and high accessibility to traditional financial services, making them more likely to accept big data-based digital payments and play the role of big data-based digital payments in promoting household healthcare expenditure.

H3: The use of digital payments contributes more to household healthcare expenditure if the household has higher traditional financial accessibility, the household head is young or middle-aged, and the household head is more educated.

DATA AND METHODS

Model Setting

Referring to Liu et al. (49) and Zhang et al. (13), this paper develops an empirical model to explore the impact of digital payment use on household healthcare expenditure. The specific model is set up as follows.

$$Expenditure_{ijt} = \alpha_0 + \beta_0 Digital\ payments_{ijt} + \gamma_0 Control_{ijt} + \varphi_i + \delta_t + \varepsilon_{ijt} \quad (1)$$

The explanatory variable $Expenditure_{ijt}$ is household healthcare expenditure from the t th year and j th province and i th household. The household healthcare expenditure in the past year is obtained by logarithmic treatment. The core explanatory variable $Digital\ payments_{ijt}$ is the big data-based digital payment, which is represented by the frequency of Internet business activity of the household head in the usual case. We focus mainly on the coefficient β_0 to see the impact of digital payments on household healthcare expenditure. A positive coefficient indicates that big data-based digital payments boost household healthcare expenditure. If the coefficient is negative, it indicates that digital payments reduce household healthcare expenditure. $Control_{ijt}$ is the household head-level and household-level control variables, φ_i denote household fixed effects, and δ_t denote time fixed effects. Since households may be correlated in the same province, we cluster the standard errors to the provincial level.

Indicator Metrics

Explanatory Variable: Household Healthcare Expenditure

The explanatory variable is household healthcare expenditure. Healthcare expenditures are divided into two categories in the CFPS data: household medical expenditure and household fitness expenditure. Specifically, the CFPS questionnaire addresses household healthcare costs by asking, "What medical expenditure were paid directly by your household in the last 12 months? Of these, fitness expenditure do not include expenses that have been repaid or are expected to be reimbursed, but they do include certain expenses borrowed from friends and relatives or previously paid." "How much did your family pay for healthcare in the past 12 months? Healthcare expenditures include, among other things, the cost of physical activity and the purchase of related equipment and healthcare items." It can be observed that the first question indicates the household's medical care spending, while the second question reflects the household's healthcare spending, which combined show the significance of healthcare to the household. To get the logarithmized result, we add up the medical and healthcare costs paid directly by

households in the previous 12 months to get a total, then add 1 to the total and take the natural logarithm of the value after adding 1 to get the result.

Core Explanatory Variables: Digital Payments

The frequency of our household head's Internet business activity is used as a proxy variable for the extent to which the household uses digital payments. The household head is the primary decision-maker in the household, so the behavior of the household head has a significant impact on household activities. Specifically, this variable is addressed in the CFPS questionnaire by the question, "In general, how often do you use the Internet network for business activities (e.g., using Internet banking, online shopping)?" To provide a more visual representation of the extent to which households use digital payments, we assign a value to the frequency of the household head's response. We use 6 if the home head utilizes the Internet virtually every day for work purposes. We use 5 if the household head uses it 3 to 4 times a week; 4 if the household head uses it 1–2 times a week; 3 if the household head uses it 2–3 times a month; 2 if the household head uses it once a month; 1 if the household head uses it once every few months; and 0 if the household head never uses digital payments.

Other Control Variables

In terms of the selection of control variables, this paper draws on existing literature (12, 13, 23, 50–52) to control for both household-level influences and relevant variables at the household head- level. Specifically, at the household level, we control for household size, child support ratio, elderly support ratio, and net household income; at the household head level, this paper controls for the age of the household head and its squared term, the gender of the household head, the marital status of the household head, and whether the household head has party membership.

Specifically, the larger the household, the higher the household healthcare expenditure (53); the larger the proportion of children and the proportion of elderly, the higher the household's dependency burden, which may also contribute to household healthcare expenditure (54); the higher the household's net income, the higher the household's healthcare (6); and the age, gender, marital status, and party membership of the household head may also have a significant impact on household healthcare expenditures (8, 55).

Data Sources and Descriptive Statistical Analysis

The data we utilize comes from the China Family Panel Studies (CFPS) database, which is updated every 2 years. Because the most recent released household data from this survey are available up to 2018, and digital payments have been widely utilized since 2013, we selected to use data from 2014 to 2018. Referring to existing research methods (56), we processed the data as follows: (1) We eliminated samples with key codes missing, such as household, person, urban-rural, and provincial codes. (2) Since we used panel data and the distribution of data within each household is not necessarily the same, these data may show linearly varying relationships over the survey period. As a result, we used linear interpolation to fill in certain blanks (e.g., net household income per capita and age). Variables that were missing for three consecutive periods and could not be filled in were also eliminated. In addition, samples with incomplete gender and household size are excluded. This is because the household head's gender does not change, and changing the family size is difficult in the short term, therefore the interpolation technique is not applicable. In addition, we logarithmized variables such household expenditures and household net income (adding 1 to the values of the variables and taking the natural logarithm of the new values obtained after the addition of 1 to obtain the logarithmized results). (3) Since the CFPS does not give explicit information on the household head, researchers usually treat the principal, decision-maker, property owner, and financial respondent as the household head. However, since 2014, as information such as principal is no longer disclosed in the CFPS, only the financial respondent and the property owner in the household can be the head of the household, and most studies treat the financial respondent as the head of the household. Therefore, this paper identifies household heads by financial respondents in 2014 and only retains information on household heads who are 16 years old or older. (4) We logarithmized variables with large values such as income and distance. Specifically, we add 1 to their values and then take the natural logarithm to obtain the new variables. (5) For continuity in the time dimension, we only keep households that were surveyed in all 3 years. In addition, the nature of a household may fundamentally change when a household is split into multiple households or when a household moves, so in this paper we only retain households that were not split and did not move during the sample period.

After the above processing, we obtained 24,126 samples between 2014 and 2018, and the descriptive statistical results of the relevant variables are shown in **Table 1**. Among the household head and household control variables, the mean value of age of household head is 52.98, the standard deviation is 13.15, the minimum value is 16, and the maximum value is 93; the mean value of household size is 3.786, the standard deviation is 1.876, the minimum value is 1, and the maximum value is 21; the mean value of proportion of children is 0.124, the standard deviation is 0.201, the minimum value is 0, and the maximum value is 4; the mean value of elderly dependency ratio is 0.24. The above data indicate that the age distribution of household heads is wide, but the household structure is relatively similar.

RESULTS

Baseline Regression

We present the results of estimating the impact of digital payments on household healthcare expenditure in **Table 2**. Specifically, column (1) shows the regression results without any control variables, column (2) shows the regression results after controlling for household and time fixed effects, column (3) shows the regression results after adding household head-related variables to column (2), and column (4) shows the regression results after further adding household-related variables. As seen

TABLE 1 | Statistical description of variables.

Variable	Explanation	*N*	Mean	Sd	Min	Max
Healthcare expenditure	The sum of household medical expenditure and household health expenditure	24,126	6.901	2.711	0	13.84
Digital payments	Extent of digital payments used by the household head	24,126	0.460	1.276	0	6
Age of the household head	Age of the household head	24,126	52.98	13.15	16	93
Age^2 of the household head	$Age^2/100$ of the household head	24,126	29.80	14.13	2.560	86.49
Gender of the household head (male = 1)	Gender of the household head	24,126	0.514	0.500	0	1
Marriage of the household head (married = 1)	Marital status of the household head	24,126	0.870	0.336	0	1
Party membership (party = 1)	Whether the household head is a party member	24,126	0.107	0.309	0	1
Household size	Number of families eating together	24,126	3.786	1.876	1	21
Child ratio	Number of child in the household size	24,126	0.124	0.201	0	4
Elderly ratio	Number of elderly in the household size	24,126	0.240	0.350	0	3
Net household income	Net income is the income after deducting the cost of agricultural production	24,126	9.007	1.576	0	13.83

We define a child as an individual who is not older than 16 years old, an elderly person as an individual who is 60 years old and older.

in column (1), the regression coefficient of digital payment is 0.0844, which is significant at the 1% statistical level. As seen in columns (2), (3), and (4), this paper still shows a significant positive effect of digital payments based on big data on household healthcare expenditure after controlling for household and time fixed effects as well as the household head and household level influences.

Next, we observed the coefficients of the control variables and obtained the following results. The positive coefficient on marriage indicates that married heads of households value family protection and are more willing to spend on family healthcare; the coefficient on the number of household members is also positive, indicating that the larger the family size, the higher the household healthcare expenditure; and the coefficient on net household income is also significantly positive, indicating that households with higher income also value household healthcare, and increase expenditure more.

Robustness Analysis

Endogenous Processing

Due to omitted variables, this study may have endogeneity issues. In other words, variables other than those already controlled for in this paper may be associated with the use of digital payments or with households' health care expenditure, but we do not control for these other variables. In addition to this, there may be some error between the CFPS survey data and the actual household sentiment data, so there is also the possibility of measurement error in this paper.

Therefore, this paper uses the instrumental variable method to avoid the endogeneity problem. In this paper, the spherical distance from the capital city of the household's province to Hangzhou is taken as an instrumental variable. If Alipay originates in Hangzhou, the further the household is from Hangzhou, the less the use of digital payment. Therefore, we consider that the distance from the provincial capital city to Hangzhou is highly correlated with digital payment usage of households. In addition, the spherical distance is strongly exogenous and is not affected by digital payment use of households. The specific results are shown in **Table 3**.

The results show that the F-value of the weak instrumental variable test is >10 and passes the Wald test, indicating that

there is no problem of weak instrumental variables and the instrumental variables we selected are valid. In addition, driving distance is an instrumental variable similar to spherical distance. Specifically, we use the driving distance from the capital city of the household's province to Hangzhou as the instrumental variable, and the results are still robust.

Replacing Core Explanatory Variables

Considering that the frequency of household heads using the Internet for commercial activities is not linear, in the robustness analysis, we choose to use whether household heads conduct commercial activities via the Internet as a proxy variable for digital payments in order to eliminate the effect of uneven frequency distribution. If the household head usually does not ever conduct business activities on the Internet, then we consider that the household head has not used digital payments and the core explanatory variable is equal to 0. Conversely, if the household head usually conducts business activities on the Internet, then we consider that the household head has used digital payments and the core explanatory variable is equal to 1.

We know from **Table 4** that the use of digital payments by households promotes household healthcare expenditure.

Replacing the Explanatory Variables

Household healthcare expenditure can be divided into two components: household medical expenditure and household fitness expenditure, and both components can represent to some extent the degree to which households value their health. To conduct robustness tests, we split the household healthcare expenditure into two sub-dimensions, medical expenditure and fitness expenditure. In addition, we also replace the explanatory variables with dummy variables based on the median and mean of household healthcare expenditure. If the household healthcare expenditure exceeds the median or the mean, the explained variable equals 1. As seen in **Table 5**, the results are still robust.

TABLE 6 | Robustness test: replacement sample range.

Replacing the Sample Range

To prevent some extreme values and outliers from affecting the study, we next apply winsorizing to the sample data to correct for all variables and address possible measurement errors in the regression. We can see from the results in columns (1) to (3) in **Table 6** that the use of big data-based digital payments by households increases household healthcare expenditure after a 1, 5, and 10% winsorizing process, respectively.

Mechanism Analysis

It can be found from the previous section that the use of big data-based digital payments by households significantly contributes to household healthcare expenditure. We further discuss and analyze the mechanism by which digital payments affect household healthcare expenditure using a mediating effects model, which is set up as follows.

$$Expenditure_{ijt} = \alpha_1 + \beta_1 Digital\ payments_{ijt} + \gamma_1 Control_{ijt} + \varphi_i + \delta_t + \varepsilon_{ijt} \quad (2)$$

$$Inter_{ijt} = \alpha_2 + \beta_2 Digital\ payments_{ijt} + \gamma_2 Control_{ijt} + \varphi_i + \delta_t + \varepsilon_{ijt} \quad (3)$$

$$Expenditure_{ijt} = \alpha_3 + \beta_3 Digital\ payments_{ijt} + \theta Inter_{ijt} + \gamma_3 Control_{ijt} + \varphi_i + \delta_t + \varepsilon_{ijt} \quad (4)$$

The *Inter* are the mediating variables, and the *Control* is the control variable, which is consistent with the baseline regression. The core coefficient of the mediation model is β, if the coefficients in models (2) and (3) are significant, and pass the mediating effect test and are consistent with the theoretical hypothesis, then the mediating effect exists.

Household Use of Big Data-Based Digital Payments Eases Household Credit Constraints

We use the household's loan balance to determine credit availability and thus measure the household's credit constraint status. If the household has any debt, then credit availability is equal to 1. If the household has no debt, then its credit availability is equal to 0. In the CFPS questionnaire, the relevant questions related to credit availability are: "Does your family have any outstanding bank loans to buy or build or renovate your house?", "Apart from your mortgage, does your family have any other outstanding bank loans at present?" "Do you have any outstanding loans from organizations or individuals other than banks, such as private credit institutions, relatives, friends, acquaintances, etc., for the purchase or construction or renovation of your home?" and "Pending loans from friends, relatives and private individuals" Does your household owe money to organizations or individuals other than banks (e.g., private credit institutions, relatives, friends, acquaintances, etc.) for reasons other than borrowing for the purchase or construction of a house, and has it not been repaid?" If the household head answers "yes" to any of the above questions, the household is certified as having a loan month and their credit availability is 1.

****, **, and * indicate significant at the 1, 5, and 10% statistical levels, respectively, with t-values in parentheses.*

As we can see from column (2) in **Table 7**, the use of digital payments by households has a significant positive effect on the credit availability of households. We can also see by column (3) that the coefficient of the core explanatory variable becomes smaller when credit availability is added to the regression. Moreover, both the Sobel test and the Boostrap test show that the mediating effect is significant at the 1% confidence level, a phenomenon that confirms the existence of a partial mediating effect and suggests that the mediating effect explains 2.3% of the total effect.

The reason is that households generate big data when they use digital payments, and these big data can empower both

the supply side and demand measurement of financial services, reducing households' credit constraints and ultimately benefiting the increase of households' healthcare spending. Specifically, on the one hand, financial institutions use big data to analyze the payment behavior activities of households, which helps financial institutions accurately assess the risk status of households, thus the risk of financial institutions providing credit to households is reduced, and financial institutions have more incentives to provide loans to households. On the other hand, big data can provide households with precise information of various types, including not only information about credit services that are suitable for them, but also information about the household's financial income and employment. As a result, households are more likely to increase their applications for credit services, and their incomes are likely to increase. And higher-income households are more likely to have their credit applications approved. In summary, household use of big data-based digital payments promotes household healthcare spending by easing household credit constraints.

Household Use of Big Data-Based Digital Payments Increases the Social Capital of Households

We use household spending on human gifts to measure the social capital of the household. With respect to favor gift expenditure, the CFPS questionnaire addresses the question, "Including in-kind and cash, how many total favor gifts did your household give in the past 12 months?" In order to correct for bias, we talk about the expenditure on favors to be logarithmic. The specific regression results can be seen in **Table 8**. We can see through column (2) that the use of digital payments by households has a significant positive effect on social capital. We can also see through column (3) that the coefficients of the core explanatory variables become smaller when social capital is added to the regression. In addition, both the Sobel test and the Boostrap test show that the mediation effect is significant at the 1% confidence level, a phenomenon that confirms the existence of a partial mediation effect and suggests that the mediation effect explains 7.24% of the total effect.

In other words, when households use digital payments based on big data, digital platforms exert social attributes. The digital platform uses big data to mine families' usage data and promotes subjects on the digital platform to families, such as relatives, friends, and medical institutions, in order to strengthen their dependency on the digital platform while also increasing their social capital. On the one hand, increasing a family's social capital allows them to share knowledge with other people and expand their information channels. Families may be able to receive more healthcare information via their social networks, lowering the cost of looking for healthcare information and allowing households to increase healthcare spending. On the other hand, increasing households' social capital allows them to be more closely connected with medical institutions, banks, and other subjects, allowing medical institutions and banks to better understand households' situations and provide health care services to them, thereby increasing household health care expenditures.

FURTHER DISCUSSION: THE HETEROGENEITY OF HOUSEHOLD HEALTHCARE EXPENDITURES

The previous analysis found that households' digital payment use increases households' healthcare spending by alleviating credit and information constraints. So, does this effect differ for households with different endowments? We examine the heterogeneous impact of digital payment use on households' health care expenditures separately from differences in financial

availability, age of the household head, and education level of the household head.

Financial Accessibility of Households

In this paper, we refer to Beck et al. (27) and use the number of bank branches per capita in each province as a proxy variable for traditional financial accessibility. After that, this paper divides the sample into two groups, low traditional financial accessibility and high traditional financial accessibility, based on the average of the number of bank branches per capita in each province. As seen in **Table 9**, the coefficient of digital payment in areas with low traditional financial accessibility is 0.0809 and is significant at the 5% level. This indicates that in places with high traditional financial accessibility, households can more easily participate in traditional financial services and have higher financial literacy. Therefore, this group can use digital payments more easily and give full play to the role of digital payments empowered by big data.

The Age of the Household Head

The household head has a substantial impact on the household's decision-making, and age is an essential aspect of the household head. Based on whether the household head is <60 years old, we split the sample into a young and middle-aged group and an older group. Young and middle-aged household heads usually have a higher level of awareness, recognize the advantages of digital payments, and have a stronger willingness to use them. In addition, young and middle-aged heads of households usually have a higher risk tolerance. They are also more open-minded, and they are more willing to try new things. Most older heads of household may have a relatively lower level of awareness and are more traditional and conservative in their thinking. They will be more concerned about the risks associated with digital payments, such as suffering losses due to fraud, than the benefits that come with them. So they may be reluctant to use digital payments.

As seen in **Table 10**, in the young and middle-aged group, the coefficient of digital payments is 0.0563 and is significant at the 10% confidence level. This result is also more consistent with our common sense. Generally, younger household heads are more capable of learning, and they are receptive and willing to learn to use digital payments.

Education Level of the Household Head

We separated the sample into two groups, less educated and more educated, depending on whether the household head has fewer than 6 years of school, and then regressed them, because around 43.37 percent of household heads had <6 years of education. The results in **Table 11** show that the coefficient of digital payments in the group with higher education level is 0.0536 and is significant at the 10% confidence level. These results suggest that the more educated household heads may have a stronger learning ability and are more receptive to new things such as digital payments, so they are able to take full advantage of digital payments and thus increase their healthcare spending.

CONCLUSION

This article investigates the effect of big data-based digital payments on household healthcare expenditure from a big-data perspective. This research analyzes 24,126 sample data from 2014 to 2018 from the China Family Panel Studies (CFPS) to investigate the effect of big data-based digital payments on household healthcare expenditure. This research uses benchmark regression to examine the intermediary effect and heterogeneous influence of household digital payment on household health care expenditure, in order to improve knowledge of household health care expenditure and assist families in making better use of digital payment and maximizing its role in promoting a healthy lifestyle.

The following are the findings of this study. First, big data-based digital payments can dramatically raise household healthcare expenditure; that is, the higher a family's mobile spending, the higher the household healthcare expenditure. Second, the mechanism analysis demonstrates that by reducing household credit limitations and collecting social capital, the household application of big data-based digital payments can enhance household health care expenditure. Third, in families

headed by middle-aged and young individuals with high education and financial access, the use of digital payment has a larger role in promoting household healthcare expenditure. Fourth, the conclusions of this work are still robust when using the instrumental variable technique, substituting the indicators of household healthcare expenditure, replacing the indicators of digital payment, and shortening the tail of the variables.

This paper, however, may have the following flaws. First, this article only looks at the influence of digital payments on household healthcare expenditure, but it ignores the impact on individual health outcomes, which is a finding that needs to be explored more in the future. Second, because China's digital payment includes a variety of types, including mobile payment, bank electronic payment, digital RMB payment, etc., this paper examines the impact of digital payment in general from the perspective of big data, rather than providing a more detailed classified discussion on digital payment. As a result, researching the effects of various digital payment methods is an area that has to be addressed in the future.

INTRODUCTION

In the process of improving people's quality of life, China pays more and more attention to the healthy development of human beings. Although people have deepened their understanding of human health under the promotion of this information age, China's research in the field of children's physical and mental health development still needs to be further deepened (1). Intelligence, also known as intelligence, refers to the people's response and processing ability to the surrounding environment and things. Human beings have extremely high intelligence, which is characterized by observation ability, memory ability, and thinking ability. Children's health diagnosis and intellectual development are extremely important factors during their childhood and even in their future life. Only when children grow up healthily, they will get good development in the future (2). In the field of children's health, diagnosis of children's intelligent health is the top priority. Children's intelligent health diagnosis aims to maintain and promote the children's

healthy development, and is determined to let children have a good state of health and provide a better future for the children's physical and mental health development (3). The biological basis of intelligence is the structure and function of human brain. The key to improve the intelligence level of infants is to improve the quality of brain development, especially the early development of brain. Children's physical and mental health development inspectors are still in the manual stage of processing the children's physical condition data, which not only increases the workload of children's physical condition inspectors, but also may delay the treatment of children's condition (4). In the great project of improving population quality and cultivating socialist successors, the cultivation of infants' health diagnosis and intellectual development ability is a key link that cannot be ignored. It is the basic project to improve the children's physical and mental health development. This foundation must be laid well and firmly. With the rapid progress and development of information technology, various industries have accumulated a large amount of information and data. How to mine valuable information from these data is a problem that all fields need to face (5). As one of the main methods of data analysis, machine learning is widely used in data mining.

Based on machine learning and health information statistics, this paper studies the development of infant health diagnosis and intelligence, physical and mental health. Pre-process the sample data and use the filtering method based on machine learning and health information statistics for feature screening. Finally, using multiple machine learning algorithms, from single classifier, integrated classifier to fusion classifier, the advantages and disadvantages of multiple machine learning models are systematically explored to improve the prediction accuracy and fitting effect of the models (6, 7). Compared with traditional statistical methods, machine learning and health information statistical methods can better obtain the hidden information in the big data of children's physical and mental health development, and have a better learning ability and generalization ability (8). Machine learning is the study of making computers to imitate the way of human learning and thinking, and making computers have the ability of self-learning. Through learning, the computer can constantly update and reorganize the existing cognitive style, so that its performance can be continuously improved. Machine learning is the core of the development of artificial intelligence and the fundamental way to make inanimate computers intelligent. Machine learning is a process in which computers can identify and acquire knowledge through programming language and mathematical principles, and continuously improve the performance of infant health diagnosis and intelligence development, which can be roughly divided into supervised learning and unsupervised learning. The self-learning ability of machine learning is very important for data analysis, and it is of great significance for regression prediction and classification problems. The regression function can play a great role in finance, economic market, transportation, and benefit management. The core idea of machine learning is not to design a specific learning mode to let the machine learning algorithm do it, but to let the machine learning algorithm learn the laws and essential characteristics of data by itself. There are two kinds of unsupervised learning ideas. The first unsupervised learning idea is that when the training network parameters don't specify accurate data set classification, it adopts a weighted incentive and punishment system, which can increase and decrease the size of network parameters in the network. Supervised learning establishes a prediction model by analyzing the logical relationship between features and target variables, so as to obtain the prediction results of unknown data (9). Unsupervised learning analyzes the logical relationship of sample data without objective variables. Clustering analysis and association rule analysis are typical unsupervised learning.

When there is category imbalance in the development of physical and mental health in the health information statistical dataset of machine learning, it will have a great impact on the classification sensitivity of machine learning (10). In fact, in the real world, the data are unbalanced. Class imbalance problems are widely used in many aspects. In the use of all descriptions, a few classes have high sensitivity, and its information is the target. In the big data technology based on machine learning and health information statistics; massive data sources are a necessary requirement for big data analysis (11). Based on the machine learning and health information statistics, newborn should be trained to crawl and walk on time, on the basis of child's health diagnosis of hand movements. Training child to crawl can expand the range of child's activities, enable them to move freely, and make efforts to get in touch with interested objects, which have a positive effect on the development of perception and intelligence. The healthcare for toddler around 1 year old is mainly to gradually train to stand and walk. Only with the data analysis method supported by sufficient data can we provide a good personalized solution for children's physical and mental health development for children's health diagnosis and intellectual development, and improve their living habits and lifestyle (12). When training infant language through machine learning, we should combine language with knowing concrete things. It is necessary to combine language teaching with specific activities, such as pointing to apples and saying "This is an apple" when giving children apples, and knowing the specific thing of apples while teaching the pronunciation of apples. Use machine learning theory to analyze and mine children's health diagnosis and intelligence development, establish a health state model, and intuitively show people the health status of children's physical and mental health development in the form of data (13, 14). Moreover, the continuous accumulation of these big data is very important in the scientific research in the field of medical and health driven by big data.

RELATED WORK

The study (15) suggests that early childhood is the top priority of all aspects of children's development, and the problems related to children's education during this period can't be ignored, especially the significance to children's development can't be underestimated. In the game, let children learn something, which has a profound impact on the development of children's intelligence. Early childhood is the most important period to

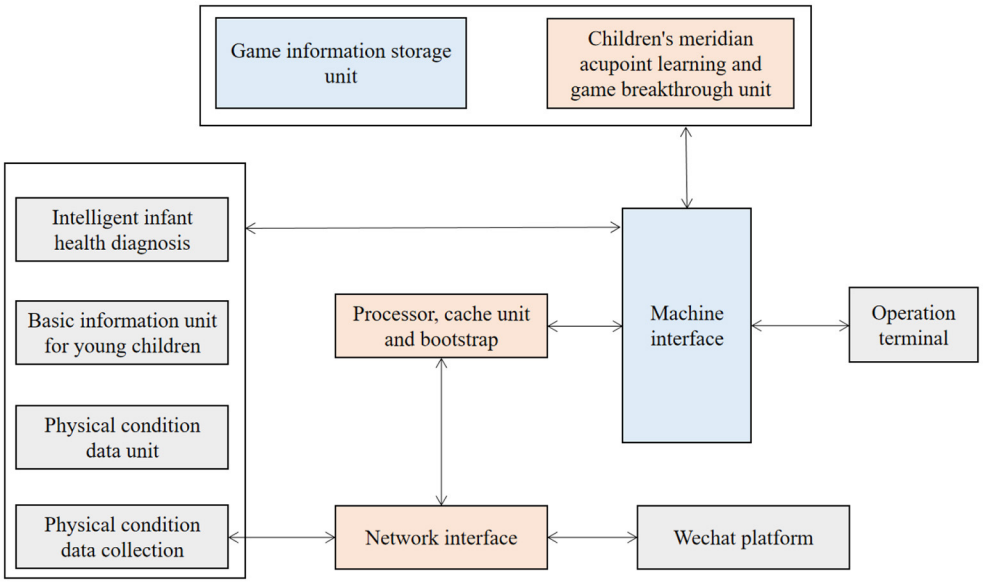

FIGURE 1 | Schematic diagram of the structure of infant intelligent health diagnosis and intelligence development.

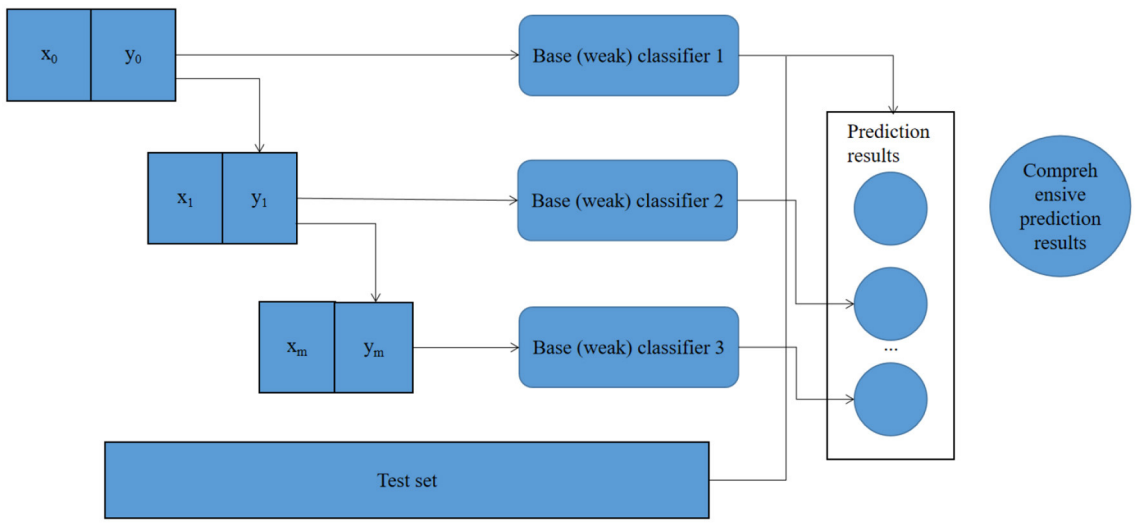

FIGURE 2 | Training flow chart of logistic regression algorithm model.

enhance the intelligence level of children. Education in the game mode is one of the important methods for enhancing the intelligence development of children.

The study (16) suggests that through the method of big data analysis, the newborn is crying, and others can't make it quiet, while the mother is in her arms. When the newborn touches the mother's skin and hears the mother's heartbeat, it will be quiet. Parents and relatives often make intimate and affectionate skin contact with the newborn, which is not only conducive to the development of the child's body and mind, but also conducive to the development of the child's intelligence.

A literature (17) research shows that 40–72% of the abnormal data processing actions of children's health data processing are an empty processing program or only record processing. In the worst case, this lack of proper action will not only not solve the problem, but even also lead to the bad development of the situation.

The study (18) suggests that mothers show affectionate skin contact by hugging, kissing, and gently massaging newborn child, especially skin contact and early sucking within half an hour after birth. This can not only compensate for the lost close skin contact in the mother's body, but also extend and expand the feeling of

comfort, so that the newborn can form a positive skin feeling conditioned reflex.

The study (19) shows that through the method of big data analysis, skin contact and massage is a physiological need of human beings and all warm-blooded animals. When child can't get this kind of need or satisfaction, skin hunger will happen, which will affect their psychological mood, normal psychological development, and intelligence development.

The study (20) shows that to improve the children's intellectual development, parents and teachers both need to drive children to participate in games, especially more games conducive to improving their intelligence, which cannot only make children have game experience, but also improve the children's subjective initiative and cognitive ability while playing games, so as to obtain intellectual development.

A study (21) suggests that the treatment of children's abnormal physical condition in kindergartens at this stage is still in the artificial stage, which is inefficient and takes a long time, which not only increases the workload of kindergarten staff, but also may delay the treatment of children's condition. The study (19) shows that through the big data analysis method, for kindergartens, today's preschool teachers choose to educate children. The contents that preschool teachers think are "interesting" and children are not easy to operate. In addition, they will place too much emphasis on learning in the classroom and ignore the diversity of learning styles. Therefore, this will not necessarily promote the development of children's intelligence.

Research (22) shows that after birth, because newborns love their mothers, when they come into contact with their mothers' skin, they will feel happy and have enough sense of security, which is also an important test for early newborn health care. Skin sensation is the earliest sensation in infants, followed by smell, taste, and hearing.

The study (23) proposes that children's information is uploaded to the cloud to update the database, and parents can view the children's information through mobile app. In 2017, Li Qingyi and song Xueliang disclosed an all-in-one kindergarten morning check-up and medical care machine, which proposed to integrate the kindergarten common disease check-up and nursing materials. Parents can view nursing suggestions through mobile app.

For the problem of infant health diagnosis and infant intelligence development, this research project proposes to study infant health diagnosis and intelligence development based on machine learning and health information statistics. Developing children's mental and physical health through learning and playing can improve the children's subjective initiative and help children's motivation, knowledge, and ability.

PRINCIPLE AND ALGORITHM OF MACHINE LEARNING

This topic integrates the automatic detection of children's physical and mental health development, the automatic management of children's information data and children's intelligence development. It has high degree of automation, strong reliability, and diversified functions, which is conducive to children's health and intelligence development. As shown in **Figure 1**.

The infant intelligent health diagnosis and intelligence development device comprises an operation terminal, an infant health self-test device, a processor, an infant intelligence development trainer, a computer interface, and a network interface. The operation terminal is connected with the processor through the network interface, and both the infant health self-test device and the infant intelligence development trainer are connected with the processor through the interface. The processor includes a processor and a storage unit, and the infant

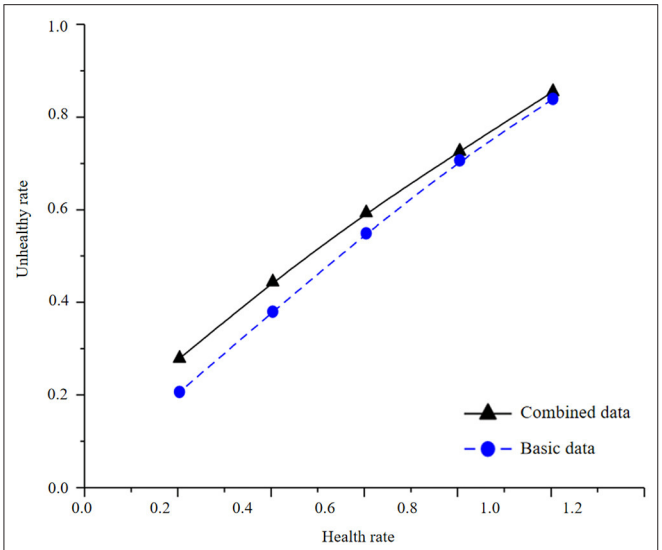

FIGURE 3 | Health information statistics of logistic regression combined data and basic data.

health self-test device and the infant intelligence development trainer, respectively, include the infant health self-test unit, the infant intelligence development training unit, and their respective boot programs and storage units.

Machine learning algorithm is used to construct the model of child health diagnosis and intelligence development. When using machine learning to solve problems, logistic regression is usually the first choice and then other complex algorithms are used on this basis. In order to solve the classification problem, firstly, the sigmoid function is used to construct the prediction function, that is, the classification task. Then, the $J(\theta)$ function is derived from the maximum likelihood estimation. Finally, the optimal model coefficients are solved by the gradient descent algorithm.

The function form is as follows:

$$g(z) = \frac{1}{1+e^{-z}} \tag{1}$$

The independent variable z is any real number, and the range is [0,1]. That is, the conversion from numerical value to probability is completed by sigmoid function, and the prediction function is as follows:

$$h_\theta(x) = g\left(\theta^T x\right) \frac{1}{1+e^{-\theta^t x}} \tag{2}$$

where x is the dataset introduced in the form of matrix, $\theta_0 x_0 + \theta_1 x_1 + \ldots\ldots + \theta_n x_n = \sum_{i=0}^{0} \theta_i x_i = \theta^T x$, and the best parameter is $\theta = [\theta_0, \theta_1, \ldots \theta_n]^T$.

For the binary classification task (0,1), the prediction function is constructed as follows:

$$P\left(y=1 \mid x,\theta\right) h_\theta(x), P\left(y=0 \mid x.\theta\right) = 1 - h_\theta(x) \tag{3}$$

For the sake of simplicity, the two-category tasks can also be integrated into

$$p\left(y \mid x;\theta\right) = \left(h_\theta(x)\right)^y \left(1-h_\theta(x)\right)^{1-y} \tag{4}$$

Based on the prediction function, the maximum likelihood estimation $J(\theta)$ function is constructed as follows:

$$J(\theta) = \frac{1}{m}\log p\left(y \mid x,\theta\right) = -\frac{1}{m}\sum_{i=1}^{m}\left(y_i \log h_\theta(x_i) + (1-y_i)\log\left(1-h_\theta(x_i)\right)\right) \tag{5}$$

$J(\theta)$ converting the gradient ascending task into the gradient descending task.

The optimal coefficient θ_j^* can be obtained by solving the first-order equation of $J(\theta)$ to θ_j.

$$\frac{\partial J(\theta)}{\partial \theta_j} = \frac{1}{m}\sum_{i=1}^{m}\left(h_\theta(x_i) - y_i\right) x_i^j \tag{6}$$

where x_i^j represents the sample value of row I and column J.

Finally, the optimal solution is obtained by parameter updating.

$$\theta_j^* = \theta_j - \alpha\frac{1}{m}\sum_{i=1}^{m}\left(h_\theta(x_i) - y_i\right) x_i^j \tag{7}$$

The logistic regression requires simple input data of the model. The feature set can be classified variables or continuous variables, and the modeling process is also convenient. Therefore, it is a widely used classification model. In the field of disease prediction, unconditional logistic regression model is widely used.

Let the separation hyperplane separate the linearly separable sample set $T = \left\{\left(x_i, y_i\right), i = 1, \ldots, N\right\}$ correctly, that is

$$y_i = \begin{cases} 1 & w \cdot x_i + b \geq 1 \\ 0 & w \cdot x_i + b \leq 1 \end{cases} \tag{8}$$

The classification interval of the separation hyperplane is defined as

$$d = d_+ + d_- = \frac{|w \cdot x + b|}{\|w\|} = \frac{1}{\|w\|} \tag{9}$$

Among

$$d_+ = \min_{i:y=1}\left\{\left(w \cdot x_i + b\right) / \|w\|\right\} \tag{10}$$

$$d_- = \min_{i:y=-1}\left\{\left(w \cdot x_i + b\right) / \|w\|\right\} \tag{11}$$

Indicates the distance between the sample points and the decision surface equation. To maximize the hyperplane classification interval d, it can be transformed into a set of w &b to minimize $\|w\|$. For the later calculation aspect, it is transformed into a set of

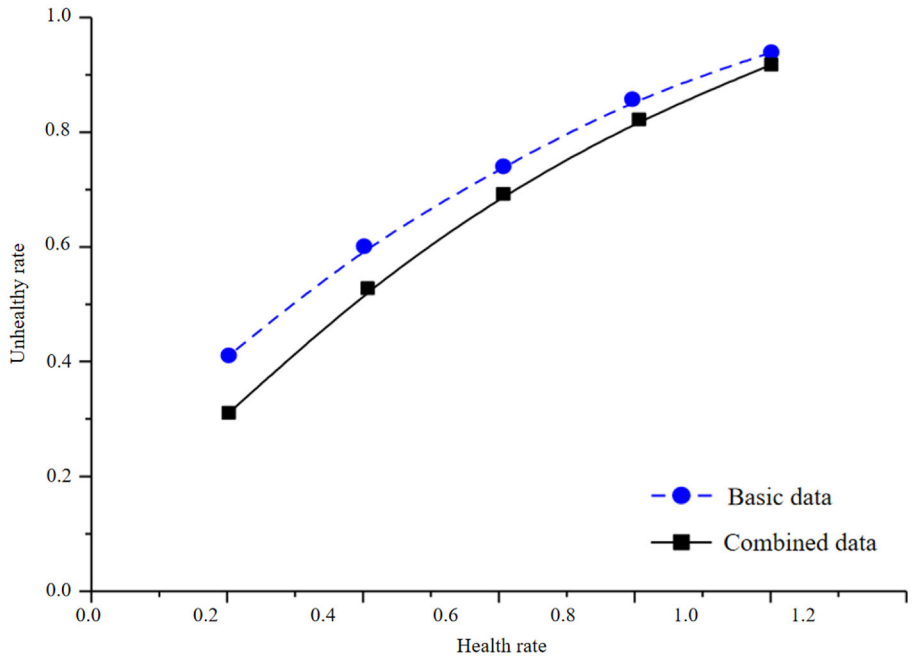

FIGURE 4 | Health information statistics of logistic regression combined data and basic data.

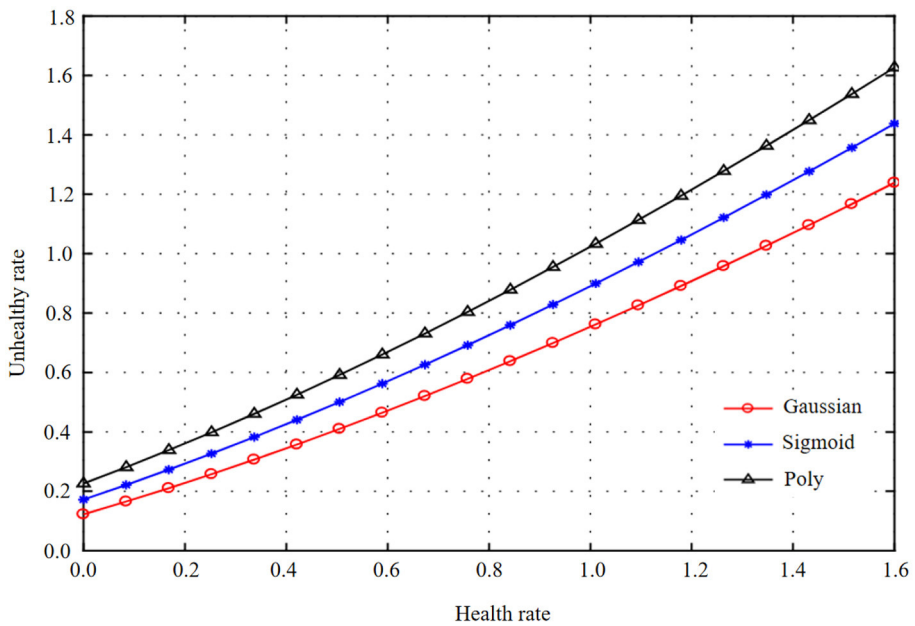

FIGURE 5 | Curve representations of three kernel functions of machine learning basic data and health information statistics.

w & b, which minimizes $\|w\|^2$. When the similarity between the collected characteristic information of infant's physical condition and a disease in the case information database is 0, the infant does not have the disease; when the similarity is not >0.4, the infant's physical condition is sub-healthy for the disease; when the similarity is >0.4, the infant is suspected to have the disease. Judgment of infant's physical health or suspected illness, when the similarity between the collected infant's physical condition characteristic information and all the illnesses in the case information base is 0, the infant is healthy; If the similarity of all diseases is not <0, i and not more than 0.4, the child's body is in a subhealth state; If the similarity of all diseases is not <0.4, the infant suffers from diseases, and the disease with higher similarity value is taken as the preliminary diagnosis result.

Different machine learning algorithms are obtained due to different function selection. However, the training process of

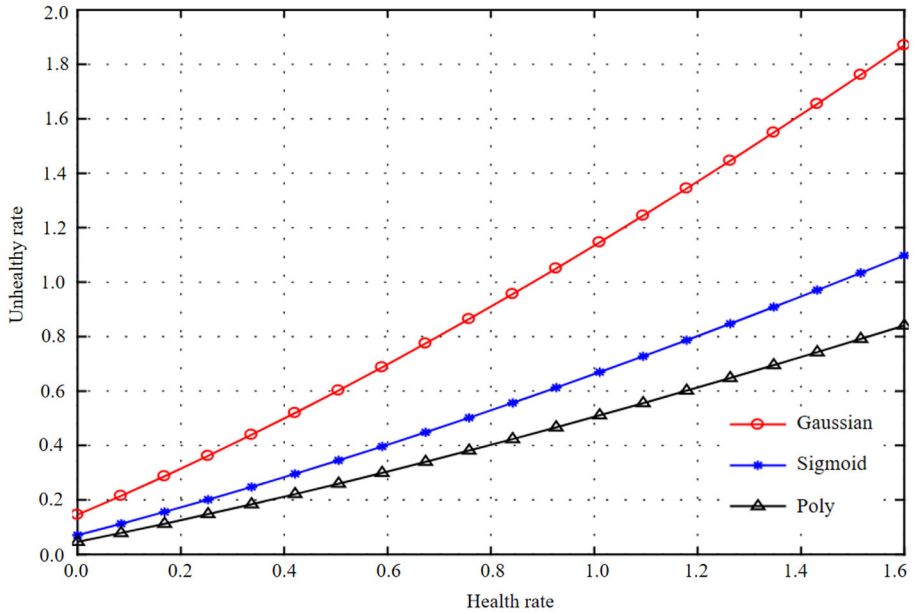

FIGURE 6 | Curve representations of three kernel functions of machine learning basic data and health information statistics.

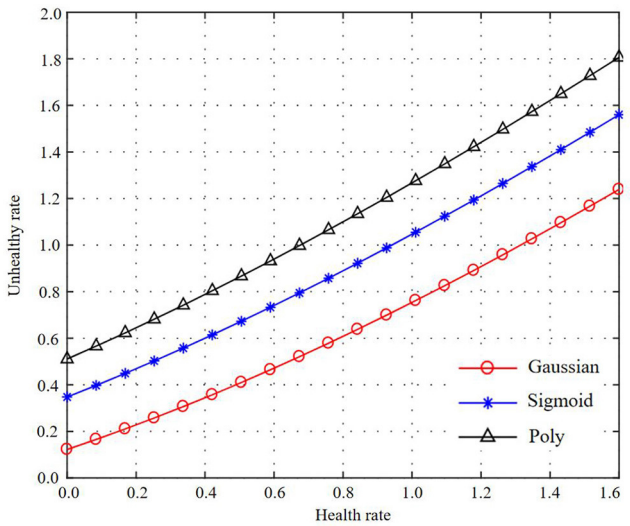

FIGURE 7 | Curve representation of three kernel functions of machine learning basic data and health information statistics.

logistic regression algorithm is to train each weak classifier in step form, and then combine the weak classifiers into strong classifiers in a certain way to obtain the comprehensive prediction results, as shown in **Figure 2**.

Considering the model principle and the data characteristics of this study, the logistic regression algorithm in machine learning algorithm will be used to construct the model of infant health diagnosis and intelligence development, and to find the most suitable model for infant health diagnosis and intelligence development.

INFANT HEALTH AND INTELLIGENCE DEVELOPMENT

Intelligent Diagnosis and Disease Treatment

Identification of Young Children

With the development of information technology, there are more and more forms of identification technology, which can be summarized into the following three categories: the first category is the things you can know, such as passwords, which are easy to crack and have the lowest relative security; The second category is the things you can own, such as smart cards, which are not easy to save, easy to lose, and low in security. The third category is the personal characteristics held by everyone, such as face and iris. These characteristics are unique to everyone. Compared with the first two categories, the third category is more trustworthy. Ensure the nutrition requirement of the first rapid proliferation of brain cells in the fetal period, and increase the number and quality of brain cells as much as possible with sufficient and high-quality nutrition. Pregnant women should pay attention to strengthening nutrition, eating reasonably and supplementing folic acid and trace elements such as zinc, iron, and copper. Iodine deficiency leads to dementia, and iodine deficiency areas should pay special attention to iodine supplementation. The important role of early education can't be replaced and compensated by any other form of education in the future. Long-term emotional stress and anxiety of pregnant women, fright, fear, sadness, high-dose radiation, organic mercury, lead and other toxic substances, tobacco and alcohol, virus infection, pregnancy poisoning, diabetes and hypothyroidism, taking phenytoin sodium, antithyroid drugs, perinatal hypoxia, and birth injury, etc. Grasp the "best age,"

that is, it is easier to learn certain knowledge or behavior at a certain age, faster to master and better to remember, and to carry out education in advance or delay, and the effect is far less than the best age. For babies, the facial movements should be trained first. Modern scientific research has proved that the more and more complex fingers move, the more they stimulate the brain, thus promoting the development of intelligence, so we should pay attention to the training of child's facial movements.

The specific steps of children's face training or recognition algorithm are as follows:

① Connect the camera.

② Camera device captures children's faces.

③ Extract and mark the captured children's faces.

④ For face training, name the captured child's face and store it in the child information database for training. For face recognition, compare the captured child's face with the child's face in the child information database. If the comparison is successful, extract the child's student status number, name, and other information; otherwise if you choose to continue, carry out infant face training. If you choose to end, carry out the next step.

⑤ End.

Children's Physical Condition Information Collection

Children's physical condition information collection is the premise of intelligent diagnosis of children's physical health. Its collection includes temperature acquisition, cough, diarrhea, runny nose, and so on. Genetically speaking, the development of human brain is influenced by genes and environment. The structure and function of brain are directly related to the quality of genes, but also influenced by environmental factors. Brain development is a process that determines the gradual expression of genes in the brain. In the process of gene expression, unfavorable or even harmful environmental factors can inhibit gene expression, causing brain development disorder or damage, while appropriate and favorable environmental factors can effectively promote gene expression, making the brain structure and function develop fully and perfectly. Early education is the most effective environmental stimulation factor to promote brain development, which can fundamentally improve the fine structure and function of brain, make it fully developed and perfect, not only improve the development quality of normal brain, but also significantly improve the intelligence level of mentally retarded people. Emphasize the nutritional conditions and further improve the quality of brain cells. Breast milk is the most ideal natural food, and breastfeeding is the most concerned issue in all countries today. The WHO requires that babies should be breastfed for at least 4 months after birth, just to meet the nutrition needs of the second rapid proliferation of brain cells. There are some differences in the reports about the influence of diet on physical development in different places. In some places, it is reported that children are eating too much animal protein at present; in some areas, children are eating too much plant food, and the proportion of nutrition intake among children in different areas is also different.

Strengthen the healthcare of infants' physical and mental health development. Infant immune system is imperfect and prone to diseases. Many diseases affect intellectual development. Therefore, active prevention and treatment should be carried out to minimize the occurrence of diseases and shorten the course of disease, so as to ensure the healthy development of the brain. In the past, when talking about the impact of diet on children's physical development, people immediately thought of malnutrition, which is indeed a very important aspect. How to ensure the healthy growth and development of children on the basis of solving the problem of malnutrition? There are many literature reports that with the improvement of material living standards, there are many new problems in children's physical development in China, such as children's obesity, anemia, precocity, physical decline, and so on. The non-contact infrared thermometer is used to obtain the temperature of children, which is wirelessly sent to the wireless receiver and stored in the collection unit of children's physical and mental health development. The utility model has the advantages of high accuracy of the measured body temperature. After obtaining the temperature of children, analyze whether the temperature is normal based on medical knowledge, and analyze the degree of fever for abnormal temperature. Biological studies have confirmed that the diet structure is closely related to children's physical and psychological growth and development, and is related to the occurrence of many diseases. In this paper, based on machine learning method, children's identity is recognized by automatically collected physical condition data and faces, and children's health status is diagnosed by case-based reasoning by using physical condition data of children. However, only for sick children, the treatment scheme of over-the-counter standing drugs is given by man–machine combination according to their severity. Therefore, on the basis of the proposed training method of intelligent infant health diagnosis and intelligence development, this paper designs an intelligent infant health diagnosis and intelligence development device. This research device has strong reliability and diversified functions, which are beneficial to the infant's health and intelligence development, but there are still some areas that need further research. Even people's personality characteristics, ability tendency and intelligence level are also related to diet. Chinese children's unreasonable diet has various manifestations. According to the literature, the main reason is that the food is too delicate and destroys the content of vitamins and minerals of the food. The relationship between unreasonable dietary structure, nutritional imbalance, and intellectual disability has been recognized by the society, such as iodine deficiency and intellectual disability, and the impact of zinc deficiency on intelligence. However, how to make children with normal development have better intelligence has not attracted extensive attention from the society. The children's perception and cognitive ability, as well as the flexibility and accuracy of children's hands, are trained through three links: self-study of human meridians and acupoints, chapter test, and game breakthrough. Comparative analysis shows that the proposed method can integrate learning, entertainment, and healthcare, and play a role in enhancing the physical and mental health of children and also in developing the children's intelligence.

Results and Analysis

After the original data are processed by SMOTE algorithm, the new dataset is modeled by the same method and its performance is compared. The recall rate, f-score, accuracy, and Area under curve (AUC) of the random forest model are higher than those of the other two models, and the specific results are shown in **Tables 1**, **2**.

Through the investigation of kindergarten a, the specific results of children's physical condition are shown in **Table 3**.

In the process of infant health diagnosis and intelligence development based on machine learning and health information statistics, the accuracy, precision, recalls rate, F1 value, and AUC value are used to evaluate the effects of basic data model and combined data model. By constructing Logistic regression model, the results are shown in **Table 4** and **Figures 3**, **4**.

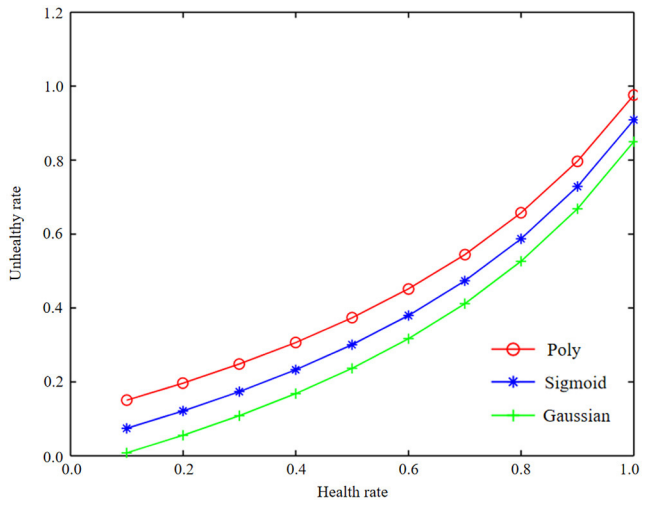

FIGURE 10 | ROC curve performance of three kernel functions under machine learning combined data.

By comparing the modeling results of basic data and combined data, it is found that there is an obvious gap between the modeling results of basic data and combined data. The AUC of the test set of combined data is 83.66%, and that of the test set of basic data is 81.33%. In logistic regression modeling, the AUC of the combined data model is 2.33% higher than that of the basic data, and the accuracy, accuracy, recall F1 values are also greatly improved, indicating that the precision of the model is also improving accordingly. It can be seen from the observation figure that the gap between the AUC results of the training set and the test set is small in the combined data and the basic data, and there is no obvious gap between the accuracy, recall, and F1 value of the training set and the test set of the combined data and the basic data, indicating that there is no overfitting phenomenon in the model.

Using basic data for modeling, the optimal parameters and model evaluation results of different kernel functions are obtained. Get Working characteristic curve (ROC) curves of different kernel function test sets and training sets, as shown in **Figures 5–7**. At the same time, the accuracy, precision, recall rate, F1 value, and AUC value of each model are shown in **Table 5**.

As can be seen from **Figures 5–7**, the test set accuracy of Gaussian kernel function is 74.54%, which is <83.72% of polynomial kernel function, but the recall rate and F1 value of polynomial kernel function are low, indicating that although polynomial kernel function ensures the model precision, the recall rate is low. In addition to the accuracy, other indexes of Gaussian kernel function are the best; especially the AUC of the test set of Gaussian kernel function is 82.57%, which is the largest among all kernel functions. The gap between the training set and the test set of the three SVM kernel functions is small, indicating that there is no fitting phenomenon in the training process. Through comprehensive comparison and analysis, the Gaussian kernel SVM model with C = 1 and gamma = 0.01 is finally selected as the best model for basic data modeling.

Using the combined data to model different kernel functions of SVM, the optimal parameters and model evaluation results of different kernel functions are obtained. The values of accuracy, precision, recall, F1, and AUC are shown in **Table 6**. Meanwhile, ROC curves of different kernel functions are shown in **Figures 8–10**.

As can be seen from **Figures 8–10**, in the machine learning algorithm, the accuracy of Gaussian kernel function is slightly less than polynomial kernel function and Sigmoid kernel function, but other indexes are the best, and the gap between the test set and training set of SVM model of Gaussian kernel function is small, which shows that the model has hardly been fitted. According to the comprehensive comparison of index accuracy, precision, recall rate, F1 value, AUC value, and fitting effect, we finally choose the Gaussian kernel SVM model with C = 1 and gamma = 0.01 as the best model for combined data modeling.

CONCLUSIONS

Children's health level and intellectual development level are the basis of children's other aspects. Although the current products can carry out children's morning examination and daily management of kindergartens, with the development of modern information technology, it is necessary to design a product to integrate children's health examination and intellectual development, as well as learning and entertainment. Based on the training methods of intelligent children's health diagnosis and intelligence development based on machine learning and health information statistics, this paper designs children's intelligent health diagnosis and intelligence development device. The research device of this subject has strong reliability and diversified functions, which is conducive to children's physical health and intelligence development, but there are also places that need to be further studied. Based on machine learning, several basic learners are integrated to train and predict the data, and the prediction effect is usually better than the traditional machine learning model. The method of intelligent infant health diagnosis and man-machine combination for infant disease treatment is proposed. This method recognizes the identity of children through the automatically collected physical condition data and face, uses the child's physical condition data to diagnose the child's health condition based on case-based reasoning, gives the treatment scheme of over-the-counter standing drugs for the sick children according to their severity, and publishes the diagnosis results and treatment suggestions to parents through WeChat platform.

The popularity of mobile gaming has become a common sight in rural areas, and the problem of left-behind children's mobile gaming has become the biggest challenge faced by rural education, and has become a hot topic in the education sector and society. The stage of left-behind children is the golden period of learning and growth. However, this stage is also the period when they have the greatest fluctuations in their ideology due to various factors such as guardians and youths. With the development of big data, it has been applied to various aspects of people's life. This article is mainly based on qualitative research, with the interview and observation as the main methods, supplemented by a questionnaire survey method. In the empirical analysis part, this article has a certain degree of expansion in data selection and research methods. Compared with previous studies, we increased the scale of the research data, making the research results more meaningful. In the research method, the ordinary least squares method (OLS), the propensity score matching method (PSM) and the two-stage least square method (2SLS) are used, and multiple control variables are selected. The factor analysis of the original scores of the historical knowledge test and the original scores of the two-dimensional cultural value evaluation are carried out to obtain the factor scores of cognitive ability. The emotion of the child is expressed by the depression score, and factor analysis is also performed on the depression score. Cognitive abilities refer to reasoning or thinking, processing speeds, and one's ability to solve problems in novel situations, independent of acquired knowledge. OLS regression results show that left-behind children are inferior to non-left-behind ones in cognitive ability. Moreover, left-behind children are more likely to be emotionally depressed. And whether the children are accompanied by migrant or rural parents, there is no significant difference in their cognitive ability and emotions. Because there are unobservable factors that affect whether children are left-behind and children's cognitive abilities and emotions, the sample may have a self-selection bias. This research focuses on the phenomenon of left-behind children's mobile gaming, revealing the compromised cognitive abilities of these marginalized children groups. Our study might put a wake-up for authorities on the education in rural areas.

INTRODUCTION

In recent years, various mobile games have been surging and swept across the country with strong momentum. As of 2019, the number of mobile Internet users in China was 847 million, an increase of 29.84 million from the end of 2018. The proportion of Internet users using mobile phones to access the Internet has increased by 99.1% from 98.6% at the end of 2018 (1). Among the netizens, the students are the most. Among them, the netizens with junior high school, high school/technical school/technical school degrees accounted for 38.1 and 23.8%, respectively; the netizens with college, university, and undergraduate education accounted for 10.5%, respectively. It can be seen that junior high school students use the Internet more often (2). As of June 2019, the number of national online game users reached 494 million, an increase of 9.72 million from the end of 2018, accounting for 57.8% of the total netizens; the number of mobile online game users reached 468 million, an increase of 8.77 million from the end of 2018, accounting for 55.2% of mobile netizens (3). From this point of view, mobile Internet users will play some mobile games to a certain extent, and mobile games are very popular among junior high school students. The survival of marginalized children's mobile gaming has become a common sight in rural areas, and the problem of marginalized children's mobile gaming has become the biggest challenge faced by rural education, and has become a hot topic in the education sector and society (4). Marginalized children incorporate hand-held games into their lives. Hand-held games have become a way of life and another living space for them. In the process of playing hand-held games, they have generated their own culture and civilization, forming a distinctive two-dimensional cultural landscape (5). However, the outside world's understanding of mobile games is still living under moral "panic." Therefore, mobile games have raised various criticisms, ignoring their positive significance and inherent cultural value of mobile games. This research cuts into the phenomenon of mobile games of left-behind children in rural areas from the perspective of the two-dimensional culture, which has theoretical penetrating power and profoundness (6).

The mobile game survival phenomenon of left-behind children in rural areas is a product of the times and a generation that has been "sacrificed" under social structural reforms. At the same time, the phenomenon of marginalized children's mobile game survival is the primary issue that rural education needs to face directly, and requires sufficient attention from the education sector (7). For mobile games, we should get rid of all kinds of prejudices and panic, look at new things with a rational and dialectical perspective, attach importance to their derived cultural functions historical values, understand their inner spiritual needs and respect their cultural choices and the right to play, and what needs to be done is to guide rather than prohibit. The evolution of civilized and restrained hand demonstrations of left-behind children in rural areas requires a multi-faceted effort. Family education and school education are the top priorities, and then changes in the social structure, social environment, and ethos are the most important to solve the root of the problem (8). At the same time, there are data showing that the playtime of left-behind children is significantly higher than that of non-left-behind children: "playing 4–5 hours a day" accounted for 18.8 and 8.8%, respectively, and "playing more than 6 hours a day" accounted for 18.8% respectively (9). Therefore, marginalized children have become the main force among young players. The survival of marginalized children in mobile games has aroused the attention of all parties and the appeal of experts, setting off a wave of "turbulent waves." Under the panic of "playing mobile games is sapping the spirit" the government, experts, society, and distressed parents tried to find various measures, but with little effect (10).

The mobile game survival phenomenon of left-behind children in rural areas has attracted attention from all quarters. However, by searching the literature on mobile games and the two-dimensional culture, it was found that the two overlapped very little. The factor analysis of the historical knowledge level and the two-dimensional cultural value evaluation are carried out to obtain the factor scores of cognitive ability. The emotion of the child is expressed by the depression score, and factor analysis is also performed on the depression score. Therefore, this research analyzes the behavior of the marginalized children's hand march from sociology, and takes an insight into the fetters of the marginalized children and mobile games from the perspective of the two-dimensional culture, explores the deep-level educational sociology of the phenomenon, and at the same time reveals the mobile games. The nature of the phenomenon and the cultural connotation it contains not only provide theoretical results for the research on the phenomenon of left-behind children's mobile games, but also inject blood into the theory of the two-dimensional culture and keep pace with the times. Through the investigation and research on the phenomenon of left-behind children's mobile games, it helps us understand the deep-seated needs and living conditions of left-behind children's mobile game players in the virtual game zone, to better guide the gaming behaviors of left-behind children, and at the same time, to provide a new way out and a new reference for solving the problem of left-behind children's mobile game addiction, and to trigger thinking about rural education and the education of left-behind children.

RELATED WORK

Some scholars' research on the two-dimensional culture and film is basically focused on aesthetics. They believe that two-dimensional culture changes the aesthetic style of domestic films. This change is manifested in: first, the characterization of characters. The characters are set with "cute" as the element and tend to be soft and beautiful. Second, time and space reconstruction. Using virtual reality (VR) technology to create a virtual space-time, this space-time can travel through different eras, and achieve the ideal utopia for human beings. Third, the method of film narration uses ACG elements. Of course, there are also changes in audiovisual language, values, and plot settings. Wang (11) believes that the two-dimensional culture has an impact on the concept, audience change,

and aesthetic aspects of film and television creation. Recent advances in information technologies and data science have enabled convenient access, storage, and analysis of massive on-site measurements, bringing about a new big-data-driven research paradigm (22). With the development of Internet of Things (IoT), 5G, and cloud computing technologies, the amount of data from manufacturing systems has been increasing rapidly (23).

In terms of film aesthetics, Fu and Zhao (12) elaborated on the influence of the two-dimensional culture on the aesthetic tendency of films from three aspects: character image, time and space landscape, and value concept. Next, Li et al. (13) believed that the two-dimensional culture has the effect of reducing the aesthetic cracks in the film aesthetics and enhancing the value of the characters, but at the same time it also has the negative effect of excessive commercial consumption and disintegrating the character archetypes. He believes that the two-dimensional culture has brought unique creation to the film. The method also brings a relaxed, cheerful, vigorous and youthful values that are different from the traditional ones, and establishes a unique aesthetic outlook. Niu et al. (14) inherited the research of predecessors and elaborated on film techniques, film styles and film values, and proposed a kind of aesthetic and healing film aesthetic values. He believed that under the influence of the two-dimensional culture, the narrative method and aesthetics of the film have changed a lot, and the two-dimensional culture is the source of motivation for creating excellent movies to integrate the two and avoid being symbolized and conceptualized as the research focus. Researchers believe that the two-dimensional culture has a negative impact on college students who are self-proclaimed and detached from society. On the basis of questionnaire surveys, they understand their psychological needs, and put forward corresponding countermeasures and opinions from schools, families and themselves (18). Li et al. (15) explained that the "cute" factor in the secondary culture can dispel the "scars" and "cruel" gray tones of traditional youth movies, blend the aesthetics of business, culture, and audiences, and then propose movie narratives which is influenced by the two-dimensional culture. It has a personality and reflects the unique aesthetic style of youth. At the same time, in the pursuit of youth, there is a mentality of escaping from reality and confusion, and a cultural mentality that is both lost and recognized. Regarding the two-dimensional culture to promote the development of movies, Liu and Zhou (16) proposed that according to the characteristics of the two-dimensional culture, it should pay attention to learning from and absorbing its outstanding characteristics, and on this basis, form its own unique style to promote the creation and development of film and television.

In terms of countermeasures to reduce the impact of the two-dimensional culture on students, Yue et al. (17) believes that the two-dimensional virtual culture has unique characteristics, attracting a wide range of young people to join, and also leading to the emergence of primary school students' "Internet addiction": improving laws and strengthen supervision; parents strengthen education, supervision and care for their children; schools strengthen quality education and enrich after-school

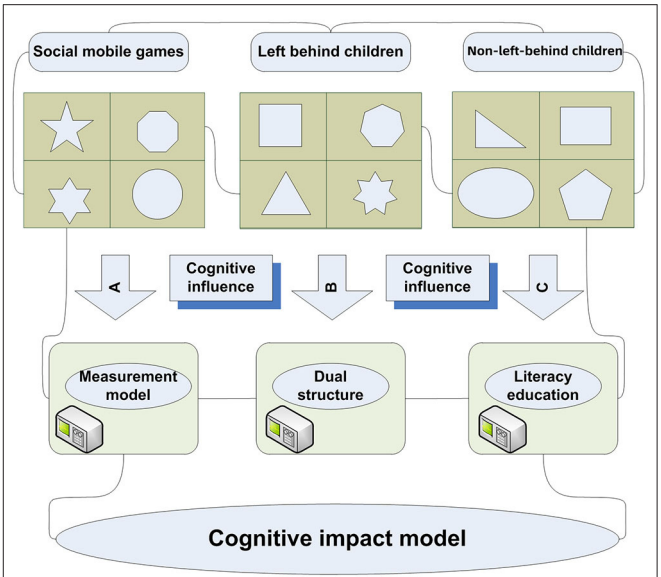

FIGURE 1 | Schematic diagram of the cognitive measurement model of left-behind children.

life; providing a good growth environment. The research is more specific-self-awareness. It is proposed that the different types of secondary culture and the length of contact time have different effects on the development of self-awareness of junior high school students. The corresponding countermeasures are presented: updating concepts and improving media literacy awareness; secondary media self-discipline, ingenious two-dimensional resources; forming educational synergy to promote media literacy education; giving full play to the main role of junior high school students to improve students' self-awareness level (19, 20). In terms of information dissemination, some scholars have their own unique opinions. They believe that under the influence of the two-dimensional culture, the information they choose is to blur the boundaries of countries, ethnicities and regions, but at the same time they have a strong patriotic sentiment and pay attention to national current affairs. However, they remain skeptical of the official information, and hope that the Internet will answer this. Moreover, they remain calm about the information and do not blindly follow the trend, but they pay more attention to their own interests (21).

CONSTRUCTION OF A MODEL OF THE COGNITIVE IMPACT OF SOCIAL MOBILE GAMES ON LEFT-BEHIND CHILDREN

Cognitive Levels of Left-Behind Children

After several developments, the original connotation is no longer there, but the group of left-behind children has received more and more attention. Left-behind children are the product of the urban-rural dual structure. They are both disadvantaged groups and "marginal people." Their educational problems and

generation methods touch the nerves of society and are difficult to ignore. **Figure 1** shows a schematic diagram of the cognitive measurement model for left-behind children.

The first measurement model used in this article is ordinary least square (OLS). Ordinary least squares estimation is to find the estimated values of the parameters, so that the sum of squared deviations of the below formula can be minimized. In the formula, the weight of each square term is the same, which is the parameter estimation method of ordinary least squares regression.

$$X = \{x(t) \in R | t = 1, 2, 3, .., T\} \tag{1}$$

The explanatory variable is a definite variable, not a random variable; the random error term has zero mean, same variance, the random error term is not correlated with the explanatory variable; the random error term obeys zero mean, same variance, and zero covariance normally distributed, ordinary least squares estimation is a linear unbiased estimation of the minimum variance of the regression parameters.

$$p(X|t) = \sum_{t} p(X|z, t)p(t|x) \tag{2}$$

Among them, y is the explained variable, including children's cognition and depression (emotion), children is the attention variable, which represents the type of child. Taking the non-left behind children as the benchmark group, we construct left-behind children relative to non-left behind and migrant children relative to each other. As a binaryz duzmmy variable for non-left behind children, X is the control variable, including the child's gender, child's age, education investment in the child in the past year, mother's childbearing age, father's childbearing age, mother's years of education, and father's years of education and per capita net income of the household last year, it is a random interference term.

$$p(C|X) = \prod_{s}^{T} p(c(s)|c(1), c(2), ..., c(s-1), X) \tag{3}$$

In order to control the self-selection problem, this paper introduces a propensity score matching model. The basic idea is to find similar individuals in the treatment group (left-behind children/migrated children) in the control group (non-left behind children). The probability of these individuals becoming left-behind children/migrated children is similar and comparable, and can be matched and estimated.

$$t = \ln sig(\overline{s(x)} - s(\bar{x})) = \frac{1}{1 + \exp(\overline{s(x)} - s(\bar{x}))} \tag{4}$$

Specifically, the binary treatment variable divides the children in the sample into two groups. For the child individual i ($i = 1, 2, \ldots, N$), it means that the child is a non-left behind child/migrated child (treatment group), it means that the child is a non-left behind child (control group). There are two potential outcome variables, $x(0)$ and $x(1)$. As shown in formula, the average processing effect of left-behind children/migrating children interested in this article on cognitive level and emotion is:

TABLE 1 | Cognitive level distribution table of left-behind children.

Group index	Historical knowledge	Two-dimensional cultural value evaluation	Overall Cognitive ability score	Depressive emotion score
1	0.261	0.433	0.058	0.228
2	0.441	0.667	0.095	0.366
3	0.221	0.352	0.048	0.178
4	0.132	0.423	0.065	0.281

$$x(t) = \begin{cases} t, 0 < t < 1 \\ a * s(t) + (1 - a) * s(t - 1), t > 1 \end{cases} \tag{5}$$

Among them, $E[Y(1)|D(i) = 1]$ is the counterfactual mean value that cannot be obtained from the observable information. Generally, $E[Y(1)|D(i) = 0]$ can be used instead, but this method will cause self-selection bias due to factors that affect the type of children and also affect cognitive ability and emotion. The idea of propensity matching score can solve this selective bias.

$$y(x) - (a(0) + a(1) * c(t) + a(2) * x(t)) = 0 \tag{6}$$

The propensity matching score needs to meet two conditions. The first hypothesis is the conditional independence hypothesis. The content of this hypothesis is that given a series of control variables, the value of the result variable $Y(i)$ is independent of the binary processing variable $D(i)$. The second hypothesis is the common support, that is, the value ranges of individual propensity scores of children with the characteristics of the control variables overlap. If the assumptions are meet, such as the formula, the average processing effect of left-behind children/migrated children on cognitive level and emotion is:

$$A(X) = E[Y(1)|D(i) = 1] - E[Y(0)|D(i) = 1] \tag{7}$$

Since whether a child is a left-behind child or a migrant child is affected by the choice of parents who go out to work, at the same time, whether the parents go out to work will also affect the child's cognition and emotion, the ordinary least squares method has endogenousness. **Table 1** shows the cognitive level distribution table of left-behind children. Therefore, this paper introduces the child type instrumental variable—the proportion of the labor force in the village who go out to work in the total labor force, and uses the two-stage least squares method (2SLS) to solve the endogenous problem of the model.

TABLE 2 | Analysis of operating elements of social mobile games.

Variable item	Constant term	Sample size	*R*-squared
A	1.793	2,355	0.343

E	3.061	2,615	0.281

Operating Elements of Social Mobile Games

A narrowly defined mobile game refers to a form of the game that can only be run on mobile phones. In a broad sense, mobile games refer to a form of games that can be run on mobile phones and various devices. With mobile phones as the carrier, it is mobile, so it is also called mobile games. With the popularity of mobile phones and the Internet, mobile games have become more popular than ever. There are many types of mobile games and various fancy styles, but Multiplayer Online Battle Arena (MOBA) mobile games are strong and popular among gamers. Among them, "Honor of Kings" is a milestone in MOBA mobile games, pushing MOBA mobile games to a climax. MOBA, also known as a tactical competitive game, is based on strategy and teamwork, emphasizing competition and cooperation. "Honor of Kings" combines role-playing, battlefield kills, intellectual victory, teamwork, and social attributes into one. It not only meets the needs of players for "happy enmity" and a vivid battlefield, but also meets friends and emotions of the need for communication. **Table 2** shows the analysis of operating elements of social mobile games.

In people's communication activities, meaningful gestures have begun to work. Significant gestures related to the use of symbols always presuppose that everyone involved in communication activities has the ability to imagine their actions from the standpoint of others and to play the role of another. In symbol communication, people interpret each other's attitudes and actions based on the meaning produced by the interpretation of symbols. The process of human communication involves actors constantly making self-conscious adjustments to the actions of others, that is, repeatedly adapting to each other's actions through definition and redefinition, interpretation and reinterpretation. The application of symbolic interaction theory in this research is embodied in two aspects. On the one hand, the interaction between left-behind children in rural areas and groups in the life world is affected by symbolic interaction theory, including both peer groups and their guardians; on the other hand, the interaction between children and the group in the network virtual space is influenced by the theory of symbolic interaction, and the group mainly includes managers and other game players. When a teammate shows contempt for the equipment of left-behind children in the countryside, they tend to spend more money to buy the equipment. When other players pursue a certain hero, the marginalized children will make the same approach as other game players, and tend to choose the hero.

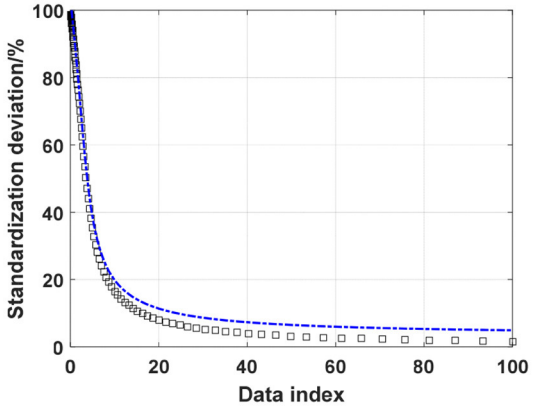

FIGURE 2 | The distribution of the standardized deviation curve of the cognitive impact model.

Cognitive Impact Model Optimization

The mobile game market has become popular recently, which has brought huge economic benefits and also caused a certain negative impact. Among them, marginalized children, as a vulnerable group, are deeply affected when they come into contact with this mobile game. Therefore, this article first defines related concepts such as "left-behind children in rural areas" and "cognition." The research object is identified as left-behind children in rural areas. Through in-depth interviews with them, we can understand their views on mobile games and their attitudes toward the historical figures in the design. In order to dig out the impact of mobile games on the cognition of left-behind children in rural areas, we further analyze the reasons for this impact, and propose practical and feasible measures to resolve the negative impact. Secondly, we carry out relevant literature collection and draw on the research of related scholars on games and marginalized children. In the model estimation of the left-behind children, the standardized deviations after the control variables were matched were all reduced to $<10\%$ except for the quadratic term of the father's age, and the t-test results were not significant, that is, the model estimation of the left-behind children satisfies propensity matching to score the assumption that the control variables of the treatment group and the control group are balanced. **Figure 2** shows the distribution of the standardized deviation curve of the cognitive impact model. In the model estimation of left-behind children, the standard deviation of most control variables after matching fell below 10%. Although the per capita net income of the family is above 10%, it has dropped a lot from the 24.3% before matching. We satisfy the assumption that the control variables of the propensity matching score treatment group and the control group are balanced.

This article mainly adopts qualitative research methods, including the interview method, and observation method. We read a large number of literature materials, based on previous

studies, through induction, comparison, analysis and other steps, to understand the current academic research on the impact of mobile games on marginalized children's cognition abilities, and put forward our research direction, and refer to relevant research results in a targeted manner. It is a face-to-face purposeful conversation between the researcher and the researchee. According to whether the interview is structured or not, it is divided into structured interviews, semi-structured interviews and unstructured interviews. This study mainly adopted a semi-structured interview method, and mainly selected six marginalized children as interview subjects. During the survey process, as participants, we carefully observe the emotional expression of marginalized children during interviews, and observe the family environment of the left-behind children in rural areas to understand the family's educational atmosphere, and observe their verbal expressions when answering questions to prove the authenticity of the answers.

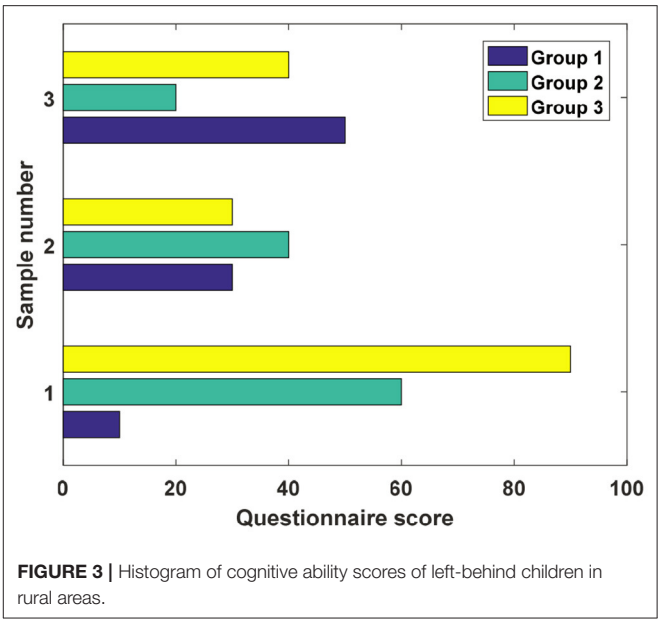

FIGURE 3 | Histogram of cognitive ability scores of left-behind children in rural areas.

APPLICATION AND ANALYSIS OF THE MODEL OF SOCIAL MOBILE GAMES' COGNITIVE IMPACT ON LEFT-BEHIND CHILDREN

Cognitive Analysis of Left-Behind Children in Rural Areas

According to the research objectives, this article mainly focuses on the development of questionnaires for left-behind children in rural areas. Distributed 466 questionnaires for students, 349 for left-behind children, 117 for non-left-behind children, excluding 8 doodles and incomplete questionnaires, and 115 valid questionnaires for non-left behind children were recovered. The recovery rate was 98.2%. There were 343 left-behind children, and the recovery rate was 98.3%. It also conducts a scientific and systematic analysis of the statistical data, provides a factual basis for the education status of left-behind children in rural areas in the region, and provides microdata support for the study. This article mainly compiles the questionnaire from the basic structure of the family of left-behind children and non-left behind children, the strength of family nurturing functions, and the children's performance in historical knowledge level and two-dimentional cultural value evaluation. The basic structure of the child's family includes who the guardian is at home, the education level of the guardian. Whether it is an only child, the parenting function of the family includes the care and supervision of guardians and parents of migrant workers in their children's historical knowledge level and two-dimensional cultural value evaluation, which includes the level of knowledge about historical figures and stories (such as narrative, ancient poetry, extracurricular reading, etc.), as well as attitudes and evaluations related to two-dimensional culture. **Figure 3** shows the histogram of the cognitive assessment scores of left-behind children in rural areas.

It can be seen that about 86.1% of left-behind children are taken care of by their grandparents (grandparents or grandparents), about 8.7% of left-behind children are taken care of by uncles and uncles (or relatives), and left-behind children living alone account for 5.2% of the total number of left-behind children. After controlling for the endogenity of the model, the type of child has no substantial effect the performance in historical knowledge level. The significant effect in the OLS model is due to the inclusion of other uncontrolled unobservable factors. The gender of children has no significant effect on their original scores on the performance in historical knowledge level, but for every year the children's age increases, their original scores on historical knowledge test increase by 1.447 on average, and this result is significant at the 1% level. **Table 3** shows the standardized deviation distribution of the control variables before and after model matching.

There is no significant impact on children's educational investment, mother's childbearing age, mother's childbearing age square item, father's childbearing age square item, mother's years of education, and children's performance in historical knowledge level test raw scores. The original score on the historical knowledge test was reduced by 0.275, and this result was significant at the 10% level. For every additional year of the father's education years, the original score on the children's historical knowledge level test increases by an average of 0.195, and this result is significant at the 1% significance level. Household net income per capita has no significant effect on the raw scores of children's historical knowledge test.

Evaluation of Social Mobile Games in the Rural Economy

Because of regional differences and informants are affected by some objective conditions, the subjects of the interview program are only students in 11 classes from the second to sixth grade of elementary school, of which there are two classes in each of the second, third, fourth, and fifth grades, 51 informants were obtained by purposeful sampling. The number of each class are:

TABLE 3 | Standardized deviation distribution of control variables before and after model matching.

Attributes number	Group A		Group B	
	Before matching	After matching	Before matching	After matching
Age	9.5	5.8	2.4	1.7
Gender	4.8	7.2	5.9	6.7
Educational investment	12.2	11.2	2.9	3.6
Net income per capita	5.6	7.4	11.6	9.2

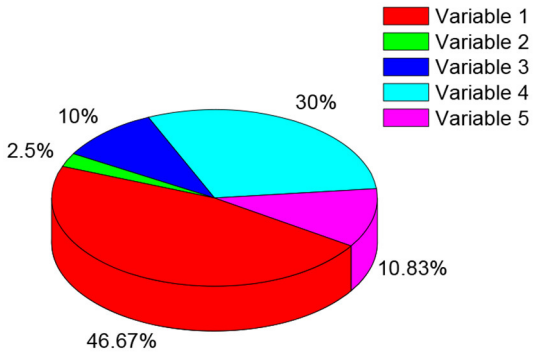

FIGURE 4 | Cognitive abilities distribution of left-behind children among the explained variables.

44 in class 2 (1) and 11 left-behind children; 47 in class 2 (2) and 12 left-behind children; 41 in class 3 (1) and 8 left-behind children; class 4 (1) with 46 people, 10 left-behind children; class 4 (2) with 45 people, 14 left-behind children. There are 42 students in the class and 12 left-behind children. There are three classes in grade six, each with 40 students in class six (1) and nine left-behind children; 39 students in class six (2) and 10 left-behind children; 40 students in class six (3) and 13 left-behind children.

Figure 4 shows the cognitive fan distribution of left-behind children among the explained variables. The child's cognition in the explained variable uses a set of two-dimensional culture value questions and a set of historical questions to test and evaluate the cognitive level of all respondents who need to complete the self-answer questionnaire (that is, children aged from 10–15 years old). The factor analysis of the original scores of the historical test and the original scores of the two-dimensional cultural evaluation test is carried out to obtain the factor scores of cognitive ability. This article's measurement of children's emotions (depression) combines six related questions in the questionnaire: "How often did you feel depressed, and unable to do anything when you played "Honor of Kings"? How often did you feel nervous when you played "Honor of Kings"? How often did you feel restless and difficult to stay calm when you played "Honor of Kings"? How often did you feel hopeless in the future when you played "Honor of Kings"? How often did you find it difficult to do anything when you played "Honor of Kings"? When you played "Honor of Kings", do you think life is meaningless?" According to their own circumstances, the interviewees chose the answer that best suits them among the answers: "never, sometimes, half the time, often, almost every time." For answering option: "never = 1 point; sometimes = 2 points; half the time = 3 points; often = 4 points; almost every time = 5 points". This article uses two measurement methods. The first is to add the answers to the six questions to the depression score, and the second is to perform factor analysis on the answers to the six questions to obtain the factor score of depression.

Example Application and Analysis

It can be seen that the average original score of the historical knowledge test for the full sample is 10.51 points, that is, 10.51 of the 24 questions for non-left children with registered permanent residence are answered correctly, but the standard deviation is 4.53, and the fluctuation is large. A total of 34 test questions were designed for the two-dimensional cultural value evaluation. On average, 20.81 questions were answered correctly by non-left children, but the standard deviation was 7.51, and the scores between children were quite different. The children's total scores for the 6 emotional questions answered were 26.99 points. The overall children interviewed had a more positive emotional state. **Figure 5** shows a line graph of cognitive ability factor and scores depression factor scores for different data points. Cognitive ability factor scores and depression factor scores are derived from factor analysis, and the mean value is 0, and the variance is both 1.

Among the interviewed children, non-left children, left-behind children, and migrant children accounted for 31, 49, and 20%, respectively. The proportion of non-left children was very high, and the proportion of left-behind children was the lowest. Among the interviewed children, boys accounted for 53% and girls accounted for 47%. There were slightly more boys than girls, all aged from 10–15 years old. The average education investment per child is 1,600 yuan per year, and the average education investment is at a relatively low level, and the standard deviation is 2.65, which is quite fluctuating. The average childbearing age of the interviewed mother is 26.34 years old, and the father is 28.03 years old. The average childbearing age of fathers is slightly higher than that of mothers. The average childbearing age is within the normal range, but the minimum childbearing age of the interviewed mothers is 20 years old and the youngest father is 22 years old. Similarly, some villagers do not have a scientific

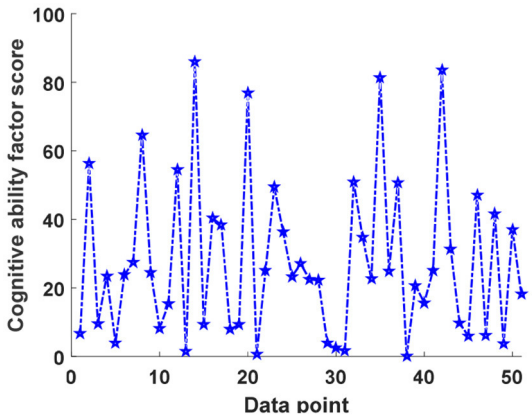

FIGURE 5 | Line chart of cognitive ability factor scores and depression factor scores for different data points. The *symbol indicates the child who takes the cognitive ability test. Y-axis indicates score. There are 51 children in the test.

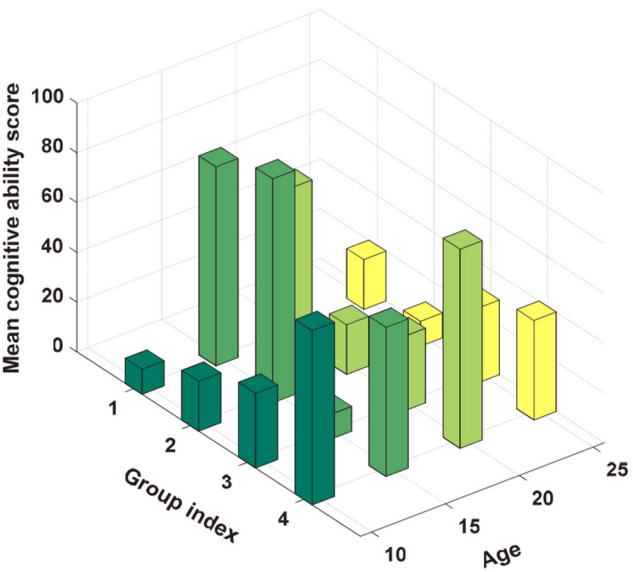

FIGURE 6 | A three-dimensional histogram of the average cognitive ability scores and depression factor scores of left-behind children in different age groups.

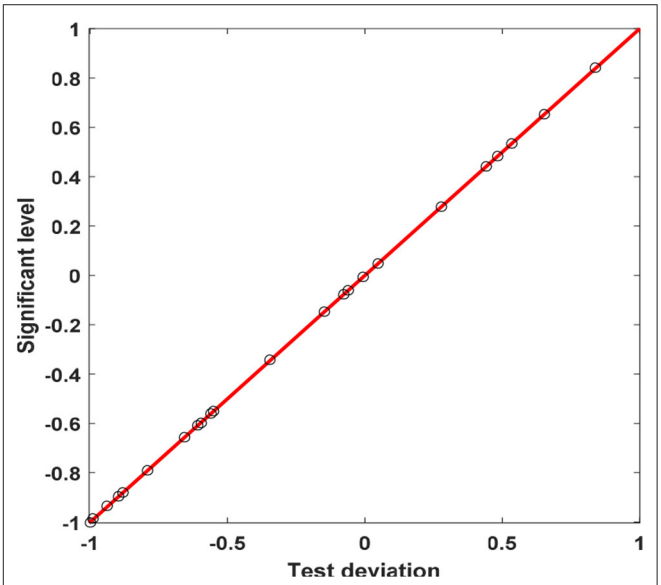

FIGURE 7 | Significance level distribution of cognitive ability test of left-behind children.

understanding of the issue of childbearing age. The mother's average education years is 8.22 years, and the father's 9.82 years. The parents' educational level is relatively low, and the grandparents' education years are at least 1 year, which is basically equivalent to ignorance. This will definitely have a negative impact on the children's cognition. Parents with low educational level generally get married and have children earlier. The average per capita net income of households is 6,350 yuan, which is much lower than the urban per capita income level, indicating that the national urban-rural income gap is still not optimistic. The standard deviation is 5.97, indicating that the per capita net income of the interviewed households is also very different.

The average proportion of the labor force working outside the village is 33.48%. There is a large gap in the proportion of the labor force going out in different regions. This is directly related to the imbalance in national economic development. It is also mentioned in the analysis of the current situation of children that the economically backward central and western regions have a relatively high proportion of migrant workers, while the economically developed eastern regions are much lower. Left-behind children are also mainly concentrated in the central and western regions, and in the economically developed regions. **Figure 6** shows a three-dimensional histogram of the average cognitive ability scores of left-behind children in different age groups. The average depression scores of non-left behind children, left-behind children, and migrant children were 77.11, 86.37, and 66.96, respectively. From descriptive statistics, it can be seen that non-left behind children rarely have depression, followed by children with migration. Left-behind children are most likely to have depression emotions. The depression score is the direct sum of the interviewed children's scores for answering six questions, and the depression factor score is a factor analysis, which is equivalent to standardizing the interviewed children's depression scores, which can be seen from descriptive statistics. The scores of depression factors of left behind children are the highest, and non-left behind children are the lowest.

Figure 7 shows the distribution of the significance level of the cognitive ability test for left-behind children. On the premise that other conditions remain unchanged, the average original score of left-behind children in the two-dimensional cultural value test is 0.585 lower than that of non-left children, but this result is not statistically significant. On average, the original scores

of male children's two-dimensional cultural value evaluation tests are 1.308 lower than female children, and this result is significant at the 5% level. However, gender has no significant effect on the original scores of two-dimensional cultural value test. Every time the child's age increases by 1 year, the original score of the two-dimensional cultural value test will increase by 1.435 on average, and this result is significant at the 1% significance level. For every additional 1,000 yuan invested in children's education, their original two-dimensional cultural evaluation scores increase by 0.195 on average, and this result is significant at the 5% level of significance. For every additional year of mother's years of education, the original score of the children's two-dimensional cultural value test increases by an average of 0.177, and this result is significant at the 5% level. For every year of father's education, the average increase of the original score of the children's two-dimensional cultural value test is 0.458, and this result is significant at the 1% significance level, because fathers generally pay more attention to children's learning. For every 1,000 yuan increase in family net income per capita, the original score of children's two-dimensional cultural value test increases by 0.032 on average, but this result is not statistically significant.

CONCLUSION

The stage of left-behind children is the golden period of learning and growth. However, this stage is also the period when they have the greatest fluctuations in their ideology due to various factors such as guardians and youths. The popularity of mobile gaming has become a common sight in rural areas, and the problem of marginalized children's mobile gaming has become the biggest challenge faced by rural education, and has become a hot topic in the education sector and society. This research focuses on the impact of mobile games on the cognition of left-behind children in rural areas, the reasons for the impact, and suggestions on how to solve the negative impact. Through research, it is found that mobile games have two main influences on the cognition of left-behind children in rural areas: first, the positive impact is conducive to expanding the knowledge reserves of historical figures and two-dimensional culture of left-behind children in rural areas, and is conducive to promoting these marginalized groups in learning and interpreting those knowledge. Secondly, the negative impact is in the microfocus, dispelling the right image of traditional historical or two-dimensional culture figures, is not conducive to the formation of a clear knowledge construction; in the macro structure, it is not conducive to the formation of a correct view of history or two-dimensional values for left-behind children in rural areas. Because unobservable factors affect the types of children and a series of dependent variables in this article, this paper selects instrumental variables to conduct empirical analysis again. However, there are still limitations in this study. This experiment uses the achievements related to historical knowledge level and two-dimensional culture evaluation of left-behind children as a reference, but the reliability as a single factor needs to be studied. In the future, multiple factors should be used for analysis at the same time. The results of instrumental variable regression of all groups indicate that whether staying or not staying in rural area, children accompanied by parents have no significant difference on their cognitive abilities and emotions. And furthermore, the left-behind children suffered significant impact on their cognitive abilities and emotions, compared with the non-left behind ones. This article adopts the method of horizontal comparison and vertical comparison. Horizontal comparison is to compare the various learning behaviors and academic performance of left-behind children and non-left-behind children in the process of cognitive abilities. Longitudinal comparison is to compare left-behind children within themselves, so as to find out the differences among left-behind children among the problems of left-behind children, so as to adopt different suggestions and policies for different left-behind children when making suggestions and countermeasures.

Brain development and atrophy accompany people's life. Brain development diseases, such as autism and Alzheimer's disease, affect a large part of the population. Analyzing brain development is very important in public healthcare, and image registration is essential in medical brain image analysis. Many previous studies investigate registration accuracy by the "ground truth" dataset, marker-based similarity calculation, and expert check to find the best registration algorithms. But the evaluation of image registration technology only at the accuracy level is not comprehensive. Here, we compare the performance of three publicly available registration techniques in brain magnetic resonance imaging (MRI) analysis based on some key features widely used in previous MRI studies for classification and detection tasks. According to the analysis results, SPM12 has a stable speed and success rate, and it always works as a guiding tool for newcomers to medical image analysis. It can preserve maximum contrast information, which will facilitate studies such as tumor diagnosis. FSL is a mature and widely applicable toolkit for users, with a relatively stable success rate and good performance. It has complete functions and its function-based integrated toolbox can meet the requirements of different researchers. AFNI is a flexible and complex tool that is more suitable for professional researchers. It retains most details in medical image analysis, which makes it useful in fine-grained analysis such as volume estimation. Our study provides a new idea for comparing registration tools, where tool selection strategy mainly depends on the research task in which the selected tool can leverage its unique advantages.

INTRODUCTION

Image registration plays an essential role in image fusion, pattern recognition, and voxel-wise group analysis. Establishing correspondences across brains for comparison and group analysis is almost universally done by registering images to one another directly or *via* a template. Image registration is generally categorized into two groups, rigid and non-rigid registration. Rigid registration only consists of rotation and translation (1). Non-rigid registration is more complex and would take deformation methods, such as affine transformation and spline transform. There are a large number of optimized non-rigid registration algorithms and available registration tools, including

advanced normalization tools (ANTS), analysis of functional neuroimages (AFNI), automated image registration (AIR), Drop, FMRIB's software library (FSL), and statistical parametric mapping (SPM). Thus, a comprehensive evaluation of different registration methods has become a research topic of interest. It is the basis for users to choose the most suitable methods for the specific research problem and for algorithm developers to be better informed theoretically (2). However, it is hard to assess image registration algorithms under different research contexts accurately. According to literature and survey, the main obstacles to building a unified evaluation standard of registration algorithm are as follows:

(1) No ground truth results are supplied in practice. In reality, the registration results are mainly assessed by an experienced expert. The lack of golden truth makes the evaluation research less convincing in terms of data. Also, it is hard to be flexible and straightforward to evaluate the performance of registration methods in a complex reality.
(2) Various parameter configurations for registration algorithms may lead to registered images of different quality. Experienced investigators can set appropriate parameters based on images' information. For the same input image, the difference in parameter setting would cause different registered outcomes (3).
(3) The same image data may be processed with different registration techniques to complete various tasks. Therefore, the data sets should be classified first and then preprocessed by other data registration methods according to different data characteristics.
(4) Data quality and raw data quality substantially impact registration results, which means that the data received by the registration program are quite different. The same algorithm may make a profound difference in the registration outcome when dealing with data with a significant quality difference.

Some researchers have done relevant research about the evaluation and comparison of registration algorithms to investigate this topic. Hellier et al. compared five different fully automated non-linear brain image registration software programs using the quantitative measures (4–6). Klein et al. evaluated 14 non-linear deformation algorithms applied to human brain MRI registration on four datasets and ranked these algorithms (7). Rajagopalan and Pioro investigated disparate voxel-based morphometry (VBM) results between SPM and FSL software in patients with ALS to determine which tool has the best performance of VBM in the ALS disease setting (8). Most recently, Dadar et al. compared publicly available linear MRI stereotaxic registration techniques by viewing the registered images by an expert rater to assess the quality of the registrations (9). At the same time, Viergever et al. made a retrospective view on the past two decades of medical image registration. They mentioned that "validation of registration methods and translation of image registration research results to the clinical practice still is the highlighted research and be more urgent than two decades ago (10)." Meanwhile, Rohlfing provides experimental evidence that registration accuracy measures such as tissue label overlap scores, image similarity, image difference, or transformation inverse consistency error, even when used in combination, cannot distinguish accurate from inaccurate registrations (11). Some previous accuracy standards are no more extended evaluation standards. Simulated data and a database with expert landmark annotations have been employed for comparison in the last decade to measure accuracy.

The registration of brain MRI with common templates is a long-standing problem. Different individuals' brain shapes and cortical topology are very different, especially in diseases affecting brain morphology and structure, such as brain atrophy. Previous researches mainly focus on registration accuracies, such as overlap, volume similarity, and registration error. However, the choice of registration technology has a more significant impact on image registration results. Few studies have used different registration tools to process image features. This means that the existing studies on the selection of image registration technology are insufficient. The image registration methods used in many studies are not standardized, and the accuracy level after registration is unknown and difficult to be quantified. Such problems will significantly affect the results of follow-up research. Therefore, the evaluation of image registration technology only at the accuracy level is not comprehensive. When facing different image processing projects, researchers need a flexible selection scheme to help them select the appropriate registration technology according to data sets' characteristics and personalized needs. Here, we investigate the performance of three publicly registration tools in two typical different disease cases, aiming to find a suitable registration tool for different disease types and research focus. Our research uses ABIDE and TCGA date sets to conduct experiments and deeply compares the registration performance of FSL, SPM12, and AFNI. In addition, we compare the three mainstream image registration technologies in terms of user experience and recommend them to different groups.

Our research investigates the registered results in two disease types, autism spectrum disorder (ASD), and glioma. Glioma may cause deformation in the morphology of the brain, and physicians can use high-resolution structural MRI images to detect the focus of infection and glioma grades. By contrast, ASD is connected with brain function and emotion and is often a pervasive developmental disorder. The pathogenesis of ASD is related to heredity, so the patient would have ASD at a very young age. The structural MRI and functional MRI images can be used to diagnose ASD in the clinic. We collect the MRI image data from public databases to construct our disease dataset. We do not intend to evaluate accuracy and error by manual labeling and check which are not available in reality. We plan to compare the features and characteristics of different tools' results because registration techniques are designed for follow-up analysis and application. We focus on the difference in registered results under various analyses, such as texture and edge-gradient features, voxel-based morphometry, and the impacts of this inter-method discrepancy on prediction and detection. From the application's perspective, we investigate the difference between three mature and powerful software to provide instructions for

TABLE 1 | Dataset information.

different researchers to select a suitable tool and more quickly get better achievements.

The structure of our study is as follows: in Materials and Methods, we describe the data acquisition and registration tools, then the strategy for data processing, and the ABIDE II and TCGA-LGG data set used to assess different registration tools. We focus on the difference in registered results under various analyses, such as texture and edge-gradient features, voxel-based morphometry, and the impacts of these inter-method discrepancies on prediction and detection. As a result, we instruct different researchers to select a suitable tool and more quickly get better achievements by investigating the difference between three mature and powerful software. Finally, in the discussion, we summarize the current work, emphasize the importance of selecting appropriate registration methods, and discuss the limitations and future improvement ideas.

MATERIALS AND METHODS

Data Acquisition and Quality Control

This section introduces the basic information of ABIDE II-ETH and TCGA-LGG. **Table 1** presents the basic information of the database.

(1) ABIDE II-ETH. Autism Brain Imaging Data Exchange II was established to further promote discovery science on the brain connectome in ASD (12). It is a multi-center and multi-scanner study involving 19 sites, ten charter institutions and seven new members, overall donating 1,114 datasets from 521 individuals with ASD and 593 controls (age range: 5–64 years). We select the ETH dataset to finish our research. There are 37 samples in the ETH set (age range 14–31 years), 13 for ASD and 24 for typical control (TC). Then, we manually check the ETH dataset to discard the bad quality image with serious artifacts.

(2) TCGA-LGG. The Cancer Genome Atlas Low-Grade Glioma (TCGA-LGG) data collection is part of a more significant effort to build a research community focused on connecting cancer phenotypes to genotypes by providing clinical images matched to subjects from The Cancer Genome Atlas (TCGA) (13). It contains CT and MRI data collected from 199 patients, and the number of studies in TCGA-LGG is 224. To gain the low-level glioma data with the same scan sequence and quality similar to the autism data set, we manually select a small part of the subject containing T2-w and T2-Flair sequence MRI data to finish our research.

Registration Tools

SPM12

The SPM has several versions, and the latest is the SPM12 (14, 15). SPM12 is designed to work with MATLAB to run on Windows systems, while other similar tools are always supported by Linux or Mac and are easy to install. If someone is new to imaging, SPM12 is a recommended choice because plenty of tutorials give practical instructions on how to implement the various methodologies.

The spatial normalization method in SPM12 is a unified model based on a probabilistic approach. It combines the functions of image registration, tissue classification, and bias correction in the same generative model. The model is based on a Gaussian mixture and is extended to incorporate a smooth intensity variation and non-linear registration with tissue probability maps (15).

FSL

FSL is a software package developed by the Oxford Center for Functional MRI of the Brain (Oxford University), composed of image analysis and statistical tools for neuroimage data study. Flirt or Fnirt performed image registration in FSL. Flirt uses a multi-start, multiresolution global optimization method (16, 17), tailored explicitly for volumetric registration of brain images to give a reliable estimate of the worldwide minimum given some time restriction. The optimization algorithm uses four resolution levels: $n = 8, 4, 2, 1$ mm. Initially, the procedure starts with a large-scale search at 8 mm resolution (e.g., applying a set of initial rotations). Following this, various local optimizations are performed with multiple starting points in the local neighborhood of the best issues identified in the search. Then a series of multi-start local optimizations at 4 mm resolution is completed.

AFNI

AFNI is a leading software suite of C, Python, R programs, and shell scripts primarily developed to analyze and display anatomical and functional MRI (fMRI) data (18). The software is made to run on virtually a Unix system with X11 and Motif displays and is a widely used tool for image preprocessing. There are plenty of functions to perform registration, e.g., @auto_tlrc, 3dWarp, 3dWarpDrive, 3dAllineate, @toMNI_Awarp, @toMNI_Qwarp. The common function for registration is @auto_tlrc. This function is run by default parameters. Here, we use @auto_tlrc to execute registration (19).

Data Processing

We download data from the website and also check the quality and image label. After eliminating unqualified data, there are 33 for autism data sets (ASD + TC) and 45 for glioma data sets (glioma + TC) as a study data source. It is learned from **Table 2** that the available data formats for each tool are not entirely the same. Firstly, we convert images of DICOM format

TABLE 2 | Format requirements.

Public tools data format	DICOM	ANALYZE	NIFTI_PAIR	NIfTI-1	NIFTI_GZ	HEAD/BRIK	MINC	CTF	ASCII
SPM	√	√	√	√					
FSL		√	√	√	√				
AFNI	√	√	√	√	√	√	√	√	√

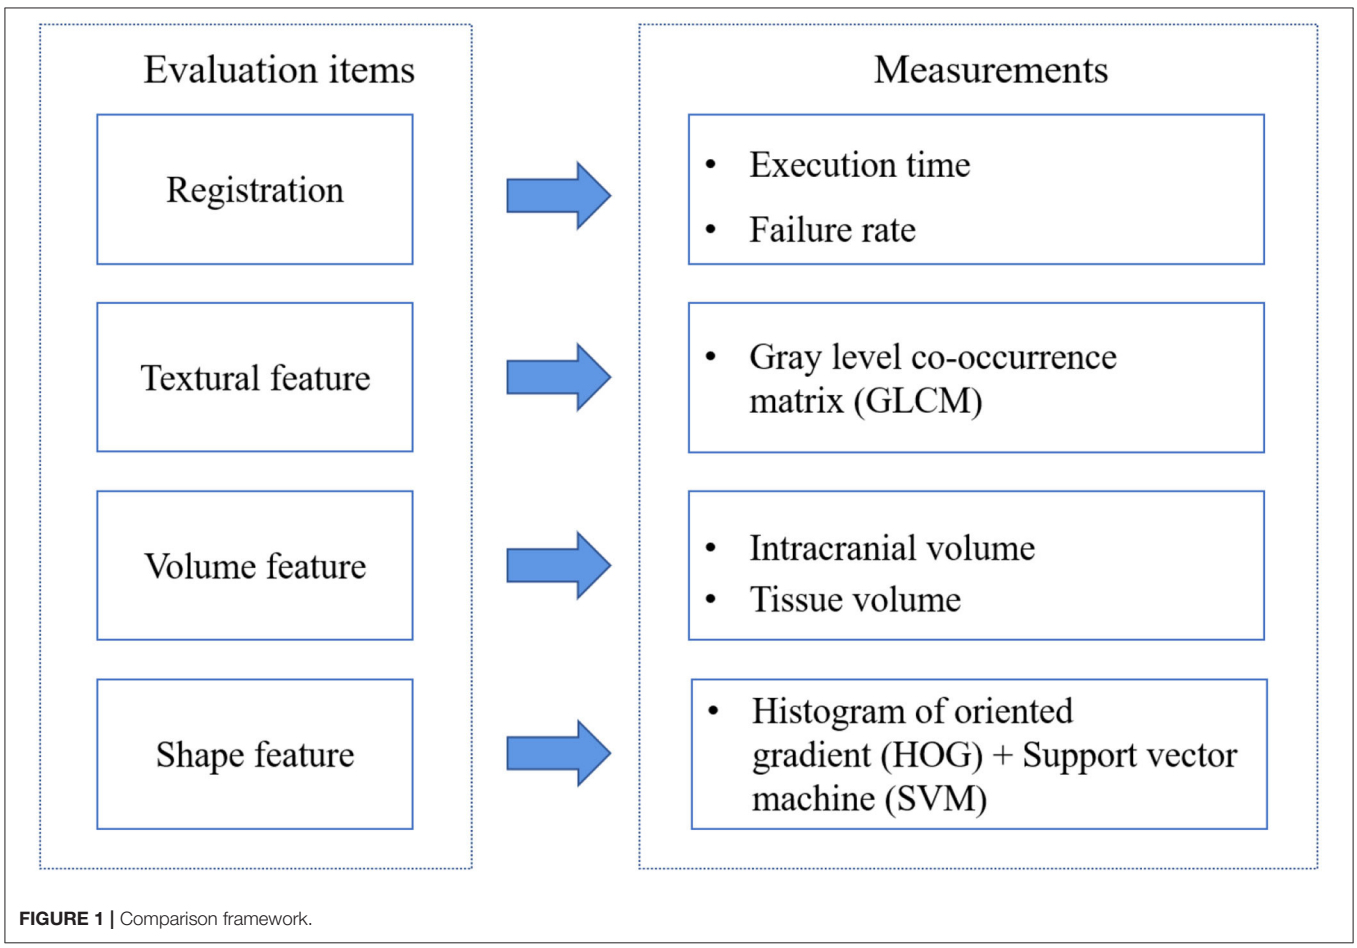

FIGURE 1 | Comparison framework.

into NIFTI-1 format. NIFTI-1 format is also the most commonly used international MRI format.

To explore the features difference among the three tools registered results, we construct the comparison framework shown in **Figure 1**. After organizing the dataset, we execute the registration step by AFNI, SPM, and FSL. T1-w and T2-FLAIR images were all registered to the standard space. SPM12 operations are finished on MATLAB R2012a. FSL and AFNI are installed and run in Ubuntu14 on a virtual machine.

There are three primary features for images: color, texture, and shape. Here, MRI images are gray images without color features. We consider volume as one of the evaluation items. Then we will introduce each item and its measurements.

Textural Feature

A textural feature is a diagnostic tool for physicians when reading MRI images. Learning from this, Zacharaki et al. extract MRI texture and shape features, constructing the feature vector to train a support vector machine (SVM) classifier to classify brain tumor type and grade (20). A textural feature is usually employed for tumor grading in tumor studies because it provides fine-grained, repeatable information. Besides, for autism, commonly diagnosed by behavioral, chemical, clinical, structural, and functional changes in the brain, MRI texture represents a new image feature, which can supplement the traditional image features (such as volume measurement). Vidhusha and Anandhan focused on extracting texture features for autistic and control subjects, and validated them using neural classifiers to achieve automatic detection of autism (21). Textural features are extracted from original MRI ROI images rather than registered results, but here, we explore the textural difference between results suffering different processing pipelines, and we will do a single statistical analysis to discuss the significant difference.

The textural feature has several extraction methods, including statistical, model, signal processing, and geometric forms. Here, we choose the gray level co-occurrence matrix (GLCM) proposed by Haralick et al. regarded as one of the most promising texture analysis methods (22, 23). It estimates the image properties related to second-order statistics. GLCM is a joint distribution describing the gray level of two pixels with a particular spatial positional relationship. Five derived variables were calculated from the GLCM matrix, contrast, correlation, energy, homogeneity, and IDM to investigate the difference between textural features. Then these computations will be described in detail next.

Contrast. The deeper the texture groove, the greater the contrast and the clearer the visual effect; conversely, the contrast is small, the groove is shallow, and the effect is blurred.

$$contrast = \sum_{i=1}^{N_g} \sum_{j=1}^{N_g} (i-j)^2 p(i,j) \tag{1}$$

Correlation. It represents the consistency of the image texture. If there is a horizontal direction texture in the image, the COR of the horizontal direction matrix is larger than the COR value of the remaining matrix.

$$correlation = \frac{\sum_{i=1}^{N_g} \sum_{j=1}^{N_g} p(i,j)ij - \mu_x \mu_y}{\sigma_x(i)\sigma_y(j)} \tag{2}$$

Energy. It is the sum of the squares of the gray level co-occurrence matrix values, so it is also called angular second moment, which reflects the uniformity of image gray distribution and texture thickness. A large energy value indicates a textured pattern that is more uniform and regular.

$$energy = \sum_{i=1}^{N_g} \sum_{j=1}^{N_g} (p(i,j))^2 \tag{3}$$

Homogeneity. It reflects the density of elements in GLCM relative to the diagonal distribution of GLCM.

$$homogeneity\,1 = \sum_{i=1}^{N_g} \sum_{j=1}^{N_g} \frac{p(i,j)}{1+|i-j|} \tag{4}$$

Inverse Difference Moment. IDM measures the local homogeneity of an image and reports the inverse difference moment of an image. IDM weights are the inverse of contrast weights. It has the value that determines whether the print is textured or non-textured.

$$IDM = \sum_{k=0}^{N_g-1} \frac{p_{x-y}(k)}{1+k^2} \tag{5}$$

Volume Feature

Volume could provide significant information on pathological study and can capture volume change in the brain. Quantitatively detecting the density and volume of brain tissue at the voxel level can reflect the differences in brain tissue components and characteristics in different brain regions. The latest study explores that the inter-method discrepancies in brain volume estimation may drive inconsistent findings in autism (3). In this part, we employ SPM12 as the brain volume estimation tool. The images are segmented into gray matter (GM), white matter (WM), and cerebrospinal fluid (CSF) volume in the native space to estimate the volume by using the New Segment tool of SPM12 (6). Spm_get_volumes script is used to calculate the tissue volumes using c1, c2, and c3 images corresponding to native space tissue maps of GM, WM, and CSF, respectively. Native space volumes are selected to minimize volume changes due to spatial transformations. Total intracranial volume (TIV) is calculated as the sum of the GM, WM, and CSF volumes in the native space of the structural MRI images.

Shape Feature

We calculate textural matrix to understand the textural feature and compare the brain tissue volume estimation, but it is hard to compare shape differences for shape features. Thus, we employ machine learning algorithms using shape features as the input and record the prediction accuracy to evaluate the shape feature performance. Based on the shape features extracted from MRI, machine learning algorithms could find the standard classifier function to distinguish the healthy and disease cases. To capture shape features in MRI images, we extracted the histogram of oriented gradient [HOG; (24)], a prominent local image feature widely used in computer vision applications, from MRI images to establish the feature sets. The HOG technique counts occurrences of gradient orientation in localized portions of an image. When studying the brain tumor, the HOG could describe local object appearance and shape within an image by distributing intensity gradients or edge directions. Thus, this descriptor can detect the abnormal edge of the tumor issues and help physicians find the lesions. About ASD, the HOG descriptor may also find some markers to distinguish the healthy and disease cases.

Then, the classification method is the support-vector machine (SVM), the supervised learning model. The combination of HOG and SVM is the classical strategy in object detection, especially in human detection (24). In the model, the cross-validation (CV) method is used to evaluate the performance of classifiers trained by different MRI data sets registered by three tools. The widely used methods in brain image analysis include leave-one-out cross-validation (25, 26), leave-two-out cross-validation (27–29), k-fold cross-validation (1), and stratified k-fold cross-validation (30, 31). The cross-validation results are conducted from the strategy that divides the raw data into K groups (K-fold), and each subset of data is used as a verification set. The remaining K-1 subset data is used as a training set. Then the K models, respectively, evaluate the results in the verification set, which effectively utilizes limited data, and the results are as close as possible to the model's performance on the test set. According

to review studies and previous research, we use stratified ten-fold cross-validation to measure classification performance. All operations are performed in python3.7 in Ubuntu14 on a virtual machine.

RESULTS

Time and Failure Rate

Execution time is a crucial factor that needs to consider, which can reflect the effectiveness of tools. During the registration step, we calculate the time in each registration pipeline. **Table 3** and **Figure 2** show that AFNI gets the best speed performance and then SPM12 while FSL is the slowest.

Registration is also regarded as an optimization process, which means there are failures in this step. We also collect the failure rate in the registration step. From **Table 3**, the failure rate in AFNI is higher than in FSL, and in FSL it is higher than in SPM. Auto-registration in SPM12 is based on prior knowledge using the tissue probability map to find the optimum transformation to achieve high and accurate registration. What is more, in SPM12, there is no feedback mechanism, and the final transformed results will be returned, whether good or bad. By contrast, FSL and AFNI both have the mechanism that if the cost function cannot be optimized, they will return the failure message and some additional suggestions to help the user optimize the registration command and get better results. So, AFNI and FSL have improvable abilities while SPM12 is poor.

The purpose of our study is not to attempt to find the most accurate one that has been investigated in many previous studies (7, 9, 32–34). We compare the registered results in the image to explore the degree of change in the features and structures made by the three registration tools and find the difference between these changes to help the user select the registration tool based on their registration results difference and research purpose.

TABLE 3 | Time acquisition and failure rate.

	ABIDE II-ETH		TCGA-LGG	
	Time (Average)	Failure rate (%)	Time (Average)	Failure rate (%)
SPM12	94 s	0	100 s	0
FSL	110 s	0	4 min	16
AFNI	78 s	0	86 s	20

Texture Feature

We extract valuable features from the registered images by different tools to find the difference. Brain regions were extracted using the brain extraction tool [BET; (35)]. We extracted textural features from disease data sets to study the difference between registration tools and disease types (36, 37). Input images are brain-extracted MRI images to gain whole-brain texture GLCM matrix and calculate the five features, i.e., contrast, correlation, energy, homogeneity, and inverse difference moment (IDM).

Figure 3 shows the results of the comparison of texture features. The value distribution is similar among SPM, FSL, and AFNI and shows no significant difference. But FSL gets a higher value, implying that FSL is more inclined to retain more uniform and regular texture patterns. AFNI has a higher correlation value corresponding to its biggest size of MRI holding more pixels and details that could be measured more similar pattern.

In the statistical analysis, SPM12 values shows significant difference with AFNI ($p = 0.017314065 < 0.05$, 95%) and FSL ($p = 0.046368617 < 0.05$, 95%), indicating that SPM12 registered images have more sharp textural changes. A larger contrast value correlates with a greater disparity in intensity values among neighboring voxels, suggesting that SPM12 processed results have more sharp intensity changes and deeper texture grooves. Next, the inverse difference moment, also known as

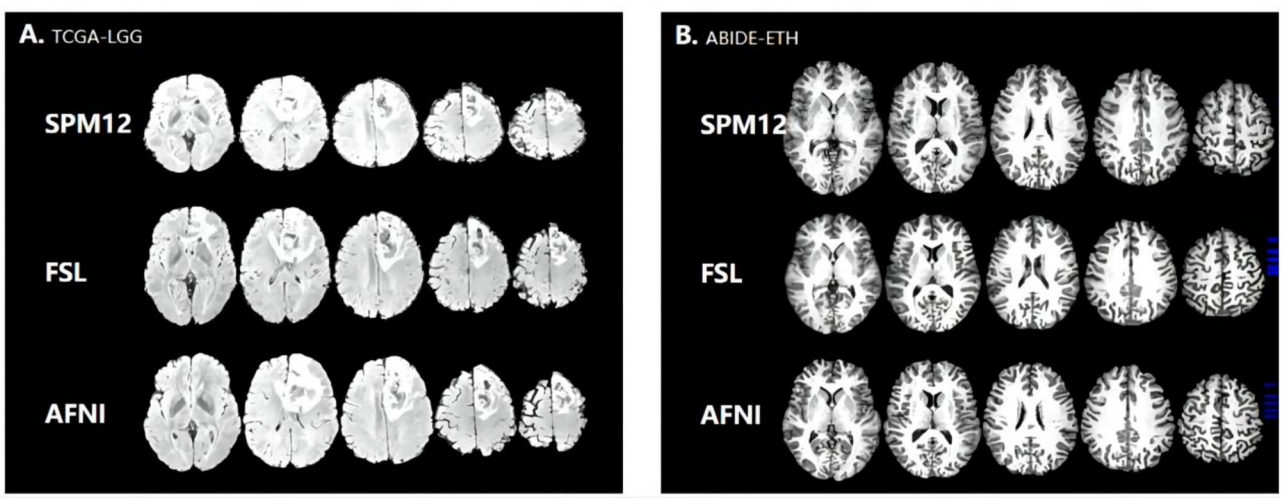

FIGURE 2 | Registered results by three tools. **(A)** TCGA-LGG. **(B)** ABIDE-ETH.

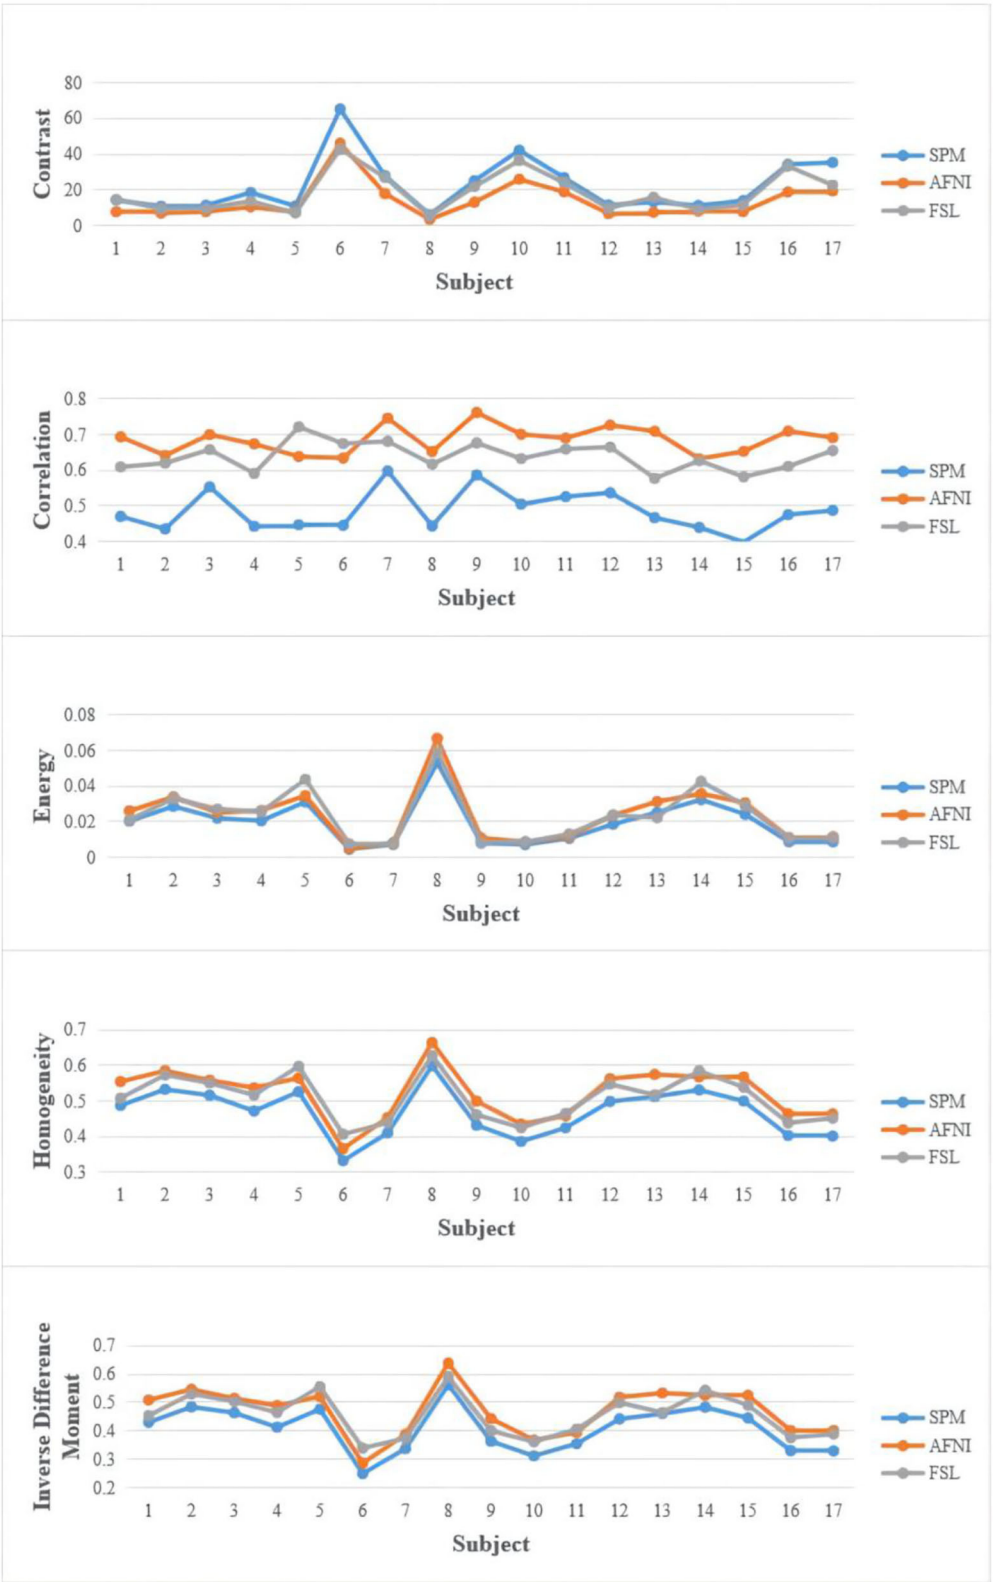

FIGURE 3 | Texture feature extracted from the dataset.

TABLE 4 | Brain volume estimation results.

	TIV (mean)	GM% (mean)	WM% (mean)	CSF% (mean)
TCGA-LGG	1.5364	39.89	45.17	14.94
SPM (TCGA)	1.9012	35.41	41.61	22.97
AFNI (TCGA)	1.8936	36.08	45.13	18.79
FSL (TCGA)	1.5123	33.62	43.89	22.49
ETH	1.2960	58.79	32	9.21
SPM (ETH)	1.8776	54.21	30.17	15.02
AFNI (ETH)	1.8977	55.63	29.63	14.74
FSL (ETH)	1.5641	55.81	28.01	16.19

ETH = ABIDE II-ETH.

the inverse variance, reflects the clarity and regularity of texture. The images with clear, regular, easy to describe texture would have a larger value demonstrating that these images are more in line with human feelings. The AFNI is clearer than the other two data sets in **Figure 2**, which is consistent with our calculated values. SPM12 also has significant difference with AFNI ($p = 0.018590934 < 0.05$, 95%) and FSL ($p = 0.044412676 < 0.05$, 95%) as well. We guess the reason is that AFNI retains more detailed information, including uniform and sharp textural change, while SPM12 abandons these details and hold sharp textural feature.

Brain Volume Estimation

Some brain diseases may give rise to the volume change in the brain, such as edema, which is obvious in the image. We calculate the TIV and the percentage of gray matter, white matter, and CSF in the original and registered structural MRI images. We set the volume estimation from the MRI in the original space as the standard result. From **Table 4** and **Figure 4**, AFNI shows the closest results with similar GM, WM, and CSF percentages, and sometimes overestimates the total volume. The whole-brain volume estimated by SPM was always higher than the standard TIV. FSL estimates of CSF are the highest.

Shape Feature-Based Classifier

Finally, we compare the evaluated accuracy of the cross-validation. For the ASD dataset, the number of healthy and disease cases is 22 and 11, respectively. For the glioma dataset, the number of healthy and disease cases is 22 and 17, respectively, and the k that we use in k-fold is 10.

From **Table 5**, we can observe the difference between the registration tools. The performance of SPM shows the highest accuracy, while AFNI is better than FSL. Since the HOG feature represents the shape information by edge directions, which collects contrast information, this result is consistent to compare results found in the texture feature part. MRI images registered by SPM retain richer contrast sources, which may mean that SPM is a suitable preprocessing tool when dealing with structural problems. The SPM performs best in our structural HOG feature model.

DISCUSSION

To estimate the performance of registration algorithms of SPM, FSL, and AFNI, we calculate the registration time, compare the texture feature extracted from skull-striped structural MRI images, and investigate the inter-methods discrepancies in brain volume estimate. Finally, we compare these registered images' applied performance in the classification model and we get the conclusion that SPM12 is usable for newcomers or employed when dealing with basic and normal processing workflow because it is like a black box that users cannot know the registration process details. FSL is a powerful toolkit for research. Its function-based integrated toolbox facilitates researchers for the different hierarchy of requirements. However, FSL's semi-integrated design cannot meet scholars' requirements for function module combinations and workflow model optimization. In contrast, AFNI is cumbersome and complex to use. However, it can provide some personalized customization and allow some threshold adjustments, which is very useful for many professional researchers, but it may be difficult for novices to use.

According to our analysis conclusion, tool selection mainly depends on research tasks. If the focus of studies is only MRI images' single feature, it is wise to choose the feature-targeted tools, for example, the contrast feature of texture feature for SPM, and if studies require multiple features or detailed features, AFNI will be a good choice. When involving multi-modal MRI sequences, like DWT, PET, and DTI, FSL would become the first choice. For glioma and autism spectrum disorder, the glioma is more sensitive to contrast features, so SPM12 may perform better registration results when studying the glioma dataset. When using the shape features like HOG, SIFT, or LBA, SPM12 may have the best performance on comparing AFNI and FSL. Tumor detection, prediction, and classification are likely to employ these structural and edge-related features, and so SPM12 will be an advisable process tool with stable performance and feature-sensitive advantages, facilitating tumor study.

Image registration research is still progressing steadily, and new research results are emerging. At present, there is still no unified evaluation criterion. Experience and habits are still the main factors affecting people's choice of methods and tools. Our study provides a new idea for the comparison of registration tools. Using data sets from different diseases, we study the differences in texture features, structure, and classification performance of the three registration tools, discuss their characteristics, and analyze the causal correlation between features and classification models. Our study is not without limitations. The focus of this study is only on structural images, while the registration between functional images and other modal data has not been investigated in detail. Secondly, only three kinds of public registration tools are selected, and some tools in current research are omitted. In addition, the default parameter settings are adopted in the study. Still, in the specific analysis, different parameter settings will significantly impact the results, and the appropriate parameter configuration can optimize the processing results. There is some research on MRI registration

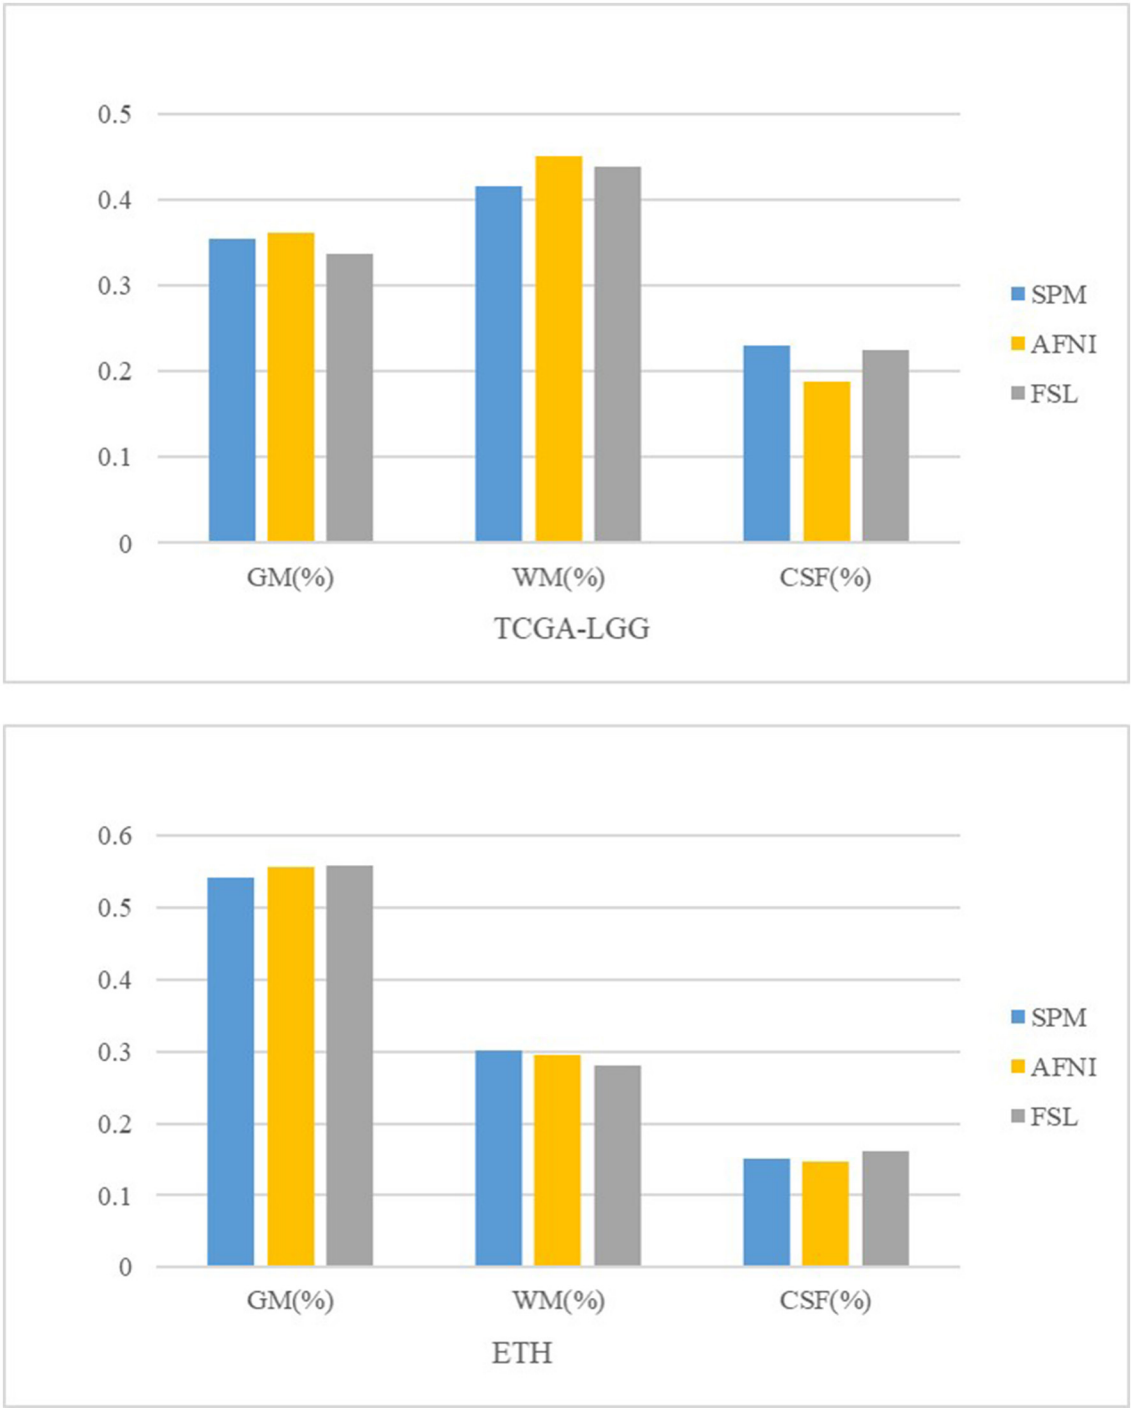

FIGURE 4 | Brain tissue volume comparison.

using a deep learning algorithm, which may achieve better performance than traditional MRI registration methods. In the next step, we need to compare and analyze the registration results of these methods (38, 39).

CONCLUSIONS

Although SPM has the most stable performance, it also produces poor registered results when dealing with low-quality data

TABLE 5 | Prediction results on two datasets.

ABIDE II-ETH dataset	SPM %	AFNI %	FSL %
Accuracy (high)	78.79	72.73	63.64
Accuracy (low)	69.70	63.64	54.55
TCGA-LGG dataset	**SPM %**	**AFNI %**	**FSL %**
Accuracy (high)	92.31	88.83	81.17
Accuracy (low)	86.24	80.52	72.08

sets. According to its advantages and drawbacks, SPM12 has a stable speed and success rate but does not guarantee the processed results, especially when handling low-quality images. FSL is a mature and widely applicable toolkit for employers, with relatively stable performance, a success rate, and complete functions. Its graphical user interface provides basic processing flow operation, while multi-parameter settings and failure feedback mechanisms can realize complex user processing and meet the optimization requirements. It is an excellent toolbox for beginners and proficient hands. Last, AFNI, with quite a fast speed and complex modules, can meet various requirements. But it is not friendly to newcomers, even though it offers an integrated processing function-similar function and modules, unique data format, and command-line operation, all confusing to beginners.

The texture feature is significant in image registration. SPM registration enhances the contrast feature of the texture feature, giving up other detailed information. FSL registration contains enough contrast information and most of the details. AFNI registration is apparent to view details in the brain structure. Due to plentiful details, too much information may make finding key features to differentiate brain structure by single textual features. Therefore, SPM registered image is easy to distinguish the different and distinct tissue types in the images. MRI images processed by AFNI and FSL are more suitable for complex and fine-grained investigations.

In conclusion, AFNI will be a good product application for its immediate and quick response with processed results but requires extra steps to ensure quality. It also plays an essential role in academics and research with its excellent flexibility, which could quickly test various combined processing steps in research. It is also the only MRI registration tool that supports all formats. SPM12 always works as a guide tool for newcomers to medical imaging. A rich online teaching resource and simple and easy-to-learn operations make everyone accomplish the basic processing flow and get stable results. Its support for the Windows environment is the main reason for its popularity. FSL combined advantages of both, providing GUI for basic and simple processing flow and customized parameters setting for flexible and optimized procedure. In addition, FSL is a suitable tool for other MRI sequences like DWT and has been widely used in numerous studies.

One of the most common causes of death from cancer for both women and men is lung cancer. Lung nodules are critical for the screening of cancer and early recognition permits treatment and enhances the rate of rehabilitation in patients. Although a lot of work is being done in this area, an increase in accuracy is still required to swell patient persistence rate. However, traditional systems do not segment cancer cells of different forms accurately and no system attained greater reliability. An effective screening procedure is proposed in this work to not only identify lung cancer lesions rapidly but to increase accuracy. In this procedure, Otsu thresholding segmentation is utilized to accomplish perfect isolation of the selected area, and the cuckoo search algorithm is utilized to define the best characteristics for partitioning cancer nodules. By using a local binary pattern, the relevant features of the lesion are retrieved. The CNN classifier is designed to spot whether a lung lesion is malicious or non-malicious based on the retrieved features. The proposed framework achieves an accuracy of 96.97% percent. The recommended study reveals that accuracy is improved, and the results are compiled using Particle swarm optimization and genetic algorithms.

Keywords: cancer, lung cancer, machine learning, artificial intelligence, deep learning, cancer detection

INTRODUCTION

The most well-known reason for death because of malignant growth is lung cancer. The second most habitually analyzed type of malignancy is lung cancer. Pneumonic nodules are apparent in the lung to evaluate metastases from different malignancies (1, 2). Computed tomography (CT) is the most significant image mode for assessing progress/crumbling and for observation and decision-making malignant lung growths. As a result of the precocious presentation of lung malignancy by CT, doctors can be suggested more productive treatments (3, 4). Guess and recuperating components for scattered sickness with precise malignancy stages are required for orderly and consoling treatment (5). The early conclusion of the period of lung malignancy is firmly connected to the patient's continuance rate (6). In clinical terms, the disease is known to be strange hyperplasia and significantly beyond what 200 sorts can influence the individuals (7). According to the ACS (American Cancer Society), lung malignancy is the main cause of death in both men and women in the United States. about a total of 2,28,820 new lung malignancy cases were estimated, with 1,35,720 deaths (8). It causes a larger number of deaths than other malignant tumors. Early recognition of

tumorous lung nodules is the key factor for patient survival rate. When contrasted with chest X-ray imaging, CT perceives the tumorous nodules consistently at an underlying stage (9). Practically all radiologists use CT by exploring multiple pictures from a solitary patient. Thus, the exhaustion of the radiologists can prompt wrong analysis. Hence, the exact physical valuation measure is tedious and colossally inconsistent (10). A precise segment is noteworthy for the right valuation of nodule improvement and for the arrangement of malignant nodules (disease cells) from benign ones (non-disease cells). The reason for this work is to exactly recognize the nodules over the CT lung pictures.

The proposed instructional method pulls back, utlilizing a middle method to reduce confusion based on the CT image. Second, a crossover division approach is utilized to isolate the lung zone from its environmental factors. The proposed division strategy utilizes the Otsu thresholding to eliminate superfluous groups, consequently isolating the specific lung locales, and nodules of interest can be decisively characterized by cuckoo inquiry advancement. Third, the assortment of surface highlights for the particular nodule is undisturbed by parallel neighborhood examples at the feature stage. Finally, the highlights of the sectioned lung nodules are prepared by the CNN classifier to distinguish the lesions as malignant or non-malevolent.

RELATED WORK

In 2019, Ananya et al. (11) developed a multi-approach system for lung cancer categorization using genetics. They assessed false negatives and true positives for classification accuracy in this study, but not detected accuracy.

In 2019, Venkatesh et al. (12) developed an innovative approach to detect lesions based on a GA and LBP. This process achieves an accuracy of 90%.

In 2019. Preeti et al. (13) introduced a lung cancer detection framework based on the fuzzy c-mean clustering and SVM classifier techniques

In 2019, Senthil Kumar et al. (14) introduced an approach for detecting lung lesions using GCPSO. In this work, multiple optimization techniques are used to classify cancer in CT images. The process obtained a precision of 95%.

In 2018, Perumal et al. (15) proposed an ABC algorithm for malignancy recognition and classification. This guidance attained a 92% accuracy.

In 2017 Ammar et al. (16) established an early diagnostic architecture for genetically altered tumor detection. In this study, the authors achieved an accuracy rate of 84%.

In 2017 Kamil et al. (17) introduced a DWT-based lung lesion detection system. In this method by using subtraction and erosion techniques images are analyzed to remove the cancer region. This approach yielded an accuracy of 89%.

In 2016 Mukesh et al. (18) introduced a DWT-based method for assessing a high volume of tissues in chest X-ray images. Using this method, the authors were able to achieve an accuracy of 86%.

In 2014 Santos et al. (19) described an area development and Hessian matrix to identify minor respiratory lesions. The presented approach achieves a classification accuracy of 88.4%.

In 2014, Jinsa and Gunavathri (20) reported an ANN-based lesion categorization technique. They were able to classify with an accuracy of 93.3%.

The principal gap has indeed been extended due to the lack of research publications that demonstrate computations. Because of poor directionality, slower processing, greater calculation time, and complex computations, the methods suggested by the authors mentioned above are less effective in all cases. As a result, an interactive technique for identifying lung cancer in CT images is suggested in this article, which uses the otsu threshold-based Cuckoo search algorithm, Local Binary Pattern for image retrieval, and CNN for classification to conquer all of the shortfalls of the existing methods. By selecting the most cost-effective strategy, optimization algorithms tend to produce a solution for image processing processes.

MOTIVATION AND CONTRIBUTION

Lung cancer is confirmed by physicians after a thorough examination of CT scans, which requires a lot of time and is not always accurate. To create imagery as precise, operational, and efficient as possible, state-of-the-art optimization techniques and image processing approaches were required. The proposed technology will aid doctors in accurately identifying lung nodules at an early stage, as well as studying the internal anatomy. As a part of the contribution, some glitches related to lung cancer detection are discussed here. The region of interest is retrieved using Otsu thresholding and cuckoo search optimization, which is a novel approach to segmentation. This proposed partitioning approach requires only a few parameters to precisely separate nodules of varied sizes and shapes.

Proposed Methodology

Figure 1 depicts the prospective lung malignancy diagnostic procedure, which comprises five phases: (1) contrast enhancement and Noise reduction through pre-processing, (2) Otsu thresholding based cuckoo search algorithm to segment the lesion from its backgrounds, (3) retrieval of regions of concern, (4) retrieval of descriptors from segmented lung lesions, and, in the last phase, (5) SVM has been used to assess if the lesion was abnormal or normal. The next sections provide detailed descriptions of the above-mentioned phases.

Image Acquisition

It is the basic step before proceeding with other critical steps. It is a method for processing a digital image from a database (21). Numerous sorts of scanners, such as X-Ray, MRI, and CT, are used to obtain the images. The CT image was captured using a CT scanner. It is a type of scanning that creates cross-section scans for each pixel (22).

Pre-processing

The equations should be inserted in editable format from the equation editor. It is then procedure to improve image details. The basic idea is to suppress noise, which corrects undesired distortions and enhances the associated attributes of the image for subsequent processing (23). Because all techniques are sensitive to noise, efficient images pre-processed allow for better

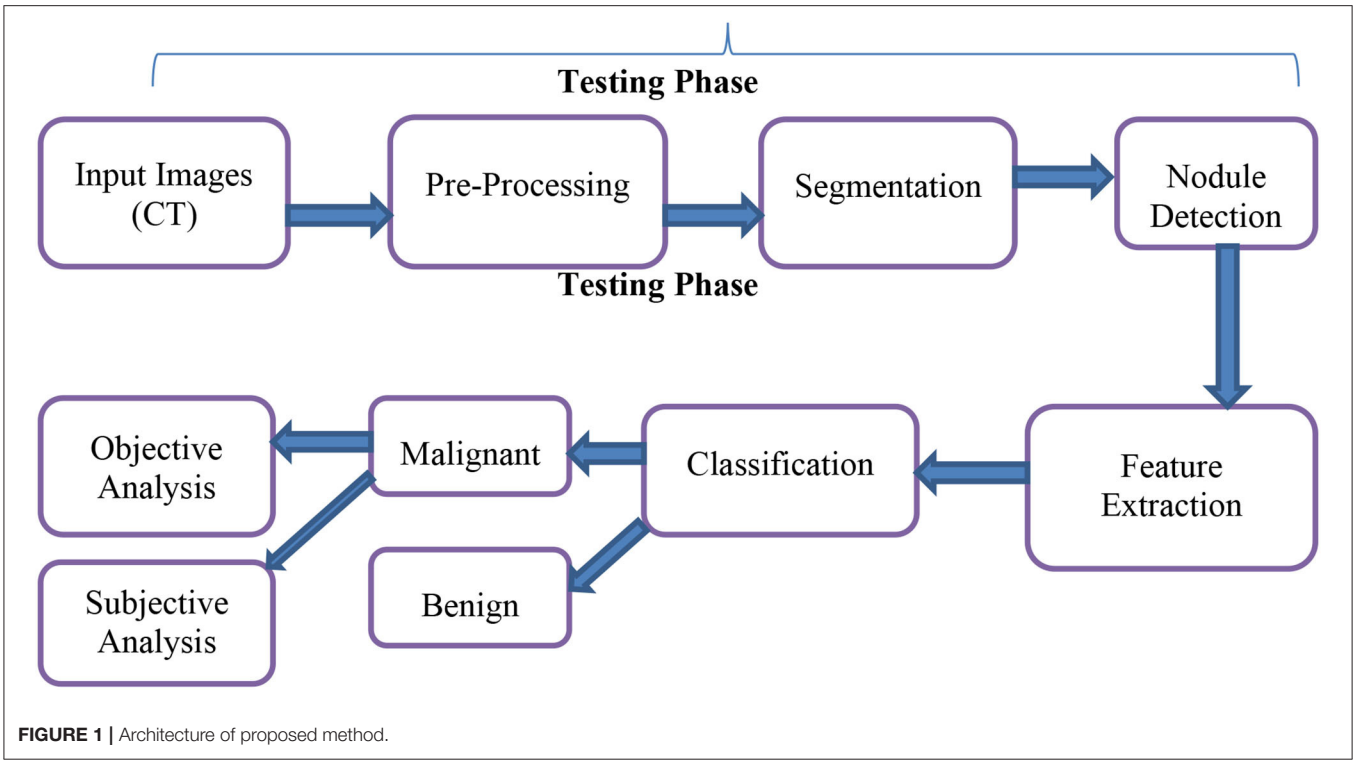

FIGURE 1 | Architecture of proposed method.

segmentation and, as a result, better classification. The size of the pixel area could be used to classify pre-processing procedures. Image enhancement employs these techniques. Enhancement operations operate on the image pixels of the neighborhood and the corresponding values of the neighborhood. Contribute quality to the images by decreasing noise and distortion (24).

$$\mathbf{f}(x) = \mathbf{a}_0 + \sum_{n=1}^{\infty} \left(\mathbf{a}_n \cos \frac{n\pi x}{\mathbf{L}} + \mathbf{b}_n \sin \frac{n\pi \mathbf{x}}{\mathbf{L}} \right)$$

Median Filtering

Salt and pepper noise can be found on CT scans. The finest features are obscured by these impacts. By keeping the frontier of the image as fine as possible, this filtering lowers salt and pepper noise (12). This filter gathers information from a sample within a non-averaged window (25). The edges of the filter are better managed than those of other linear filters. The following equations are used to get the median value.

$$\mathbf{M}(g) = \sum_{k=1}^{n} |x_k - \mathbf{g}| . \quad (1)$$

$$\mathbf{g} = \mathbf{median}\{x_1, x_2, \ldots\ldots\ldots x_n\} . \quad (2)$$

Otsu Thresholding Segmentation With Optimization

Otsu Thresholding

The goal of this strategy is to scour specified like-classes of pixels in a picture for the closeness of neighboring pixels in order to generate a concentrated image object. Separating the background and sub-regions in medical imaging is tough (26). The Otsu segmentation algorithm works better to "recognize" or "smear" the context contents of the front objects. It is an adaptive threshold binarization procedure proposed by OTSU in 1979. This procedure uses the highest within-class variance between the context and the target based on the rule of threshold assortment (27). It segments the image into the forefront and the contextual based on the characteristics of gray level values. If the finest threshold is attained, the gap between the two regions is the highest. The Otsu algorithm, in general, utilizes the greatest within-class variance. The larger the variance value, the wider the difference between the two areas, since variance is a useful determinant of uniform gray distribution. If some areas are wrongly segmented into contextual or if some contextual is segmented into areas, then the gap is too small between the two areas. As a result, if the variance among groups is higher, the likelihood of incorrect classification is lowered, resulting in cohesive segmentation.

The following is the main principle of OTSU-based threshold segmentation:

Let us call the gray values g and the number of pixels nx. Then

$$\mathbf{P} = \sum_{x=0}^{\mathrm{L}-1} n_x = n_0 + n_1 + n_2 + \ldots + n_{\mathrm{L}-1} \ldots \quad (3)$$

where g = 0, 1,..., L-1, and P indicate the number of pixels. Suppose C1 and C2 are the two kinds of pixels. C1 pixels have

a range of [0,x] while C2 pixels have a range of [x+ 1,L1].

$$\sigma_{Gv}^2 = \sum_{g}^{L-1} (g - m_{Gv})^2. \quad (4)$$

$$\sigma_{Bv}^2 = P_1(m_1 - m_{Gv})^2 + P_2(m_2 - m_{Gv})^2 \quad (5)$$

The below-mentioned calculations are used to compute the mean intensities.

$$m_1 = \frac{1}{P} \sum_{g}^{x} g.P_g \quad (6)$$

$$m_2 = \frac{1}{P} \sum_{g=x+1}^{L-1} g.P_g \quad (7)$$

$$m_{Gv} = \sum_{g=0}^{L-1} g.P_g \quad (8)$$

where m 1 and m 2 are the C1 and C2 pixel average intensities, and m Gv is the global mean intensity. Lastly, the ratio τ , which is provided below, is used to determine the ideal threshold.

$$\tau = \frac{\sigma_{Bv}^2}{\sigma_{Gv}^2} \quad (9)$$

Cuckoo Search Optimization

The cuckoo generation function is projected using this approach, which reduces the implications. A large number of nests are accessible during the search procedure. The location of the cuckoo egg has been discovered as a novel solution (28). The steps in the search procedure are as follows. A cuckoo bird places one egg at a time in a randomly chosen nest. The parasite nests were static, and the number of eggs in the nests would increase until they reach their highest level. When the cuckoo's egg is spotted, the host bird seems to have the choice of chucking the egg away or scrapping the nest and forming a new one.

The Levy flight theory has improved the CS algorithm (29). This CS technique is used to calculate the appropriate threshold for eliminating the lung nodule.

The following analogy is incorporated into the proposed technique for optimum selection (**Algorithm 1**):

The new solution, which depicts the subcategory of thresholds, is depicted by the egg of a cuckoo. This is also utilized for segmentation of the lung nodule. The grade of eggs for each host nest is either 0 or 1, which mimics the segmentation procedure's threshold partition. Pa is the probability that a cuckoo's egg will be discovered by the host bird. Pa has a predefined threshold. It demonstrates the principle of removing the least relevant threshold subgroups and, as a result, removing these threshold values from further analysis.

Feature Extraction

The LBP operator was established to determine texture in the first place (30). By thresholding an image with the central pixel value and taking the result as a binary quantity, the operator applies a mark to each pixel (31). The picture of the Lung CT could be considered as a micro-pattern structure that the LBP operator can well portray. The steps for extracting the characteristics are outlined below.

Algorithm 1 | Cuckoo search algorithm.

Step1: Initialization parameters: n, Pa, & M where n=number of host nests; pa : probability of discovery of alien, M: maximum number of iterations

Step2: Generate initial n host, n_i^t

Step3: Evaluate f(n_i^t)

Step4: Generate a new solution $n_i^{t+1} = n_i^t + \alpha \oplus Lev'y(\gamma)$

Where the symbol $\oplus$ is entry-wise multiplication,
$\alpha > 0$ indicates the step size, Levy(γ)= $g^{-\gamma}(1 < \gamma \leq 3)$

Step5: Evaluate $f(n_i^{t+1})$

Step6: Choose a nest $n_j$randomly

Step7: If $(n_j^t) > (n_j^{t+1})$ then Replace n_j^t *with* n_j^{t+1}

Step8: Confiscate a worse nest with Pa

Step9: Construct new nest using Levy flights

Step10: Retain the best solutions

- Divide the window looking at into cells.
- In a cell, collate each pixel with its neighbors.
- If the value of the center pixel is larger than the value of the neighbor pixel, assign "1"; otherwise, assign "0".
- A binary number is created by comparing all of the pixels.
- Lastly, over the cell, compute the histogram. The LBP value can be calculated using the expression $LBP_{X,Y}^U$ where U represents uniform pattern and X,Y indicate neighborhood.

$$LBP_{X,Y} = \sum_{0}^{m-1} s(P_s - P_c)2^s \quad (10)$$

$$s(t) = \begin{cases} 1 & t \geq 0 \\ 0 & t < 0 \end{cases} \quad (11)$$

P_c is the gray value of the center pixel, P s is the intensity value of the location pixels (m = 0, 1,.....m-1), and m is the image element well within range R where R is higher than zero (R > 0), creating a regionally oriented neighborhood set. After identifying each pixel in a picture, a histogram is created to define the texture image (32, 33).

CLASSIFICATION

CNN belongs to DNN group which is comprised of numerous hidden layers, like RELU, fully linked, pooling and convolution layer, etc. CNN securities weights in the coevolutionary layer, which lowers the network latency, and enhances network performance (34). CNN's prominent features are prevalent weights, local networking, and neuronal 3D sizes. A feature map is created with a kernel by a convolution layer of diverse sub-regions of the input image (35). Then, a nonlinear function is added to the RELU layer to progress the convergence possessions when the error is small. The architecture of CNN is as shown in **Figure 2**.

In relation to complex layers, CNNs quite often incorporate pooling layers (36). They are principally used only for lessening the dimensions of the tensor and speeding up estimations (37). All such layers are simple. So, the image

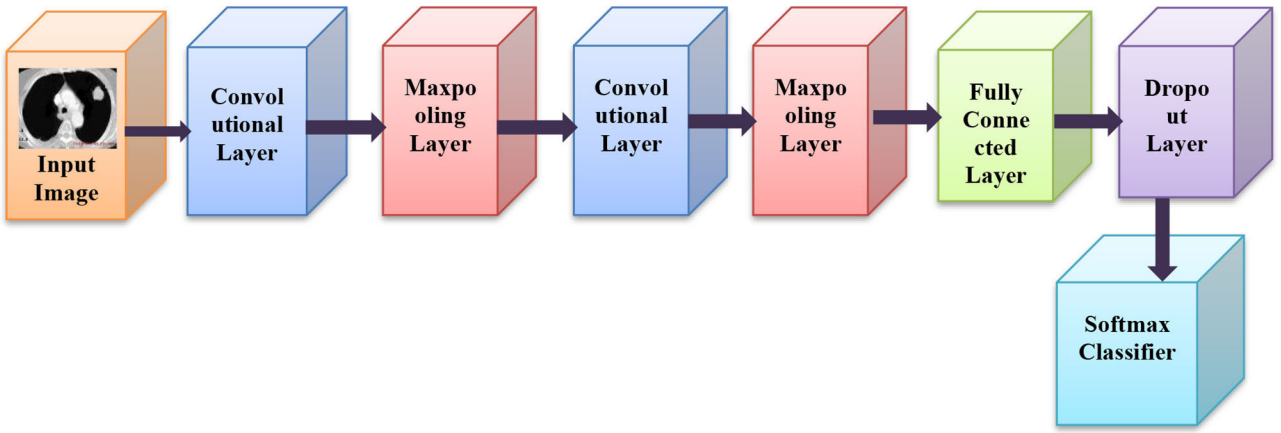

FIGURE 2 | Architecture of CNN.

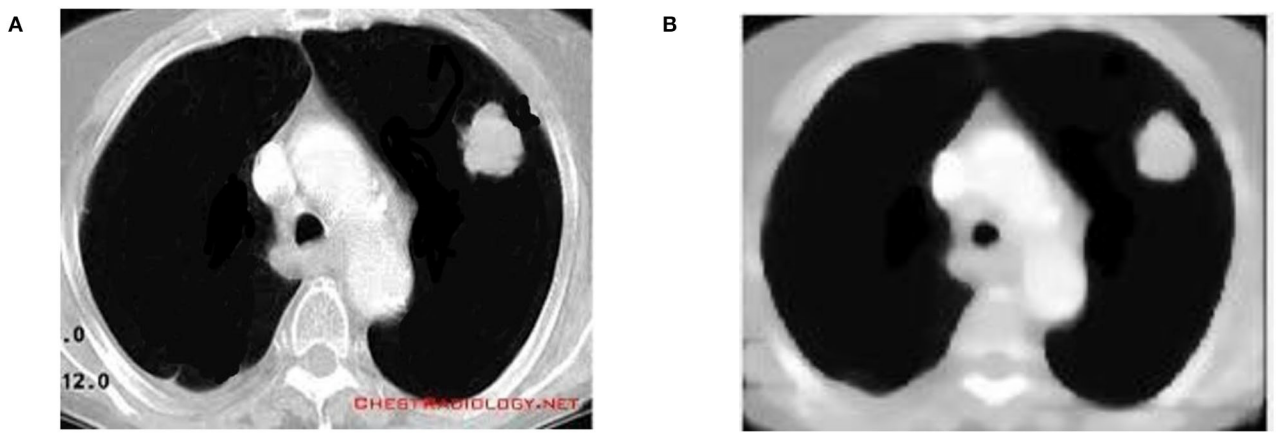

FIGURE 3 | (A) Input CT image. **(B)** Filtered output.

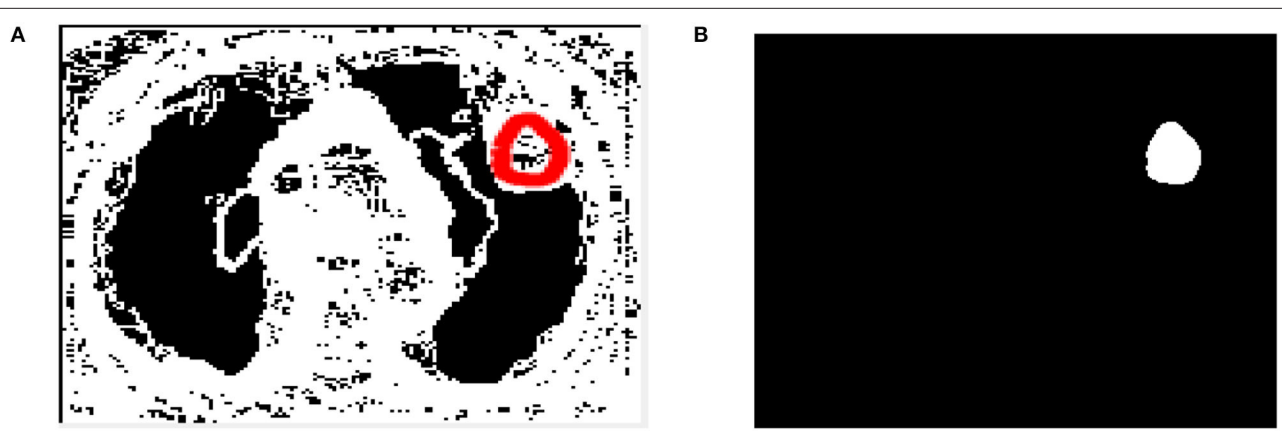

FIGURE 4 | (A) Extracted output. **(B)** Segmented output.

is to be split up into smaller portions in the pooling layer and for each portion, the maximum value is selected and then accomplished in some process for each portion (38). After being portioned, it is placed in the output in the respective position. RELU is a rectified linear unit, as well as a form of hidden layers. The activation function is

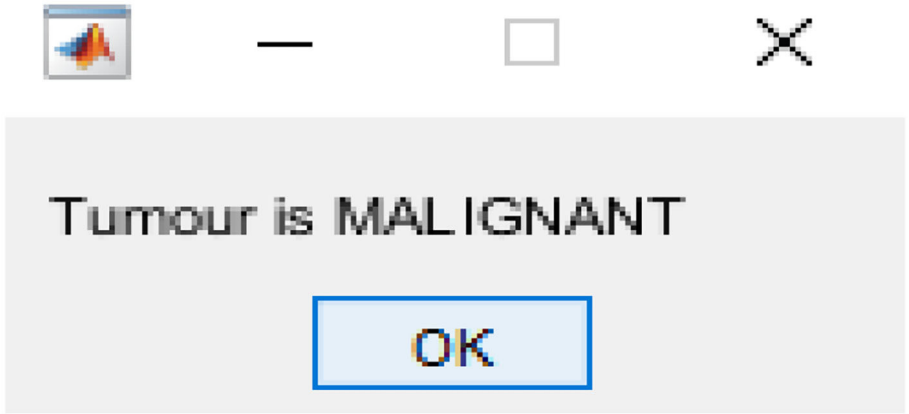

FIGURE 5 | Classification output.

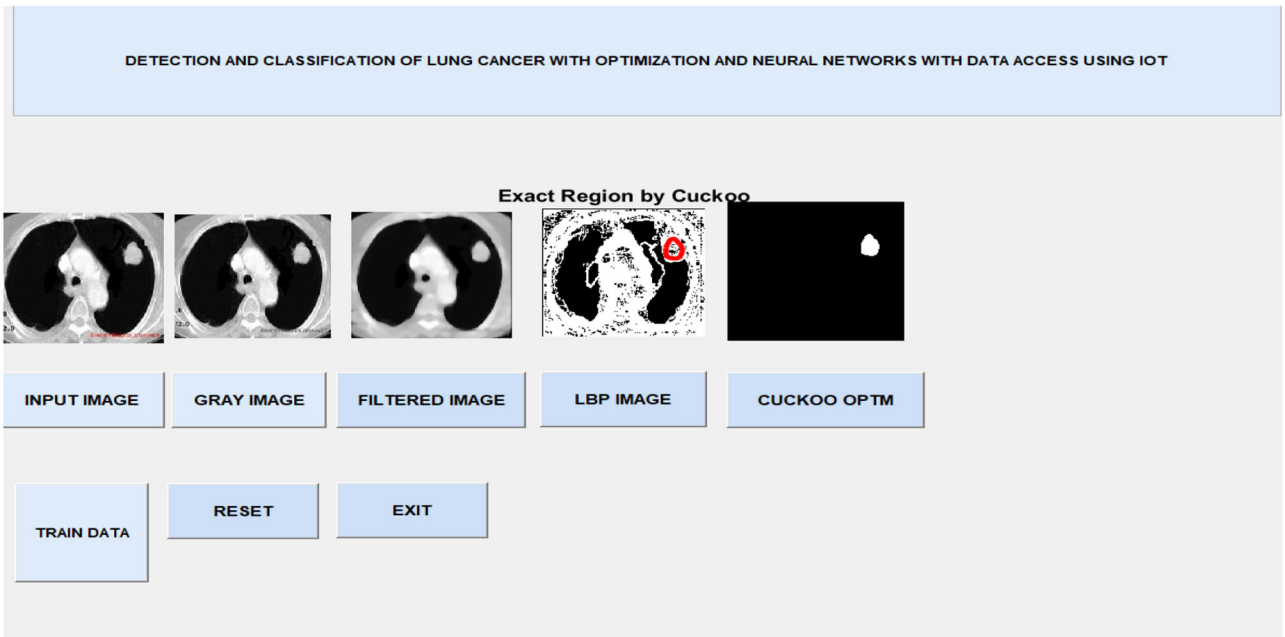

FIGURE 6 | GUI output.

most popularly used in neural networks, predominantly in CNNs (34).

SIMULATION RESULTS

Lung cancer is diagnosed in CT medical images using the novel cuckoo search algorithm and attributes are determined in this study. Lung cancer CT images were collected from a private hospital (Satyam diagnostic center, Anantapur). The adaptive threshold issue in this study is referred to as an optimization problem and it can be resolved using the CSA approach. In this study, the outcomes of the suggested method were compared to those of the PSO and GA algorithms. This work has been carried out by MATLAB software. When compared to open-source tools, MATLAB has a great affinity with deep learning techniques as well as hardware tools. Also, open-source tools have a hard time bringing all of the libraries together in one spot.

This study relies on my prior work (39), in which the outcomes were produced using a Genetic algorithm and particle swarm optimization approaches in addition to LBP and CNN. Cuckoo search optimization is used in this work, together with CNN and LBP, to enhance the accuracy. The input and median filter output of CT lung cancer pictures are depicted in **Figure 3**. Low-frequency noise

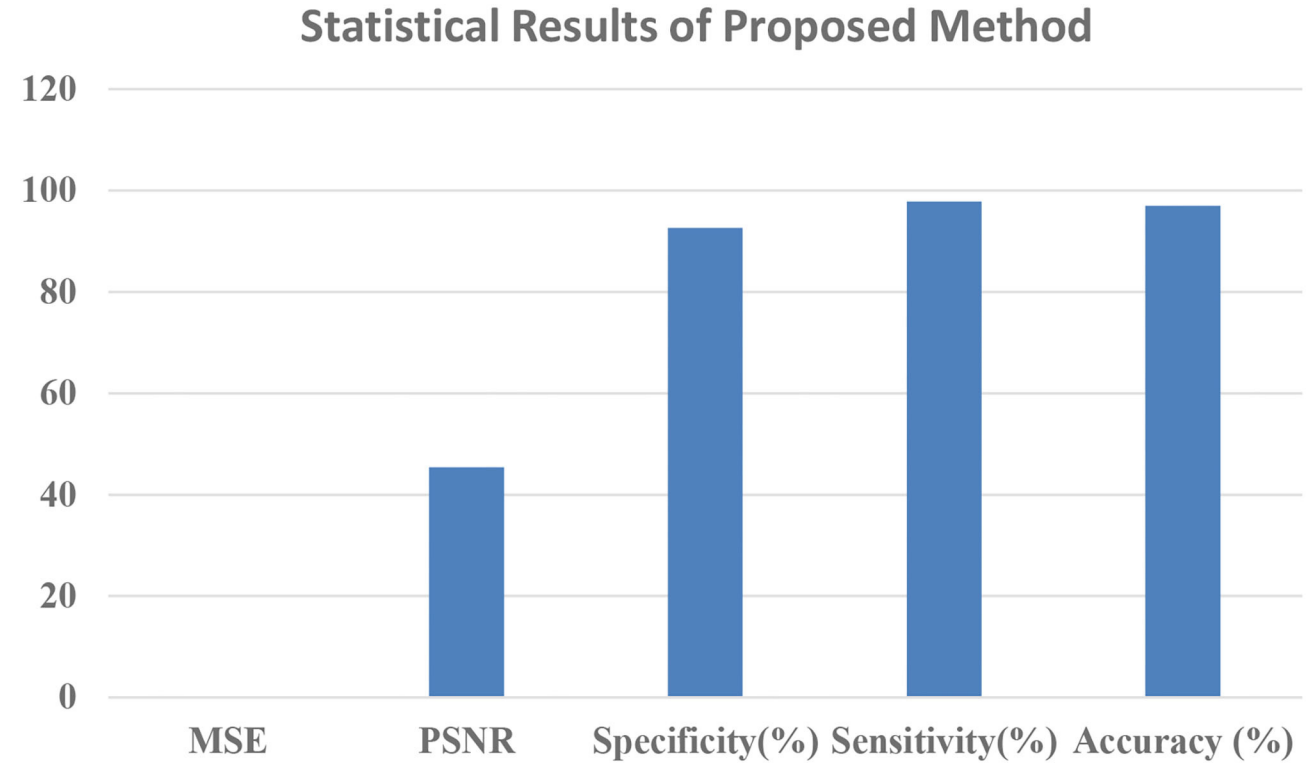

FIGURE 7 | Statistical results graphical representation.

and distortion are common in CT scan images. To reduce noise and distortion, the input image is processed with a median filter.

To identify lung lesions in the CT image, it is split into multiple clusters and then optimized using the Otsu thresholding approach. The CT scan is first split using simple Otsu thresholding, which improves the segmented classes' variation, or "all class variance." The result of the thresholding technique can be enhanced by processing it with cuckoo search optimization. Following partitioning, the image is subjected to LBP feature extraction, which extracts the textural features before extracting the detected output (see **Figure 4**).

After image retrieval, the image is given to CNN classification, which assesses the image as normal or abnormal by showing a message such as "Tumor is MALIGNANT" or "Tumor is BENIGN," as illustrated in **Figure 5**. The system's general function is created in a GUI, as seen in **Figure 6**. The statistical results like performance metrics obtained by 200 iterations for the input image are shown in graphical representation in **Figure 7**.

Table 1 showed that the suggested approach yields higher accuracy of 97%, the sensitivity of 97.8%, specificity of 92.6%, PSNR of 45.38%, and low MSE of 0.013 than conventional systems. These optimum results are obtained for 200 iterations (Our earlier proposed systems).

TABLE 1 | Attributed obtained from the proposed method.

Parameters	Proposed Method (CSO+CNN+LBP)
MSE	0.013
PSNR (%)	45.38
Specificity (%)	92.672
Sensitivity (%)	97.806
Accuracy (%)	96.979

TABLE 2 | Comparative Results with proposed method.

Parameters	Proposed Method (CSO+CNN+LBP)	(PSO+SVM+LBP)	(GA+SVM +LBP)
MSE	0.013	0.0301	0.0651
PSNR	45.38	33.2788	27.5311
Specificity (%)	92.672	60.0000	90.4950
Sensitivity (%)	97.806	96.5783	83.7143
Accuracy (%)	96.979	96.9391	90.4937

Table 2 shows that the suggested approach has higher accuracy (97%) than conventional systems (Our earlier proposed systems). The Comparative Results Graphical Representation is shown in **Figure 8**.

CONCLUSION

In this article, a strong approach for recognizing lung cancer in CT images is developed. For exact cancer diagnosis in CT lung images, the Otsu thresholding-based cuckoo search optimization and CNN classifier approach were used. Based on the simulation findings, it is observed that the suggested method reliably segments CT images and detects lesions of various forms and sizes. Subsequently, the proposed approach comprises successive stages that continuously yield the last detection result. The techniques that are utilized in different stages are basic and simple to actualize.

Based on the simulation findings, the accuracy of the proposed framework' is calculated to be 96.97%, which is greater than any other demonstrative framework found in the literature. As for future work, a powerful strategy could be created by supplanting the CNN Classifier with a profound deep learning method and CAD tools. One may improve the structure for images of lung cancer in different modalities.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

AUTHOR CONTRIBUTIONS

CV: conceptualization, methodology, software, and visualization. KR: data curation, writing—original draft, data analysis, and investigation. SL: software, validation, and editing. [1] Department of Pharmacy, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [2] Department of Gynecology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Objective: To explore the effects of osimertinib combined with pulmonary rehabilitation and health care training on pulmonary function, complications, and the quality of life (QOL) in patients after radical resection of lung cancer.

Methods: The data of 120 patients with radical resection of lung cancer admitted to *The First Affiliated Hospital of Zhengzhou University* from February 2020 to February 2021 were retrospectively analyzed. According to the order of admission, they were equally divided into group p and group q. All patients were given pulmonary rehabilitation and health care training, and group p was treated with osimertinib, while group q received the treatment of pemetrexed combined with cisplatin. The pulmonary function, the incidence of complications, and QOL between the two groups were compared.

Results: Compared with group q, the pulmonary function was higher ($P < 0.001$), the incidence of complications was significantly lower ($P < 0.05$), and QOL scores were markedly higher in group p after treatment ($P < 0.001$).

Conclusion: The combination of osimertinib and pulmonary rehabilitation and health care training can improve the pulmonary function of patients with non-small cell lung cancer (NSCLC) with radical resection of lung cancer, and reduce their postoperative morbidity, thereby improving their QOL, which is conducive to reducing the patient's and society's medical burden.

Keywords: osimertinib, pulmonary rehabilitation and health care training, radical resection of lung cancer, pulmonary function, quality of life

INTRODUCTION

Lung cancer is a malignant tumor originating from the mucosa or gland of the trachea and bronchus. According to the differences in histopathological characteristics, lung cancer is generally divided into non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC) in the clinic. NSCLC accounts for approximately 85% of all patients with lung cancer, while SCLC accounts

for only 15% (1, 2). In recent years, with changes in the social environment and living habits, the clinical characteristics of lung cancer have seen a substantial transformation in China (3, 4), but the main treatment option of patients has not been affected. Surgery is still the main treatment for patients with early, medium, and some advanced NSCLC, and 90% of patients are supplemented with chemotherapy after surgery (5) to improve QOL. At present, chemotherapy has an exact effect on SCLC, and about 1% of patients can be cured by chemotherapy (6). However, the effects of chemotherapy in patients with NSCLC are unsatisfactory, and patients can only relieve the clinical symptoms through chemotherapy drugs, which cannot effectively improve pulmonary function (7). For patients with NSCLC with the EGFR gene mutation, the T790M mutation will lead to an increase in chemoresistance, and patients who are insensitive to the conventional pemetrexed often get worse after treatment (8). In recent years, the third generation of epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) developed by AstraZeneca has been used in the treatment of the NSCLC with the EGFR gene mutation. The drug has a significant therapeutic effect on the central nervous system with mild toxicity and favorable safety. The postoperative rehabilitation and health care training based on medication can effectively improve the endurance and strength of patients' respiratory muscles, thereby reducing the bodily oxygen consumption, enhancing the cardiopulmonary and muscular function, and providing a benign physiological basis for medication (9) and improving the patients' QOL. There is no study on the effects of osimertinib combined with pulmonary rehabilitation and health care training on patients with NSCLC with thee radical resection of lung cancer by reviewing the previous literature. Based on this, 120 patients were selected to explore the actual effects of osimertinib combined with pulmonary rehabilitation and health care training. The reports are as follows.

MATERIALS AND METHODS

Research Design

This retrospective study was conducted under the guidance of the Declaration of Helsinki (2013) (10) to explore the effects of osimertinib combined with pulmonary rehabilitation and health care training on pulmonary function, complications, and QOL in patients after radical resection of lung cancer. The blind level of this study was double-blind. The study subjects and researchers did not know the grouping of this experiment, and the research designers were responsible for arranging and controlling the experiment. This study was approved by the ethics committee of The First Affiliated Hospital of Zhengzhou University.

General Information

The data of patients with radical resection of lung cancer admitted to *The First Affiliated Hospital of Zhengzhou University* from February 2020 to February 2021 were retrospectively analyzed, and the patients were included according to the following criteria: (1) Patients with the pulmonary CT examination as punctiform or patchy shadows who were diagnosed with lung cancer by pathological examination, which met the diagnostic criteria in the Chinese guidelines on the diagnosis and treatment of primary lung cancer (2015 version) (11); (2) Patients who had the EGFR T790M mutation-positive non-small cell lung cancer (12); (3) Patients who had surgical indications for radical resection of lung cancer; (4) Patients who had no disease affecting the motor nerve, joint, and muscle; (5) Patients who were not malnourished; (6) Patients who had an expected survival time of more than 6 months; (7) The Karnofsky performance status score was more than 60 points in patients; (8) The age of the patients was more than 18 years old; and (9) Patients who had good tolerance and compliance. In the following circumstances, patients were not included in this study: (1) Patients with some factors such as hearing impairment, language disorders, unconsciousness or mental illness, and patients who could not communicate with others; (2) Patients with a grave organic disease or dysfunction in vital organs; (3) Patients with complications, such as pulmonary infection and respiratory failure; (4) Patients with malnutrition or excessive obesity; (5) Patients with the expected survival period <6 months; and (6) Patients with the training participation rate $<80\%$.

All 120 patients included in this study were aware of the purpose, significance, content, and confidentiality of this study and they signed their informed consent. They were equally divided into group p and group q according to the order of admission. There was no significant difference in general information between the two groups ($P > 0.05$), which can be used as the research subjects. See details in **Table 1**.

Standards of Withdrawal From Experiment

In the following conditions, the study group judged that the patients were unable to continue the experiment, and their case record forms were retained, but the data analysis was not performed. These conditions were: (1) Patients who had sudden exacerbation during the experiment and (2) In the experiment, subjects who were unwilling to continue the clinical trials, and who applied to the study group for withdrawal from the experiment.

Methods

All patients were given pulmonary rehabilitation and health care training. A team on rehabilitation and health care training was constructed, and the team members included the attending physicians, supervisor nurses, and primary nurses. After admission, the primary nurses collected the clinical information of patients, carried out the health promotion for patients, and improved their training compliance. The team on rehabilitation and health care training developed programs of the pulmonary rehabilitation's exercise training based on the actual circumstances of the patients. The patients were given deep pursed lips breathing at 1–2 weeks after discharge, with a daily training for 0.5 h. The deep pursed lips breathing meant that the patients inhaled slowly with the nose until the gas could not be inhaled, and then exhaled slowly with the mouth in contracted lips after 5 s. The relaxation and contraction exercise in muscles of the whole body was implemented in the third week after discharge, with daily training for 0.5 h. The 1–3 weeks of training

programs were repeated in the fourth week, with daily training for 1 h. On Wednesday and Sunday, the centralized training was performed. At first, the patients were asked to repeat the deep pursed lips breathing, followed by progressive respiratory muscle contractions. After the patients took a semi-recumbent position, they took a deep breath slowly for three times and then held their breath, and they should contract the respiratory and abdominal muscles. When the patients could not persist, they could exhale quickly, and then gradually relax the muscle groups, and finally contract the muscles of the whole body. After the patients took a semi-recumbent position, the muscle contraction was performed from far to near and from top to bottom. Patients stretched themselves for 5 s with the taut muscles, and the muscles of the whole body were relaxed. In addition, the patients could jog according to the actual situation, first walking slowly at a speed of 30 steps/min, then walking fast at a speed of 75 steps/min, and finally jogging.

In addition, group p was treated with the osimertinib, and they were given 80 mg of osimertinib mesylate (AstraZeneca Pharmaceutical Co., Ltd.; specification: 80 mg; NMPA approval No.: J20180027) once a day. Group q received the treatment of pemetrexed and cisplatin. The 500 mg/m^2 of pemetrexed disodium (Sichuan Huiyu Pharmaceutical Co., Ltd.; specification: 500mg; NMPA approval No.: H20173301) was intravenously infused on the first day, and 75 mg/m^2 of cisplatin (Shandong Luoxin Pharmaceutical Group Co., Ltd.; specification: 10 mg; NMPA approval No.: H20046375) was intravenously infused on the second day with 3 weeks as 1 cycle. The routine examinations, such as blood routine, hepatorenal function, electrocardiogram, and dexamethasone (Guangdong Luofushan China National Medicines Co., Ltd.; specification: 0.75 mg; NMPA approval No.: H44024841) and folic acid tablets (Jiangxi Pharmaceutical Co., Ltd.; 0.4 mg; NMPA approval No.: H36020872) were given before chemotherapy.

Observational Criteria

General Information

The patients' data on social demography and clinic were collected including gender, age, body mass, BMI, pathological types, TNM staging (13), surgical procedures, resection range, educational level, monthly profit, living habits, and place of residence.

Pulmonary Function

The forced expiratory volume in one second (FEV_1), forced vital capacity (FVC), FEV_1/FVC, the percentage of maximal ventilatory volume in predicted value (MVV%), and maximal vital capacity were recorded before treatment and at 1 month after treatment using a pulmonary function instrument [Body Plethysmograph, NMPA (I) 20172071024] in Medical Graphics Corporation.

Incidence of Complications

The types of complications were recorded, the number of patients with complications was counted, and the incidence of complications was calculated. The incidence of complications = (the number of patients with complications/total cases) ×100%.

QOL

The QOL instruments for patients with cancer: lung cancer (QLICP-LU) (14) developed by Wan Chonghua et al. was used to investigate patients' QOL before treatment and 1 month after treatment. The scale included the somatic function (7–35 points), psychological function (12–60 points), social function (6–30 points), common symptoms and adverse reactions (7–35 points), and specific modules (8–40 points) with the test-retest reliability as 0.78. The α value of internal reliability in various fields and the test-retest reliability were above 0.70, which had favorable reliability and validity.

Statistical Treatment

In this study, the experimental data were processed by SPSS20.0, and GraphPad Prism 7 (GraphPad Software, San Diego, USA) was used to draw pictures of the data. The items included in the

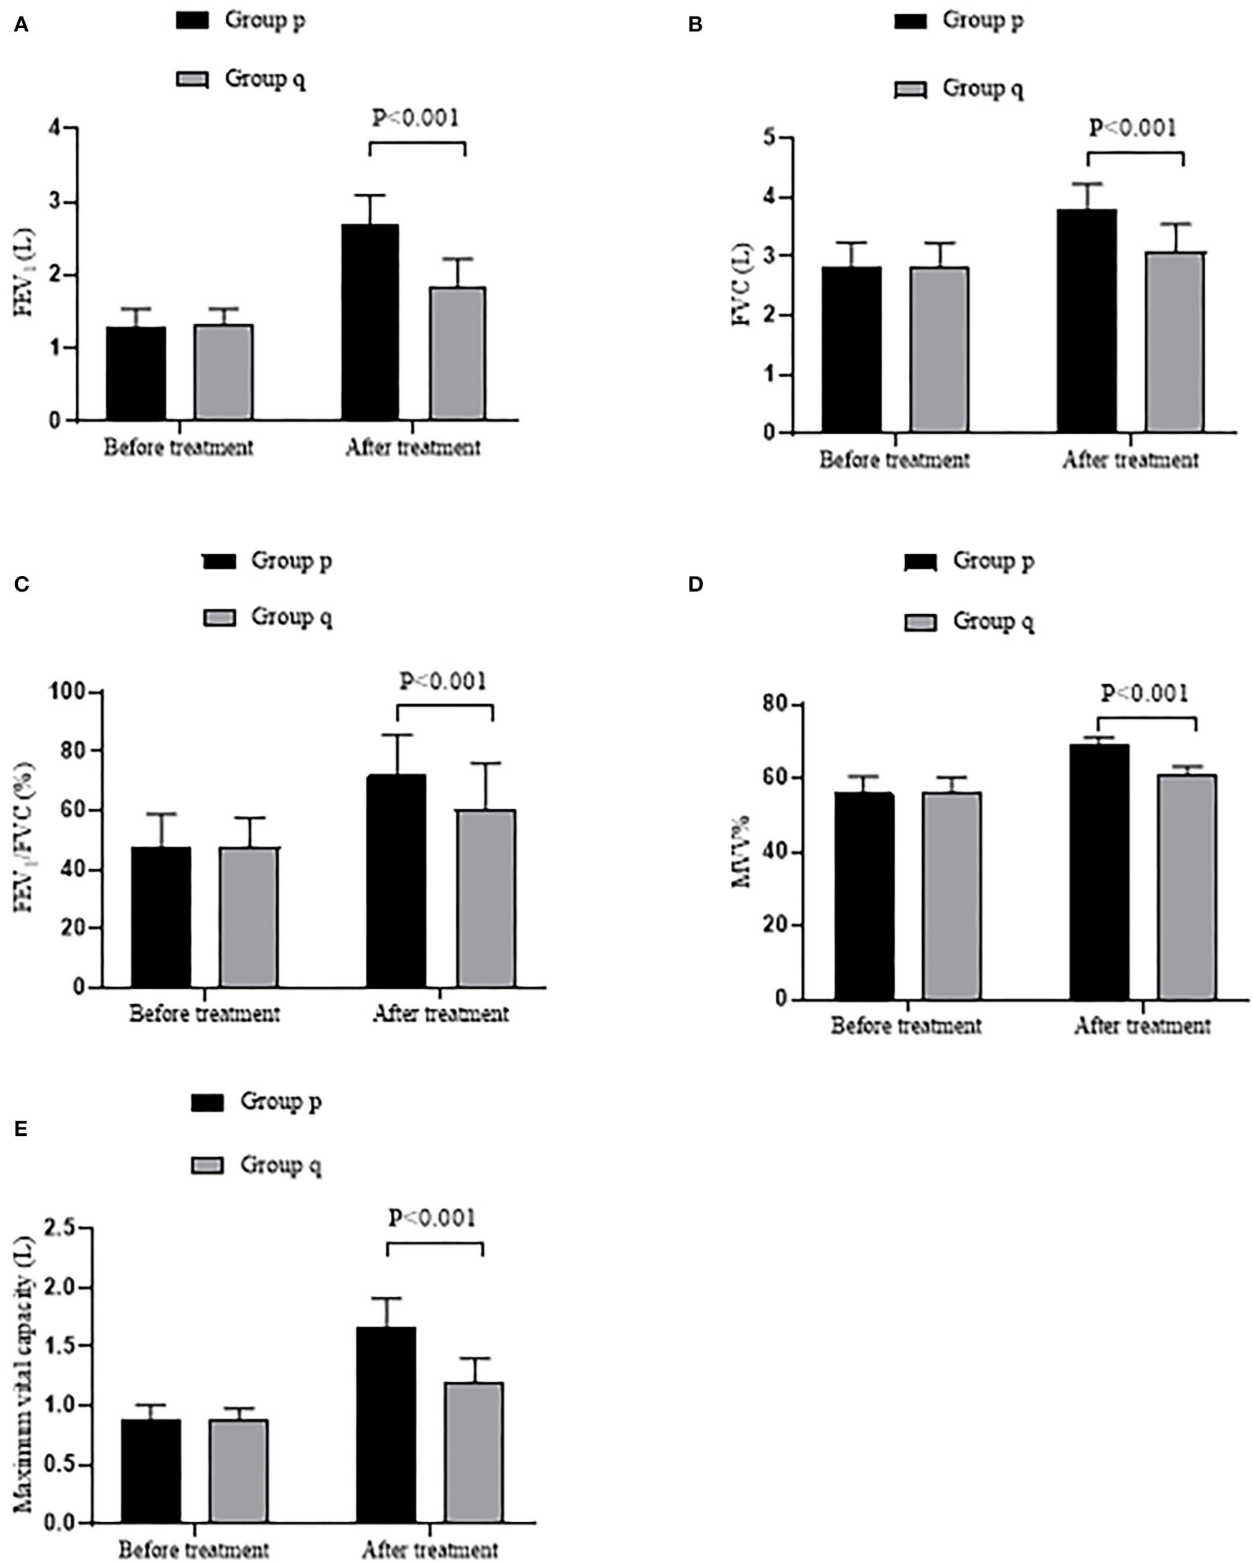

FIGURE 1 | Comparison of patients' pulmonary function (x ± s). **(A)** showed the FEV_1 (L). **(B)** showed the FVC (L). **(C)** showed the FEV_1/FVC (%). **(D)** showed the MVV%. **(E)** showed the maximal vital capacity (L).

TABLE 2 | Comparison of patients' incidence of complications [n (%)].

Groups	Group p ($n = 60$)	Group q ($n = 60$)	X^2	P
Pulmonary infection	0 (0.0)	1 (1.7)	1.008	0.315
Dyspnea	2 (3.3)	5 (8.3)	1.365	0.243

The number of occurrences	4 (6.7)	12 (20.0)	4.615	0.032

study were enumeration data and measurement data tested by x^2 and t–tests. When $p < 0.05$, the differences were considered to be statistically significant.

RESULTS

Comparison of Patients' General Information

There was no statistical difference in the general information between the two groups ($P > 0.05$). See details in **Table 1**.

Comparison of Patients' Pulmonary Function

Compared with group q, the pulmonary function was observably higher in group p after treatment ($P < 0.001$). See details in **Figure 1**.

Compared with group q, the FEV_1 level, FVC level, FEV_1/FVC level, MVV% level, and maximal vital capacity were observably higher in group p after treatment (2.68 ± 0.41 vs. 1.82 ± 0.40, 3.78 ± 0.45 vs. 3.08 ± 0.47, 71.82 ± 13.98 vs. 60.41 ± 15.75, 68.98 ± 2.10 vs. 60.77 ± 2.47, and 1.67 ± 0.24 vs. 1.21 ± 0.19, all $P < 0.001$), with no significant difference before treatment (1.30 ± 0.24 vs. 1.32 ± 0.22, 2.80 ± 0.44 vs. 2.81 ± 0.42, 47.73 ± 11.17 vs. 47.74 ± 9.96, 55.98 ± 4.50 vs. 55.90 ± 4.48, and 0.89 ± 0.12 vs.0.88 ± 0.10, all $P > 0.05$).

Comparison of Patients' Incidence of Complications

Compared with group q, the incidence of complications in group p was significantly lower ($P < 0.05$). See details in **Table 2**.

Comparison of Patients' QOL

Compared with group q, QOL scores in group p were observably higher after treatment ($P < 0.001$). See details in **Figure 2**.

Compared with group q, the somatic function score, psychological function score, social function score, the score of common symptoms and adverse reactions, and the score of specific modules were markedly higher in group p after treatment (26.20 ± 1.90 vs. 22.20 ± 1.91, 40.20 ± 1.84 vs. 31.27 ± 1.97, 24.17 ± 1.92 vs. 20.23 ± 1.89, 31.78 ± 1.66 vs. 26.22 ± 1.93, and 35.12 ± 1.70 vs. 30.18 ± 1.92, all $P < 0.001$), with no significant difference before treatment (20.17 ± 2 vs. 20.23 ± 1.95, 28.27 ± 1.85 vs. 28.25 ± 1.89, 20.18 ± 1.96 vs. 20.20 ± 1.95, 24.25 ± 1.93 vs. 24.18 ± 1.94, and 29.95 ± 1.93 vs. 29.58 ± 1.75, all $P > 0.05$).

DISCUSSION

According to the epidemiological data in 2018, the incidence and mortality of lung cancer ranked first in the malignant tumors in China. About 1.8 million patients died from lung cancer each year, accounting for 18.4% of all cancer death cases (15, 16). After the pathological types are clarified, the comprehensive treatment measures for patients can effectively reduce their mortality and prolong their survival period. The comprehensive treatment measures mainly include surgery, chemotherapy, and radiotherapy. Since SCLC often has metastasis in the early and middle stages, chemotherapy and radiotherapy were generally adopted in the clinic (17), while patients with NSCLC with a limited disease are often treated with surgery and postoperative radiotherapy and chemotherapy. Although radical resection of lung cancer can remove the lesions of lung cancer and reduce the clinical symptoms of patients with NSCLC, it cannot effectively improve the pulmonary function of patients (18, 19). In this study, patients were given pulmonary rehabilitation and health care training after the radical resection of lung cancer. The training methods mainly included subjective testing, breath instruction, and intensive training, which could regulate the respiratory contraction motion of patients to the maximum extent, improve the function of tracheal epithelium, and enhance the elimination effect of airway ciliary, thereby reducing the incidence of complications such as respiratory tract infection. In the process of the repeated exercises, patients could produce sufficient compensative capacity and enhance their lung capacity and lung function (19). Therefore, the pulmonary function indexes such as FEV_1 and FVC in the two groups after treatment were improved. Scholars Van Haran Robert M et al. have found that the pulmonary function indexes, such as FEV_1 and FVC of patients, were significantly improved by the application of the pulmonary rehabilitation and health care training in the rapid rehabilitation of lung cancer patients after surgery, indicating that the rehabilitation training method has a clear effect on lung cancer patients (20). However, the patients in group p had a more significant increase in pulmonary function compared with those in group q. The reason is that the pemetrexed used in group q has an anti-tumor effect, but the therapeutic effect on NSCLC is not obvious, while the osimertinib used in group p has a targeted therapeutic effect on the patients with NSCLC with EGFR gene mutation.

In general, postoperative chemotherapy for patients with SCLC can often obtain an ideal therapeutic effect, but the chemotherapy effect in patients with NSCLC is not very clear,; patients with the feeble constitution, poor bone marrow function, or dysfunction in vital organs are especially unsuitable for chemotherapy (21–24). Patients with NSCLC with the EGFR gene mutation even get worse after chemotherapy, so patients with NSCLC should be careful with chemotherapy and look for more effective treatment methods. Osimertinib, a third generation of EGFR-TKI, is the primary therapeutic drug after patients have drug resistance to the first and second generation of targeted drugs. Phase I and III clinical trials have shown that simertinib is effective in patients with locally advanced or metastatic EGFR mutation-positive non-small-cell lung cancer

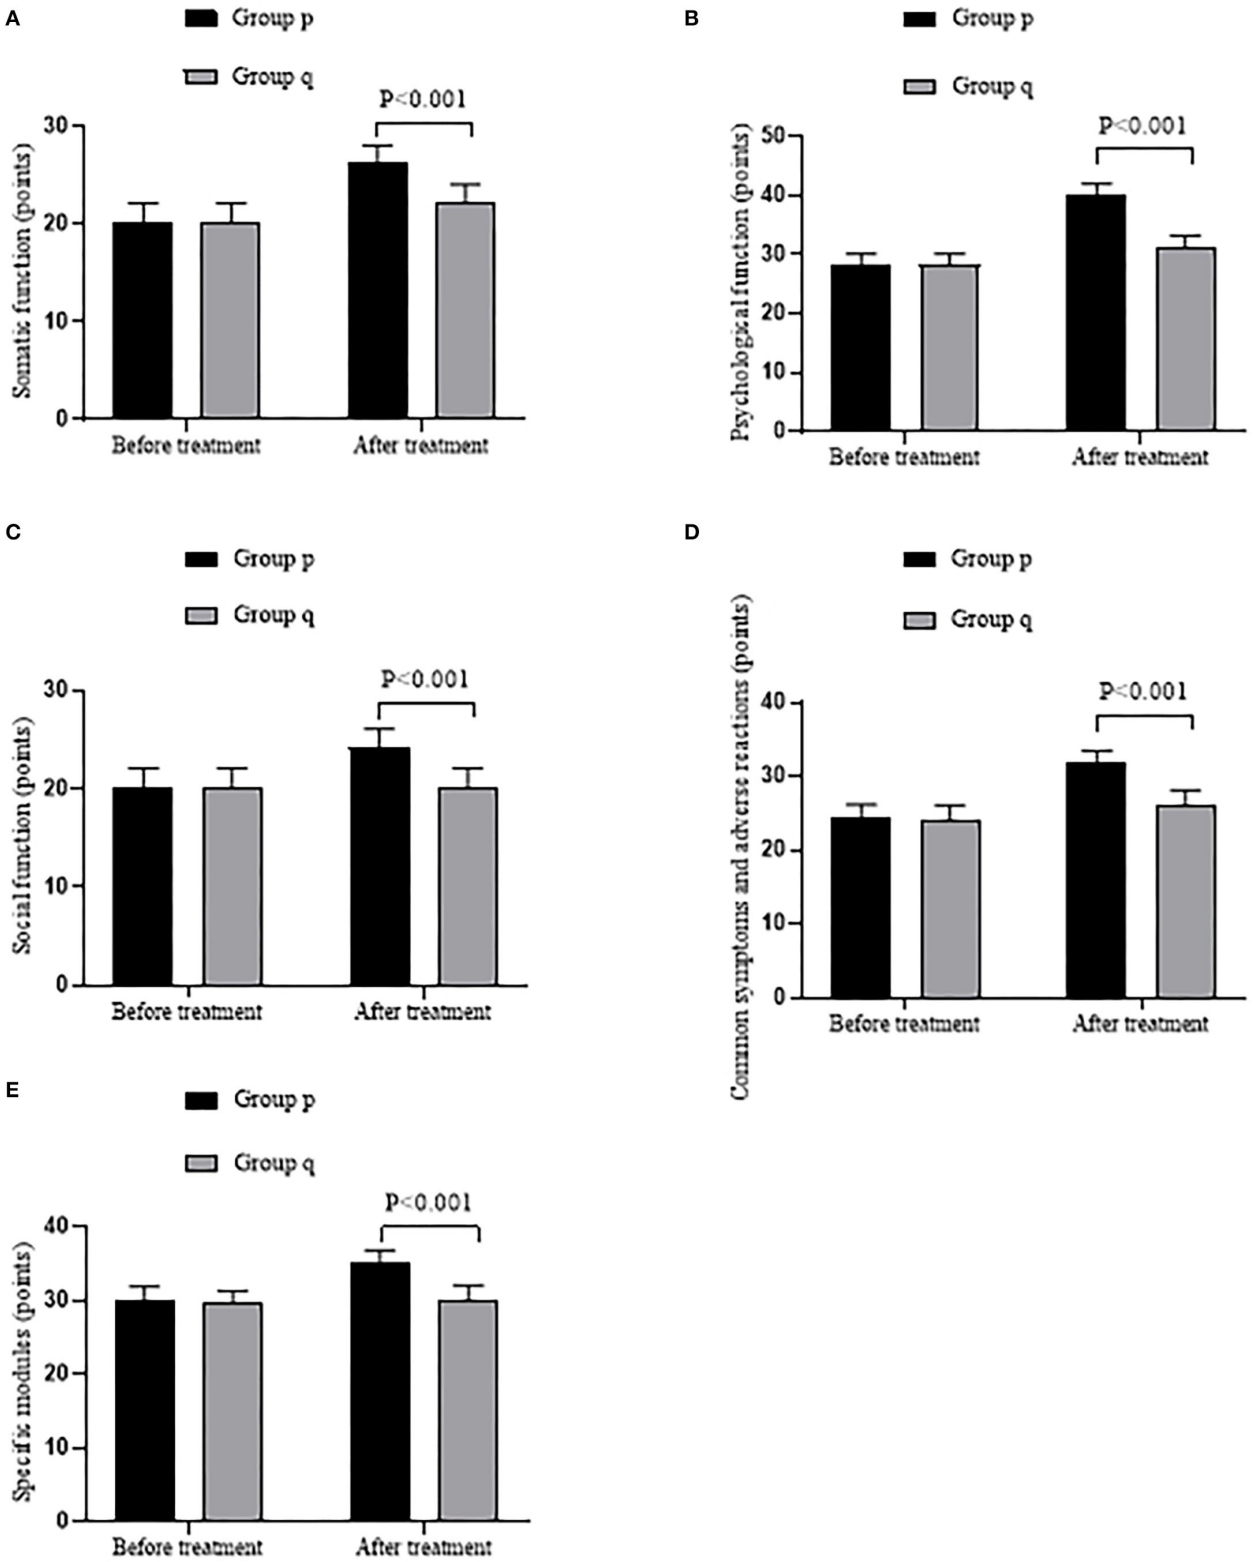

FIGURE 2 | Comparison of patient's QOL ($\bar{x} \pm s$, points). **(A)** showed the somatic function. **(B)** showed the psychological function. **(C)** showed the social function. **(D)** showed the common symptoms and adverse reactions. **(E)** showed the specific modules.

(25). After the previous EGFR-TKI treatment, patients in the disease progression received the simertinib, with a disease control rate of 92.0%. Therefore, osimertinib is certified as a ground-breaking therapy drug for NSCLC by the FDA (26, 27). The mechanism of osimertinib is that the acrylamide contained in osimertinib can form the covalent bonding with C797 at the edge of the ATP binding site in the catalytic domain of the EGFR gene, and then the irreversible binding occurs with the specific EGFR mutations, to solve the problem of abnormal signal transduction pathway in downstream cells caused by EGFR mutation, inhibit the excessive proliferation and mutation of tumor cells due to the EGFR mutation, and reduce the metastasis rate. The adverse reactions of osimertinib are mild compared with the conventional chemotherapeutic agents such as pemetrexed, and osimertinib shows a better tolerance in most clinical trials. Zhao Yang et al. have found that patients with osimertinib have no toxic reaction at a dose of 240 mg/d, and the incidence of severe adverse reactions is only 2%. Therefore, patients treated with osimertinib have a better organismal tolerance and an ideal long-term QOL (28). Chul et al. have confirmed that patients treated with osimertinib have significant progress in psychological and social functions, with a significant improvement in QOL (29), and the results are in accordance with this study. It is worth noting that the effect of osimertinib in improving the QOL of patients was mostly studied individually in current academia. This study paid attention to the combined application of osimertinib and other treatment measures, which found that osimertinib could improve the effect of pulmonary function training, and the higher QOL score in group p was consistent with the argument.

It is worth noting that long-term use of osimertinib will also produce drug resistance. No drug is available for patients with osimertinib resistance in the current practice. Scholars Xueting et al. have found that dihydroartemisinin can overcome the drug resistance (30), but there still lacks a large number of control studies. The fourth generation of EGFR-TKI drugs needs to be developed with osimertinib as a breakthrough point. At present, patients should be given the osimertinib combined with the pulmonary rehabilitation and health care training in the clinic, thereby providing a favorable physiological basis for the treatment of patients, reducing the postoperative morbidity, and improving their QOL.

In conclusion, the combination of osimertinib and pulmonary rehabilitation and health care training can improve the pulmonary function of patients with NSCLC with radical resection of lung cancer, and reduce the postoperative morbidity, thereby improving their QOL, which is conducive to reducing the patient's and society's medical burden.

Breast cancer is the most menacing cancer among all types of cancer in women around the globe. Early diagnosis is the only way to increase the treatment options which then decreases the death rate and increases the chance of survival in patients. However, it is a challenging task to differentiate abnormal breast tissues from normal tissues because of their structure and unclear boundaries. Therefore, early and accurate diagnosis and classification of breast lesions into malignant or benign lesions is an active domain of research. Over the decade, numerous artificial neural network (ANN)-based techniques were adopted in order to diagnose and classify breast cancer due to the unique characteristics of learning key features from complex data *via* a training process. However, these schemes have limitations like slow convergence and longer training time. To address the above mentioned issues, this paper employs a meta-heuristic algorithm for tuning the parameters of the neural network. The main novelty of this work is the computer-aided diagnosis scheme for detecting abnormalities in breast ultrasound images by integrating a wavelet neural network (WNN) and the grey wolf optimization (GWO) algorithm. Here, breast ultrasound (US) images are preprocessed with a sigmoid filter followed by interference-based despeckling and then by anisotropic diffusion. The automatic segmentation algorithm is adopted to extract the region of interest, and subsequently morphological and texture features are computed. Finally, the GWO-tuned WNN is exploited to accomplish the classification task. The classification performance of the proposed scheme is validated on 346 ultrasound images. Efficiency of the proposed methodology is evaluated by computing the confusion matrix and receiver operating characteristic (ROC) curve. Numerical analysis revealed that the proposed work can yield higher classification accuracy when compared to the

prevailing methods and thereby proves its potential in effective breast tumor detection and classification. The proposed GWO-WNN method (98%) gives better accuracy than other methods like SOM-SVM (87.5), LOFA-SVM (93.62%), MBA-RF (96.85%), and BAS-BPNN (96.3%)

Keywords: breast cancer detection, computer-aided diagnosis, supervised learning, texture features, ultrasound imaging, wavelet neural network

1 INTRODUCTION

Breast cancer is one among the most prevailing cancers diagnosed in women across the globe. It can occur in both men and women, but is more prevalent in women. According to the American Cancer Society (ACS) and World Health Organization (WHO), around 1.7 million people are diagnosed with breast cancer every year (1). Breast cancer can be treated and restored if it is detected at an early stage. Therefore, early detection of breast cancer is of prime importance for increasing the survival rate of patients (2). Screening is the best way of reducing mortality rate from breast cancer. Medical images are crucial sources of useful information. Several imaging techniques including mammography, ultrasound (US) imaging, and elastography are being widely used for diagnosing breast cancer (3, 4). Mammography is the most popular imaging technique for detecting cancer. However, it has some limitations like low sensitivity over ionizing radiations and is not suitable for dense breasts (5–8). Therefore, US or sonography is a valuable tool over mammography owing to its speed, inexpensiveness, and robustness (9), thereby it is safe and well tolerated by patients. Furthermore, US does not use any harmful radiation and has the ability to detect and differentiate benign from malignant tumors. Sonogram images are visualized, analyzed, and diagnosed manually by the physician or radiologist, but these are relatively tedious and time-consuming processes (10). In addition to this, manual analysis relies upon physician experience. Even experienced physicians may follow different diagnosis methods for manual analysis and have a sensitivity of 84% and specificity of 91% in breast cancer diagnosis. Therefore, there is a requirement to propose an efficient computer-aided diagnosis (CAD) system for US image analysis to enhance the diagnosis accuracy and help physicians make accurate timely decisions. An automated CAD system can help the physician to analyze the US image precisely and emphasize the suspected areas that need further investigation. Numerous methods for breast cancer diagnosis and developing sophisticated methods for enhancing the diagnosis accuracy have been carried out in the past years (11). A CAD involves five major phases: preprocessing, segmentation, feature extraction, feature selection, and classification (12). formulated a hybrid method for breast cancer diagnosis by integrating particle swarm optimization (PSO) and support vector machine (SVM) algorithms (13, 14).

PSO is mainly adopted for feature selection. The multiple instances learning-based breast cancer classification method is investigated by (15). This method is based on extracting the features from enhanced images and adopting SVM for segmentation (16). A self-organizing map (SOM) is used for converting the instance space to concept space. Finally, SVM is used for diagnosing breast cancer (17). proposed a classification approach for breast cancer diagnosis. Here, the US images are preprocessed with histogram equalization and the gamma correction method. Subsequently, texture features are extracted and classified as benign or malignant with the SVM classifier (18). reduced the speckle noise from breast US images by using an enhanced oriented despeckling anisotropic diffusion bilateral filter (19, 20). developed a method for increasing the classification accuracy. Here, the input images are preprocessed and segmented using the watershed algorithm. Morphological and texture features are obtained and fed as input to the classifier (21). employed an ANN for formulating the breast cancer diagnosis system. They computed feature scores based on breast imaging reporting and data system (BIRDS) criteria and then they used the biclustering method by (22, 23) to generate the hidden features. A hybrid model based on the fruit fly optimization algorithm (FLA) and SVM was assessed by (24). They employed FLA for tuning SVM parameters (25). The proposed particle swarm optimization, non-domination sorting with classifier technique model, and Bayes' theorem help to select the most significant parameters and achieve optimum accuracy in breast cancer prediction (26). Jain et al. (2021) (27) proposes ensemble learning methods while making predictions. Bayes, K-nearest neighbors, AdaBoost, Gradient boosting, XGBoost, Random forest, ensembles, and neural networks are used for analyzing and predicting the dataset. It gives 87.248% and 87.7934% validation accuracy for predicting SARS79 CoV and SARS-CoV-2 virus respectively. The proposed algorithm produced the most accurate results, with 0.919 AUC and 87.248 percent validation accuracy for predicting SARS-CoV and 0.923 AUC and 87.7934 percent validation accuracy for predicting SARS-CoV-2 virus. Gupta et al. (2021) (28) proposed multimodal textual data consists of different emotions have been handpicked through the real time tweets related to COVID-19.After evaluating the most frequent word,modal vector has been created by using term frequency-inverse document frequency. Results showed that FLA-SVM achieved better classification accuracy. However, most of researchers have used machine learning models to perform classification tasks. Though machine learning is a powerful tool for image classification, it has some limitations like overfitting, increased learning time, and the fact that developing an optimal network structure is a tedious task and requires more time. Furthermore, optimizing parameters of the network is a difficult task. Parameter optimization is usually accomplished by experimentation. The major intention of this research is to

propose a CAD system to diagnose breast cancer in an automated manner so as to overcome the limitations of the aforementioned existing techniques given in the literature. The major contributions of this work are as follows:

(1) To develop an automated CAD system by adopting a meta-heuristic algorithm and machine learning (2), to optimize the wavelet neural network with the grey wolf optimization algorithm to improve the classification accuracy in US breast cancer diagnosis, and (3) to compare the obtained outcomes with prevailing methods so as to project the preeminence of the proposed CAD system. The paper is structured as follows. Section 2 demonstrates the proposed CAD system for breast cancer. Section 3 provides experimental results and comparison with the existing methods. Section 4 concludes the paper.

2 PROPOSED CAD SYSTEM

Research studies proved that ANN is an effective tool for breast cancer identification. Many researchers have employed ANN for developing a CAD system and showed comparatively better results. However, determining the optimal topology of ANN is a very difficult task. The number of hidden layers, hidden neurons, weights, and bias is usually determined by the trial-and-error method. This is a time-consuming process. To deal with this issue, bio-inspired algorithms like the genetic algorithm (GA), particle swarm optimization, and the fractional lion algorithm have been used for optimizing ANN parameters. The basic articulation of the suggested CAD system has been depicted in **Figure 1**.

2.1 US Image Preprocessing

Preprocessing is a crucial process in medical image processing. The aim of preprocessing breast US images is to improve the image quality and to remove unwanted information. **Table 1** shows the symbol's nomenclature. In this research work, preprocessing involves two processes: enhancement and despeckling. A sigmoid filter is applied to breast US images to improve the quality. Let an input breast US image be assumed as *H*. Mathematically, the sigmoid filter can be expressed as Equation 1:

$$H_{enh} = (H_{mx} - H_{mn}) \times \frac{1}{1 + e^{\left[\frac{A-a}{\gamma}\right]}} + H_{mn} \quad (1)$$

Where, *H* is an input image, H_{enh} is an enhanced image, mn is the minimum gray value, mx is the maximum value, and α and γ represent the center and width, respectively. In this paper, *lpha* = 4 and γ = 7 is used. **Figure 2** shows the processed images after enhancement.

After enhancement, interference-based despeckling followed by anisotropic diffusion (IDAD) is applied to the enhanced image to remove speckle noise. The bright and dark regions of the US image represent constructive and destructive interference, respectively. The IDAD filter will suppress only destructive interference without losing any image information. The

TABLE 1 | Nomenclature.

S.No	Symbol	Description
1	X	Input network
2	Y	Output network
3	H	Input breast US image
4	mn	Minimum gray value of the image
5	mx	Maximum gray value of the image
6	W	Weights between the layers
7	Ψ	Wavelet activation function
8	α	Center of the image
9	γ	Width of the image
10	*i*	Wavelet number
11	j	Wavelet level
12	k	Translation parameter
13	F	No. of features in the network
14	y	No. of classes in the network
15	Z	No. of hidden layers in the network
16	b	Bias
17	D	Modified distance vectors
18	C,E	GWO parameters

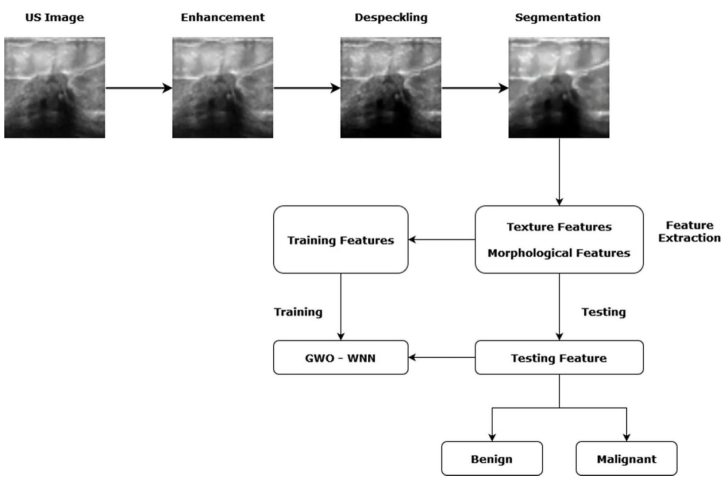

FIGURE 1 | Articulation of the Proposed CAD system.

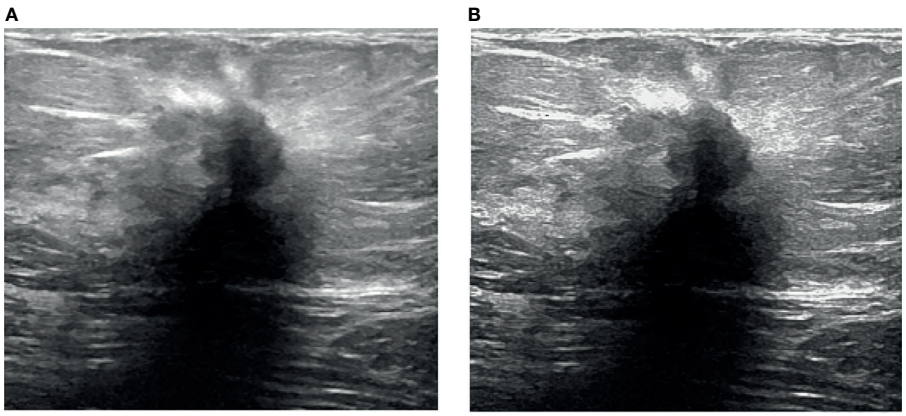

FIGURE 2 | Processing results. **(A)** Ultrasound image and **(B)** enhanced ultrasound image.

function of IDAD can be divided into two processes: median filter and interference suppression. A median filter with a kernel size of $n \in n$ is applied to the enhanced image. Image pixels are filtered with an $n \in n$ kernel around each pixel, replacing the central pixel value with the central value of all the pixels present in the kernel, and are mathematically represented in Equation 2.

$$H_{\text{med}}(X,Y) = \underset{i,j \in k_{n,n}}{\text{med}} \left[k_{n,n}(i,j) \otimes H_{\text{enh}}[X+i, Y+j] \right] \quad (2)$$

To prevent over-filtering, the kernel size was set to 3. Destructive interference suppression is expressed in Equation 3.

$$H_c(X,Y) = \max\left(H_{\text{enh}}(X,Y), H_{\text{med}}(X,Y)\right) \quad (3)$$

Where, A_c denotes the constructive interference image. Constructive interference suppression done by applying the median filter is applied to H_c to remove the remaining extreme single pixels. **Figure 3** shows the breast US image after despeckling. It was clearly observed that the IDAD filter preserves the edges and boundaries of the image.

2.2 Segmentation

Image segmentation plays a significant role in breast cancer diagnosis. It is mainly employed to isolate the lesion region from its background. In recent years, clustering methods such as fuzzy C-means (FCM) and k-means algorithms were adopted for image segmentation. The FCM algorithm can separate lesions precisely. This algorithm is sensitive to noise and other artifacts. On the other hand, the k-means algorithm is faster than FCM but it has some limitations like incomplete detection of malignant lesions. This research presents an automatic segmentation method by combining the FCM and k-means algorithms in order to obtain accurate segmentation. The despeckled image is used as input in the segmentation process. The proposed segmentation method starts with initialization of the number of clusters, M, maximum iterations, and the termination parameter. The cluster centers can be mathematically expressed in the following Equations 4 and 5:

$$\text{Initial mean} = \frac{(1:M) * n}{M+1} \quad (4)$$

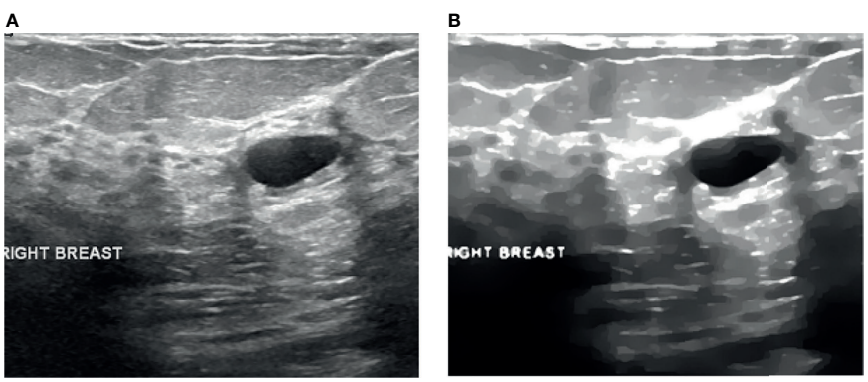

FIGURE 3 | Despeckling results. **(A)** Raw US image and **(B)** filtered image.

and,

$$n = \max(US\ \text{image}) + 1 \quad (5)$$

We assign each pixel to the nearest cluster center according to the minimum distance by examining the distance between the cluster centers and pixel value, and then recalculate the new cluster centers. This process repeats until the termination criterion is met. Both soft and hard clustering are used in the cluster formation. Hard clustering assigns each point based on the nearest cluster, in contrast, soft clustering assigns every point based on the degree of membership value. The clustered image is converted into a binary image with the thresholding method. Image binarization is one of the essential processes in image segmentation. The output of the binarization is the segmented image with a dark background and white foreground (lesion region). Active contour methods have been employed for segmentation and boundary tracking. In this research, active contour by the level set method is applied to track the boundary of the segmented lesions. The active contour by the level set method starts with initial boundary shapes represented as contours and is iteratively changed by executing shrinkage or expansion based on the constraints. The main advantage of active contour by level set is dividing the image into sub-images with continuous boundaries. A sample outcome of the segmentation process is shown in **Figure 4**.

2.3 Feature Extraction and Selection

The crucial steps in breast cancer classification are feature extraction and feature selection. It is well known that benign and malignant lesions differ in both shape and pixel values. It is important to select the features related to shape and boundary of the lesion. Morphological features depict the characteristics such as shape and border of the lesion. Benign tumor margins are smoother, round or oval-shaped, and regular, whereas, malignant margins are angular, irregular shaped, and edged. It is also important to consider texture features for breast cancer classification since there are differences in boundary and internal echoes of malignant and benign lesions in US images. Therefore, the proposed CAD system employs two features to conduct differentiation amid benign and malignant lesions. Various texture and morphological features that were selected for conducing this experiment are provided in **Figure 5**. The obtained morphological and texture features are combined in order to obtain a single feature set. Principal component analysis (PCA) has been adopted to reduce the size of the combined features so as to speed up the training and testing processes, and also to improve the classification rate.

2.4 Classification

Classification has been identified to be applicable in different domains including medical image classification. The classification task largely relies on how efficiently the discriminant features and classifiers were selected. In recent years, numerous computational intelligence (CI) techniques such as the feed forward neural network, SVM, and wavelet neural network (WNN) have been used for image classification due to their ability to learn and find the relation between input and output variables *via* a training process. However, the feed forward neural network is largely popular and the most commonly used to diagnose medical images. Wavelet is a mathematical tool used to analyze a signal or an image in different resolutions. It offers the potential of obtaining spatial and frequency domain features of a signal or an image. This paper develops a classifier by combining a neural network and the wavelet theory WNN to obtain a higher classification rate when compared to its peers. The peculiar advantages in using WNN when compared to multilayer perceptron (MLP) and SVM include the fact that WNN can handle non-linear, noisy, and periodic signals. Thus, it works well in determining the abnormalities in breast US images. Moreover, WNNs are robust and require only smaller training samples for tuning the parameters when compared with MLP and SVM. Also, WNNs offer faster convergence when compared with MLP and SVM. Hence, this proposed method employs WNN owing to these aforementioned enhanced features.

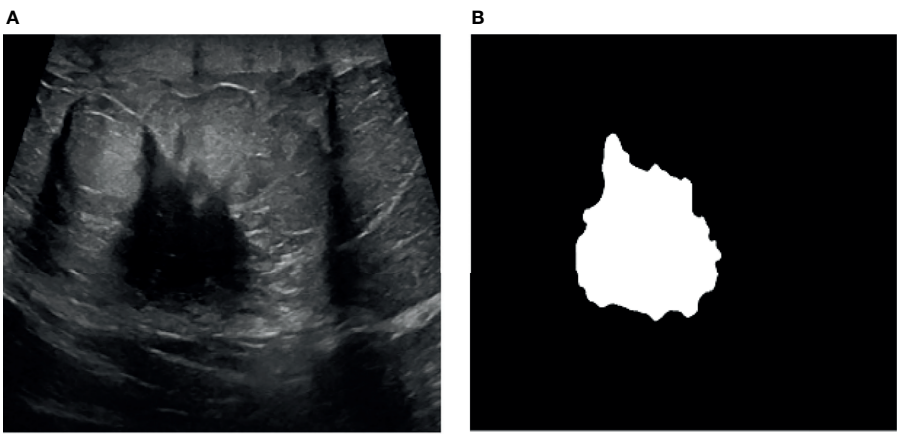

FIGURE 4 | ROI segmentation. **(A)** Ultrasound image and **(B)** segmented image.

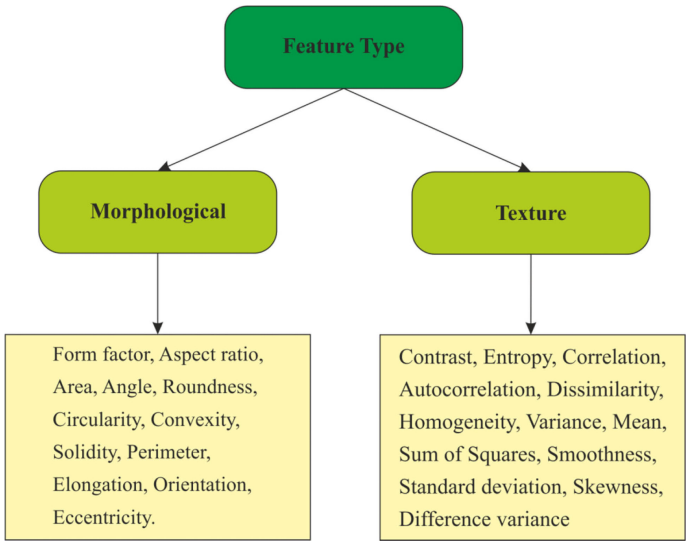

FIGURE 5 | Selected features for this proposed scheme.

Figure 6 shows the general structure of WNN. A typical WNN has three layers which are the input, hidden, and output layers. The input layer is responsible for receiving input signals or feature vectors from the source. The hidden layer has hidden neurons similar to neurons in standard neural networks (NNs). In standard NNs, the sigmoidal activation function is utilized at the hidden layer. Wavelets are subsequently incorporated as the activation function in the hidden layer of WNNs. Finally, the output layer corresponds to the linear combination of the wavelet basis function. The error between predicted values and expected values is calculated by cost function, and also represents itself in the format of a single real number. Based on the nature of problems, the cost function could be framed in various ways. There is no standard rule for selecting the mother wavelet function as the activation function.

In general, there are numerous categories or families of wavelets such as Daubechies, Symlets, Coiflets, biorthogonal, Haar wavelets, etc. In this paper, the Haar wavelet is employed owing to its characteristics toward simple structure and increased memory efficiency. The Levenbergmarquart (LM) algorithm is employed for minimizing the error and also to update the weights of WNN. It is noted that psi signifies the wavelet activation function. In a standard neural network, the tan sigmoidal activation function is used at the hidden layer. But, in the case of a wavelet neural network, wavelets are employed as

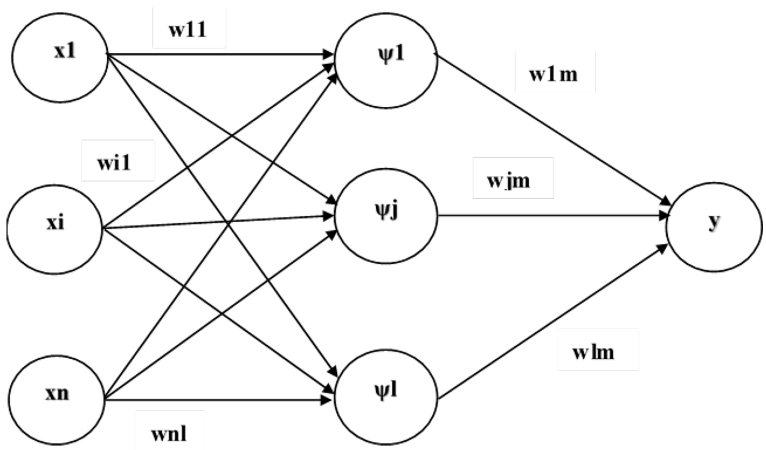

FIGURE 6 | Structure of WNN.

the activation function, thus, psi corresponds to the mother wavelet.

Let the input signal be represented as X={x_1, x_2, x_3,…,x_n} and the output signal be signified as Y={1, 2, 3, …, m}, with w_{ij} and w_{jk} corresponding to the weights between the layers. Ψ is the wavelet activation function. The weighted summation of the wavelet basis function at the hidden layers is closely related to the output layer. The output of the network with respect to the corresponding Haar wavelet function can be represented in the following Equations 6 and 7:

$$Yp = \sum_{j=1}^{I} W_{jk} \Psi ab \left[\sum_{i=1}^{n} X_{ij} W_{ij} + bi_j \right] \tag{6}$$

$$\Psi_{ab}\left(net_j\right) = \Psi \left[\frac{net_j - b_j}{a_j} \right] \tag{7}$$

Where a and b are the wavelet scale and translation parameter of the j_{th} hidden neuron. Although WNN is a promising tool for pattern recognition, optimizing the parameters of WNN like learning rate, weight, number of hidden neurons, etc., are quite difficult. The features of the Haar wavelet function that was employed in this proposed method are described below.

Let us assume, m = 2, k = 0,1,1,3,… $.m - 1, j$ = 0,1,2,3, and $i = m + k + 1$. Where i signifies the wavelet numbers, j corresponds to the wavelet levels, J signifies the highest resolution, and k corresponds to the translation parameter. The highest value of i is selected as i=2M and the lowest value is selected as i=2. The typical Haar wavelet families corresponding to $t \in [A,B]$ shall be mathematically expressed in the following Equations 8 and 9,

$$h_i(t) = \begin{matrix} 1 \text{ for } t \in |\xi_1(i), \xi_2(i)| \\ \& \\ -1 \text{ for } t \in |\xi_2(i), \xi_3(i)| \\ 0 \text{ for otherwise} \end{matrix} \tag{8}$$

Here,

$\xi_1(i) = A + 2k\mu\Delta x$, $\xi_2(i) = A + (2k+1)\mu\Delta x$, and $\xi_3(i) = A + (2k+1)\mu\Delta x$

$$\text{Also, } \mu = \frac{M}{m} \quad \Delta x = \frac{B-A}{2M} \tag{9}$$

The scaling function $h_{1(t)}$ shall be mathematically signified in Equation 10:

$$h_1(t) = \begin{cases} 1 \text{ for } t \in [A,B] \\ 0 \text{ for otherwise} \end{cases} \tag{10}$$

In general, the Haar wavelets are orthogonal with respect to each other. Hence, the orthogonality property shall be specified in Equation 11:

$$\int_A^B h_i(t) \times h_s(t) = 2^i \delta_{ij} = \begin{cases} 2^j \text{ i = s = } 2^j + k \\ 0 \qquad \text{i} \neq \text{S} \end{cases} \tag{11}$$

The orthogonality property of this Haar wavelet is mainly employed to enhance the efficacy of the present method. The basic function y(t) within the interval [A,B] shall be extended to the Haar wavelet and this wavelet extension shall be expressed in Equation 12:

$$y(t) = \sum_{i=1}^{2M} a_i h_i(t) \quad a_j = 2^j \int_A^B y(t) \times h_i(rmt)dt \tag{12}$$

To address the aforementioned limitations, the GWO algorithm is employed for tuning the WNN parameters. GWO is a category of nature-inspired algorithms motivated by the hierarchical organization and hunting attitude of grey wolves. GWO was initially formulated by (29). All grey wolves like to live as a group, thereby this GWO optimization algorithm possesses a social dominant hierarchy.

In a GWO algorithm, α represents the leader wolf since his/her order should be obeyed by the group. Here, α is responsible for making the decision regarding hunting, sleeping place, and so on. The β wolf should respect the leader, but commands δ and ω. Delta wolves should respect α and β, but dominates ω. The ω wolves have to submit to α, β, and δ. It was observed that the GWO algorithm possesses good exploration and exploitation characteristics when compared to particle swarm optimization, the genetic algorithm, and the cat swarm optimization algorithms. The corresponding pseudo code for the GWO algorithm which was employed in this experiment is given in the following Equations 13-23.

Initialize search agents, S randomly, variables v, and maximum iterations, I_{max}, a, C, and E.

$$D^U = \left| E^u X^u p(t) - X^U(t) \right| \tag{13}$$

$$X^u(t+1) = X^u p(t) - C^u \cdot D^u \tag{14}$$

$$C^u = 2.a \,.\, r1 - a \tag{15}$$

$$E^u = 2.r2 \tag{16}$$

Evaluate the fitness values of each agent.

X_α – First prime agent,
X_β – Second prime agent ,
X_δ -Third prime agent

$$D_a^U = E_1^u \,.\, X_\alpha^u - X^u \tag{17}$$

$$D_\beta^U = E_2^u \,.\, X_\beta^u - X^u \tag{18}$$

$$D_\delta^U = E_1^u \,.\, X_\delta^u - X^u \tag{19}$$

$$X_1^u = X_\alpha^u - C_1^u \cdot (D_\alpha^u) \tag{20}$$

$$X_2^u = X_\beta^u - C_1^u \cdot \left(D_\beta^u\right) \tag{21}$$

$$X_3^u = X_\delta^u - C_1^u \cdot \left(D_\gamma^u\right) \tag{22}$$

While (il_{max})for j = 1:S

In this proposed method, GWO-WNN is employed for developing WNN and is tuned with the best topology by tuning the weights, number of hidden layers and neurons, and respective learning rate. The algorithmic steps used to train and classify the breast US images are given in the following steps

Step 1: Read breast US image, *H*.

Step 2: Convert 3D image to 2D image.

Step 3: Enhance the quality of the image using Equation (24).

Step 4: Despeckle the enhanced image using Equation (26).

Step 5: Perform segmentation.

Step 6: Extract the features listed in **Figure 5**.

Step 7: Design a classifier.

Fi represents the count of features, y_o corresponds to the count of classes, and Z_n represents the count of hidden layers. The GWO algorithm determines the count of hidden neurons in each hidden layer weight and learning rate. Let g be the transfer function and it can be expressed in the following Equations 24 and 25.

$$Yp = g(Zj) \quad (24)$$

$$Z_j = \Psi_{ab} \sum_{j-1}^{n} X_i W_{ij} + b_j \quad (25)$$

$Z_p^j = \sum_v W_{v\cdot p} y_v^j + B_p$ Where, j represents the j^{th} hidden neuron, y_p is the output of the p^{th} neuron, $W_{i,j}$ is the weight, and b denotes the bias.

In this research work, the hidden layer and output layer used the wavelet activation function and linear activation function accordingly. Mean square error (MSE) is utilized as the fitness function for training, MSE can be expressed in Equation 26:

$$\mathrm{MSE} = \sum_{j \in t\mathrm{p}=1}^{\mathrm{Y}_\theta} \sum \left(\mathrm{t}_\mathrm{p}^\mathrm{j} - \mathrm{y}_\mathrm{p}^\mathrm{j}\right)^2 \quad (26)$$

Step 8: Optimize the parameter of WNN

Where t_p^j is the labeled class and y_p^j is the output obtained from the network.

3 RESULTS AND DISCUSSION

3.1 US Image Dataset

Breast US images were acquired from 346 patients from the database given below (https://scholar.cu.edu.eg/q=afahmy/pages/dataset) (30) including 249 malignant and 97 benign samples employed for assessing the effectiveness of the proposed GWO-tuned WNN. The entire dataset was divided into two sets: 70% of the data were utilized for training and the rest of the 30% were used for testing the classification ability of the system. A 10-cross fold validation was considered to test the efficiency of the presented system. The number of benign and malignant cases used in this research work is graphically displayed in **Figure 7**. The proposed scheme was implemented using MATLAB so as to analyze the efficacy of the presented system when compared to its peers.

3.2 Evaluation Indices

This section describes the evaluation parameters that were employed to analyze the efficacy of the presented scheme. Accuracy of the classification, specificity, sensitivity, positive predictive value (PPV), negative predictive value (NPV), confusion matrix, and ROC were employed to analyze the classification performance.

3.3 Performance Evaluation

Figure 8 illustrates a variety of benign and malignant breast ultrasound pictures. The preprocessed 257 benign and malignant US pictures are shown in **Figures 9** and **10**, respectively. **Figure 11** depicts the confusion matrix to discriminate the cancer (malignant) from non-cancer (benign) breast lesions. In this research work, malignant tumors were defined as true positive and benign as true negative. From **Figure 11**, it can be observed that 245 out of 249 images were correctly diagnosed as malignant tumors. Likewise, 94 out of 97 images were correctly identified as benign. Consequently, true positive, false positive, false negative, and true negative values were obtained at 70.8%, 1.2, 0.9%, and 27.2%, respectively. The results exhibit superior classification accuracy of 98% with a sensitivity of 98.8%, specificity of 95.9%, PPV of 98.4%, and NPV of 96.9%.

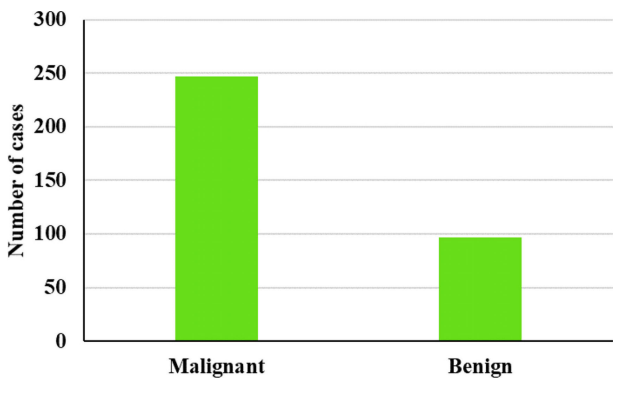

FIGURE 7 | US image dataset.

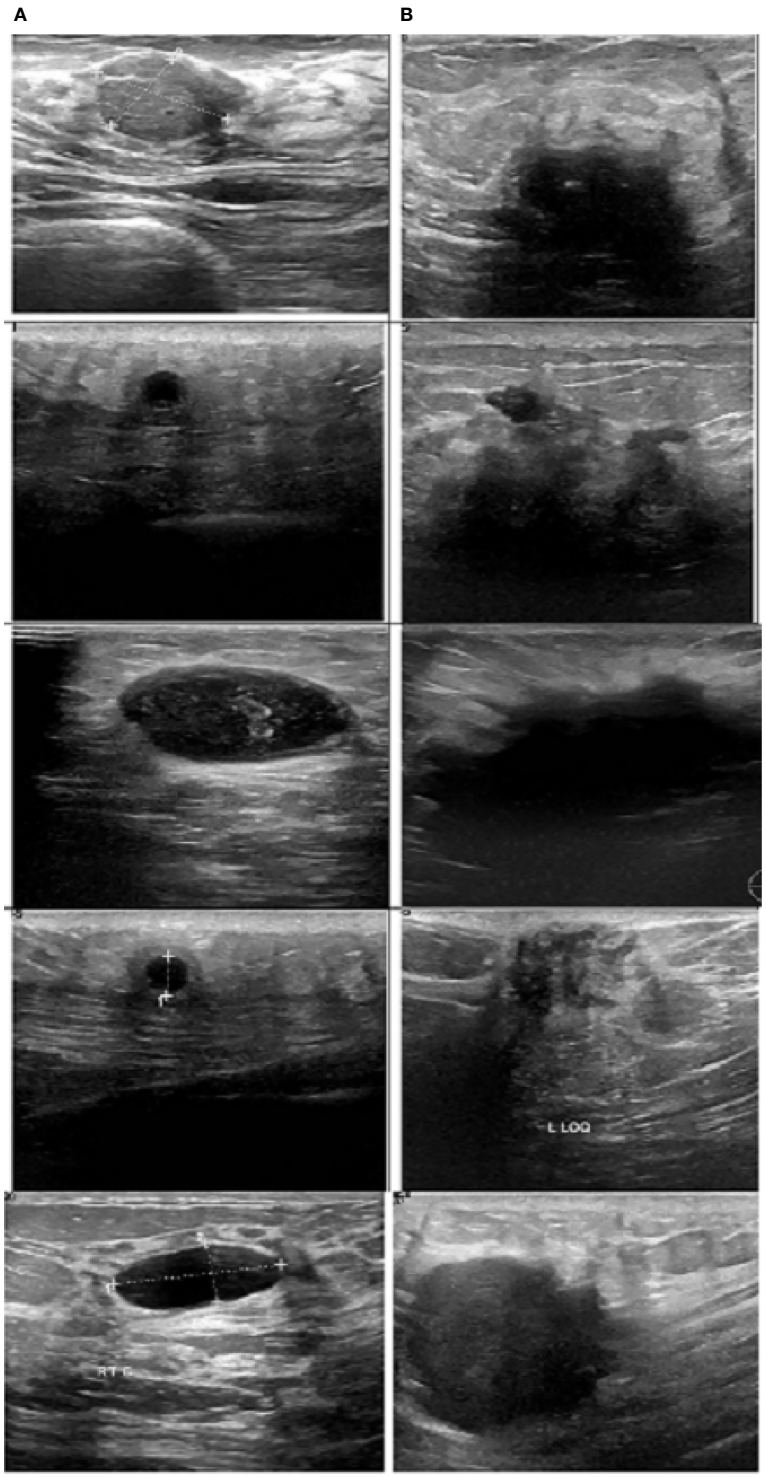

FIGURE 8 | Sample images. **(A)** Benign and **(B)** malignant (30)

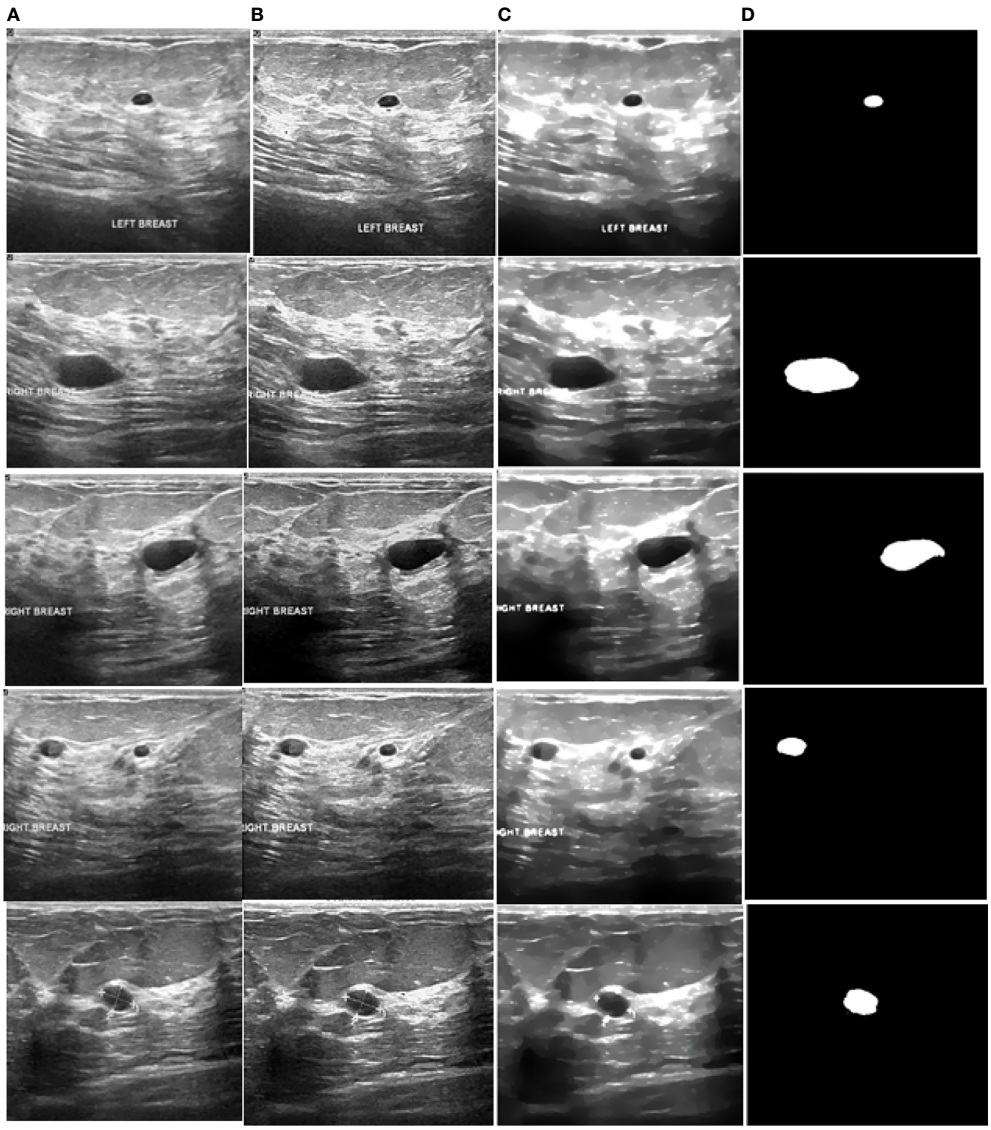

FIGURE 9 | Processed benign images. **(A)** US image, **(B)** enhancement, **(C)** despeckling, and **(D)** Segmentation.

This paper evaluated some widely used performance indicators such as the confusion matrix, receiver operating characteristic (ROC), classification accuracy, sensitivity, and specificity. Accuracy calculated the proportion between true positive and total data, and shall be mathematically represented in the following Equations 27, 28, and 29:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{27}$$

$$Specificity = \frac{TN}{TN + FP} \tag{28}$$

True positive is represented by TP, true negative is represented by TN, false negative is represented by FN, and false positive is represented by FP.

$$Sensitivity = \frac{TP}{TP + FN} \tag{29}$$

3.4 Comparison With the State-of-the-Art Existing Methods

In this paper, a CAD model in breast cancer diagnosis was proposed and implemented. The efficiency of the presented CAD system was analyzed with the current methods: SOM-SVM (15), LFOA-SVM (24), MBA-RF (31) and BAS-BPNN (32) in terms of statistical metrics and ROC curve.

Figure 12 and **Table 2** display the classification performance of the proposed GWO-tuned WNN with the existing classifiers SOM-SVM, LFOA-SVM, MBA-RF, and BAS-BPNN (15). integrated SOM and SVM [SOM-SVM] for developing a breast

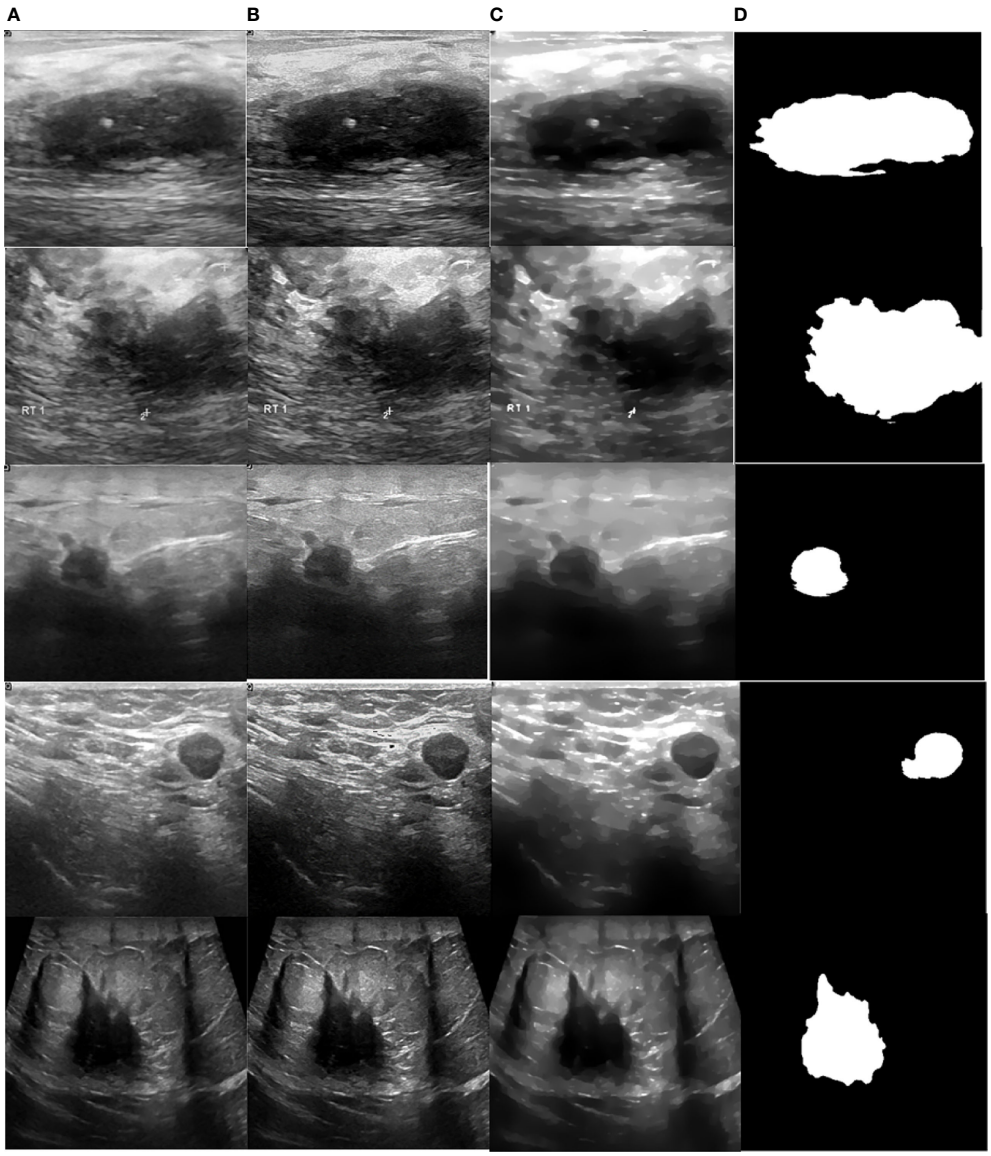

FIGURE 10 | Processed malignant images. **(A)** US image, **(B)** enhancement, **(C)** despeckling, and **(D)** Segmentation.

cancer diagnosis system. Here, the input images were preprocessed and divided into ROIs. The segmented ROIs and subregions were considered as bags and instances of bags, respectively. Subsequently, SOM was used for converting the instance space to concept space. Finally, SVM was incorporated for classifying the breast lesions. The major limitation here is that the method uses only local features for classification. Global features are also equally important for breast cancer diagnosis, thereby this is considered as a main drawback in this approach.

(24) implemented a framework by using SVM for breast cancer diagnosis. Here, the fruit fly optimization algorithm (FLA) modified by the Levy flight optimization algorithm (LFOA) was adopted for tuning the SVM parameters. High level features were obtained, normalized, and applied as input to the LFOA-SVM. However, this framework resulted in higher computational overhead, which was considered to be a focal drawback in this approach.

(31) examined the features of the modified bat algorithm (MBA) in selecting the feature vectors for breast cancer diagnosis. MBA employs the random sampling method to select features from the input data. Selected features are ranked and further employed to train the random forest (RF) classifier. This MBA-RF method exhibited comparatively better outcomes than the correlation-based feature selection method.

(32) formulated a strategy by integrating bio-inspired algorithms (BAs) and the back propagation neural network (BAS-BPNN). Here, the input data were subjected to preprocessing, feature extraction/selection, and classification.

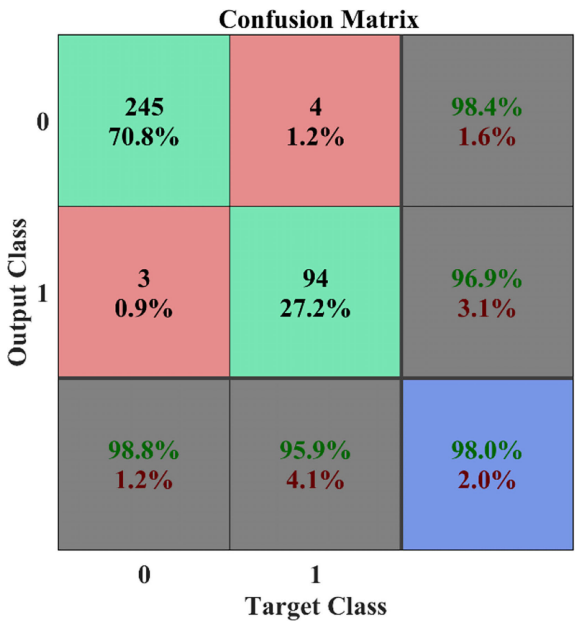

FIGURE 11 | Confusion matrix.

Moreover, three BAs were typically employed for selecting the features. Each algorithm selected corresponding subsets of features. The selected features were combined and classified by using BPNN.

(33) formulated three subnetworks, of which the first one contained the ROI, the second one contained the filtered ROI, and the third one was spread to the whole image. The first subnetwork in the CNN model was formulated using a single block, whereas the second subnetwork was formulated by two blocks and the third network was formulated by three blocks.

For datasets acquired using different scanners with different imaging protocols (34), used an efficient method by transfer learning to fine-tune the classification task in order to improve the accuracy. The mean accuracy reached 0.9 by the CNN hence accuracy in testing increased from 0.47 to 0.78 using CNN.

(35) suggested that the mixture of –spatial spectral features boost the classification precision of the CNN model which needs considerably fewer training parameters comparable with the best known system.

(36) formulated a conventional binary SVM classifier which was trained with seven features such as color and texture attributes obtained from the Gaussian model super pixels of the images belonging to WCE.

Numerous methods have been developed to analyze the strength of meta-heuristic algorithms for selecting salient features to improve the classification rate. However, these methods have some shortcomings like increased training time, overfitting, and slow convergence. Very few researchers have used meta-heuristic algorithms for tuning the parameters by

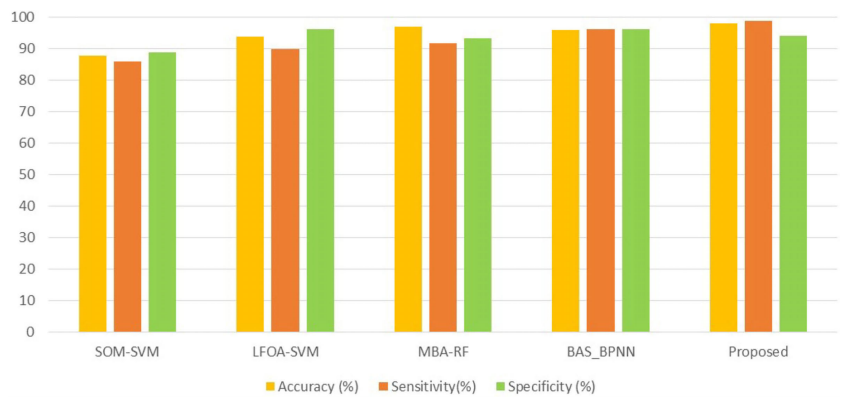

FIGURE 12 | Performance comparison with existing methods.

TABLE 2 | Classification performance of the proposed GWO-tuned WNN with existing classifiers.

Contributors	Data	Method	Accuracy(%)	Sensitivity(%)	Specificity(%)
(15)	US image	SOM-SVM	87.5	86.11	88.54
(24)	US images	LFO-ASVM	93.62	90	96.3
(31)	WDBC	MBA-RF	96.85	91.4	93.2

Proposed method	US images	GWO-WNN	98	98.8	95.9

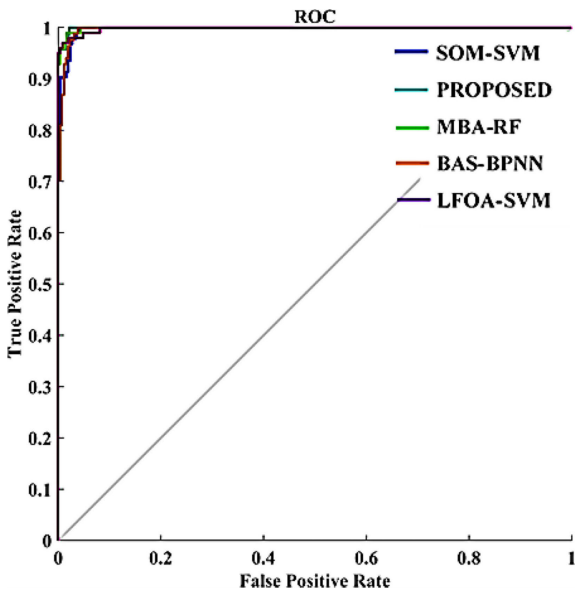

FIGURE 13 | ROC curve comparison.

machine learning. Therefore, we used the GWO algorithm for tuning the parameters of WNN to reduce the computational overhead and training time. In the proposed system, 10-cross fold validation is considered to test the efficacy.

Almost all previous research works employed BAS for feature selection. But, in this paper, we employed the GWO algorithm for optimizing the WNN parameters. Here, optimization aids to reduce computational cost and improve classification accuracy. As depicted in **Figure 13**, it was observed that existing methods were 87.5% (SOM-SVM), 93.62% (LFOA-SVM), 96.85% (MBA -RF), and 96.3% (BAS-BPNN) accurate in terms of classification (15, 24, 31, 32).

However, the proposed CAD system attained a classification precision of 98% which outperforms the other existing models SOM-SVM, LFOA-SVM, MBA-RF, and BAS-BPNN. Comparison outcomes indicate that the performance of the proposed GWO-WNN is better than other classifiers. This is because of the important scenario in the presented method of integrating GWO and WNN, and tuning WNN parameters with the GWO algorithm. GWO has a natural leadership mechanism which makes it more effective than other approaches. **Figure 13** provides the comparative analysis in terms of the ROC curve of the proposed scheme with other classifiers. From **Figure 13**, it can be seen that the area under the curve of the presented CAD system is greater than that of the state-of-the-art methods like SOM-SVM, LOFA-SVM, MBA-RF, and BAS-BPNN (0.99, 0.91, 0.93, 0.92, and 0.95). Therefore, this particular result highlights the effectiveness of the GWO-tuned WNN in US image classification. As a result, classification accuracy was improved with the proposed method.

4 CONCLUSION

Ultrasound imaging techniques are an important diagnostic tool for breast cancer diagnosis. The CAD model can assist physicians in generating more precise decisions. This paper proposed a CAD model for breast cancer diagnosis by the integration of a wavelet neural network and the grey wolf optimization algorithm. In this system, a sigmoid filter was used to increase the contrast of the images and IDAD to remove the speckle noise. An ROI was obtained from the preprocessed image, and subsequently the morphological and texture features were extracted and combined. The dimensions of the obtained features were reduced with PCA. Finally, GWO-WNN was executed to perform the classification task. Conventional WNN requires increased time for training and optimizing the parameters. This proposed scheme employed GWO for tuning the WNN parameters which eventually reduced the computation and training times. The simulation results clearly showed that the suggested CAD model system attained desirable classification accuracy when compared to its peers with respect to the classification accuracy. The leading advantages of the proposed GWO-WNN method include increased robustness, smaller training data, and faster convergence. Ultimately, since the GWO algorithm has a natural leadership mechanism, it makes it superior to other bio-inspired algorithms. Most of the former methods have employed a meta-heuristic algorithm for feature selection. But, the proposed CAD system used the meta-heuristic algorithm to tune the WNN parameters which helped to reduce the computational cost and avoid the local minima problem, thereby exhibiting improved performance. In future, few other meta-heuristic algorithms like cat swarm optimization, ant lion optimization etc., will be investigated to further improve the classification accuracy.

The global spread of the SARS coronavirus 2 (SARS-CoV-2), its manifestation in human hosts as a contagious disease, and its variants have induced a pandemic resulting in the deaths of over 6,000,000 people. Extensive efforts have been devoted to drug research to cure and refrain the spread of COVID-19, but only one drug has received FDA approval yet. Traditional drug discovery is inefficient, costly, and unable to react to pandemic threats. Drug repurposing represents an effective strategy for drug discovery and reduces the time and cost compared to *de novo* drug discovery. In this study, a generic drug repurposing framework (SperoPredictor) has been developed which systematically integrates the various types of drugs and disease data and takes the advantage of machine learning (Random Forest, Tree Ensemble, and Gradient Boosted Trees) to repurpose potential drug candidates against any disease of interest. Drug and disease data for FDA-approved drugs ($n = 2,865$), containing four drug features and three disease features, were collected from chemical and biological databases and integrated with the form of drug-disease association tables. The resulting dataset was split into 70% for training, 15% for testing, and the remaining 15% for validation. The testing and validation accuracies of the models were 99.3% for Random Forest and 99.03% for Tree Ensemble. In practice, SperoPredictor identified 25 potential drug candidates against 6 human host-target proteomes identified from a systematic review of journals. Literature-based validation indicated 12 of 25 predicted drugs (48%) have been already used for COVID-19 followed by molecular docking and re-docking which indicated 4 of 13 drugs (30%) as potential candidates against COVID-19 to be pre-clinically and clinically validated. Finally, SperoPredictor results illustrated the ability of the platform to be rapidly deployed to repurpose the drugs as a rapid response to emergent situations (like COVID-19 and other pandemics).

INTRODUCTION

Coronavirus (CoV) normally targets the respiratory tract of humans (mammals), resulting in mild-to-severe respiratory tract infections (1). In the last two decades, severe acute respiratory syndrome (SARS-CoV) and Middle East respiratory syndrome coronavirus (MERS-CoV) referred to as pathogenic human coronaviruses, have caused global epidemics with high mortality and morbidity rates (2) with a burden on the worldwide economy (3). In December 2019, Wuhan (China) experienced the third coronavirus pandemic, called novel coronavirus (SARS-CoV-2 or 2019-nCoV) disease 2019 (4). Over 79,000 confirmed cases with more than 2,600 deaths from COVID-19 or SARS-CoV-2 outbreak worldwide were reported as of 24 February 2020 along with contact transmission due to human-to-human interaction (5). Moreover, according to the World Health Organization (WHO), as of 15 February 2022, there have been a total number of 414.3 M confirmed cases of COVID-19 with 5.846 M deaths worldwide, while the United States, India, and Brazil remain the worst-hit countries (6), with worldwide economic costs of more than $16 trillion. In this connection, studies have been conducted for COVID-19 health and exploratory data analysis for classification, comparative analysis (7), and prediction using machine learning, such as done in (8) specifically targeting the Mexican and Brazilian patients. The results from the study consider data from patients under the age of 0–120 years demonstrating the application of big data technologies along with machine learning. Similarly, the relation between the spread rates of COVID-19 in high-risks countries is also studied in (9) where Pearson correlation was considered to first study the relationship between the countries under study followed by the use of PCA to categorize the countries based on the spread rates of COVID-19. Moreover, a vast number of efforts from various national and international research groups around the world have been made to obtain effective drugs for COVID-19. To date, the FDA has approved only one antiviral (oral) drug for the treatment of COVID-19, and it is regarded as a major step forward in the fight against COVID-19 (10). Owing to the lack of effective oral drugs for COVID-19, there is an urgent need to develop effective treatments for 2019-nCoV or SARS-CoV-2.

Additionally, witnessing the pandemics over the last two decades and the emergence of new diseases, the total money diverted to pharmaceutical and biomedical research has significantly increased, increasing the annual number of novel treatments approved by the US Food and Drug Administration (FDA) slightly (11). As estimated in a study, pharmaceutical companies invested $802 million in 2013 which increased to $2.6 billion in 2015 owing to the development of novel drug molecules approved by the FDA (12). Thus, the development of novel drug molecules until the approval of the FDA requires approximately $2–$3 billion investment and a time of approximately 12–15 years, with $< 10\%$ chance of success. This renders drug development a risky process that suffers from high attrition rates, substantial costs, and a slow pace (13). An effective alternative to *de novo* drug development is drug repurposing, the process of determining new indications of the already approved (FDA), failed/abandoned, or investigational drugs for use in other diseases (14). Drug repurposing reduces the time and money spent on *de novo* drug development and clinical trials (15–17) because the safety and efficacy data of the drugs to be repurposed are already known. In addition, sufficient investment of time and money is still required for drug repurposing when opting

for experimental approaches (18). The problem has been solved with the advent of computational approaches which have come along with enormous computing power to digest vast amounts of heterogeneous data for the testing of the systematic drug repurposing hypothesis (12, 13, 15–17). Moreover, targeting a single viral protein often results in high drug resistance owing to the rapid evolution of the virus genome (1). Conventional methods based on the three-dimensional structure of proteins and ligands are limited by the unavailability of protein structures that are normally encountered for most viral and human targets. Apart from that disease diagnosis studies are performed, such as done in (19). In the said study, significant features were ranked using a random tree, decision tree, support vector machine (SVM), and chi-squared decision tree models. The study results show the significance of the RT models which ultimately outperform the other models.

Moreover, *in silico* methods that predict drug–target interactions (DTI) or associations, use machine learning to train, test, and validate the machine-learning-based prediction models. DTIs are the pairs of drugs and their targets interacting with each other. Moreover, these trained prediction models are subsequently deployed to discover novel DTIs. The data on which feature-based machine-learning models are trained can be obtained from publicly available online databases or in-house laboratories. The well-known databases for DTIs and target–target interactions are DrugBank (20), KEGG (21), and STITCH (22–24). When discussing the representation of drugs and target data, people have presented them in many different forms; for example, drugs are represented by their chemical structures (25), drug expression profiles (26) side effects (27), and Anatomical Therapeutic Chemical (ATC) codes (28), while targets have been represented using their gene ontology information (28), genome sequence (21), protein–protein interaction (29), and disease associations (30). Moreover, many successful feature-based computational methods have been developed over the past decade. Feature-based methods are standard methods that require feature vectors of a fixed length as input (31). According to the literature, an earlier feature-based method (32) was used for target representation; this method performs binary vector representation of the drugs, indicating the presence or absence of functional groups in the chemical structure of the drugs with amino acid composition. Simply put, if a drug is represented by d, then the feature vector of the drug would be $[d_1, d_2, d_3,..., d_d]$. Similarly, for target t, it would be $[t_1, t_2, t_3,..., t_t]$. The drug and target feature vectors are subsequently concatenated to form a drug–target pair (d,t). In addition, many feature-based methods have been presented based on random forest (RF) (29, 30), rotation forest (33), and extremely randomized trees (34) that are formed by the ensemble of decision trees. In the given studies, many of the important features are not considered. Specifically, in most studies, only two or three features are focused on, missing the other important information. While in our work, unlike other studies, SperoPredictor® uses multiple drugs (four drugs) and disease (three diseases) features unified in binary strings covering diverse aspects of drugs and diseases data. The use of various features in our study make the classification models more generalized and accurate on unseen data. Additionally, other feature-based methods include relevance vector machines (35), KNN (fuzzy) (36), and deep learning (37–39). Additionally, most of the studies are focusing on single ML model trained and then deployed, while in our study we have trained multiple machine-learning models which are later stacked together to synergize the prediction confidence. Once the predictions are taken from the deployed machine-learning models, the need for further validation of the drugs is highly needed which most of the studies are lacking. Here, a bifold molecular docking validation is performed for the predicted drugs with host COVID-19 proteins. Moreover, there is dire need of well-trained models that are fast, accurate, and ready to be deployed as rapid response, such as SperoPredictor. Further it can also be deployed to predict the drugs for a given disease as input to the deployed model and can find the new indication for drugs given as input.

In this study, we present an integrated machine learning and molecular docking-based drug repurposing framework that systematically uncovers undiscovered DTIs. This approach is based on the notion that (i) given known and unknown sets of DTI data enriched with various aspects of drug and disease features (**Figure 1A**), (ii) machine-learning models can be trained (**Figure 1B**). The trained models (iii) can be deployed to determine new DTI pairs for a given set of proteins functionally associated with diseases causing viral infection, such as COVID-19 (**Figure 1C**). We employed this approach along with (iv) the confirmation of the indications from the literature survey and (v) by performing molecular docking to further ensure the interactions (binding affinity) between predicted drug–target pairs as shown in **Figure 1C**. Following this approach, 25 potential drug candidates were predicted for COVID-19. Literature-based validation confirmed that 12 out of 25 (48%) drug compounds were already used in COVID-19. For the remaining 13 compounds, molecular docking was performed. Based on the docking results and prediction scores, four potential drugs were suggested to be pre-clinically and clinically validated for COVID-19.

MATERIALS AND METHODS

In this step, we followed the five steps shown in **Figure 1** to identify the repurposed drugs for COVID-19 (drug repurposing).

Dataset Preparation

The dataset contains four drug features (drug chemical structures, side effects, target sequences, and drug-targeted genes) and three disease features (disease gene sequences, disease specificity indices, and disease observable traits).

Chemical Structures

Chemical structures (40) in SMILES form have been used in many studies. Simplified molecular-input line-entry system (SMILES) is the form of a line notation for describing the structures of chemical species and SMILES was obtained from DrugBank (41), PubChem (42), and ChEMBL (43) during 2021–2022 using application programming interface (API) in KNIME as shown in **Supplementary Figure 1**. To make the data machine-learning ready, one-hot encoding (44, 45) was done to convert SMILES data into a 1,430-dimensional vector called the Drug-S Vector. The vectors were subsequently collected

as the bit vector using the KNIME node called "Create Collection Column."

Drug–Target Sequences and Genes

Each drug targets one or more proteins (18, 46) and receptors on proteins are the most prominent targets for drugs. In this study, the drug–target sequences were extracted from Uniprot and DrugBank during the academic year 2021–2022 (47). Initially, DrugBank IDs were mapped to Uniprot IDs followed by using API in KNIME to retrieve sequence data from Uniprot. The "Sequence Properties" node in KNIME is used to extract the properties, such as the number of positively and negatively charged residues, mol-weight, hydrophobicity, and aliphatic index. Finally, one-hot-encoding

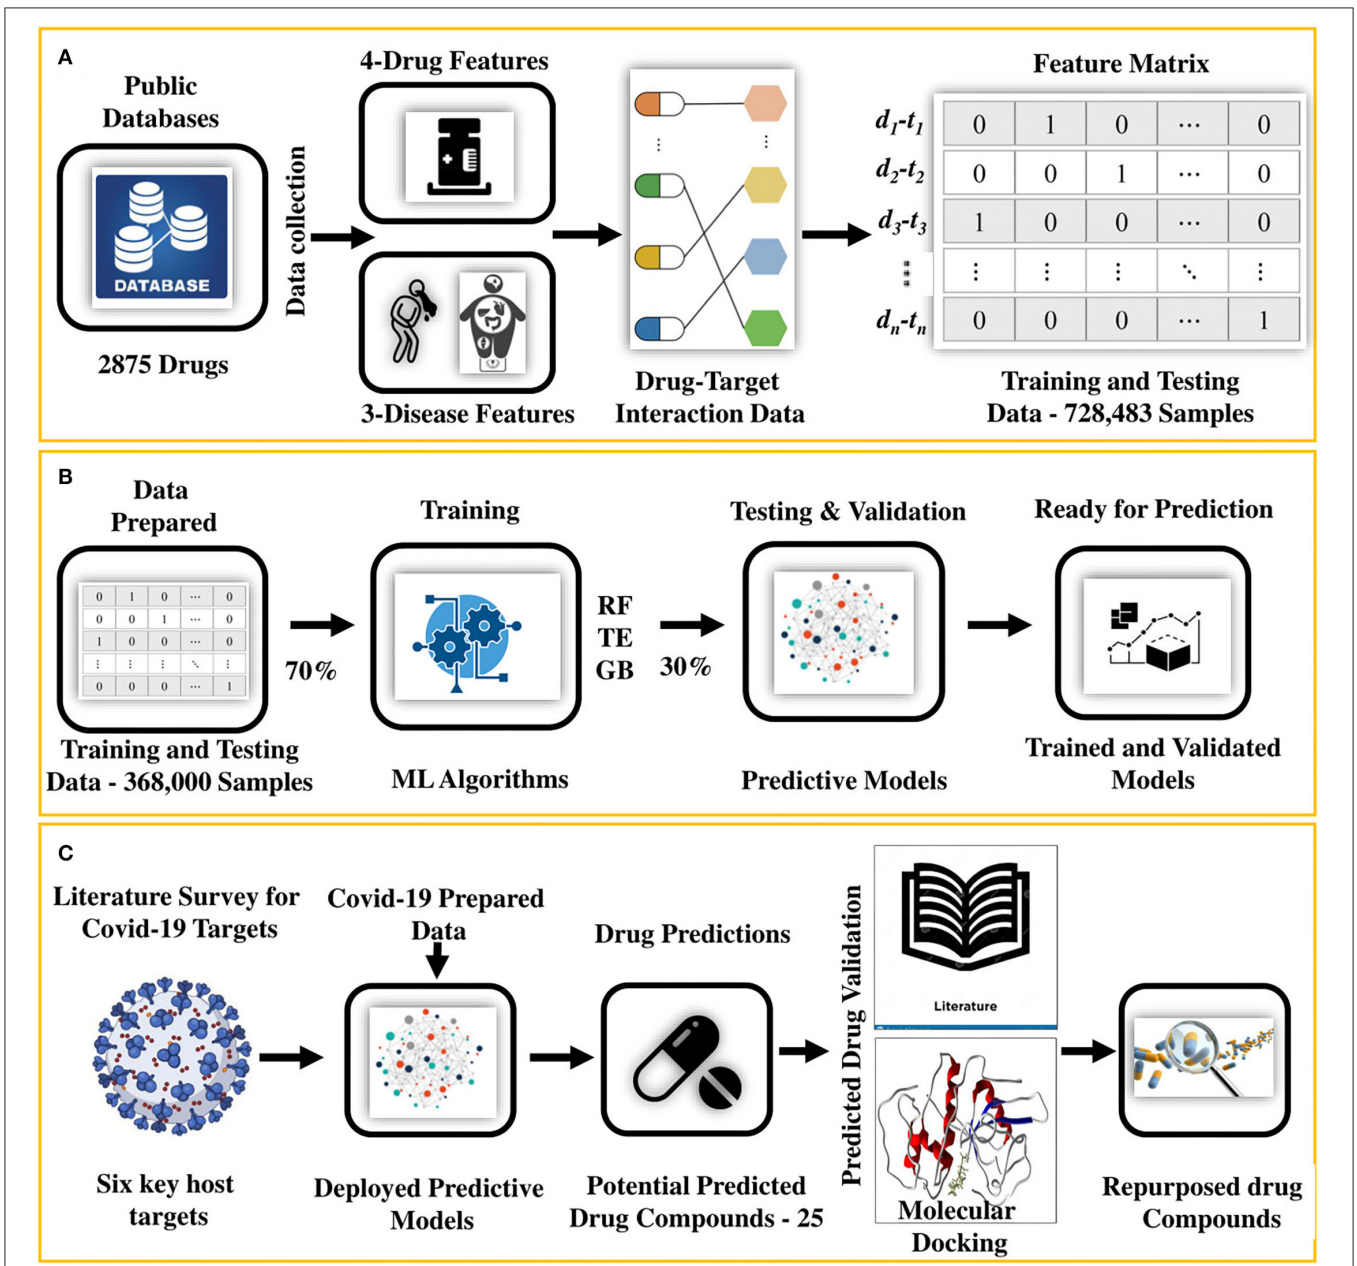

FIGURE 1 | An integrated machine learning and molecular docking-based ensemble approach for drug repurposing. **(A)** It shows that the drug and disease data collected from the public databases are first arranged and then transformed into a feature matrix, **(B)** followed by training and testing of the predictive models (RF and TE). **(C)** After training and testing, the data for the COVID-19 host targets are prepared from the literature review and fed to the predictive model for getting the potential repurposed drugs. Potential hits are then validated by using literature mining and collecting the evidence in the form of papers, patents, and database evidence. For the remaining predictions, molecular docking is performed to find the binding affinity of the drugs. Finally, the drugs with the highest binding affinity are prioritized as the potential repurposed candidates ready for the preclinical and clinical tests.

(48) was applied to extracted features and drug genes to transform features into the bit representation of the 2,294-dimensional vector.

Drug Side Effects

As a common hypothesis, drugs with similar side-effect profiles share similar therapeutic effects through a shared mechanism of action (49). The drug side-effect data of 1,430 FDA-approved drugs were downloaded from the SIDER database (27). SIDER provides mapping to PubChem which was used to map side effects to drug structures, protein sequences, and gene data, as shown in **Figure 2**. To make side-effect data machine-learning-ready, one-hot encoding was used in the KNIME analytics platform as shown in **Supplementary Figure 2** resulting in a binary vector string of 5,868-dimension called Drug-Se.

Disease Gene Sequences and DSI

In recent years, there has been a tremendous increase in the knowledge accumulation of gene–disease associations. It is important to facilitate clinical practice using this knowledge (50). In our study, gene-disease associations (GDA) were collected from DisGeNET (51–53) that contains more than 400,000 GDA across all databases (54). Moreover, the Uniprot IDs were used along with gene symbols from DisGeNET to extract gene sequences from the Ensemble database (55, 56) using API in KNIME (**Supplementary Figure 1**). Drug sequences were converted using one-hot encoding into a binary string vector. Additionally, for the disease specificity index (DSI) (51), the vectors generated are referred to as Dis-Ge for one-hot-encoded gene sequences of 1,321 length. Whereas, the DSI values are left named as DSI.

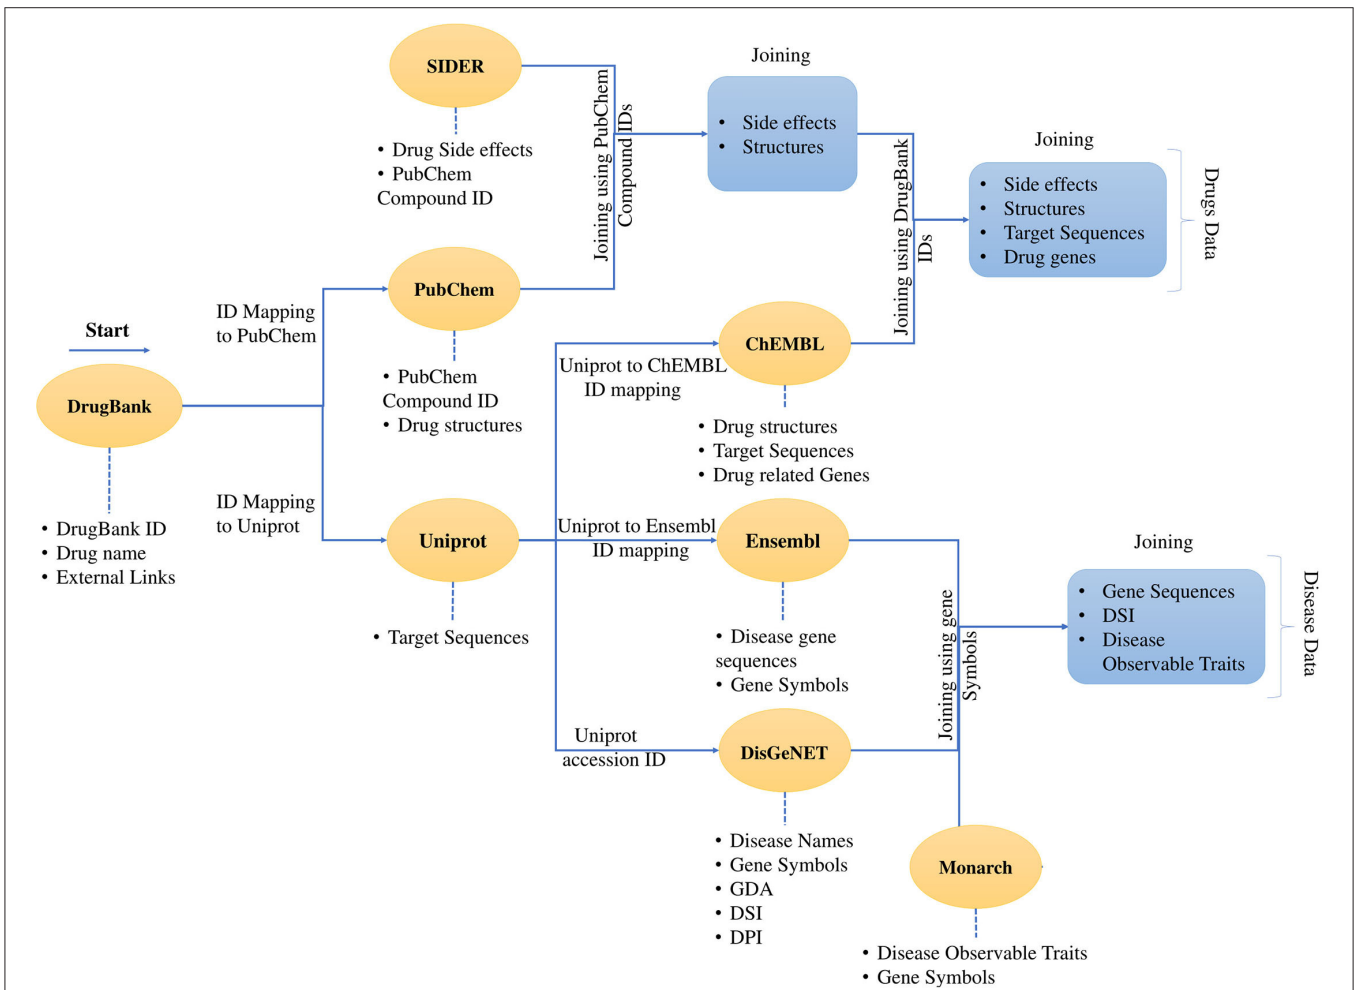

FIGURE 2 | Process of data collection and data mapping. It shows the creation of a dataset and merging of different data sources using cross-database identifiers. The dataset contains the data for the drugs and the data for the diseases. The data download was started with DrugBank data with external links. Then the data was mapped to PubChem and Uniprot. It was followed by the mapping of the SIDER data using the PubChem IDs and the mapping continues through ChEMBL and all the four drug features are presented in a tabular form with identifiers from mentioned databases. The same process follows for the disease data, and finally, the disease data is also represented in the tabular form. The developed dataset contains the drug and disease-related data enriched with various features.

TABLE 1 | Drug and disease features in the dataset created.

Dataset	Drug features				Disease features			Dataset features	
	Drug structures	Drug–target sequences	Drug related genes	Drug side effects	Disease gene sequences	DSI	Disease observable traits	+ve	-ve
	1,430	2,294	2,893	5,868	1,321	1,321	5,212	368,483	360,000

The table mentions the total number of each feature in the dataset. It contains four drug features and three disease features. The details of the different features and their mapping process are discussed in detail in Section Dataset Preparation.

Disease Observable Traits

Disease observable traits have been utilized for drug discovery and development (57–59). Drugs discovered based on phenotyping screens have surpassed the drug screened and developed through a molecular drug–target-based approach (60, 61). In this study, 10,881 human diseases with 8,662 phenotypes were retrieved from the Monarch database (62). The phenotypes were encoded using a one-hot encoder which produced vectors (Dis-Tr) of 5,212 lengths as shown in **Table 1**.

Positive and Negative Samples

After collecting the known drug- and disease-related features data (DTIs), we assumed them to be positive samples, and the unknown interactions achieved through the randomized shuffling of the positive samples were assumed to be negative samples (63) followed by upsampling of the negative samples to create a balanced dataset. The rationale behind this is that conventional methods of unknown interactions between targeted drugs as negative examples may result in bias because unknown interactions between targeted drugs may contain undetected interactions between the targeted drugs. This was overcome by finding the duplication between the positive and negative samples and it was ensured that no pair from positive samples matches exactly to negative samples.

Model Prediction Techniques

For bioinformatics research, machine learning plays a significant role in the filtering and comprehension of patterns in a given dataset (63). Our proposed study presents machine-learning models trained on various aspects of the drugs and disease data. The statistics for the datasets used in this study are provided in **Table 1**. The overall purpose of the workflow was to predict DTIs for COVID-19. The process can be divided into five steps. First, the models were trained using the training data, and second, the trained models were tested and cross-validated using the testing and cross-validation data, respectively. In this study, different machine-learning models were tested and evaluated. The ML models (algorithms) used in this work are Random Forest (RF), Tree Ensemble (TE), and Gradient Boosted Trees (GB).

Random Forest

It contains multiple individual decision trees that function as divisions. Every individual decision tree is bounded by predictions guided by the class, layer, and the soundest prediction results in the model. RF performs efficiently with large types of data elements from one decision tree, and its accuracy can be maintained even if the data contain missing values. In addition, the fair training time complexity expressed as $O(n*log(n)*d*k)$ and excellent space complexity of the RF models given as $O(depth\ of\ tree\ *k)$ makes it a good choice in such applications. In the given time and space complexity notations, "n" shows the number of training examples, "d" shows the data dimensions, and "k" shows the number of models. In our work, we used the KNIME node "Random Forest Learner" with the parameters shown in **Supplementary Table 1**. The model (RF) in this study functions in two ways. First, it was trained, tested, and validated; then, the results from the model were used individually and combined or averaged with other models. Finally, predictions for the COVID-19 DTI data were obtained after training and testing.

Tree Ensemble

Similarly, we used the KNIME node "Tree Ensemble Learner" to develop the TE model. It contains an ensemble of decision trees. Typically, each tree in ensemble learning is developed using different sets of rows or columns. Whereas, rows are called records and columns are called attributes. The key idea behind ensemble learning is that a group of weak learners combine to form a strong learner. Moreover, like RF, the time complexity of the TE algorithm is fair, and it is represented by $O(n*log(n)*d)$ and the space complexity of the TE is excellent. Similarly, in the given time and space complexity notations, "n" shows the number of training examples and "d" shows the data dimensions. In, this work, we used the "Tree Ensemble Learner" with the parameters listed in **Supplementary Table 1**. Like RF, TE learning algorithms also function in two ways. Additionally, the data prepared for COVID-19 were used to predict the DTIs to repurpose potential drugs for COVID-19.

Gradient Boosted Trees

Aiming at classification, it learns gradient boosted trees. It uses regression trees in a shallow form. Along with RF and TE, we used the "Gradient Boosted Trees Learner" node in KNIME for model development. The time and space complexity of the GB trees is also like the other two. Following the other two, GB was trained, tested, and validated, and the results from the model were combined and averaged with other models. After training and testing, predictions for the COVID-19 DTI data were obtained. The parameters used for the GB trees are also given in **Supplementary Table 1**.

Training and Testing Procedure

The prepared dataset was split into three portions: training, testing, and validation using the train-test split method. For each of the classifiers (Section Model Prediction Techniques), 70% of the data were used as training data that were randomly drawn and contained both positive and negative samples. The remaining 30% of the data were used for performance testing (15%) and validation (15%).

While selecting the best models, we used a part of the training data and tuned the hyperparameters. This procedure was followed by the testing of the trained models with 15% of the data split for the testing purpose. The process was repeated to fine-tune the hyperparameters. Once the testing accuracy was sufficiently high, the validation data were used to perform the 10-fold cross-validation of the models. During this initial procedure, we eliminated GB because it did not perform appropriately, compared to RF and TE. Therefore, we developed and trained the models; the list of parameters is given in **Supplementary Table 1**. The models were subsequently run on the validation datasets to observe the predictive performance using the evaluation parameters (Section Model Evaluation Techniques) that testifies to the effectiveness of the training performed. At the end of the training, the best-performing models as per the Mathew correlation coefficient (MCC) and other important parameters were selected. Finally, the models were either used in the combination (averaging the output of the models) or only the RF.

Model Evaluation Techniques

The different parameters used to evaluate the machine-learning model are discussed below.

Accuracy

This is the ability of a classifier to differentiate between positive and negative samples correctly. To determine the accuracy, true positive and true negative should be known across all cases. The accuracy can be measured using Equation (i).

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad \text{(i)}$$

Here, TP is true positive, TN is true negative, FP is false positive, and FN is false negative.

Precision and Recall

Precision refers to the correct ratio of positive reactions, whereas recall shows the ratio of positive samples that have been predicted correctly. Precision can be calculated as per Equation (ii), and recall can be calculated according to Equation (iii).

$$Precision = \frac{TP}{TP + FP} \quad \text{(ii)}$$

$$Recall = \frac{TP}{TP + FN} \quad \text{(iii)}$$

F1 Score

This measures the balance between precision (p) and recall in the system. Equation (iv) was used to calculate the precision.

$$F1\ Score = \frac{2*[\ Precision*Recall\ ]}{[\ Precision + Recall\ ]} \quad \text{(iv)}$$

Mathew Correlation Coefficient

The value of MCC ranges from −1 to 1. In this range, −1 is a zero-credible binary-learning method, whereas 1 is a completely confident binary-learning method. The calculation formula for MCC is given by Equation (v).

$$mcc = \frac{TP*TN - FP*FN}{\sqrt{((TP + FN)*(TN + FP)*(TP + FP)*(TN + FN))}} \quad \text{(v)}$$

Prediction Validation Techniques

After the training, testing, and validation, the models were deployed. The data for COVID-19 host targets were collected from the literature. The information sources of the collected host targets for COVID-19 are given in **Table 3** along with other information. The data were pre-processed, and the predictions were obtained from the deployed ML models. The predictions (new DTI) were validated in the following two ways.

Literature-Based Validation of the New DTI Predictions

After the new DTI predictions were obtained for the COVID-19 targets, we performed a manual literature search. We used combination models (RF and TE) and individuals, and for both types of models, literature-based evaluation was performed (64, 65). As a result, we labeled the new predicted DTIs valid when at least one publication or database evidence showed the use of the predicted drug in COVID-19. This can be further divided into two categories: first, the evidence from the publications that could mention either the computational approach or a combination of the computational approach along with wet-lab experiments, and second, the database evidence. The databases, such as DrugBank, mention drugs along with their indications and are updated periodically.

Molecular Docking

After initial validation based on the literature, molecular docking was performed using AutoDock Vina for the unconfirmed DTIs. Moreover, for docking experiments, the co-crystallized structures of the host COVID-19 targets were downloaded from the Protein Data Bank (RCPDB) along with their PDB IDs. PyMol (66, 67) visualization software was used to visualize the target protein and extract the binding sites after deleting the water molecules and removing the backbone ribbon structure of the protein. Additionally, all the ligand molecules were also removed. The prepared protein structures were later used as inputs to Auto Dock Vina (67) for molecular docking, where hydrogen atoms and Gasteiger charges were added to the structures.

For the ligands, 3D structures were downloaded from PubChem (68) in structured data format (SDF). The structures were first converted into Protein Databank (PDB) format in

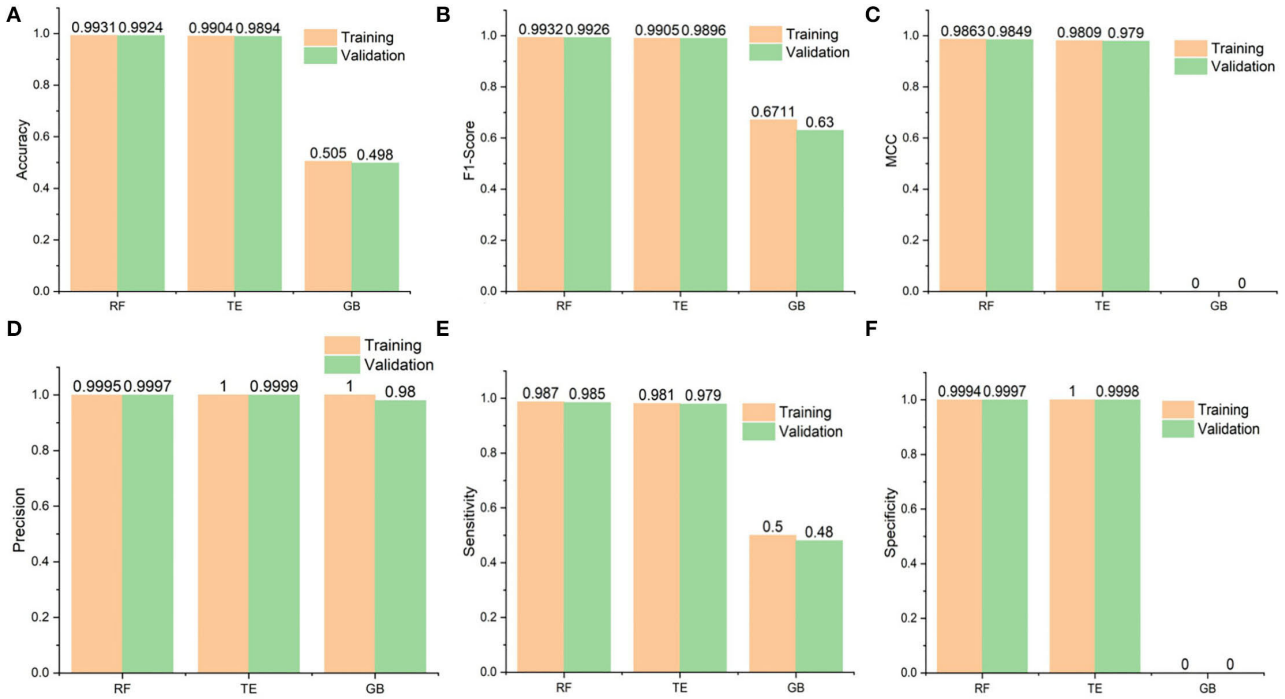

FIGURE 3 | Performance statistics of the algorithms used in the study. Additionally, it shows the training and 10-fold cross-validation results of the Random Forest (RF), Tree Ensemble (TE), and Gradient Boosted (GB) classifiers. **(A)** Shows the accuracy results of the classifiers and RF seems to perform best followed by the Tree Ensembl predictor, **(B)** in case of F1 scores, RF again performs better than the rest whereas the GB performance is worst, **(C)** whereas MCC values are also best for the RF but **(D)** Precision results are best for the TE during training and validation followed by the RF and GB, finally **(E,F)** for the Sensitivity and specificity, respectively, RF performs best and GB is constantly worst.

PyMol, followed by structure preparation in AutoDock Vina. The prepared ligand structures were named PDBQT format. Before performing docking, binding pockets were created using the known binding sites in the crystal structure, and docking was run for 10,000 iterations. The results for each ligand–target docking were collected separately and analyzed for binding affinity values. Finally, ligands with higher binding affinity values were prioritized, and then the re-docking procedure was carried out in AutoDock Vina with 10,000 iterations. Based on the docking and re-docking results, comparison potential COVID-19 drugs were suggested for preclinical and clinical validation.

RESULTS AND DISCUSSION

Here, we discuss the results obtained from our proposed machine-learning-based prediction models (SperoPredictor®) for DTI implementation on the generated drug–disease (DTI) dataset, followed by novel DTI prediction for COVID-19, their literature-based validation, and molecular docking-based validation.

SperoPredictor Training, Testing, and Validation

In our work, we handled the DTI prediction for COVID-19 as a binary classification problem. The developed BioSpero's SperoPredictor® accepts the drug–disease data in a one-hot-encoded format and performs binary predictions between drugs and targets as active (valid or interacting) or inactive (invalid or non-interacting) for a given set of protein targets. The predictions were further validated using literature-based evidence and molecular docking, as shown in **Figure 1**. Moreover, to train the models, we generated a multiple feature-based dataset for DTIs from multiple databases. The data collection for 1,430 drugs and 2,265 protein targets (**Table 1**) was partially performed through an application programming interface (API) in the KNIME analytics platform, and subsequently processed and transformed using KNIME nodes. API automatically extracts the data from databases using a set of identifiers and the data-mapping process is shown in **Figure 2**. To validate the models, we split the dataset into training (70%), testing (15%), and validation (15%) datasets. Moreover, 10-fold cross-validation was performed on the tested models, and the performance statistics are shown in **Figure 3**. The results are further summarized in **Supplementary Table 2**, illustrating the accuracy, MCC, F1 score, precision, sensitivity, and specificity, whereas the corresponding results are shown in **Figure 3**. The given parameters were calculated during testing and cross-validation.

The accuracies of the RF model during testing and validation were 0.9931 and 0.9924, respectively. Similarly, the TE accuracies remained at 0.9904 and 0.9894, respectively, during the testing and validation of the model. In addition, the precision-recall

values are also presented for the proposed models. It is important to mention that precision is also referred to as positive predictive value (PPV) and recall (sensitivity) is referred to as the true positive rate (TPR) (63); specificity, also called true negative rate (TNR), is also mentioned in **Supplementary Table 2**. Higher values for precision, recall, and specificity indicate the greater predictive performance of the trained models.

Comparison With the Existing Methods

In this section, we provide a comparison between SperoPredictor and three recent state-of-the-art methods. The first method proposed efficient machine-learning methods with a case study on COVID-19 (63). In these studies, SVM, RF, XGBOOST, and DBN were used. DTIs were predicted using RF and SVM for COVID-19. They predicted drugs for ACE2 with 100% confidence. Another method is based on the deep learning structure model (CNN) to gain the sequences (Amino acid) in 1D representation. According to the results, the use of CNN for data representation improved the performance, compared with traditional methods, and the performance among all models is quite visible. The other method offers a novel approach to developing negative DTI. In this study, many lasso models were used to combine multiple sets of features to examine the prediction power and DITs (69). Lasso DN's suggested comparing the performance to Lasso, support vector machine (SVM), standard logistic regression (SLG), and DNN models. Additionally, another study proposed DTI prediction using Lasso with RF. FP2 and PsePSSM fingerprints were used for feature extraction, followed by the removal of redundant information (70). Our method performs better than all the other methods, achieving the best results in testing and cross-validation, as shown in **Table 2**. As shown in **Figure 3** and **Table 2**, the highest accuracy achieved in our work is 0.9931 (99.31%) in the case of RF and 0.9904 (99.04%) in the case of the TE algorithm which is approximately 5% higher than the first (63), 6% higher than the second (69), and 7% higher than the third (70). Similarly, when the results are compared for other parameters, such as MCC, our proposed models exhibit better performance at 0.9863 for RF and 0.9809 for TE as compared to other studies done in (63, 69, 70). Another recent study done in (71) uses SVM and RF models to repurpose the drugs for COVID-19. The accuracies of the classifiers as shown in **Table 2** are 0.90 and 0.82, respectively, outperformed by RF and TE models presented in our study.

TABLE 2 | Model performance comparison between related and our work.

Study	The methods	Accuracy	MCC
Efficient machine-learning model (63)	RF	0.947	0.945
	SVM	0.93	0.917
Lasso-DNN method (69)	SVM	0.81	-
	ANN	0.9277	-
Lasso with random forest (70)	RF	0.9809	-
Repurposed drugs for COVID-19 using AI and ML (71)	RF	0.82	-
	SVM	0.90	-
Our proposed work	RF	0.9931	0.9863
	TE	0.9904	0.9809

The models from the related were listed along with their performance parameters. The accuracy and MCC of the Random Forest and Tree ensemble classifiers were matched with the state-of-the-art methods from the literature.

Application in COVID-19

De novo drug development takes 12–15 years with a $2–3 billion investment. Drug repurposing has emerged as an effective alternative solution to respond in case of epidemics and pandemics. In this regard, repurposing potential antiviral drugs for COVID-19 is the only solution to counter the sudden emergence of pandemics. Moreover, the recurrence of COVID-19 is significantly affected by the response of the human immune system. To date, there has been extensive research conducted involving different methods (such as the data-driven method) on COVID-19. These methods use different resources for data collection and analysis, such as DrugBank, TTD, STITCH, and ZINC. Additionally, antiviral drugs targeting COVID-19 can be placed in one of two categories. First, antiviral drugs target the host targets of the virus to impede the aggregation of the virus, and second, drugs boost the immune response over a wide spectrum (72).

Moreover, a study using the deep learning model (73) conducted pre-training on the interactions, and MT-DTI identified the EGFR receptor successfully as the drug–target that has been associated with 30 candidates out of 1,094 from the DrugBank. This study did not require 3D structural information to predict the interactions between drugs and targets. However, there is no evidence to support the positive action of drugs in COVID-19 (74). The drug Atazanavir exhibited reasonable efficacy and binding affinity toward COVID-19-target proteins. In addition, the FDA approved Remdesivir for use in patients aged 12 years and above (75). Another study performed drug repurposing for COVID-19 using a literature-based approach (76). They used a scientific approach called the literature-based discovery (LBD) and compared it with three other similar models. They concluded that semantic models are most suitable for drug repurposing.

A recent study (77) suggests the application of AI to accelerate the drug repurposing process (78). This further demonstrates the importance of different AI approaches and discusses the different drugs that are currently under clinical trials in various phases. Similarly, another study discusses how AI models are used in precision medicine and how AI models can accelerate drug repurposing in COVID-19. Furthermore, AI along with network-based approaches, can be a powerful and innovative alternative to drug repurposing. According to these reviews, AI-based tools can be used to reposition drugs for other human-related diseases, focusing on COVID-19.

Here, we focused on predicting DTIs using SperoPredictor, the proposed machine learning and molecular docking repurposing framework that was trained on drug–disease-enriched data (the corresponding statistics are shown in **Table 1**). The data were collected from multiple sources and mapped to a single table using the cross-database identifiers and the mapping process is shown in **Figure 2**. In our study, to predict the repositioning drugs for COVID-19, we deployed our trained models with high

TABLE 3 | Key host-target proteins in COVID-19.

12	DB13876	Brofaromine	TMPRSS2 CTSL ACE2	0.948	(101)

The mentioned drugs are the results of the drugs from the Random Forest model and model combination (Random Forest + Tree Ensembl). The first two drugs are the result of the combination models. Moreover, the table contains the drugs and their DrugBank IDs which are validated from the literature for their use in COVID-19. It supports and adds to the credibility of our developed ML models. Additionally, the COVID-19 targets in the form of Uniprot IDs along with prediction confidence and literature-based evidence.

accuracy and specificity of 99.3–99.94% (RF) and 99.0–99.98% (TE), respectively.

To get the predictions for potential repurposed drugs for COVID-19, a literature survey was conducted, and the key host-target proteins of COVID-19 were collected. The target proteins are shown in **Table 3**. After collecting the targets, the data, including the observable traits, Ensembl gene ID, and DSI index, for these targets were prepared, as shown in **Supplementary Table 5**. The observable traits were collected from the Monarch database, whereas gene IDs and DSI indices were collected from the Ensemble database. The data were subsequently fed into the workflow for processing and gene sequence extraction, and the workflow is shown in **Supplementary Figure 3**. Following the processing and transformation of the COVID-19 target data, they were provided as input to the deployed RF and TE model for the predictions, as shown in **Supplementary Figure 4**. The models were used in two configurations: first, the combination of both models was used, and as a result, two drugs were predicted; second, the RF model was used, and a total of 25 drugs were predicted.

Our strategy for validating the prediction was based on literature-supported evidence and molecular docking. Two drugs predicted from combination models (RF and TE) were validated from the literature, and evidence suggested their repurposed use in COVID-19. Whereas 12 out of 25 drugs predicted using RF were found in the literature, suggesting their use in COVID-19. This means 48% of the predicted drugs were known to have anti-COVID-19 activity. All predicted drugs, along with evidence found in the literature, are specified in **Table 4** with prediction confidence and literature evidence. Whereas, all 25 predicted drugs, along with the information, are specified in **Supplementary Table 3**.

Molecular Docking and Re-docking for Binding Affinity Prediction of Compounds Against SARS-CoV-2 Host Targets

AutoDock Vina was used to perform molecular docking between the predicted ligands (for SARS-CoV-2) and SARS-CoV-2 host protein targets. All the selected host COVID-19 targets are listed in **Table 3**. The binding sites and PDB IDs of the selected proteins are shown in **Supplementary Table 4**. Ligand structures were downloaded in 3D SDF format from PubChem and converted to the PDB format using PyMol software. The preparation of 13 ligands (not confirmed in the literature) and six targets was conducted in the AutoDock Vina environment. Each ligand molecule was docked against all the six selected host COVID-19 protein targets. The binding affinity results are shown in **Figure 4**. As a result of molecular docking, the lowest binding affinity score was found as −5.4 (kcal/mol), and the highest score was −10 (kcal/mol). The top-scoring drugs for Adaptor Protein 2-Associated Kinase 1 (AAK1) with binding affinities ranging from −9.0 to −10.0 kcal/mol were Balaglitzone ($\Delta G = -9.9$ kcal/mol), Cortivazol ($\Delta G = -9.9$ kcal/mol), Ganaxolone ($\Delta G = -9.1$ kcal/mol), and Velusetrag ($\Delta G = -9.1$ kcal/mol) (**Supplementary Table 6**). Similarly, for Cyclin-G-Associated Kinase (GAK), the highest-scoring drugs were Balaglitzone ($\Delta G = -9.6$ kcal/mol), Velusetrag ($\Delta G = -10.0$ kcal/mol), 16-alpha Bromoepiandrosterone ($\Delta G = -9.0$ kcal/mol), and Rolofylline ($\Delta G = -9.1$ kcal/mol) (**Supplementary Table 6**). For the Angiotensin-Converting Enzyme 2 (ACE2), Cortivazol ($\Delta G = -10.0$ kcal/mol)

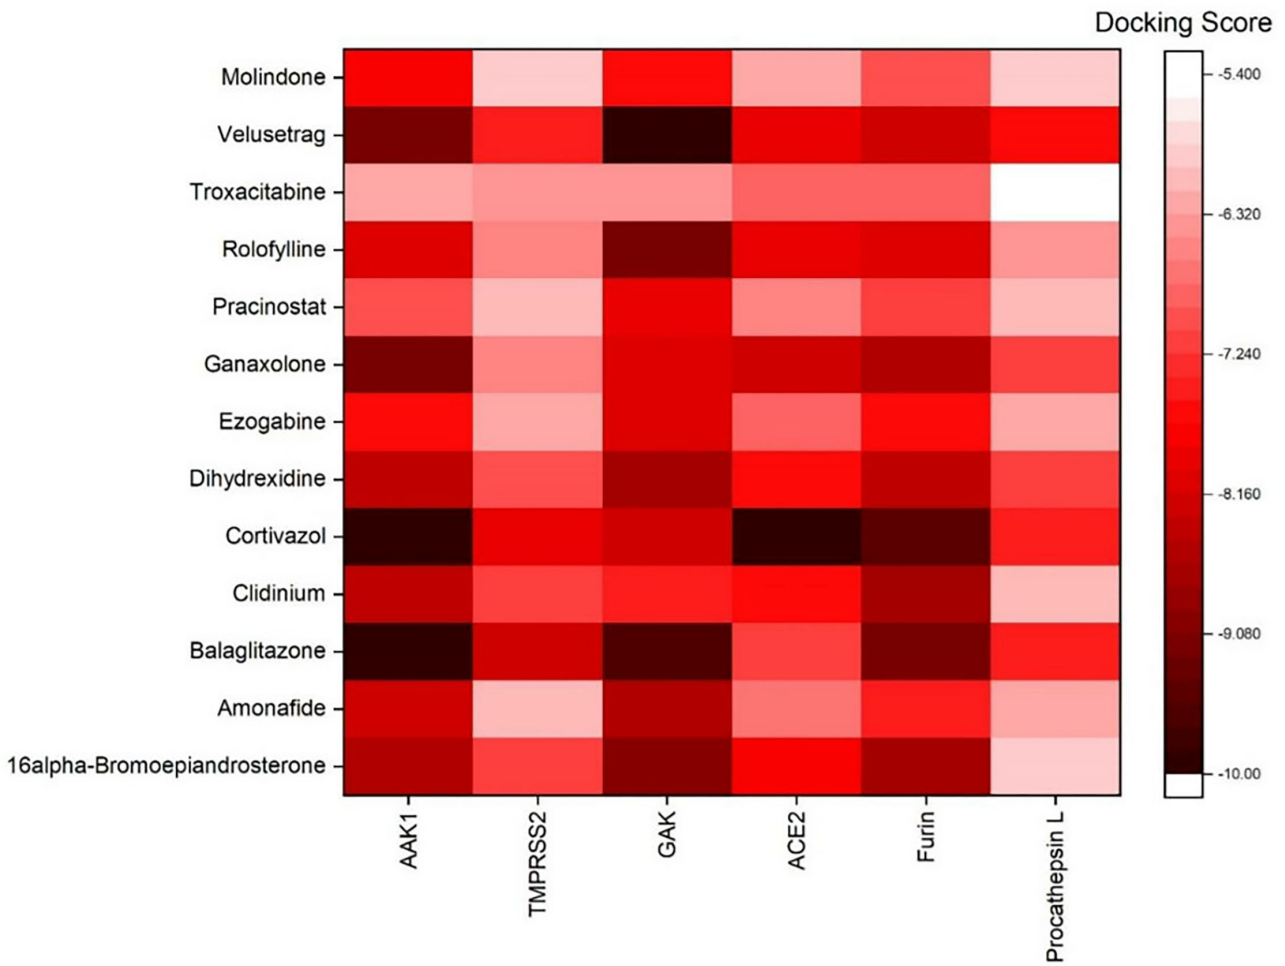

FIGURE 4 | Binding affinity or docking scores of the predicted repurposed drugs against six COVID-19 host proteins. The candidate predicted drugs are mentioned along the y-axis whereas the host COVID-19 protein targets are mentioned along the x-axis. The Docking score bar is showing the maximum to the minimum value, where the dark red color presents the maximum score of −10 and the white fed color shows −5.4. The highest binding affinities of 9.0 to −10.0 kcal/mol were achieved for Velusetrag-GAK, Cortivazol-ACE2, Balaglitazone-AAK, and Cortivazol-ACE2 complexes.

performed the best and for Furin, Cortivazol ($\Delta G = -9.4$ kcal/mol), Balaglitzone ($\Delta G = -9.1$ kcal/mol), and 16-alpha Bromoepiandrosterone ($\Delta G = -8.7$ kcal/mol) demonstrated the best results (**Supplementary Table 6**). Additionally, for the Transmembrane Protease Serine 2 (TMPRSS2) and Procathepsin L, the docking score of all the drugs was found to be below −8.0 kcal/mol, as shown in **Figure 4**. To further validate the top hit (six) drugs, re-docking was performed and results were found consistent as shown in **Supplementary Table 6**. Finally, the top hit predicted drugs interacting with high-binding affinity to at least two host targets based on the molecular docking score were analyzed and suggested as an effective treatment to be pre-clinically and clinically validated for COVID-19 (**Table 5**).

Moreover, the molecular interaction of the top four hit molecules (four drugs) interacting with at least two host COVID-19 targets based on the molecular docking scores are shown in **Figure 5**. This indicates the binding interaction along with the different host protein targets, their residues, and interaction scores highlighted in **Figure 5**. Based on the docking scores, small-molecule drugs (**Table 6**), such as Balaglitazone, are suggested for preclinical validation against Adaptor Protein 2-Associated Kinase 1 (AAK1) (**Figure 5A**), Cyclin-G-Associated Kinase (GAK) (**Figure 5C**), and Furin (**Figure 5H**). Similarly, the other top-ranked candidate drug Cortivazol is recommended against host COVID-19 targets, such as Adaptor Protein 2-Associated Kinase 1 (AAK1), Furin, and Angiotensin-Converting Enzyme 2 (ACE2), followed by Velusetrag, recommended for Cyclin-G-Associated Kinase (GAK) (**Figure 5D**), and Adaptor Protein 2-Associated Kinase 1 (AAK1) (**Figure 5I**); 16 alpha Bromoepiandrosterone is suggested for Furin (**Figure 5G**) as well as for Cyclin-G-Associated Kinase (GAK).

Furthermore, looking at the severity and state of emergency COVID-19 has caused, there is a dire need for effective

TABLE 5 | Finally suggested four drug candidates for COVID-19 with their target information.

	Drug bank ID	Drug name	COVID-19 targets	Free energy of binding (Kcal/mol)	Free energy of binding (Kcal/mol) Re-docking	Prediction score
1	DB13003	Cortivazol	Adaptor protein 2 associated kinase 1 (AAK1)	−9.9	−10.0	0.94
			Angiotensin-converting enzyme 2 (ACE2)	−10	−10.0	
			Furin	−9.4	−9.4	
2	DB12702	Velusetrag	Adaptor protein 2 associated kinase 1 (AAK1)	−9.1	−8.6	0.944

			Cyclin-G-associated kinase (GAK)	−9.6	−9.7	
			Furin	−9.1	−9.1	

Docking and pre-docking scores in kcal/mol are given which confirm the docking results as valid. Additionally, the prediction results of the drugs from SperoPredictor are also shown here.

treatments. One way to respond to the urgent need is to use Biotechnology platforms to swiftly repurpose the potential drug candidates. The emergence and re-emergence of pandemics emphasize the need of building accurate and robust drug repurposing platforms like SperoPredictor to make the process of drug discovery smooth and faster. Moreover, the proposed work offers many benefits, such as it contains ML models trained on drug–disease data enriched with multiple features. Drug data were enriched with four features, however, disease data were enriched with three features. Rigorously trained ML models were tested, cross-validated, and can be applied to any disease, such as was deployed for COVID-19 to repurpose the drugs with high accuracy. Despite the highly accurate and confident prediction results limitations, such as lack of data (1,430 Drugs) and preclinical validation models, are acknowledged and will be taken as a potential future direction that will enhance the effectiveness of the SperoPredictor. Since the trained machine-learning models yield high testing and validation accuracies (RF = 99.3 % and TE = 99.04 %) and the predictions were confirmed from the literature (12/25–48%), these drugs cannot be directly used in clinical trials. Currently, this study excludes the preclinical and clinical validation of the prioritized drugs. Most importantly, the limitation of the available data for drugs and disease is by far the major limitation of this study followed by the lack of negative data samples (which were later upsampled) which could lead to machine-learning models resulting in a high false-positive rate. Additionally, the validation of the remaining (not confirmed from literature) DTI was performed using the molecular docking approach. A lot of research work has been done and molecular docking approaches are used for the prioritization of the anti-COVID-19 drug compounds, still these approaches are not perfect. To overcome the uncertainty and improve the confidence in the results, we used the docking in two steps: first docking of the remaining drugs (13) followed by the prioritization based on the docking scores as shown in **Supplementary Table 6** (6/13 were prioritized). Second, re-docking for the shortlisting of prioritized drugs was done and the results are shown in **Supplementary Table 6**. Finally, the four drugs were prioritized based on the number of COVID-19 targets and docking results. Each drug should have more than one target as shown in **Table 6**.

CONCLUSION

The past and present efforts are focused on accelerating the drug development process through an alternative approach called drug repurposing. In this study, we present SperoPredictor, a machine learning and molecular docking-based repurposing framework with a use case in DTI prediction for COVID-19. The RF (99.3%) and TE (99.03%) can classify the DTIs with high accuracy. SperoPredictor, is a generalized framework that can be deployed as a rapid response. Additionally, most previous methods have focused on the features of proteins and sequences, involving the physical and chemical properties

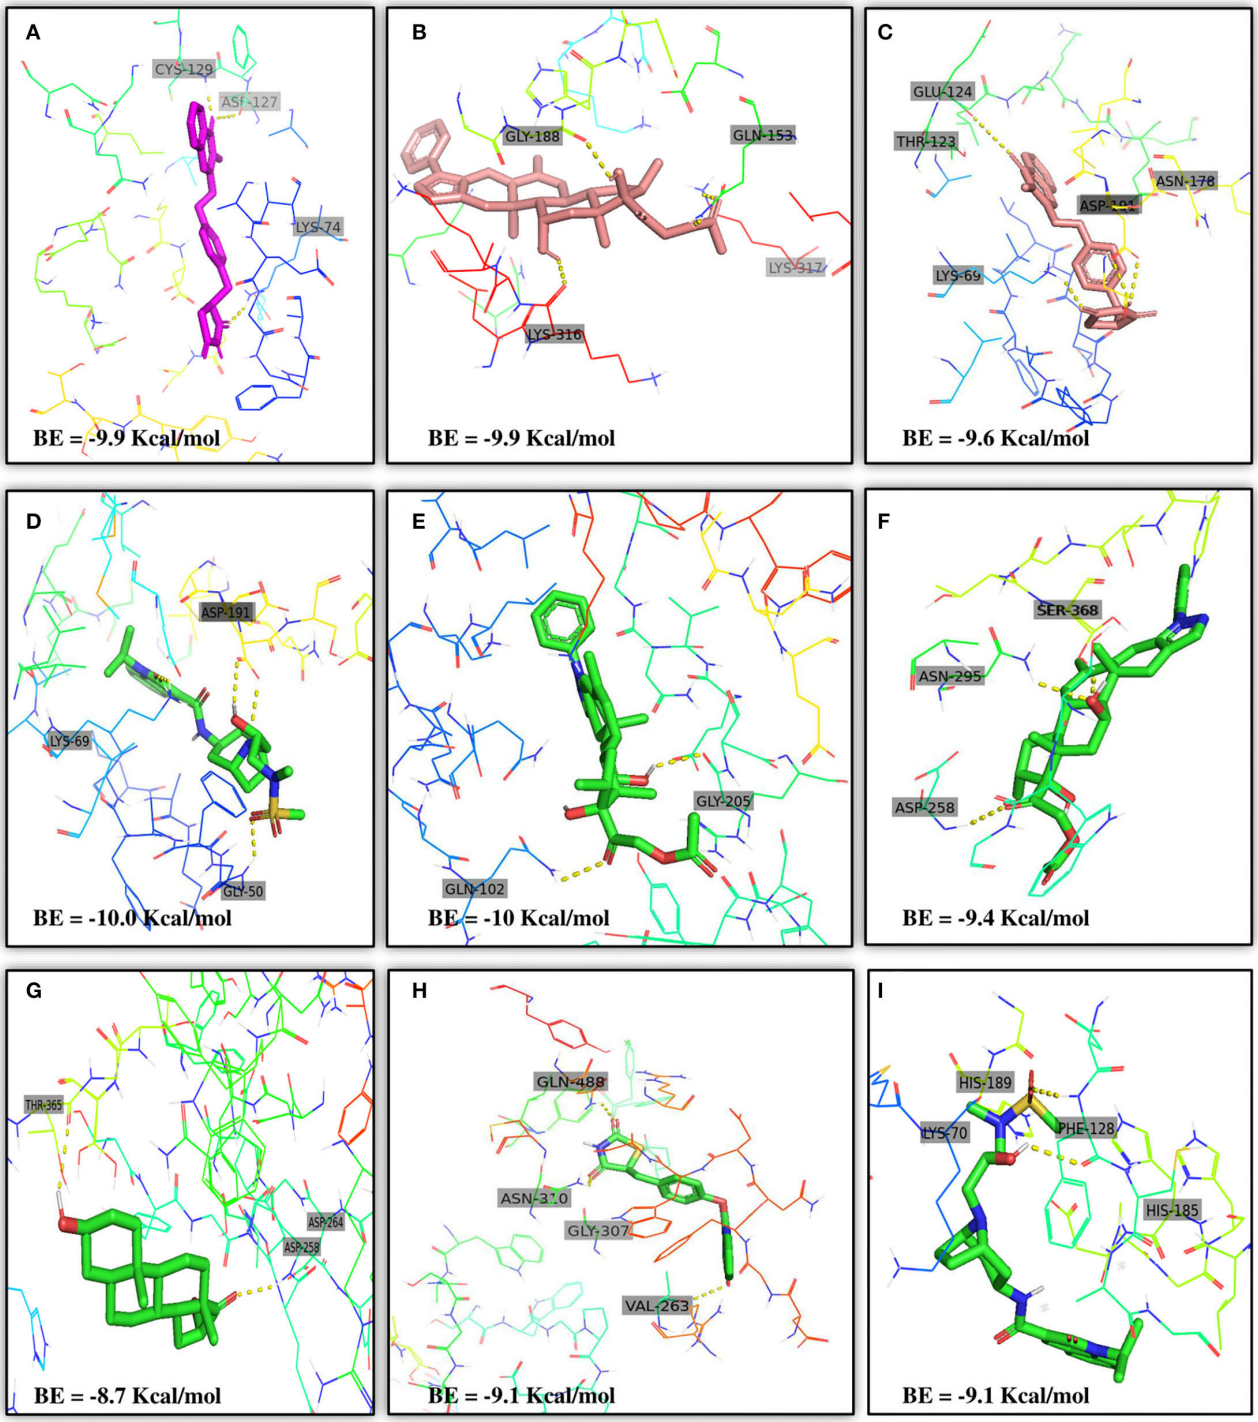

FIGURE 5 | Results of the molecular docking of the potential predicted drugs. Further, it shows the molecular interaction, residues, and scores. **(A,B)** It shows the interaction of Adaptor Protein 2-Associated Kinase 1 (AAK1) with Balaglitazone, Cortivazol, and Velusetrag, respectively. The docking score of the small molecules is −9.9 for the first two and −19.1 for Velusetrag which suggests strong binding affinity during the interaction. Additionally, in **(C,D)** interaction of Cyclin-G-associated kinase with Balaglitazone and Velusetrag is shown, respectively, with docking scores of −9.6 and −10.0. Whereas **(E)**, shows the molecular interaction between Angiotensin-converting enzyme 2 (ACE2) and Cortivazol with a docking score of −10 followed by **(F–H)** Cortivazol, 16 alpha-Bromoepiandrosterone, and Balaglitazone results with Furin. The docking score for Furin-Cortivazol complex is −9.4, for Furin-16 alpha-Bromoepiandrosterone, the docking score is −8.7, and for Furin-Balaglitazone, the docking score is −9.1. **(I)** Cortivazol binding affinity with Adaptor Protein 2-Associated Kinase 1 (AAK1).

	Drug name	DrugBank ID	Original indication	Repurposed for	Host COVID-19 targets
1	Cortivazol	DB13003	Cluster headache-investigational (NCT00804895)	COVID-19	Adaptor protein 2 associated kinase 1 (AAK1) Angiotensin-converting enzyme 2 (ACE2) Furin
2	Velusetrag	DB12702	Gastroparesis and Alzheimer's-investigational	COVID-19	Adaptor protein 2 associated kinase 1 (AAK1) Cyclin-G-associated kinase (GAK)
3	16-alpha Bromoepiandrosterone	DB05107	Non-productive inflammation	COVID-19	Cyclin-G-associated kinase (GAK) Furin
4	Balaglitazone	DB12781	Diabetes mellitus, type 2–investigational	COVID-19	Adaptor protein 2 associated kinase 1 (AAK1) Cyclin-G-associated kinase (GAK) Furin

of drugs. The current proposed data integration method that accommodates the various aspects of drugs and diseases makes the predictions more confident. Similarly, a simple data pre-processing method saves running and processing time and space complexity. Moreover, using SperoPredictor models, we predicted 25 drugs (repurposed) for the SARS-CoV-19 host targets. According to the literature, 12 (48%) of the predicted drugs (25 drugs) have already been tested for SARS-CoV-19. Among the remaining 13 drugs based on molecular docking, re-docking and prediction confidence results of four drugs showing strong binding affinity are suggested for use in COVID-19. These drugs are Balaglitazone, Cortivazol, Velusetrag, and 16-alpha Bromoepiandrosterone. However, the majority of the predictions are validated by various literature sources and two-tier molecular docking validation is also performed. Thus, all the recommended drugs must be validated in various COVID-19 assays and clinical trials before being used in patients. We acknowledge the limitations in this study which will be taken as potential future directions and work along with possible drug combinations. This study is limited to the computational approach and excludes the *in vitro* validation. Additional limitations of this study include a limited number of drugs (1,430 drugs) and corresponding drug–target (2,294 targets) data along with the lack of negative data samples. Whereas, a higher number of drugs could contain and result in more potential anti-COVID-19 drugs and balanced data samples could result in better classification. Finally, the analysis of the novel DTI prediction for COVID-19 indicated that our approach could infer a list of novel DTIs that are practically applicable for drug repurposing. Moreover, the proposed approach can be used to repurpose the drug for any disease of interest following the same approach and this method can be applied in other ways to find the alternative uses for the existing drugs. However, in the future, the efficiency of this approach can be further enhanced by adding more data to train the models and using some state-of-the-art deep learning methods. In conclusion, predictive results of the SperoPredictor supported by literature evidence (12/25–48%) and good docking results between repurposed drugs (ligands) and SARS-CoV-19 host targets prove that our proposed models successfully identify potential repurposed candidates for COVID-19 treatment with high accuracy and confidence.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding author.

AUTHOR CONTRIBUTIONS

FA contributed to methodology, conceptualization, formal analysis, investigation, validation, writing the original draft, molecular docking, and machine learning. JLe and AS contributed to methodology, formal analysis, investigation, and validation. YK, IK, and FM contributed to formal analysis, investigation, and validation. KK contributed to conceptualization, formal analysis, validation, and writing, reviewing, and editing the manuscript. JLi contributed to formal analysis and validation. KC contributed to conceptualization, investigation, resources, supervision, and funding acquisition. All authors contributed to the article and approved the submitted version.

FUNDING

This research was supported by the Technology Innovation Program (or Industrial Strategic Technology Development Program-Development of disease models based on 3D microenvironmental platform mimicking multiple organs and evaluation of drug efficacy) (20008413) funded by the Ministry of Trade, Industry and Energy (MOTIE, Korea).

SUPPLEMENTARY MATERIAL

The majority of the current-generation individuals all around the world are dealing with a variety of health-related issues. The most common cause of health problems has been found as depression, which is caused by intellectual difficulties. However, most people are unable to recognize such occurrences in them, and no procedures for discriminating them from normal people have been created so far. Even some advanced technologies do not support distinct classes of individuals as language writing skills vary greatly across numerous places, making the central operations cumbersome. As a result, the primary goal of the proposed research is to create a unique model that can detect a variety of diseases in humans, thereby averting a high level of depression. A machine learning method known as the Convolutional Neural Network (CNN) model has been included into this evolutionary process for extracting numerous features in three distinct units. The CNN also detects early-stage problems since it accepts input in the form of writing and sketching, both of which are turned to images. Furthermore, with this sort of image emotion analysis, ordinary reactions may be easily differentiated, resulting in more accurate prediction results. The characteristics such as reference line, tilt, length, edge, constraint, alignment, separation, and sectors are analyzed to test the usefulness of CNN for recognizing abnormalities, and the extracted features provide an enhanced value of around 74%higher than the conventional models.

Keywords: convolutional neural network (CNN), depression characteristics, emotion recognition, machine learning (ML), perception

INTRODUCTION

Teenage mental illness is a major psychological condition that causes constant emotional distress as well as a loss of enthusiasm and energy in accomplishing any work. It has an impact on teenage thoughts, feelings, and behavior characteristics, resulting in emotional failure with functional and personal concerns. Teenage pupils who are experiencing depression have significant problems carrying out daily tasks and performing in various situations.

According to a poll (1) more than 21% of teenagers in India reported suffering from serious depression in the previous year. Friendships and emotional bonds between families and friends are harmed by depression. It has a potential to slow down or halt the growth of the children. As a result of this, suicidal thoughts and attempts may result. Handwriting analysis, video and audio analysis, gesture and movement analysis, and psychological evaluation are among the many different approaches for detecting depression and other mental illnesses that might be created utilizing machine learning (ML) and deep learning methodologies (1). Depression is also one of the primary causes of the disability in teens. Often, a person who is going through this is hesitant to seek help from a counselor. In this case, technology can play a critical role and be the first line of defense. As people become more active on social media, their patterns can be exploited to identify physical and mental illnesses in simpler manner. Several ML algorithms for regression, such as random forest, linear regression, Bayesian network, Naive Bayes, support vector machine (SVM), *k*-nearest neighbor, and deep learning algorithms for feature extraction, such as Convolutional Neural Networks (CNN), have been used and successfully tested on various datasets containing video, audio, texts, and images fed to a classifier, applicable on affective and personality computing with feature analysis.

In the previous eras, there was an increase in the use of media information in an online method for recognizing, measuring, and tracking changes in the event of an illness. The universal design of web-based media presents an opulent case for improving the data available to psychological wellness therapists and analysts, allowing for an education expert and a well-organized expressive comfort field. Furthermore, entities are influenced by communicable cynical attitudes in informal associations, which stimulate dejection and other psychological diseases. Dysfunctional conduct is known to be a substantial risk factor for self-destruction; about 80% of those who attempt or die by self-destruction have been diagnosed with some form of psychological instability. Wretchedness is the most well-known psychological disorder, although it has remained unknown or untreated due to its recognition or denial. Early recognition of a significant sorrow's signs and therapy through optimal mediation can help to prevent the onset of a significant sorrow. Numerous studies have identified physical and psychological disorders as a result of the vast amounts of data available on the internet, including a few studies that focused specifically to depression.

LITERATURE SURVEY

Anxiety, despair, stress, and other mental health concerns occur too frequent in youth. It is critical to detect such mental diseases earlier to avoid future effects. Currently, numerous methodologies based on AI-based approaches and algorithms for detecting depression and other mental diseases have been developed. The researchers created a ML model that analyzes social media posts and tweets to detect depression. The researchers used data gathered from social media profiles, activity, and tweets to train their model for this project. The test dataset findings reveal that the critical values for classification error metrics are determined by the sample-based features collected from social media analysis. The model's accuracy will increase as the number of features increases. This is a data-driven paradigm in which the performance and outcomes are determined by data and characteristics (2). The researchers aimed to develop a method for examining facial features and detecting depression scales using image processing techniques. They used characteristics and facial expressions to train the classifier for pleasant and bad emotions. A teen student's video is collected and sent into the system. Using Gabor filters, the model extracts the face and its features. The collected characteristics are then classified into different classes using an SVM technique with supervised learning classifier classification. The number and severity of depressive patients are computed using a neural network to analyze depressive emotions taken from a video sample. The class coordinator and parent are advised about the student's disturbed mental situation after the depression is calculated using the Beck's Depression Inventory (BDI-II) scale. Other characteristics used by the system include academic performance, extracurricular performance, and conduct opinion (3).

Deep learning algorithms have a wide range of applications in the treatment and analysis of mental health and other mental disorders to better identify biomarkers relevant to unique characteristics between them, and they can be better identified in a variety of situations, such as mental depression, where no models exist. Furthermore, the state of sadness is described as an event sequence, allowing users to compute psychological infection or severe ML circumstances. Traditional researches have stated that generated models are implemented with strategic tools that pre-process MRI data, such as MRI scanning tomography, for extracting all independent functionalities from deep learning models that are used as input data to validate the model. All of these aforementioned gadgets, on the other hand, collect data based on the prior knowledge of the reference set. As a result, certain datasets that might be used to predict mental disease or healthy cases of depression may be misplaced. Cooperation was incorporated in the analysis to improve the accuracy of the outcomes of this multi-modal investigation. Researchers worked with the National Institute of Neurological Disorders and Stroke, the Centers for Disease Control and Prevention (CDC), and the American Psychiatric Association (APA) to aggregate the data, in addition to the CAN–BIND study. This combined effort could hopefully result in easily available biological assays that can accurately and efficiently guide treatment selection for depression (4). Daily chores such as drawings or writings might be used to detect depression, anxiety, or any other mental problems. Emotional State Recognition from Handwriting and Drawing (EMOTHAW) is a public database that contains handwriting and drawing samples pertaining to an individual's emotions and mental state. This collection contains handwritten and drawn samples from 129 people who are facing mental and emotional problems. The participants were given the task of sketching a pentagon, a house, a circle, and a clock, as well as writing a cursive statement. The elements from the sample are used to analyze a person's personality and emotional

aspects, resulting in a personality and character profile. Starting point, gradient, size, border, weight, spacing, strokes, and areas are some of the features analyzed from the handwriting sample that distinguishes it from other samples. The results of the sample analysis were uploaded to their database. To classify and evaluate the samples, the researchers employed a random forest approach. This ML approach is based on an ensemble-based decision tree learning, which includes a feature rank procedure. To study an individual's mental state, feature ranking is used to rank and find the key elements in the sample (5–18).

Artificial intelligence (AI) (i.e., ML) has been introduced into the therapeutic field as a means of improving exactness and accuracy while reducing the number of time-consuming tasks that require human intervention (19). There is emerging evidence that ML's innovation might potentially discover and considerably enhance therapy of complicated mental problems such as despair (20). The researchers devised a system capable of detecting doom with minimal human intervention: man-made reasoning mental assessment. This structure consists of a brief human-PC intelligent assessment that employs artificial consciousness, namely, profound learning, to predict if a member would be deterred by palatable execution. Because of its ease of use, this innovation could provide a useful tool for mental health professionals to spot signs of distress, allowing for quicker intervention. Furthermore, by providing a more targeted assessment, it may minimize the difficulty of identifying and decoding profoundly complicated the physiological and social biomarkers of misery (6). Based on the patient's condition and the doctor's viewpoint, a comprehensive literature review is conducted. Visits to various clinics are used to obtain information. With Doctor's consent, information is accessed and reviewed (21, 22). While conducting a depression analysis, several fields of doctors' opinions on depression are examined. Types and causes of depression are investigated to develop a solution for prediction (17, 23–27).

Depression is a psychiatric condition that obstructs a person's growth by causing behavioral, emotional, and mental alterations.

Due to the lack of marking and measuring standards for the depression scale, the psychiatrist may be unable to recognize it. Electroencephalogram (EEG) signals can be used to identify detrimental alterations in the cerebrum's functioning. Thus, the suggested method can scale the downturn measure and recognize the degree of the illness using EEG data using AI methodologies. The highlights from the cerebrum's transitory region are isolated using six (FT7, FT8, T7, T8, TP7, and TP8) channels in this study. Delta, theta, alpha, beta, gamma1, and gamma2 band power, as well as their associated unevenness and matching lopsidedness, are the straight highlights used. Sample entropy (sample) and detrended fluctuation analysis (DFA) are two non-straight highlights used. The following classifiers were used: SVM bagging alongside three distinct piece capacities (polynomial, Gaussian, and sigmoidal). Relief-F is the highlight selection approach that was used. Using SVM (Gaussian Kernel function) and Relief-F as a highlight option, the most notable arrangement precision of 96.02 and 79.19% was achieved for the location and seriousness scaling of darkness. The investigation revealed that a decline has an impact on the worldly portion of the mind (temporo–parietal region). It is indicated that the presence of downturns in the system is having the capability to directly affect the equator reference band structures. It may also be deduced that, among the many components of SVM, the Gaussian bit is more capable than other bits. The combination of all combined unevenness and deviation revealed exceptional arrangement precision (exactness of 90.26% for depression discovery and exactness of 75.31% for seriousness scaling) (7) among the many highlights. Normally, determining gloom necessitates a thorough examination by a knowledgeable expert. Recently, much more thoughts have been devoted to programmed melancholy expectation to conduct a more thorough and fruitful examinations of unhappiness. In this research, a unique approach is proposed that uses a two-stream profound spatial–temporal architecture to estimate the level of downturn from video data. The Inception-ResNet-v2 network is used in our method to extract the spatial data. A volume neighborhood directional number is described, which is based on a powerful component description to capture facial movements. Then, the element map obtained from the Very-low-density lipoprotein (VLDN) is applied to a convolutional neural network to obtain more discriminative highlights. Furthermore, by combining the worldwide middle pooling strategy into the model, a multi-layer bidirectional long transient memory model is planned to obtain transitory data. On the transient parts of spatial and worldly highlights, the TMP method is used. Finally, a thorough study of two testing datasets, AVEC-2013 and AVEC-2014, demonstrates that the proposed strategy outperforms the current methodologies for predicting suffering levels (8). **Table 1** indicates the Model Summary for feature extraction.

Research Gap and Motivation

The major objective of the proposed work is to overcome the disadvantages that exists in the prediction model using handwritten statements where multiple formats are not present is any existing models (1–29). In addition, only occasional treatments are provided for predicting depression with low complexity algorithms. Even the researchers have examined

the implementation model with handwritten statements where complexity of prediction is much higher. Moreover, in the presence of electrograph signals, it is much easier to predict different characteristics of depression but an electrical utensil is needed in this kind of detection. This in turn will create several back-end problems in the near future and the data gathering approach is much reduced in processing of signals. Therefore, to overcome the abovementioned gap, the proposed method on depression prediction using CNN has been implemented.

Proposed Methodology

The features derived from the output samples are used to analyze a person's personality and emotional components, resulting in a personality and character profile. Handwriting samples are examined for the properties such as reference line, tilt, length, edge, constraint, alignment, separation, and sectors that distinguish them from other samples. Handwriting samples of teens are collected and processed using a computerized deep learning utilizing the BDI-II scale. Samples are classified according to their rigorousness in the suggested model architecture to identify, scale, and classify depression using handwriting samples of teenagers. This study examines several depression scores and categories, such as anxiety or stress from 0 to 13, mild depression/anxiety from 14 to 19, moderate depression/anxiety from 20 to 28, and severe depression/anxiety from 29 to 63. In addition, for analyzing handwriting photographs, CNN is used with image recognition techniques to extract deep features from the sample. The CNN, or advanced neural network layers, is a type of deep learning technology that has been effectively used to solve real-world problems.

The network architecture is set up in such a way that extracting and analyzing features from images, audio signals, text, and video segments can be done quickly and efficiently. The proposed method on depression prediction is implemented using CNN for extracting all necessary features by processing the captured input images. In addition to input images, a handwritten sample is trained using hidden layer approach. This type of processing technique provides additional advantage as all dataset features are obtained using compatible mode of operation even if the images are provided at low resolutions. However, the images are converted to high resolution in the CNN model thus data is gathered after classification mechanism. All the steps are implemented under small time scale where errors are minimized at corresponding stages. Furthermore, during feature extraction, the accuracy of detection using CNN is maximized using rotation and scaling techniques.

Objectives

The proposed method on predicting different characteristics of depression aims to solve a multi-objective case study that can be described as follows:

- To minimize the errors that are present in existing models using CNN and maximize the accuracy of prediction by implementing two different sample sets.
- To implement BDI-II scaling for images during classification and extraction techniques where high-resolution images can be processed.
- To integrate cloud storage for storing all monitored parametric values using reference line measurements.

Study Structure

The remainder of this study is laid out as follows. The proposed work's design technique is discussed in Section Design Methodology. The feature categorization technique is discussed in Section Optimization Algorithm: Classification and Regression Development with a step-by-step implementation. The results and overall consequences are discussed in Section Results and Discussions, and the importance of the projected model is described in Section Conclusions.

DESIGN METHODOLOGY

A model has been constructed in this architecture to detect an individual's emotional state using handwriting and drawing examples. The model starts with handwriting and drawing samples as input, which it runs through a CNN-based classifier. A database is created for this system by collecting handwriting text and drawing samples from 250 people. A separate work was also provided, which required students to draw a pentagon, a house, a circle, and a clock, as well as write a statement in cursive. Individuals were given a tablet on which to draw and write for the assignment indicated in **Figure 1**. The samples are stored in a database once the process is completed. In addition, the database is separated into the following three categories: Training, testing, and validation, with an 80:10:10 ratio.

Various characteristics of drawing and handwriting samples, such as reference line, tilt, length, edge, constraint, alignment, separation, and sectors, that distinguish one sample from another are examined. Wide separation between words/lines, increasing benchmark, unbalanced left and right edges, and less top edge were a few of the overall highlights of the database. The most commonly observed features for scale are as follows: Maximum weight, broadness at left-edge and top-edge, blended inclination, broadness dispersing in the middle of the lines, maximum slanting in letters such as F, G, H, K, and R, maximum slanting in letters such as F, G, H, K, and R, maximum slanting in letters such as F, G, H, K, and R, maximum slanting in letters such as F, G, H, K, and R. The features are accurate inclination, wide separation between lines/characters, and blended gauge on a scale ranging from 14 to 19, which are collectively defined as a mild depression/anxiety class. The highlights of the lopsided gauge, lopsided edge, long bending within alphabets such as Y, G, F, and so on, enormous dimension of alphabets, wideness in the left-edge, and broad dispersing in the middle of sentences for scale 20–28 are defined as a moderate depression/anxiety class. The top-most and leftmost edge wideness, blended/leftmost inclination, falling gauge, and asymmetrical dispersal in the midst of the sentences are the highlights for the nervousness–anxiety class. Maximum weight, rightmost inclination, blended standard,

small size, rising benchmark, lopsided edge, huge bends with alphabets such as S, G, Y, F, and so on. are seen in the sadness–nervousness–stress class, while odd edges, linear gauge, linear/rightmost/leftmost inclination, and average sizing are seen in typical classes.

Handwriting samples were collected and used as a tool for validation, assessing intellectual deficiency, and assessing character attributes. In truth, collecting handwriting samples is non-intrusive, simple, and low-tech, and requires no administrative expertise. The following samples are saved in

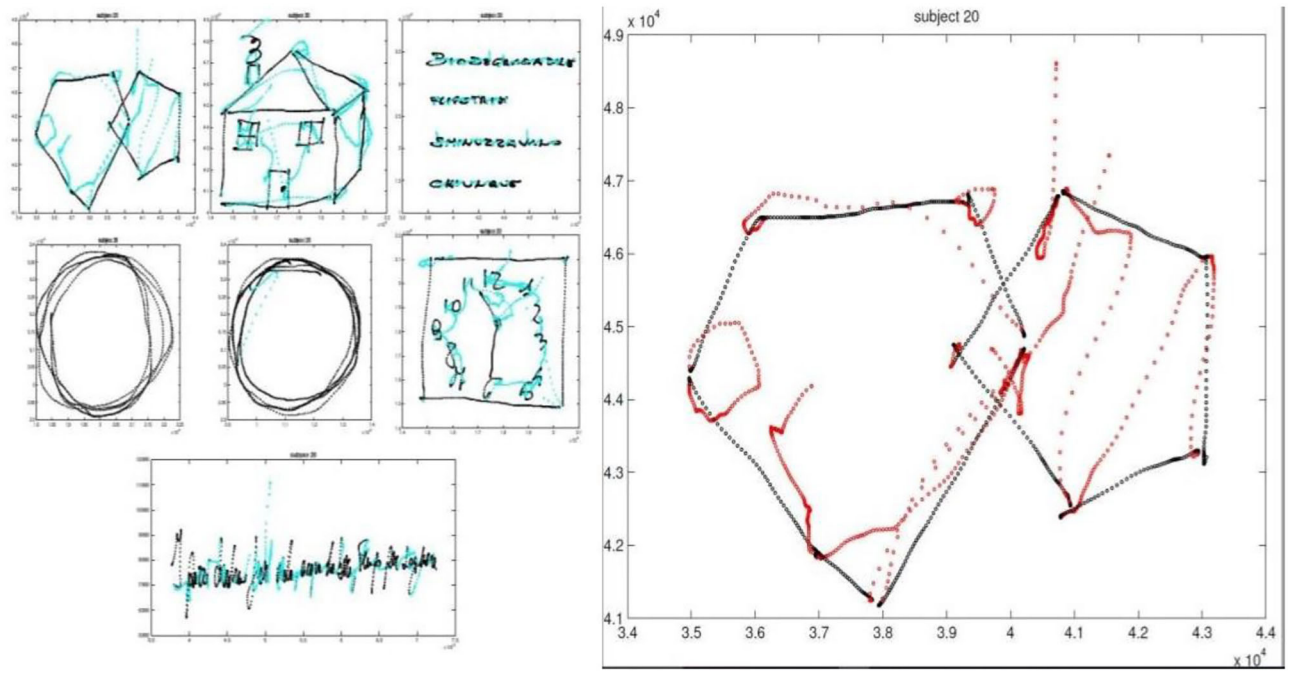

FIGURE 1 | A sample task to draw a pentagon, a house, a circle and a clock and text in cursive.

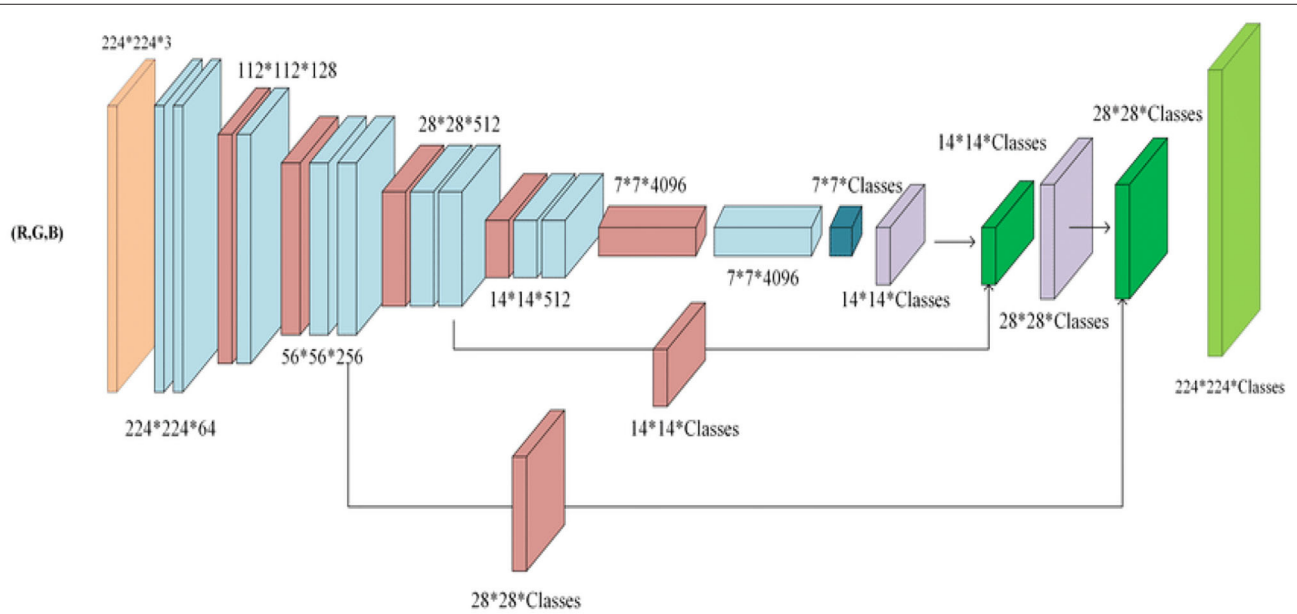

FIGURE 2 | Network architecture for eight-layered CNN.

Switched Virtual Circuit (SVC) records, where SVC stands for record expansion. The SVC extension documents are typically presented in standard American Standard Code for Information Interchange (ASCII) formats that can be accessed using applications such as Microsoft Word, Google Docs, and other common trending applications. The following benchmarking parameters are applied to the data samples:

- Location in x-hub.
- Location in y-hub.
- Time stamp.
- Pen up = 0 or Pen down = 1.
- Dimension of the pen as for the tablet.
- Dimension of the pen as for the tablet.
- Pen point pressure applied by the pen.

Additional data, such as speed highlights (quickening, speed), prompt direction point, brief dislodging, time highlights, and features highlights, can be produced using this arrangement of dynamic data.

Feature Extraction From Handwriting and Drawing Samples

The generated dataset is pre-processed by rotating, scaling, and translating it in order. The photos are resized and normalized to be compatible with the system. This dataset was used to train the convolutional neural network model. Following training, a new input image is given to the neural network to extract features and predict the BDI-II scale, as shown in **Figure 2**.

The component maps are used to lower the dimensionality of the convolutional layers using the created pooling layer. The framework executes the maximum pooling layer into the properly defined element map that are unpredicted upon the indicated size, and the largest component is chosen from the framework. There is a complete layer bound after the mixing of various layers, which bundles the highlights to address questionable classes utilizing the increased level features from the Convolutional Layer/Pooling Layer. Soft-max functions are engaged as the last layer, which fixes multiple yields from each unit to the features from beginning to final values. By assessing the vulnerability at each layer, the total cross-entropy job analyses the presentation of collecting ideals. The error that is corrected at the yield layer must be reduced.

The reverse engendering method, which is carried out by the inclination drive technique, attempts to reduce the error by progressing regressively over distinct levels by modifying multiple assessments of loads and tendencies. A cross-approval approach has been used in the development model for evaluating AI models by preparing a group of datasets and measuring using correlative separations on the dataset. The *k*-cover cross-endorsement condenses data into *k* bits of equal dimensions, with one segment adding separately for endorsement and the rest sections used for readiness in this model. The entire dataset is split into *k* wrinkles of similar size, and the model is built using $k - 1$ folds. The parametric test of the model on the *k*th overlay will begin immediately and continue in the foreseeable future. For each cover, the goof/setback, exactness is set aside. This cycle is repeated until all of the creases in the testing dataset have been applied. Accuracy stored in *k*-folds is used to resolve the typical exactness. By combining a few models, cluster knowledge representation facilitates the application of different representations in AI. A basic research control is executed a couple of times in a bunching calculation to outline for choosing from the hypotheses that are gathered. Cross-approval was used by placing persons with similar ensemble features on different planning circles and using different models for each participant in the approval process. Outfits are commonly used to obtain claimed categories that are obtainable from a collection of arrangements that produce low-precision results. As a result, the multiple layers that are used as a fundamental classifier in the proposed work will assemble the exactness after cross-approval an outfit methodology is functional where the top classifier loads out of the eight convolutional neural organization models that are used while making a gathering model as depicted in **Figure 3**.

OPTIMIZATION ALGORITHM: CLASSIFICATION AND REGRESSION DEVELOPMENT

The process of predicting depression from textual data has been implemented with high-effect analysis using long short-term memory which is indicated as productive model (30). In this model, a handwritten content is placed and by using the frequency the deep learning model predicts the true and false positivity rates. However, using the frequency of recognition accuracy of content cannot be achieved to large extent. Therefore, to achieve high accuracy many challenges with ML techniques are deliberated with suitable application platforms (31). One best application for ML technique is depression prediction where all possible problems that affects the mental health of humans are discussed (31). However, a comparative analysis will not provide solutions to overcome the problems in health-related issues which indicates that a testing model must be placed during comparison state. To have a deep insight knowledge testing model comparisons are made (32) using long short-term memory in two different directions. In this bidirectional procedure, the neural networks are incorporated and the visualization approaches are built for extracting high-feature comparisons. After extracting the characteristics from the handwriting, drawing, and audio samples, the depression scale is predicted using several ML methods, and a comparison is made based on the results. The findings of this comparative research will provide the best performing algorithm for obtaining correct results. Random forest, logistic regression, Naive Bayes, *k*-nearest neighbor, and SVM methods are used to calculate the BDI-II scale using regression techniques. Comparative analysis is used to further discuss the algorithms.

A range of elements have been derived from distinct as well as the same modality in this design, as seen in **Figure 4**. Deep neural networks are used to extract information from handwriting and artwork samples. In addition, a fusion method was used to integrate the various retrieved feature sets. After the features are extracted, a fusion approach is used to combine feature vectors from various modalities in a sequential order. This sequence was repeated twice—once before and once after the dimensionality reduction. The fusion at the decision-making level necessitates the clustering of prediction or classification findings. Based on the extracted features, the model's prediction results can be dependent on a single or the multiple modalities. The fusion in regression is considered to be difficult to use due to the existing problem with multi-collinearity, which is used to characterize the observational features from the dataset used for assessing depression class and scale. As a result, in the multi-collinearity model for binary classification, logical operations and logical gates are used to apply the decision fusion technique. Even logics are utilized to detect the presence or absence of depression and categorize them. In addition, the participants are categorized using logic operators AND and OR to fuse the classification findings. A random forest algorithm is utilized as a classifier in this methodology, which is a common way for decision fusing classifier algorithm to train parameterized scores signifying

TABLE 2 | Comparative analysis of different ML algorithms used for predicting depression from samples.

Models	Accuracy	Precision	Recall	F1-Score
SVM	82.54	84.54	83.36	8.394
Random forest	88.97	87.46	88.77	8.811
Naive Bayes	78.21	76.96	75.12	7.6028
k-Nearest neighbor	71.36	73.49	72.48	7.2981
Logistic regression	64.52	66.16	68.83	6.744

TABLE 3 | Error values of different ML algorithms used for predicting depression from samples.

Models	RMSE	Mean average error	Mean error
SVM	8.8548	8.8942	9.6363
Random forest	6,541	8.4235	8.5896
Naive Bayes	10.2254	9.2152	10.2203
k-Nearest neighbor	4,141	8.4458	10.9299
Logistic regression	12.6656	11.5569	12.6112

distance. The random forest classifier's output is utilized as an input for the next level regressors. In the case of observation utilizing regression over choice fusion, the generalized linear models are used, and expectation maximization procedures are applied to the decision fusion level, maximizing the possibilities. The major intention for choosing CNN is that in proposed method an automatic detection is needed where all features must be extracted within a short period of time. Also, to avoid human interference as system must be chosen that learns the descriptive model by its own and high computational effects can only be observed if CNN is implemented. In addition, the location of implementation is much complex in other algorithms but in CNN the implementation process can be done without any reference location thus making the model much easier during training stages. Further, the reliability of operation is much higher with a few label sets from the operating ends; thus, CNN is preferred for predicting the depression state using written sets.

Design Algorithm for Handwriting and Drawing Feature Extraction

***Step 1*:** Divide the dataset in 80:10:10 for training, testing, and validation.

***Step 2*:** Using feature ranking, set the weights and features as key parameters.

***Step 3*:** On the input image, do scaling, dimensionality reduction, rotation, and translation.

***Step 4*:** Carry out the pooling and forward propagation operations.

***Step 5*:** Using the Softmax activation layer function, calculate probabilities for each class.

***Step 6*:** Determine the model's output error.

***Step 7*:** The inclinations of the error are determined in the back propagation step by taking the incomplete subordinate for all loads. For limiting the yield blunder, the boundary values are refreshed.

***Step 8*:** For each image in the training dataset, repeat steps V through IX.

***Step 9*:** Using the provided equations, calculate the model accuracy and model loss for the proposed model for the validation dataset.

***Step 10*:** Save the optimal weights for future computations and modeling.

***Step 11*:** Create an ensemble-based learning model using cross-validation modeling.

***Step 12*:** Using the provided equations, calculate the model accuracy and model loss for the proposed model for the testing dataset.

Model Training and Evaluation of CNN

The accuracy for prediction is calculated using Eq. (1) as follows:

$$A_i = \left(\frac{CP_t(i)}{s_t(i)}\right) * 100 \tag{1}$$

where $CP_t(i)$ and $s_t(i)$ denote the total number of correct estimates and models, respectively.

The level of absolute number of right predictions to the all Outage tests is determined as accuracy. In the event that the model has a precision rate nearest to 1, it is considered as the model has more precise expectations and if the precision rate is nearest to 0, the model is viewed as less precise. The accuracy in terms of classification can be calculated as follows:

$$A_c\,(i) = \sum_{i=1}^{n} \left(\frac{tp\,(i) + tn(i)}{tp\,(i) + tn\,(i) + fp\,(i) + fn(i)}\right) \tag{2}$$

Here, $tp\,(i)$, $tn\,(i)$, $fp\,(i)$, and $fn\,(i)$ denote true positive, true negative, false positive, and false negative values, respectively.

Hence the values for sensitivity can be calculated using true positive and false negative values as follows:

$$\rho_i = \sum_{i=1}^{n} \frac{tp(i)}{tp\,(i) + fn(i)} \tag{3}$$

The value for specificity is also measured using true negative and false positive values as follows:

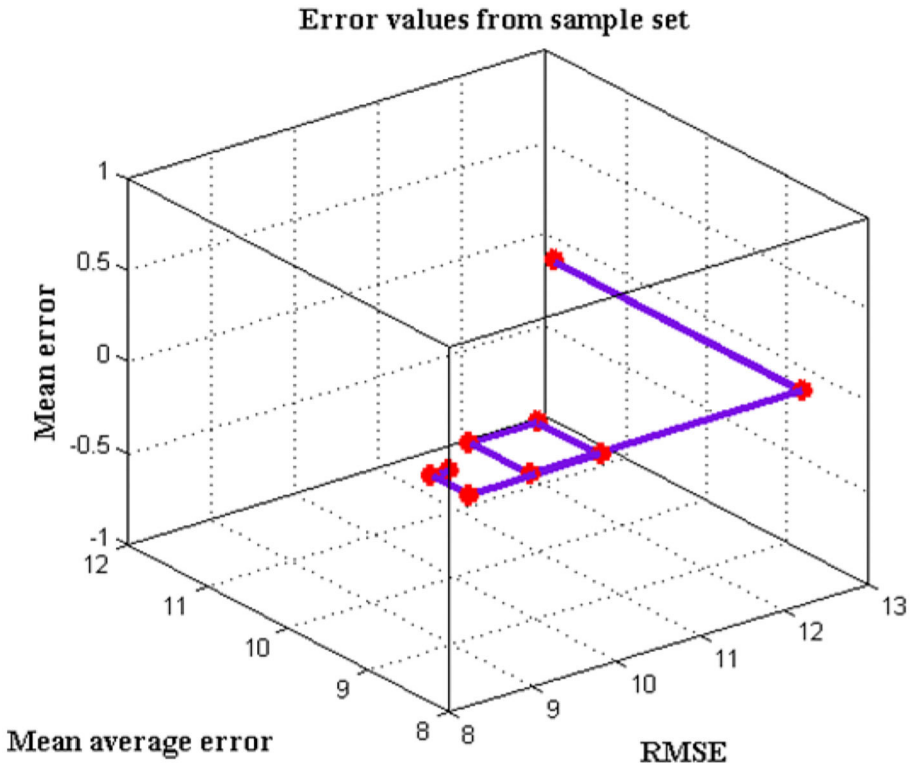

FIGURE 6 | Error values attained from sample dataset.

$$\sigma_i = \sum_{i=1}^{n} \frac{tn(i)}{fp\,(i) + tn(i)} \tag{4}$$

Similarly, the positive predictive value and negative predictive value for the proposed prediction model can be calculated using Eq. (5) as follows:

$$PV_p\,(i) = \sum_{i=1}^{n} \frac{tp(i)}{tp\,(i) + fp(i)} \tag{5}$$

$$PV_n\,(i) = \sum_{i=1}^{n} \frac{tn(i)}{tn\,(i) + fn(i)} \tag{6}$$

To evaluate the percentage error in predicting the root mean square error values are designed using the depressed and non-depressed classes by the model and thus calculating the error difference with the actually predicted values. The root mean square Error (RMSE) and average estimation error (AEE) can be calculated as follows:

$$RMSE_i = \sqrt{\frac{\sum_{i=1}^{n} (e_i - r_i)}{Total\ number\ of\ samples}} \tag{7}$$

where, e_i and r_i denote expected and reference values, respectively.

$$AAE_i = \sum_{i=1}^{n} \left| \hat{z_{in}} - z_i \right| \tag{8}$$

where $\hat{z_{in}}$ and z_i denote difference between class errors.

In analytical terms, the objective function can be defined using Eqs. (9) and (10), where the unconnected non-linear equations are established for both minimization and maximization problems.

$$obj_1\,(i) = \min \sum_{i=1}^{n} RMSE_i, AAE_i \tag{9}$$

In Eq. (9), both error values must be minimized by considering total sampling period. If errors are minimized, then the maximization problem can be framed in an automatic mode as follows:

$$obj_2\,(i) = \max \sum_{i=1}^{n} A_i, AC_i \tag{10}$$

There is no need for implementing manual procedures in Eq. (10) as the accuracy of prediction will reach maximum percentage by comparing the true and false values.

RESULTS AND DISCUSSIONS

The experiment is carried out in real time on the Google Collaborator platform with an NVIDIA GeForce graphics card.

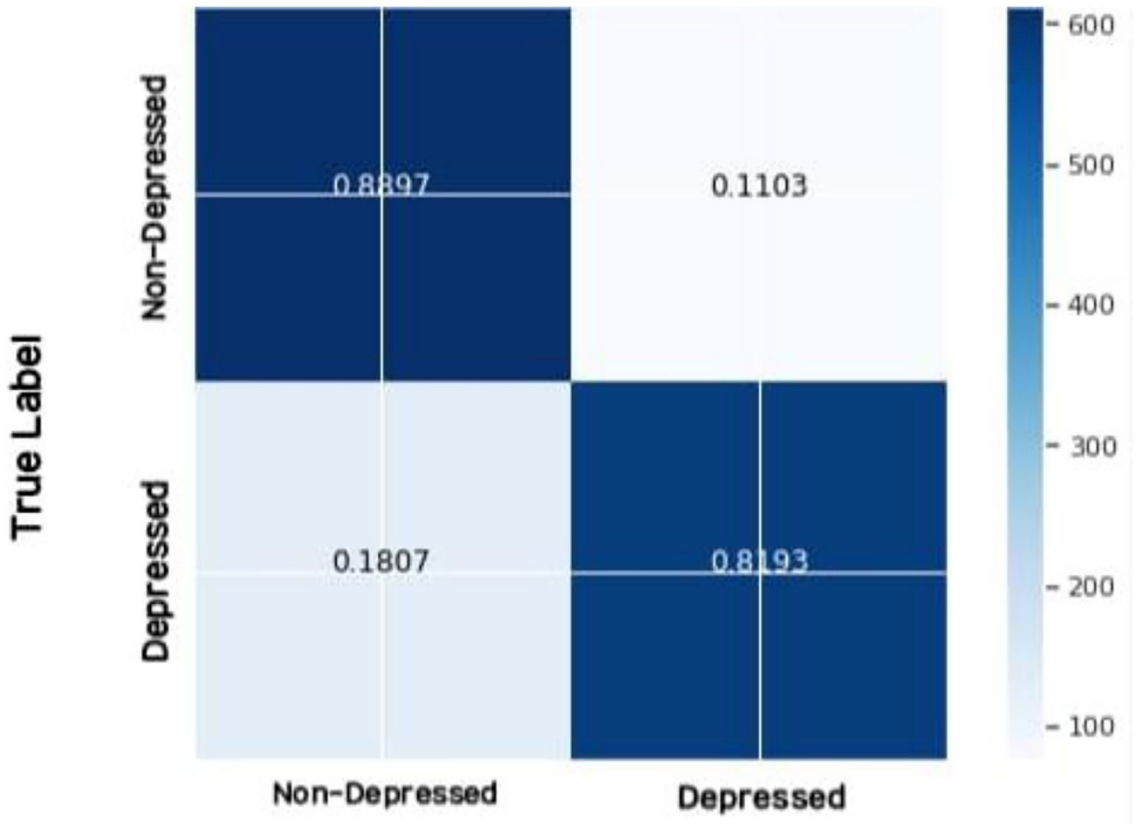

FIGURE 7 | Confusion matrix for depressed and non-depressed classes of the proposed model.

The dataset consisted over 1,500 photos, which were separated into the following three groups in a ratio of 80:10:10: Train set, test set, and validation set. The samples are further classified into eight groups, with scores ranging from 0 to 13 for anxiety and stress, 14 to 19 for mild depression/anxiety, 20–28 for moderate depression/anxiety, and 29–63 for severe depression/anxiety. The training model also includes eight convolutional layers for feature extraction from handwriting and drawing samples as well as a batch activation layer and a batch normalization layer. With modifications in the training dataset, the layered architecture remains the same in each fold. The non-linearity functions in the model are achieved using the Rectified linear unit activation function. The batch normalization procedure is used to normalize the activation from the last layer. The mean value is set to 0 and the deviation to 1 after normalization. The Max pooling approach reduces the dimensionality of the pooling layer. The first, second, and third columns, respectively, show the layer type, input image shape, and number of parameters. While training the model, the output shape of the input image is 64×64 pixels with batch size of none, indicating the input image's dimensionality.

After completing cross-validation on the dataset, eight convolutional layers are blended using an ensemble-based learning process. The suggested ensemble-based model is evaluated on a testing dataset after it has been trained and validated. The convolutional neural filter extracts the features from the handwritten sample photos layer by layer, as shown in the architectural overview. Over a 64×64 image, there are a total of eight 3×3 filters applied. First, the curves and edges are retrieved by the first convolutional layer while the higher features are extracted later by the last convolutional layer. In addition, a BDI-II score column has been added to each of the files for model training. This indicates that features are distinct from one another. In addition, the impact of each feature on the score prediction target variable is investigated. The BDI-II scale is predicted for the tested participants using a random forest regressor with 40 estimators in comparison to the proposed model.

Furthermore, the following hypothesis is considered for analyzing the model's accuracy: A person with a depression scale value is depressed and otherwise not depressed. A binary classification column is added, with the depressed person being labeled as 1. The model's performance is validated by looking for commonalities in categorization and prediction using the participants' labels. Furthermore, a manual and device study are used to make simultaneous observations. If the question was marked "yes" in the recorded session for the domain and the model also gave a higher precision for the same class, it was considered a positive response. Any disagreement or dispute

over classification is met with a negative response. Deep neural networks are used to extract information from handwriting and artwork samples. In addition, to merge these different retrieved feature sets, a fusion method is used. After the features are extracted, a fusion approach is used to combine feature vectors from various modalities in a sequential order. The findings of the comparative analysis will recommend the best performing algorithm for obtaining correct results. Following the extraction of features from handwriting and drawing samples, depression patients are accurately categorized using several ML algorithms, with comparative analysis based on the results.

The SVM algorithm has an accuracy of 82.54%, random forest algorithm has an accuracy of 88.97%, Naive Bayes algorithm has an accuracy of 78.21%, *k*-nearest neighbor algorithm has an accuracy of 71.36%, and logistic regression algorithm has an accuracy of 64.52%, according to **Figure 5** and **Table 2**. With an accuracy of 88.23% and precision of 87.46%, the random forest method was judged to be the best performing algorithm.

As a result, utilizing handwriting and drawing examples to combine their properties to forecast depression scale is an effective strategy. **Table 3** and **Figure 6** show the BDI-II scale for depressive patients utilizing various ML algorithms, with a comparison analysis based on the results.

The RMSE for the SVM algorithm is 9.8548, random forest algorithm is 8.6541, Naive Bayes algorithm is 10.2254, *k*-nearest neighbor algorithm is 10.4141, and logistic regression algorithm is 12.6656, according to comparative analysis. With a mean average error of 8.4235 and a mean error of 8.5696, the random forest method was deemed to be the top performing algorithm.

A confusion matrix is used to visualize the performance of the prediction or classification model. A testing dataset for the known true values is used to generate the table. **Figure 7** depicts the confusion matrix for the depressed and non-depressed classes.

Convergence Characteristics

The depth of integration for an algorithm defines exact coupling strength in real time implementation cases therefore it is necessary to plot convergence of CNN using iteration periods. If a fast convergence rate is attained, then the high benefits can be assured and in turn the sample that is drawn for predicting depression can be identified quickly. In addition, the system time for executing the current state can also be defined using the same characteristic model and is simulated in **Figure 8**. From **Figure 8**, it can be perceived that number of epochs is varied from 10 to 100 and for each period time of convergence is plotted. In all iteration periods, the proposed method using CNN performs well as compared to existing system (32). It can be proved when the iteration reaches 50th period and during this case, the convergence is achieved at 5.77 s whereas the existing model ranges at 8.7 s and at 80th period convergence is attained.

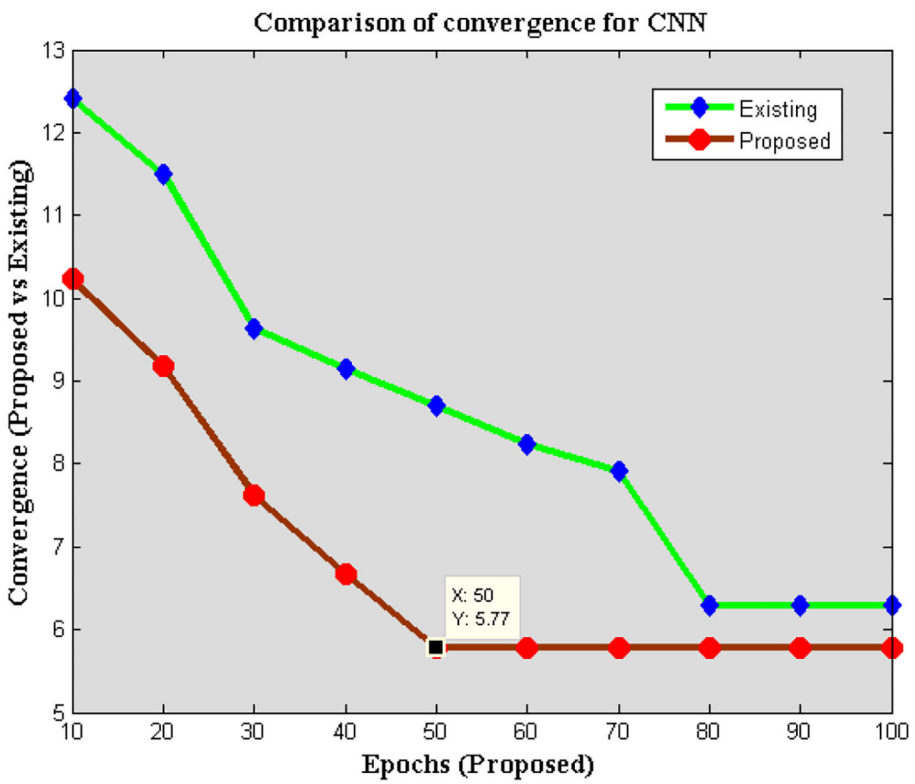

FIGURE 8 | Comparison of convergence characteristics.

This proves that the proposed method is performed at much higher rate for more than 60% in terms of the faster parametric calculations.

CONCLUSIONS

The architecture for predicting the BDI-II scale and diagnosing depression using handwriting and drawing samples was devised and implemented in this study. The model starts with handwriting and drawing samples as input images, which it then runs through a CNN-based classifier. A cloud-based database was created for this system by collecting handwriting text and drawing samples from individuals. Then they were given a task of drawing a pentagon, a house, a circle, and a clock, as well as writing a sentence in cursive. Furthermore, cross-validation in the dataset is performed with many features and were studied from the following handwriting samples: Reference line, angle, distance, control, restraint, arrangement, separation, and sectors, which distinguishes a handwriting sample from other samples. The generated dataset is pre-processed by rotating, scaling, and translating it in order. The photos are resized and normalized to be compatible with the system. The same dataset is utilized to train the deep neural network model, which involves extracting the features from the input image using the neural network architecture and results in BDI-II scale prediction. A comparison of several ML techniques is also performed, and it is discovered that all parametric values are significantly higher than conventional models. In the future, the same approach might be used with high-resolution photos, allowing all flaws to be identified at an early stage of the transformation.

The study examined the effects of swimming pools on healthcare professionals' willingness to engage in recreational activities, physical anxiety, and physical and mental well-being in the context of COVID-19. The research adopted the mixed research method, used SPSS 26.0 statistical software to test the reliability of the questionnaire, and then collected 840 valid questionnaires; first analyzed the data with basic statistics, *t*-test, ANOVA, and PPMCC test methods, and then used the interview method to collect expert opinions. A multi-check approach assembled all data and discussions. The study found that the use of personnel dynamic tracking systems or measures, combined with sodium hypochlorite and repeated filtration to stabilize water quality, could maintain the confidence of most medical workers in the swimming pool sports environment for epidemic prevention and avoid violations. The government could formulate safety prevention and control mechanisms in traffic and establish appropriate traffic routes. Next, formulated a prescription for swimming or other physical activity mechanisms for men aged 31–50 and redesigned measures for medical staff over 51 years old to have tense head issues and physical fatigue, promote blood circulation and improve sleep quality. This will promote the purpose of relieving stress and regulating the physical and mental health of medical staff after engaging in swimming.

INTRODUCTION

Since the outbreak of COVID-19 in December 2019, humanity has been facing one of the most difficult times in recent global epidemic cases and is still not free from the threat (1). In recent years, governments around the world have vigorously promoted vaccine management policies, invested a lot of medical resources, and hoped that the popularization of vaccines would increase people's

resistance (2). Governments actively call on the people to wear masks, wash their hands frequently, avoid gatherings and talk closely to avoid being infected by the virus and even spreading the epidemic (3). In recent years, a number of studies have also proposed ways to teach people how to maintain regular exercise to maintain health in the context of COVID-19 (4–9). It is expected that exercise can improve physical fitness, enhance human immunity, relieve the pressure of medical staff, achieve the goal of resisting viruses, and enhance individual physical and mental health (10).

Because SARS-CoV-2 is an enveloped virus, it is highly infectious, hydrophilic, and difficult to eradicate (11). And the virus gene gradually adapts to the human body, and the virus gene is constantly mutated (12), which increases virus transmission efficiency (13). However, the epidemic threat still exists today, and the environment is full of infection risks, which hinders the willingness to go out (14). As a result, people are full of insecurity in the social environment (10, 14), causing people to panic, anxiety, loss and other psychological pressures, affecting their physical health (3, 15). So far, there have been 513 million cases of infection in 199 countries around the world, with 6.23 million deaths, and infected people continue to be found (16). This phenomenon has impacted the medical systems of various countries, seriously the workload of medical staff and exhausting their physical and mental health (17). Therefore, some scholars believe that finding ways to improve the physical and mental stress of medical staff, provide a safe leisure environment, and promote physical and mental health will be a good way to maintain the service quality of medical staff and stabilize national public health management (10, 18). So we think this is an important research topic at present.

Swimming has the functions and characteristics of enhancing cardiopulmonary function, improving physical fitness, and improving physical and mental health (19, 20). Many countries actively build swimming pools to provide a safe and hygienic recreational sports environment, allowing people to continue swimming to maintain health (21, 22). In order to maintain the sanitation and cleanliness of swimming pool water, sodium hypochlorite has been widely used for water disinfection and environmental cleaning for a long time (21). This method has been recognized by the World Health Organization and the National Centers for Disease Control and Prevention and stated that if the effective residual chlorine in the swimming pool can be maintained above 1 ppm, it can effectively inhibit Escherichia coli and Legionella (22, 23), and decompose bacterial nuclei (24). This measure is applied to enveloped virus-type pathogens such as SARS-CoV-2. As long as the concentration of sodium hypochlorite is increased to 0.5% (5,000 ppm), highly resistant pathogens can be effectively inhibited (25–28). In addition, through effective filtration facilities, impurities in swimming pool water are repeatedly filtered to maintain the hygiene of water quality (29, 30), and sodium hypochlorite is used for environmental disinfection (27, 28). Some scholars believe these measures will provide swimming pools with a safe and hygienic exercise environment during the epidemic (25–30). Therefore, we believe that when the surrounding environment of the swimming pool and the quality of the water are guaranteed, it should be possible to create a safe leisure sports environment (31, 32). Therefore, if the medical staff is advised to go swimming in swimming pools, they should be able to obtain regular exercise, enhance cardiopulmonary function, improve physical fitness, reduce anxiety, and stabilize physical and mental health under a low-risk awareness of the exercise environment (20, 21).

However, since the current problem is not under control, there has always been an infection risk in the surrounding environment (15), which seriously affects people's willingness to go out. Therefore, there is a gap between plan and reality (8, 10). Therefore, some scholars suggest that it is necessary to understand the risk perception of the current swimming pool by medical staff engaged in swimming, as well as the changes in personal anxiety, exercise benefits, and physical and mental health feelings after going to exercise (32). However, these changes and experiences take time (33, 34). Through the awareness of environmental risk assessment, people can assess the potential crisis and risk degree of the surrounding environment (35). Through the perception of physical anxiety, medical staff's personal anxiety changes after engaging in swimming can be found (32). Through the perception of leisure satisfaction, we can find the changes in personal leisure satisfaction after medical staff engage in swimming (36). Finally, the physical and mental health perception can be used to understand the improvement of personal physical and mental health after medical staff engages in swimming (37–39). These answers can be corroborated by participants' feelings (34, 40, 41). Therefore, we believe that by discussing environmental risks, physical anxiety, leisure satisfaction will effectively improve the environmental risk perception of medical personnel, reduce anxiety, improve leisure benefits, and achieve the goal of promoting physical and mental health, and physical and mental health perception, we can know whether the physical and mental health of medical staff can be improved after swimming.

Furthermore, after analyzing the literature, we know that although the current research directions on COVID-19 and human health problems are quite extensive (1, 2, 4, 5, 17). However, most of them discussed the physical and mental health pressure and epidemic prevention measures during the epidemic (5, 25–30, 42). Although the impact of participating in tourism activities during the epidemic has also been discussed (33, 36, 43, 44), methods to improve people's health benefits have also been proposed, such as Qigong (6), intermittent fitness exercises (7), mountain climbing (4), and jogging (8). More recently, related impacts of leisure, travel, living and working environment, physical and mental health have also been discussed (36–38), as well as environmental risks, satisfaction, and physical and mental health issues (40, 41, 45). However, the researchers found that swimming was not discussed as a topic, and the environmental risks, physical anxiety, leisure satisfaction, and physical and mental health perceptions of healthcare workers engaged in swimming in SARS-CoV-2 settings.

Based on the above descriptions, we believe that taking the epidemic period as the timeline, and collecting the opinions of medical staff who continue to swim during the epidemic from the aspects of environmental risk, physical anxiety, leisure satisfaction, and physical and mental health cognition, the truth

will be obtained. These answers will help the government, medical institutions, or medical staff finds a safe exercise environment and regular exercise methods, provide effective exercise, improve resistance, maintain medical quality, and stabilize public health orders during the COVID-19 epidemic.

LITERATURE REVIEW

Leisure Environment Risk

Risk refers to the potential factors that people may develop adversely, personally, or financially (35). Sports environmental risk is mainly to understand the unpredictable but potentially far-reaching potential problems that arise when people or society face the environmental hazards of the epidemic (46). Risk causes are often at odds with everyday knowledge, even conflicting or unpredictable (47). The individual's reaction to risk is the environmental risk perception (48).

Establishing a risk requires three elements: uncertainty, the possibility of loss, and future attributes (49). Individuals feel uncertain about future outcomes, and the outcome may have a negative impact, and the higher the uncertainty, the greater the risk (50). Some scholars believe that predicting risks can usually be discussed in terms of behavior, facility and environmental safety, potential risks, economic losses, and increased social costs (48–51).

Therefore, the researchers believe that the current situation of swimming pools should be referred to as environmental risk prediction indicators. From the aspects of exercise mode, equipment safety, movement fluency, potential risks, happiness, and social costs, it is possible to understand the environmental risk perception of the public when exercising in the swimming pool.

Physical Anxiety

Anxiety refers to an individual's state of excessive, widespread, persistent, and perceived uncontrollable worry about many events or activities, almost most of the time, for at least the past 6 months (52). Anxiety assessment mainly aims to understand people's current psychological mood and distress from different aspects and provide suggestions to improve the quality of life (53). Body anxiety refers to an individual's negative subjective perceptions and feelings that stimulate the body with the environment or time (54).

The establishment of anxiety requires a pathogenic context. The operation process of a specific system, such as cognition related to information processing, emotional stimulus processing, coping, and psychophysiological aspects, are key factors (55). If the individual is worried about the phenomenon or event that continues to occur, or even a catastrophic phenomenon occurs, it may cause psychological trauma (56). Some scholars believe that physical anxiety can be assessed from the aspects of physiological behavior, psychological status, behavioral performance, and effectiveness judgment (57).

Therefore, researchers believe that the answer should be obtained based on the physical anxiety state that the research subjects may face and then referring to relevant literature on physical anxiety, psychological behavior settings (from motor behavior anxiety, tension), physiological behavior (from limb stiffness, muscle tension, stomach tension, rapid heartbeat, and other behavior), and effectiveness judgments (from the affirmation of athletic performance, achievement of expected goals, exceeding levels, and zero mistakes) to predict the state of physical anxiety.

Leisure Satisfaction

Leisure satisfaction refers to the positive perceptions of individuals engaged in leisure activities after comparing their perceived leisure experience with the actual environment (58). To put it simply, people judge according to the current leisure experience whether the acquired individual needs and satisfaction meet the expected goals, which is leisure satisfaction (43).

Leisure satisfaction uses personal activity experience to compare prior experience, personal expectations, or expectations (59). When the actual leisure environment or activity content conforms to the individual's expectations, a satisfied attitude is generated in the heart (58, 59). The higher the satisfaction, the higher the positive energy cognition obtained (60). The more satisfaction one can obtain from personal psychological needs, the more satisfied with the current life and feelings, and the more willing to revisit (58). Some scholars believe that although the influencing factors of leisure satisfaction can be divided into internal and external interference (61), it can be discussed in terms of decision-making measures, environment, facilities, and personal leisure benefits (59–61).

Therefore, researchers believe that the answer should be obtained with reference to the literature on leisure satisfaction and according to the problems that the research topic may encounter, such as decision-making measures that maintain a safe distance, people wearing masks, keeping track of personnel movements, and the environment and facilities being discussed in terms of personal hygiene of swimmers, clean water, and clean facility environment.

Cognition of Physical and Mental Health

Physical and mental health refers to people's physical, psychological, and social aspects to achieve a state of well-being (59). It can present the actual situation through scientific testing evidence such as self-assessment (58), which belongs to the analysis method of self-perception assessment (60). When the public perceives a higher health risk, the power to influence an individual's final behavioral decision will be greater (60).

Physical and mental health cognition mainly investigates the current state of individual physical and mental health and presents the impact of the current environment on people (62). Some scholars believe that physical and mental health can be divided into four levels: mental, spiritual, physical, and negative attitudes (60, 61). And people can get answers from 16 questions such as learning, fear, performance, lack of interest in things, lack of time, headache, fatigue, back pain, insomnia, stomach pain, overeating, muscle stiffness, tantrums, loss, burnout, depression, and suicide (60–63).

Therefore, the researchers believe that the answers should be obtained by referring to those mentioned above in physical and

mental health-related literature, according to the psychological, spiritual, physical, and negative attitudes and other aspects, and with the evaluation based on 16 indicators, such as learning, fear, performance, lack of interest in things, and lack of time.

METHODS

Framework

The study first collected relevant literature, analyzed the influence of swimming pool disinfection and filtration management measures on epidemic prevention and control, and referred to literature on environmental risks, physical anxiety, leisure satisfaction, and physical and mental health cognition. Took the epidemic period as the timeline, targeted those who continue to engage in swimming, and based on the literature on environmental exercise risk (46–51), physical anxiety (52–57), leisure satisfaction (58–61), and physical and mental health cognition (58–63), the study was summarized and analyzed. Looking forward to knowing whether swimming sports and venues would have the effect of providing people with a healthy and safe leisure environment, reducing personal anxiety, and promoting physical and mental health. The research structure is shown in **Figure 1**.

Process and Analysis

At present, the research direction on COVID-19 and human health issues has been quite broad (1–30). However, there has been no discussion about the environmental risks, physical anxiety, leisure satisfaction, and physical and mental health cognition of people engaging in swimming in the context of SARS-CoV-2 with swimming as the theme. Therefore, mixed research methods were used through the feelings of actual participants (33, 34, 40, 44), quantitative research methods were used to supplement the research breadth (64, 65), and qualitative research methods were used to increase research depth (66). Then the research would be discussed in a multi-check method (67–69), which could make up for the shortcomings of research methods or insufficient theory (70).

Therefore, the researchers first referenced literature on environmental risk (46–51), physical anxiety (52–57), leisure satisfaction (58–60), and physical and mental health perceptions (60–63), and then developed a questionnaire tool. First, SPSS 26.0 statistical software was used to confirm the framework of the formal questionnaire tool with basic statistical verification and EFA verification method, and then three experts with expertise in public health, leisure sports, and decision analysis were invited to check the content validity to confirm the formal questionnaire. In November 2021, samples were collected by interest sampling method and snowball sampling method, and 840 questionnaires were finally obtained.

The data were analyzed by basic statistics, *t*-test, ANOVA, and PPMCC test. Then, the semi-structured interview method was used to collect the opinions of officials, experts, and the public according to the results of the questionnaire analysis. Next, all the data in a rigorous was collected in an orderly and logical manner and then valuable information through summarizing, organizing, and organizing methods were summarized (69). Finally, the research was carried out through the multi-check method in a multi-data and multi-perspective way (67, 68, 71).

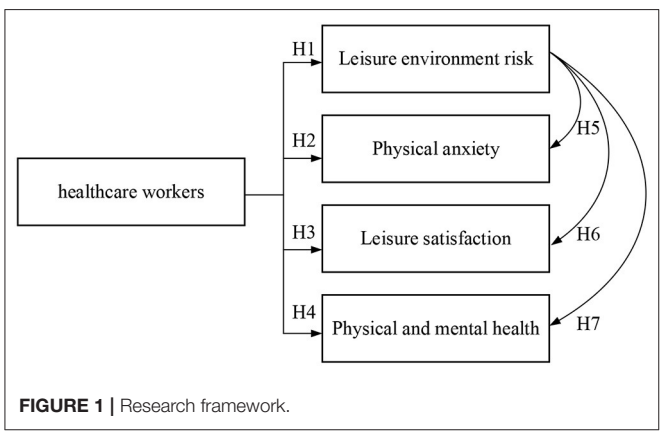

FIGURE 1 | Research framework.

Hypothesis

Due to the impact of the potential risk of epidemic infection around the world, people's willingness to go out for leisure and activities has been declined (13). As many studies had confirmed that swimming pool disinfection and filtration management measures had a certain bactericidal effect on the SARS-CoV virus (24–26), the conditions were sufficient to create a healthy and safe leisure sports environment (29, 30). These were beneficial for people to concentrate and relax their bodies during leisure sports (33, 34), effectively obtain the effect of leisure sports (19, 72), and achieve the purpose of promoting physical and mental health (19, 72). Therefore, the researchers put forward five hypotheses based on the above inferences and research framework.

Hypothesis 1. Assume that the risk perceptions of the exercise environment for swimming in swimming pools are consistent.
Hypothesis 2. The body anxiety perceptions of swimming in the pool are consistent.
Hypothesis 3. The perception of leisure satisfaction of swimming in swimming pools is consistent.
Hypothesis 4. The physical and mental health perceptions of swimming in the pool are consistent.
Hypothesis 5. Environmental risk has a positive and significant effect on physical anxiety, leisure satisfaction, and physical and mental health.

Research Tools and Analysis

The study used a mixed approach, with references to environmental risk (46–51), physical anxiety (52–57), leisure satisfaction (58–61), and perceptions of physical and mental health (37, 58–61), and then prepared a preliminary questionnaire. The questionnaire was divided into background information and variables. The background was gender (male, female) and age (under 30, 31–40, 41–50, over 51). Other variables were divided into environmental risk, physical anxiety, leisure satisfaction, and physical and mental health. There were 42 questions in total and were designed with a Likert-style

5-point scale (1 point meant very dissatisfied, 5 points meant very satisfied). After the preliminary questionnaire was edited, according to the Kaiser-Meyer-Olkin (KMO) > 0.06 in the test results, and the p-value in the Bartlett test was <0.01 ($p < 0.01$) (73), $\alpha > 0.60$. The questionnaire met the standard of good reliability issues (74), and the content of the questionnaire applicable to the subject of this research was reserved for continuous research and analysis.

According to references, edited environmental risk design six questions (47–51). The analysis results showed that the KMO was 0.837, the approximate $\chi 2$ value of Bartlett was 970.578, the df was 6, and the significance was $p < 0.001$, which was suitable for factor analysis. The total variance explained by the scale was 67.414%. After factor analysis, good and reliable topics were retained. The alpha coefficient of the total scale was 0.891. After deleting the inappropriate topics, they were four topics reserved at the end, "modifying body movements," "exercise methods will not cause infection risks," "good mood," and "no increase in social costs." Each topic scored 0.855 to 0.862. According to the above analysis results, it could be known that this questionnaire had good reliability.

Referring to (52–57) literature, 10 questions were designed to edit body anxiety cognition. The analysis results showed that the KMO was 0.683, the approximate $\chi 2$ value of Bartlett was 2,634.081, the df was 28, and the significance was $p < 0.001$, which was suitable for factor analysis. The variance explained by the scale was 38.131 and 30.148%, and the total explained variance was 68.28%. After factor analysis, good and reliable issues were retained and named psychological and physical (5 questions) and achievement performance (3 questions). The alpha coefficient of the total scale was 0.851. After deleting the inappropriate items, they were reserved at the end. There were 8 questions in total, including anxiety, tension, physical incoordination, muscle relaxation, stomach pain, performance satisfaction, achievement of goals, and surpassing level. Each question was 0.809–0.849. According to the above analysis results, it could be known that this questionnaire had good reliability.

Referring to the literature (58–61), a total of nine questions were designed to edit the cognition of leisure satisfaction. The analysis results showed that the KMO was 0.683, the approximate $\chi 2$ value of Bartlett was 2,634.081, the df was 28, and the significance was $p < 0.001$, which was suitable for factor analysis. The variance explained by the scale was 38.131 and 30.148%, and the total explained variance was 68.28%. After factor analysis, good and reliable issues were retained and named as epidemic prevention measures (3 questions), water quality and environment (3 questions), and leisure effects (2 questions). The alpha coefficient of the total scale was 0.908. After deleting the inappropriate topics, eight questions were finally retained 8 questions in total, including wearing masks, epidemic prevention distance, source of swimmers, personal epidemic prevention and hygiene literacy, clean water quality, clean facilities, environment, exercise ability, and completed actions. Each question scored 0.894–0.897. According to the above analysis results, it could be known that this questionnaire had good reliability.

Referring to the literature (62–65), a total of 17 questions were designed to edit physical and mental health cognition. The analysis results showed that the KMO was 0.756, the approximate $\chi 2$ value of Bartlett was 8,613.85, the df was 136, and the significance was $p < 0.001$, which was suitable for factor analysis. The variance explained by the scale was 38.131 and 30.148%, and the total explained variance was 68.28%. After factor analysis, good and reliable issues were reserved and named as psychological feelings (5 questions), mental state (5 questions), physical conditions (3 questions), and negative thoughts (4 questions). The alpha coefficient of the total scale was 0.908. After deleting the inappropriate topics, the remaining topics were facing environmental pressure, feeling scared, unsatisfactory performance, not interested in life, unable to make good use of time, head pressure, fatigue, pain sensitivity, back tightness, insomnia, stomach pain, eating disorders, body tension, easy tantrums, worthless, life burnout, and suicidal escapism, a total of 17 questions. Each question scored 0.894–0.897. According to the above analysis results, it could be known that this questionnaire had good reliability.

According to the above analysis results, there were 37 questions left in the background disguised, environmental risk (4 questions), physical anxiety (8 questions), leisure satisfaction (8 questions), and physical and mental health (17 questions). Finally, three experts were asked to check the content validity, confirm the content of the questionnaire, and confirm the completion of the formal questionnaire, and then investigation and analysis were conducted.

Research Scope and Object

Meizhou City is located in the mountainous area of Guangdong Province. Since the outbreak of the epidemic in 2019, the epidemic control mechanism has been continuously adjusted. Although there are still sporadic outbreaks of overall infection cases in various provinces, a number of strict control measures have been carried out on the epidemic situation in the case areas. So far, they have been effectively controlled, and no large-scale infection incidents have occurred (75). In addition, the local latitude is high, the climate change is small, and the people's willingness to invest in swimming is relatively high.

Therefore, the research team limited the sampling to medical workers who were still engaged in swimming activities during the epidemic. Taking Meizhou City as the core of the research and investigation scope, the interest sampling method was used to collect the basic sample size. At the same time, the snowball sampling method was used to invite people who had agreed to be surveyed to assist in recommending, and other samples were collected through the online questionnaire platform, which was radiated and diffused outwards, and finally, 840 samples were obtained.

In addition, the interview process invited six experts in decision analysis, public health, and leisure sports management, as well as long-term swimmers, the general public, and industry players, to obtain the interviewee's consent to the interview by using the video system and telephone calls. Then the semi-structured interview method was used to conduct the survey, and opinions were put forward on the questionnaire analysis and the results. The interview subjects and interview topics are described in **Table 1**.

TABLE 1 | Respondent's background information and an overview of the interview outline.

Identity	Gender	Residence and sports time/years of work experience	Identity	Gender	Residence and sports time/years of work experience
Swimmer	Male	31	Professor	Female	15
Swimmer	Female	41	Entrepreneur	Female	30
Professor	Male	20	Entrepreneur	Male	10
Professor	Male	16	People	Male	40
Construct	**Issues**				
Impact of tourism development	1. Do you agree that during the exercise in the swimming pool, the sports environment still feels the threat of the epidemic? What parts? What is the reason? 2. Do you agree that physical and mental health will be threatened during exercise in the swimming pool? Which parts? Why? 3. Do you agree that leisure satisfaction is affected by exercising in the swimming pool? Which parts? Why? 4. Do you agree that your physical and mental health will be affected by exercising in the swimming pool? Which parts? Why?				

Ethical Considerations

This study was conducted using a mixed-type study, with Meizhou City as the scope. The standard for collecting questionnaire samples is local people with medical work status who have continued to swim since the beginning of the epidemic. Investigators produced a brief description of the swimming pool safety research report, briefed respondents or asked respondents to read the content during the sampling period, and then began the survey. Respondents, therefore, had an understanding of the research topic and had relevant professional competence or personal experience. Therefore, all respondents agreed to and understood the purpose of this research and then cooperated with the presentation of anonymous data and under the condition of knowledge, recorded and collected data, and agreed to cooperate with the provision of relevant data for data collection. The research design and data collection process were carried out under the standards of fairness, impartiality, and openness. Therefore, the researchers believed that the research conformed to ethical standards and did not need to apply for ethical certification (75, 76).

However, during the research and investigation period, there were still some cases of epidemic transmission in China. In order to avoid the risk of infection, the research and investigation team only took the local area of Meizhou City as the on-site distribution scope. Considering the limitations of resources such as human resources, material resources, and funds of the team, as well as factors such as the time node of swimming participation and the location of swimming pools for assisting pushers, the above limitations might affect the total number of samples and analysis results. Therefore, if the results of this study were insufficient, they would be listed as recommendations for follow-up research investigations in the hope that follow-up researchers would strengthen them.

ANALYSIS AND DISCUSSIONS

The study used basic statistics, *t*-test, ANOVA, and PPMCC test methods to analyze the related issues among background information, environmental risks, physical anxiety, leisure satisfaction, physical and mental health cognition, and variables in 840 samples.

The analysis revealed that among the 840 samples, 276 (32.2%) were male and 580 (67.8%) were female. Among the age groups, 304 (35.5%) were under the age of 30, 376 (43.5%) were 31–40 years old, 152 (17.8%) were 41–50 years old, and 28 (3.3%) were over 51 years old. It could be seen that most of the samples tested were women, and the least were men; people under the age of 40 were the majority, and those over the age of 51 were the least.

Analysis of People's Sports Environment Risk, Physical Anxiety, Leisure Satisfaction, Physical and Mental Health Cognition

The analysis used basic statistics, *t*-test, and ANOVA to analyze the environmental risks, physical anxiety, leisure satisfaction, and physical and mental health cognition of people swimming in swimming pools under the epidemic and verify Hypotheses 1–4. The analysis found that the modified action (3.95) was the highest in the risk environment, and the exercise mode did not have the lowest risk of infection (3.77). In physical anxiety, tension (3.52) and performance satisfaction (3.3) were the highest, muscle relaxation (3.0) and goal achievement (3.14) were the lowest. Leisure satisfaction was the highest in terms of distance from epidemic prevention (3.61), clean water (3.6), exercise ability (3.58) while wearing a mask (3.55), clean facilities (3.55), and completing actions (3.55) were the lowest. Physical and mental health was the highest with the inability to use time well (2.79), insomnia (2.87), body tension (2.79), and easy to lose temper (2.58). Dissatisfaction with performance (2.65), head pressure (2.41), stomach pain (2.48), and no value (2.33) were the lowest. The above analysis results confirmed that Hypotheses 1–4 were invalid.

In the follow-up analysis, gender was insignificant in environmental risk and leisure satisfaction ($p > 0.01$). In terms of physical anxiety, tension, limb incoordination, achievement of goals, and transcendence were significant ($p < 0.01$), and the others were not significant. Men felt high in tension and

*$P < 0.01$.

limb incoordination, and women felt high in transcendence level. In terms of physical and mental health cognition, facing environmental pressure, performance dissatisfaction, head pressure, fatigue, insomnia, eating disorder, and no value were significant ($p < 0.01$), and the others were not significant. And men had higher feelings of head pressure, fatigue, and insomnia, while women had higher feelings of environmental stress, unsatisfactory performance, eating disorders, and worthlessness.

In addition, subjects of different ages toward the issues in good moods, showing satisfaction, reaching goals, exceeding levels, facing environmental stress, feeling scared, head pressure, fatigue, pain sensitivity, back tightness, insomnia, stomach pain, eating disorders, and life burnout were significant ($p < 0.01$), and others were not. In addition, those under the age of 30 were more sensitive to the performance of physical anxiety, exceeding the level, as well as physical and mental health issues such as head pressure, pain sensitivity, stomach pain, eating disorders, and life burnout. Those aged 31–40 were more sensitive to physical anxiety, performance satisfaction, achievement of goals, and exceeding levels, as well as physical and mental health issues such as fear, pain sensitivity, back tightness, stomach pain, eating disorders, and life burnout. Those aged 41–50 were more sensitive to environmental stress issues in achieving physical and mental health. People over 51 years old were satisfied with their performance in physical anxiety, and their physical and mental health were more sensitive to fear, head pressure, pain sensitivity, back tightness, and insomnia.

It could be seen that most people believed that swimming could modify body movements, but there was still a risk of infection. Although the performance of the exercise was satisfactory, the body was still tense, the muscles could not relax, and the exercise goal could not be achieved. Even if the distance of epidemic prevention and the clean water were reassuring, the exercise ability could be improved. However, problems such as wearing masks by the swimmers and the cleanliness of the facilities remained, and the swimmers could not complete the movements, resulting in a lack of time, insomnia, and physical tension among the people's physical and mental health. These caused different genders to have cognitive differences in physical anxiety and physical and mental health cognition. Different ages also had different views on physical anxiety and physical and mental health cognition. As shown in **Table 2**.

Correlation Analysis of Physical Anxiety, Leisure Satisfaction, and Physical and Mental Health Cognition of Sports Environmental Risks

The PPMCC test method was used to analyze the impact of environmental risks on physical anxiety, leisure satisfaction, and physical and mental health cognition of people who still engage in swimming during the epidemic. The analysis showed that environmental risk had a positive and significant positive effect on physical anxiety (0.299) and leisure satisfaction (0.299), and $p < 0.01$, but had no significant effect on physical and mental health cognition. Among them, environmental risk cognition had the greatest influence on achievement performance (0.298)

TABLE 3 | Correlation analysis of sports environmental risk on physical anxiety, leisure satisfaction, and physical and mental health cognition.

and leisure effect (0.370); it had less influence on psychology and physiology (0.253) and water quality environment (−0.126). And found that environmental risk cognition and water quality environment showed a negative significance. The results verified that Hypotheses 5-1 and 5-2 were valid, but 5-3 was not.

It could be seen that environmental risk had a positive and significant influence on physical anxiety and leisure satisfaction, among which achievement performance and leisure effect had the greatest influence, and psychological and physiological influences were the least. Moreover, when the awareness of environmental risks increased, the public's satisfaction with the water quality and environment of the swimming pool decreased. As shown in **Table 3**.

Discussions

Analysis of Background

We believed that although swimming was a whole-body exercise, there were various swimming styles, and the exercise intensity of different swimming styles varied greatly. Swimming could strengthen cardiopulmonary function, effectively improve health (19, 20), help women maintain their posture, and provide people under 40 with sufficient exercise effects. In addition, most medical workers over the age of 51 work as supervisors or important units, and the medical work has heavy tasks. As a result, medical staff over 51 years old have less leisure time and less willingness to go out to swim. Therefore, under the epidemic environment, the majority of people who were still able to continue to participate in swimming were healthcare workers under the age of 40, and women were more willing to engage in swimming than men.

We believed that enterprises should strengthen the publicity and image of epidemic prevention measures and strengthen people's confidence in the epidemic prevention measures of swimming venues. Medical institutions could cooperate with enterprises nearby to provide medical personnel with a swimming and sports environment. Competent agencies could encourage medical personnel to plan swimming exercises to improve physical and mental health. All these measures would improve the willingness of men to participate and the willingness of medical staff of other ages to swim.

Analysis of Environmental Risk of Infection, Physical Anxiety, Leisure Satisfaction, and Physical and Mental Health of Swimmers

The research deduced that under the influence of the epidemic, public transportation and open environments were still at risk of infection (3). Therefore, people reduced their willingness to take public transportation and increased the travel time to the swimming pool. This led most people to believe that the existing exercise time was squeezed. However, the exercise time was insufficient, resulting in insufficient exercise, so the body was still tense, unable to solve the problems of insomnia, limb tension, and easy tantrums. In addition, due to China's current measures to clear and prevent blockages, the government used mobile phones to control personnel dynamics. Under the long-term epidemic prevention propaganda, the public's awareness of self-epidemic prevention and keeping distance gradually increased. In addition, the swimming pool used sodium hypochlorite for water quality management and environmental cleaning, and its items could effectively reduce the activity of the new coronavirus (25, 26), coupled with the repeated water filtration mechanism, to ensure the hygiene and quality of swimming pool water. Therefore, most healthcare workers believe that the swimming pool is in line with their anti-epidemic benefits and is a safe

and healthy leisure sports environment that can help relieve tension. The exercise investment could slow down, people could maintain their own pace to modify their swimming style and technique, and swimming could increase swimming ability and life performance.

In addition, in a low-risk environment, the mentality was stable. The exercise investment could slow down, people could maintain their own pace to modify their swimming style and technique, and swimming could increase swimming ability and life performance.

Therefore, most healthcare workers believed that swimming could modify body movements, but there was still a risk of infection. Although the performance of the exercise was satisfactory, the body was still tense, the muscles could not relax, and the exercise goal could not be achieved. Even if the distance of epidemic prevention and the clean water were reassuring, the exercise ability could be improved. However, issues such as wearing masks by swimmers, cleaning auxiliary facilities, or returning to the territory had not been perfected and could not be implemented. Ultimately, physical and mental health still produced feelings of lack of time, insomnia, and limb tension.

Next, different gender dimensions were explored. Due to the degree of exercise investment in different genders, there were certain differences in exercise time planning and immunity (75). Due to the differences in innate physiological structure, men had high exercise ability and high intensity, but their metabolism was slow, which led to muscle tension. In addition, the tasks of male healthcare workers will be heavier, increasing the pressure burden. As a result, it is difficult for them to recover from fatigue, sleep, and physical and mental stress.

Women were more delicate in their minds and were more able to find measures to disperse the stress and maintain their level of exercise when facing pressure. This is also the main reason why women are valued as healthcare workers. However, due to the diversity of swimming pool activity spaces and participants' identities, as well as different sanitation and epidemic prevention literacy, the risk of infection increased. When women engaged in sports in an uncertain sports environment, they easily lost the existing rhythm of life, disrupted existing plans, and affected life behavior and sports performance. As a result, the daily routine was changed, the way of eating was affected, the frustration and loss in life increased, and the physical and mental health were damaged.

Therefore, different genders had cognitive differences in physical anxiety physical and mental health cognition. Among them, men reported higher levels of tension, physical incoordination, head pressure, fatigue, and insomnia, while women experienced higher levels of issues such as transcendence, environmental stress, unsatisfactory performance, eating disorders, and worthlessness.

Finally, different age levels were discussed. Due to differences in reaction ability, virus resistance, life behavior, and mobility at different ages, different ages had different views on physical anxiety and physical and mental health cognition when faced with an infected sports environment (77, 78). Among them, because 31–40-year-old healthcare workers were in the process of physical maturity and strong strength, and the current work stage might be starting or reaching an important growth moment, there was an urgent need for ways to relieve stress. However, although swimming pools' pool management methods and environmental cleaning measures had a certain protective power, the epidemic situation continued to appear, and there was a gap between the public's personal epidemic prevention awareness and self-protection awareness, which was prone to epidemic prevention gaps. In addition, there was a lot of pressure from work or life, but it was impossible to relieve the pressure through sufficient exercise time and amount of exercise. As a result, people's physical and mental health in the 31–40-year-old age group had not been improved.

Furthermore, most people aged 41–50 had accumulated many years of experience in life, work, family care, and personal physical and mental health management (78). Most healthcare workers had a wealth of experience and knowledge at this age. Therefore, although there might be concerns that the current surrounding living environment was still full of the risk of virus infection, reducing the amount of exercise could not achieve the expected exercise goals. However, in the face of the epidemic environment and risks, people of this age group could plan their own health and epidemic prevention techniques and strategies based on their past experience and knowledge.

In addition, although people over the age of 51 were in the peak period of life, work, family, and self-health management (79), they might be about to stabilize or decline in another life stage (77, 80). However, at the same time, they were also gradually facing a state of physical exercise ability, self-health defense function, and mechanism gradually failing (78). Coupled with the impact of the epidemic, the convenience of transportation had disappeared, and the risk to the living environment had increased (3). As a result, people over the age of 51 could use their rich personal experience to find suitable alternative exercise methods and self-health management strategies under the epidemic situation to achieve the goal of stable life and exercise quality. However, due to the heavy medical work during the epidemic, coupled with the gradual failure of the individual's self-health defense function and mechanism, and the fear of virus infection, physical and mental health would be threatened, causing tension in the head, shoulders, neck, back, and other body parts and affecting sleep quality.

Therefore, different ages had different views on physical anxiety and physical and mental health cognition. Among them, 31–40-year-olds were more sensitive to issues such as satisfaction with physical anxiety, achievement of goals, surpassing levels, and physical and mental health, as well as fear, pain sensitivity, back tightness, stomach pain, eating disorders, and life burnout. People aged 41–50 were more sensitive to issues such as meeting their goals and facing environmental pressures on their physical and mental health. Most healthcare workers over the age of 51 were more sensitive to issues such as physical anxiety, fear of physical and mental health, head pressure, pain sensitivity, back tightness, and insomnia.

We suggested that a safe and proper transportation epidemic prevention mechanism should be planned, and appropriate transportation routes should be established. The study also recommended designing swimming and physical exercise

mechanisms in line with men, improving swimmers' epidemic prevention and hygiene literacy, and providing women with a safe swimming environment. Then, according to the needs of people aged 31–50, appropriate exercise prescriptions should be well planned, and exercise measures that could eliminate head and body fatigue, promote blood circulation, and improve the quality of sleep should be well designed to improve the health problems of people over 51 years old. The researchers believe that these measures can stabilize the health of healthcare workers and achieve the purpose of improving physical and mental health.

Correlation Analysis of Sports Environmental Risk on Physical Anxiety, Leisure Satisfaction, and Physical and Mental Health Cognition

This study inferred those studies had confirmed that the use of sodium hypochlorite for disinfection and cleaning in swimming pools could inhibit the activity of SARS-CoV-2 and achieve disinfection effects (27–30, 42), and swimming could help improve physical and mental health and strengthen cardiopulmonary function (19, 20). However, since the SARS-CoV-2 virus is still raging, Omicron has a low fatality rate and a high risk of infectivity. The emergence of mutant strains has the risk of re-infection, resulting in increased resistance to people trying to restore order in life and leisure. Coupled with the limited sports environment and people's different personal epidemic prevention sensitivities, hygiene, and environmental literacy, there might still be infection risks in swimming pools. This would lead to a reduction in the swimming people's leisure performance and final sports effect, and the expected leisure benefits and sports goals could not be obtained.

Therefore, the public's environmental risk cognition had a positive and significant correlation with physical anxiety and leisure satisfaction cognition. Among them, achievement performance and leisure effect were most influenced by environmental risk cognition. When the environmental risk cognition was higher, swimming pool water quality and environmental satisfaction would decrease.

We suggested that if the swimming pool environment could maintain the existing quality of disinfection and filtration, medical workers could first be provided with different leisure sports measures to achieve the purpose of improving physical and mental health. It would be a better decision if the swimming pool staff could repeatedly remind other swimmers to abide by the epidemic prevention regulations in the swimming pool, regulate the safe exercise distance, and continue to use sodium hypochlorite to increase disinfection in other swimming pool spaces.

CONCLUSIONS AND SUGGESTIONS

Medical workers are able to maintain the effect of exercise and maintain their health by strengthening the measures of water filtration and disinfection, enhancing the confidence in the swimming pool environment and epidemic prevention and control because the operators control the living footprints of swimmers. However, the public's awareness of epidemic prevention, hygiene awareness, and environmental literacy are different, causing people to have doubts about the effectiveness of epidemic prevention in bathrooms, toilets, and parking spaces. These lead effectively improve the environmental risk perception of medical personnel, reduce anxiety, improve leisure benefits, and achieve the goal of promoting physical and mental health. Female medical workers believe that the current epidemic prevention effect is still damaged, and male medical workers believe that the current sports benefits of going swimming are not good. Those aged 31–50 feel that exercise program options are few and ineffective, and those over 51 feel they still have problems with fear, head pressure, pain sensitivity, back tightness, and insomnia. The resulting environmental risk perceptions are positively correlated with body anxiety and leisure satisfaction perceptions and affect achievement performance and leisure outcomes. The higher the environmental risk, the more pronounced the impact of pool water quality and the effectiveness of environmental maintenance on healthcare workers.

We suggested that a safe and proper transportation epidemic prevention mechanism should be planned, and appropriate transportation routes should be established. Swimming pools can plan swimming exercise mechanisms for different genders and ages, strengthen publicity and epidemic prevention mechanisms, and improve the cooperation of other swimmers in epidemic prevention. These strategies will effectively improve the environmental risk perception of medical personnel, reduce anxiety, improve leisure benefits, and achieve the goal of promoting physical and mental health. Based on the above analysis and inference results, the study suggests research on the government, venues, the public, and future studies.

About the Government

Plan a safe and proper transportation epidemic prevention mechanism, and establish suitable transportation routes. Improve people's epidemic prevention and hygiene literacy, and provide a safe swimming environment.

About the Pool Venue

The swimming pool environment should maintain the existing disinfection and filtration quality, improve the epidemic prevention measures, add slogans or voice announcements to remind the public to abide by the epidemic prevention regulations in the swimming pool sports environment, and then standardize the safe exercise distance in the existing swimming sports space. Or, in the building space, add other sports facilities, and use the disinfection effect of sodium hypochlorite to maintain the cleanliness of the sports space and facilities.

About the Healthcare Workers

Improve environmental literacy, follow the epidemic prevention measures of the government and sports venues, jointly maintain the sports environment, maintain the effectiveness of epidemic prevention, and avoid becoming an epidemic prevention gap.

Suggestions for Future Research Directions

The researchers suggest extending the discussion to different occupations or identities of people, as well as other issues. It is expected that follow-up researchers will develop swimming exercise prescriptions or other physical exercise mechanisms in line with 31–50-year-old males and design exercise measures that can eliminate head and body fatigue, promote blood circulation, and improve sleep quality for people over 51 years old. The research gaps will be completed.

Hou D, Yang B, Li Y and Sun M (2022) Utility of Scoring System for Screening and Early Warning of Cervical Cancer Based on Big Data Analysis. Front. Public Health 10:920956. doi: 10.3389/fpubh.2022.920956

Objective: To explore the utility of the scoring system for screening and early warning of cervical cancer based on big data analysis.

Methods: A total of 420 women undergoing physical examination in Shenyang from January 2021 to January 2022 were screened by convenient sampling as the study subjects. All females accepted the human papilloma virus (HPV) tests and thin-prep cytology test (TCT), a Rating Questionnaire for Screening and Early Warning of Cervical Cancer was developed, and a warning threshold was derived according to the scores of the questionnaire and the goodness of fit for the results of HPV+TCT tests. The patients were graded according to the threshold, and corresponding intervention strategies for patients of different grades were developed.

Results: Among the 420 people undergoing physical examination, 92 (21.90%) obtained scores $\geq$8 points, and 328 (78.10%) obtained scores $<$ 8 points; in diagnosing cervical cancer, the Rating Questionnaire for Screening and Early Warning of Cervical Cancer had an AUC value of 0.848, specificity of 97.22%, and sensitivity of 86.46%; after scientific intervention, HPV test results showed a significant decrease in both high-risk positive cases and low-risk positive cases ($p < 0.05$), and TCT results showed that there was a significant difference in the number of patients with CIN I before and after intervention ($p < 0.05$).

Conclusion: The scoring system for screening and early warning of cervical cancer based on big data analysis presents certain clinical value in the clinical screening of cervical cancer, which can further improve the screening coverage, is of great significance for the diagnosis and treatment of disease, and helps physician implement hierarchical diagnosis and treatment quickly and precisely.

Keywords: big data analysis, scoring system for early warning, cervical cancer screening, utility, intervention measures

INTRODUCTION

Cervical cancer is a malignant tumor disease that endangers women's health (1). Investigation and research (2) have shown that about 85% of cervical cancer patients are from developing countries, and there are approximately tens of thousands of new cervical cancer cases each year worldwide, seriously threatening women's health and life safety. According to years of basic experimental and epidemiological studies (3, 4), human papilloma virus (HPV) infection is an important factor causing the disease. Cervical cancer 3-step screening technique (step 1: cervical cytology and HPV test; step 2: colposcopy; step 3: histopathological examination) is currently the most widely used clinical diagnosis technique, and its clinical application provides an effective pathological evidence for the early diagnosis and treatment of cervical cancer in developed countries or regions (5). Early detection and treatment can effectively prevent the deterioration of the condition and minimize mortality. However, in countries and regions with relatively lagged economic and medical conditions, most cervical cancer patients are already in the advanced stage of the disease when diagnosed, leading to a lower cure rate and higher mortality. Therefore, searching for convenient and efficient means of cervical cancer screening can provide important auxiliary judgment indicators for clarifying and diagnosing the disease, and lay a strong scientific foundation for selecting clinical treatment options (6–8). There are deficiencies in every screening method in the existing medical context, and no single examination modality achieves the combination of high sensitivity with high specificity. Based on this, by reviewing a great amount of relevant materials of cervical cancer, a Rating Questionnaire for Screening and Early Warning of Cervical Cancer was developed in this trial to get the score of each patient and then develop corresponding intervention measures, thus improving the disease screening rate.

TABLE 1 | Clinical data of study subjects.

Clinical item	Proportion [%(*n*)]
Age	
18–26 years	13.10 (55/420)
27–40 years	28.33 (119/420)
41–60 years	42.62 (179/420)
>60 years	15.95 (67/420)
BMI value	
<18.5	10.95 (46/420)
18.5–24.9	40.24 (169/420)
25.0–29.9	34.29 (144/420)
≥30.0	14.52 (61/420)
Occupation	
Employee of organizations, enterprises, public institutions	10.00 (42/420)
Service personnel	32.38 (136/420)
Farmer	20.24 (85/420)
Worker	15.00 (63/420)
Self-employed entrepreneur	16.43 (69/420)
Others	5.95 (25/420)
Place of residence	
Rural area	57.86% (243/420)
Urban area	42.14% (177/420)
Educational degree	
Junior college and above	18.81% (79/420)
Senior high school	35.00% (147/420)
Junior high school and below	39.52% (166/420)
Illiteracy	6.67% (28/420)
Paying method of medical treatment	
Medical insurance	54.52 (229/420)
Self-paying	45.48 (191/420)
Family monthly income (yuan)	
≥3,000	49.52 (208/420)
<3,000	50.48 (212/420)

MATERIALS AND METHODS

General Data

A total of 420 women undergoing physical examination in Shenyang from January 2021 to January 2022 were screened by convenient sampling as the study subjects. The study met the World Medical Association Declaration of Helsinki (2013) (9) and reviewed and approved by the Hospital Ethics Committee.

Inclusion and Exclusion Criteria

Inclusion criteria: (1) Women with history of sexual life; (2) those with good understanding and could objectively and accurately fill in the questionnaire; and (3) those who voluntarily joined the study. Exclusion criteria: (1) Those who had cervical cancer and operation history; (2) those who were unable to fill in the questionnaire due to other reasons; and (3) those who were unwilling to join the study.

Methods

Content of Questionnaire

By reviewing a large number of published works on the epidemiology of cervical cancer and related influencing factors, the first version of Rating Questionnaire for Screening and Early Warning of Cervical Cancer was developed, which included the following sections. (1) The general data of the study subjects, such as their age, place of residence, occupation, educational degree, marital status, and the paying method of medical treatment;

(2) Sexual habits, such as age at first sexual activity, number of sexual partners, and whether condoms were used at the time of intercourse;

(3) Personal situation, such as number of times of miscarriages, number of times of pregnancies, presence or absence of an intrauterine contraceptive device (IUD), and presence or absence of immunodeficiency diseases; and

(4) Relevant symptoms or vital signs, such as presence or absence of cervical contact bleeding, cervical erosion, or cervical polyps.

In addition to the personal information of the study subjects, a total of 20 items were scored, and the maximum score was 20 points. The scoring method was as follows: 1 point was assigned to each question (1 for each forward-rating item, and −1 for each

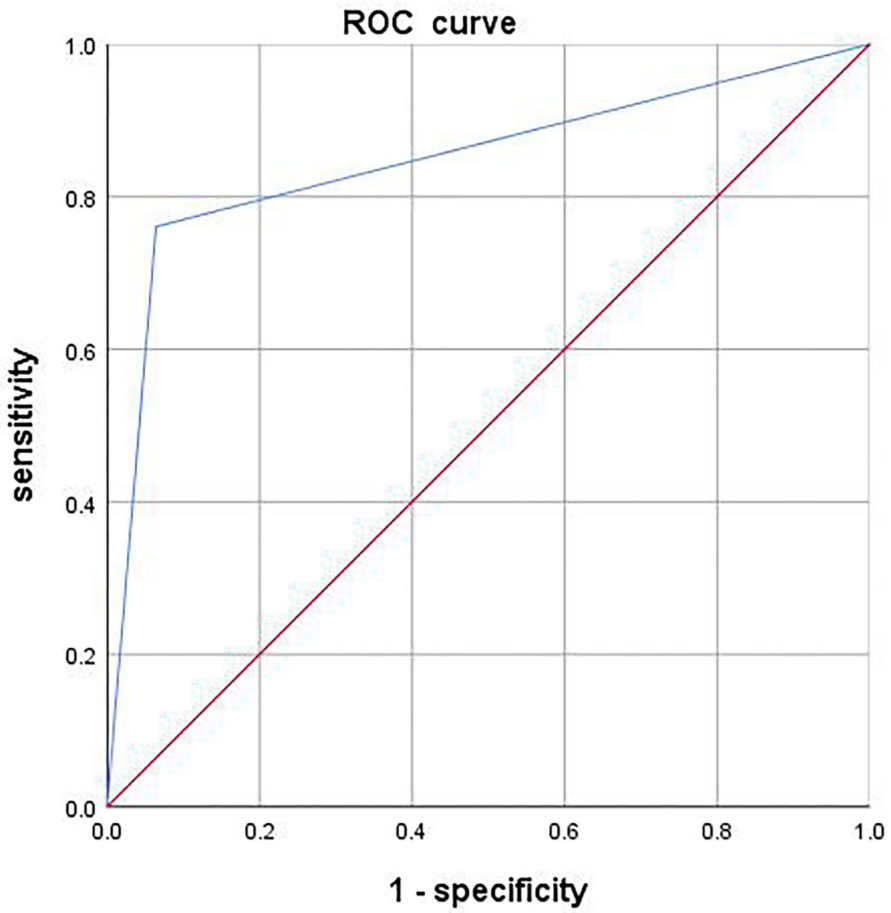

FIGURE 1 | Clinical diagnostic efficacy of the rating questionnaire for screening and early warning of cervical cancer.

backward-rating item), and higher scores indicated higher risk of illness of the study subjects.

Formation of Questionnaire

A Delphi Consultation Questionnaire was developed according to the corresponding general format. After 2 rounds of expert consultation and pre-survey to 30 females, relevant data were organized and the indicators were perfected in combination with the experts' suggestions, which then concluded that the Cronbach's α coefficient and split-half coefficient of the questionnaire were, respectively, 0.796 and 0.691, the validity index of each item level was ≥0.945, and the content validity index of the scale level was 0.950.

Test and TCTHPV Test

The HPV special sampler was inserted to the orificium externum isthmus of the subjects, rotated for 5 turns, and then slowly taken out and put into the HPV specimen bottle containing preserving liquid. The HPV subtyping genes chip was used to detect 26 types of HPV genes (such as HPV 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 6, 11, 40, 42, 43, 44, 53, 54, 55, 57, 66, 67, 73, among which 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66, 68 were high-risk types, and 6, 11, 30, 42, 43, 44 were low-risk types), and all operations were conducted according to the specifications of the apparatus and reagent.

TCT

The sampler tip was inserted into the cervical canal and slowly rotated along the axis for 5 turns, the sampling brush tip was removed and put into the cell preservation solution, the specimen underwent standardized processing and was made into a thin-layer cell smear and fixed with 95% alcohol, and then Papanicolaou stain was performed. For diagnostic gradation of cytology, the Bethesda system (TBS) was adopted, to be specific, TCT negative, referring to no CLN was seen (negatives of intraepithelial lesions or malignancy, NILM); TCT abnormalities, such as a typical squamous cells of undetermined significance (ASC-US); low-grade squamous intraepithelial lesion (LSIL), which was graded as weak CIN (CIN I); high-grade squamous intraepithelial lesion (HSIL), which was graded as moderate and expressed CIN (CIN II and CIN III) and carcinoma *in situ* (CIS); and squamous cell carcinoma (SCC).

Quality Control

Each section of the investigation was under strict quality control, in the stage of designing, the scientificity and feasibility of the scheme and questionnaire applied were verified; before investigation, the researchers were trained with uniform guidelines, and then they provided guidance and correction on any queries and errors made by the study subjects when filling in the questionnaire; after the completion of the questionnaire, 2 personnel were assigned to collect and organize the questionnaires, Epidata3.1 was used for data entry, SPSS20.0 was used for statistical analysis, and an early warning threshold of 8 points for the questionnaire was derived by comparing the analytic findings and gynecological examination results.

Early Warning Threshold

According to patients' HPV test and TCT results and the scores of the Rating Questionnaire for Screening and Early Warning of Cervical Cancer, the threshold was specified as 8 points, and detailed intervention measures were developed according to the threshold.

Intervention Strategies

Detailed hierarchical intervention measures were developed according to the threshold. (1) Below threshold: For those who were free from infection and without prior HPV testing, testing was recommended for 3 consecutive years, and if the results were negative, testing could then be done every 2–3 years; (2) Above threshold: this group was high-risk HPV infected individuals, who should visit gynecological clinics according to the TCT result, and the effectiveness of intervention measures should be analyzed by comparing the results of TCT and HPV test before and after the intervention.

Statistical Methods

The experimental data were statistically analyzed and processed by the software SPSS26.0, the diagnostic efficacy of the Rating Questionnaire for Screening and Early Warning of Cervical Cancer on cervical cancer was analyzed by the area under the Receiver Operating Characteristic (ROC) curve.

RESULTS

Clinical Data of Study Subjects

See **Table 1**.

Scores of the Rating Questionnaire for Screening and Early Warning of Cervical Cancer of the Females Undergoing Physical Examination

Among the 420 female undergoing physical examination, 92 (21.90%) obtained scores $\geq$ 8 points, and 328 (78.10%) obtained scores $<$ 8 points.

Clinical Diagnostic Efficacy of the Rating Questionnaire for Screening and Early Warning of Cervical Cancer

See **Figure 1** and **Table 2**.

TABLE 2 | Comparison of the coincidence rate, specificity and sensitivity of early warning score diagnosis.

AUC value	S.E.	Specificity	Sensitivity	95% *CI* value
0.848	0.028	97.22%	86.46%	0.794-0.902

68	29	35	23	5

Comparison of Various High-Risk HPV Infections in Different Cervical Cancer Lesions

See **Table 3**.

Control Effect of the Rating Questionnaire for Screening and Early Warning of Cervical Cancer in Cervical Cancer High-Risk Group

After scientific intervention, HPV test results showed a significant decrease in both high-risk positive cases and low-risk positive cases ($p < 0.05$), and TCT results showed that there was a significant difference in the number of patients with CIN I before and after intervention ($p < 0.05$), and no significant differences in other types were observed ($p > 0.05$). See **Table 4**.

DISCUSSION

Cervical cancer can seriously affect the quality of life of patients, lead to female infertility, and cause damage to the urinary system and vaginal bleeding, and in the late stage of the disease, cancer metastasis may occur, resulting in hydronephrosis as well as uremi. Data show (10, 11) that there are about 110,000 new cervical cancer cases in China each year. Screening of cervical cancer is able to detect precancerous lesions, and when the disease screening coverage rate is over 70%, the incidence and mortality risk of cervical cancer in the population can be effectively reduced. The pathogenesis of cervical cancer is HPV

TABLE 4 | Control effect on high-risk population above the threshold [n(%)].

Time	HPV		TCT			
	High-risk positive	Low-risk positive	CIN I	CINII	CINIII	Cervical cancer
Before intervention	35 (38.04%)	57 (61.96%)	28 (30.43%)	31 (33.70%)	24 (26.09%)	9 (9.78%)
After intervention	21 (22.83%)	36 (39.13%)	16 (17.39%)	22 (23.91%)	22 (23.91%)	8 (8.70%)

infection, and multiparity and recurrent cervicitis is also the important causes of the high incidence of cervical cancer. The occurrence and development of cervical cancer is a gradual process, from years to decades, which has a long period of reversible precancerous lesions (12). Screening is an effective means to effectively reduce the incidence and mortality of cervical cancer, which can rapidly prevent invasive cervical cancer and precancerous changes in women, and therefore the World Health Organization (WHO) recommends that cervical cancer screening should be initiated worldwide for early diagnosis and early treatment (13). Developed countries have more mature technology and methods of cervical cancer screening and more complete screening programs, so their cervical cancer prevention and control is promising (14, 15). In 2014, HPV DNA typing assay was introduced to China as an initial screening method for cervical cancer, but HPV test cannot determine the specific disease type and single diagnosis has low sensitivity and poor specificity, also, TCT alone has a high rate of missed diagnoses. In addition, with China's large population base and limited health resources, the key point of cervical cancer screening is to develop specific screening programs and select appropriate screening methods (16, 17).

In this study, by reviewing a large number of published works on the epidemiology of cervical cancer and related influencing factors, the Rating Questionnaire for Screening and Early Warning of Cervical Cancer was developed and filled in by women undergoing physical examination, aiming to explore the utility of the questionnaire in diagnosing cervical cancer. Based on the imaging and scoring questionnaires of the study subjects, the specific threshold, i.e., the lowest or highest value an effect can produce, was developed, which helped physicians make a more precise judgment of the occurrence and progression of the disease. The content of the questionnaire included subjects' clinical data, high-risk factors of cervical cancer, and awareness. Previous studies have confirmed (18) that the risk of developing cervical cancer is 2.85 times higher in women having their first sexual intercourse at an age less than 20 years than those having their first sexual intercourse at an age over 20 years, so it is believed that having the first sexual intercourse at younger age is the main reason for the higher incidence of cervical cancer, as well as one of the important factors contributing to the occurrence of the disease in young women. In addition, the risk of cervical cancer in women with more than 3 times of childbirth is 5.91 times higher than that of those with less than 3 times of childbirth, demonstrating that fewer times of childbirth could lower the risk of cervical cancer to some extent (19). And studies also confirmed that low educational degree, poor economic level, poor sanitary conditions in rural areas, etc. are also the high-risk factors triggering cervical cancer. Women with lower education levels lack self-care awareness and gynecological knowledge, and because of their conservative traditional notion, they tend to conceal their illness and avoid treatment, thus increasing the risk of cervical cancer (20). The poor economic level and poor sanitation in rural areas lead to the lack of awareness of regular physical examination among women in these areas, which results in a high incidence of cervical cancer. Therefore, corresponding measures are required to pay close attention to people at high risk of cervical cancer, such as strengthening the publicity of female reproductive health knowledge, conducting targeted implementation of the popularization and publicity of health care knowledge to women, helping women in rural areas get good living habits, strengthening the basic medical and health conditions in township hospitals, putting more efforts in cervical cancer screening for women in rural areas, and assisting women in establishing a correct medical concept (21).

In this study, the diagnostic efficacy of the Rating Questionnaire for Screening and Early Warning of Cervical Cancer in cervical cancer screening was analyzed by plotting ROC curves and taking the results of HPV test and TCT test as the "gold standard", and the results showed that the AUC value of the questionnaire was 0.848, which indicated a high-clinical application value. In addition, an early warning threshold for the questionnaire was derived in this study by analyzing the questionnaire scores and the gynecological examination findings of the females undergoing physical examination, thereby developing detailed hierarchical interventions based on the threshold. The study implemented scientific intervention measures to those above the threshold, and analyzed and compared the experimental results before and after intervention to explore the control effect. HPV typing assay is designed to target the DNA (the genetic material), through a process of PCR target preference, target amplification, automated real-time detection, and selective amplification, and then identify the corresponding HPV replication with greater precision than second-generation hybrid capture assay. Currently, TCT is the more advanced and mature screening technique for cervical cancer, but it has certain false-negative rate and false-positive rate for low-grade cervical lesions, and the concordance rate increases with higher cytological grade. Scientific means of clinical screening can screen out people at high risk of

cervical cancer, reduce the follow-up interval, facilitate effective monitoring of cervical cytological alterations and early detection of cervical lesions, and TCT combined with HPV screening is beneficial to the triage management of cervical lesions, realizing early detection and treatment of the disease. In this study, more detailed prevention and treatment strategies were developed by typing the obtained examination findings. The findings showed that after intervention, both high-risk positive cases and low-risk positive cases were significantly reduced according to the HPV test results ($p < 0.05$), and TCT results denoted that the number of patients with CINI was greatly reduced, which illustrated that the implementation of scientific control measures could lower the risk of cervical cancer to a certain extent. Studies have confirmed (22) that different degrees of TCT and different types of HPV also have significant differences in disease reversal cycles. Data from a large sample survey showed that patients with a TCT result of CIN I and low-risk positive HPV infection had a readily reversible condition, whereas those with a TCT result of CIN II and CIN III and high-risk positive HPV infection required further colposcopy examination and thus had a longer cycle of clinical intervention. Some scholars believe (23) that among multiple high-risk types of HPV, types 16 and 18 have a higher carcinogenic risk, which may be related to the strong ability of gene binding to the host cell, and their gene expression products can also affect the host cell cycle and apoptosis, leading to carcinogenesis. However, other types of viruses are prone to cause low-grade intraepithelial lesions, which may be related to the poor tolerance of the virus to the acidic environment of the vagina, poor viability, and weak pathogenic ability. Type 52 virus has a long cycle of negative conversion and obtains less effective result in clinical treatment; it is also the main genotype responsible for the development of cervicitis. The E6 and E7, biomarkers of cervical cancer caused by type 52 virus, often lead to base mutations that may exert an important function in the progression of cervical intraepithelial lesion and invasive carcinoma, and they are considered as the important carcinogens because they can inactivate the host tumor suppressor p53 and Rb (24).

In addition, unlike the general prevention and control of cervical cancer in developed countries, the comprehensive task of controlling cervical cancer in China is tough and difficult in implementation, and requires long time because of the large population and the uneven development of medical and health resources. Therefore, based on the current situation, the prevention and control measures in China can be summarized as the following 3 aspects. (1) Strengthen the infrastructure construction of the health system, invest corresponding financial, material, and human resources, strengthen the training efforts of primary care workers, and establish a complete system for AI-assisted diagnosis; (2) based on the domestic conditions, clarify the age and screening interval of subjects, identify high-risk individuals, encourage those of proper ages to actively participate in screening, establish a scientific surveillance and evaluation system, and encourage the population of the right age to get an HPV vaccination to gradually expand vaccination coverage; and (3) scientifically develop appropriate screening programs and strategies for the Chinese people to reduce the incidence of cervical cancer (25). Despite the progress of modern medical diagnosis technology, there are still many dilemmas in cervical cancer screening. As medical workers, we still need to continuously try our best to explore more efficient clinical technology, optimize the current diagnosis mode, and provide reliable data support for early screening of cervical cancer. In addition, the application of the Rating Questionnaire for Screening and Early Warning of Cervical Cancer greatly conserves medical and health resources, which is more common and low-cost. The scoring content of the questionnaire should be continually optimized in the future, so that it can be universal in various regions of China as a primary screening method for cervical cancer.

Detection of malignant lung nodules from Computed Tomography (CT) images is a significant task for radiologists. But, it is time-consuming in nature. Despite numerous breakthroughs in studies on the application of deep learning models for the identification of lung cancer, researchers and doctors still face challenges when trying to deploy the model in clinical settings to achieve improved accuracy and sensitivity on huge datasets. In most situations, deep convolutional neural networks are used for detecting the region of the main nodule of the lung exclusive of considering the neighboring tissues of the nodule. Although the accuracy achieved through CNN is good enough but this models performance degrades when there are variations in image characteristics like: rotation, tiling, and other abnormal image orientations. CNN does not store relative spatial relationships among features in scanned images. As CT scans have high spatial resolution and are sensitive to misalignments during the scanning process, there is a requirement of a technique which helps in considering spatial information of image features also. In this paper, a hybrid model named VCNet is proposed by combining the features of VGG-16 and capsule network (CapsNet). VGG-16 model is used for object recognition and classification. CapsNet is used to address the shortcomings of convolutional neural networks for image rotation, tiling, and other abnormal image orientations. The performance of VCNeT is verified on the Lung Image Database Consortium (LIDC) image collection dataset. It achieves higher testing accuracy of 99.49% which is significantly better than MobileNet, Xception, and VGG-16 that has achieved an accuracy of 98, 97.97, and 96.95%, respectively. Therefore, the proposed hybrid VCNet framework can be used for the clinical purpose for nodule detection in lung carcinoma detection.

Keywords: capsule network, convolutional neural networks, CT, MobileNet, VCNet, VGG-16, Xception

INTRODUCTION

Cancer is still regarded as a dangerous disease with severe death rates. Lung cancer has the highest mortality or death rate of any cancer and is widely regarded as the deadliest carcinoma among all types of cancer. Consequently, several researchers are focusing on ways of detecting lung cancer nodules through digital images, specifically through computed tomography (CT). CT scans use

X-rays to generate several images and create a challenge for radiologists to detect tiny nodules from these images (1). Analysis of nodules and their interpretation is the basic task performed by the radiologist for the diagnosis of lung cancer. Many scientists and researchers are working on automated solutions that will help doctors save time and money (2).

In most cases, the size and appearance of nodules give the first inference regarding cancer and can be classified as benign or malignant. Generally, lung nodules <3 cm are considered normal nodules, and those larger than 3 cm are considered malignant or lung masses. **Figures 1A,B** shows the images of benign and malignant lung cancer. Based on nodule classification and other findings, cancer probability can be assessed. AI techniques are playing a very important role in the primary level detection and classification of various types of cancer (3). A variety of disciplines, including medicine, agriculture, games, and many more, have benefited from the deployment of deep learning (DL) models in recent years. In all of these fields, DL models perform quite well, particularly in specific types of applications such as classification of images, identification of objects, and image segmentation (4). DL is a subfield of artificial intelligence, having interconnected nodes to perform complicated tasks. Instead of using pre-programmed instructions, DL algorithms are capable of learning from the training data. Many of the researchers have already worked for lung carcinoma detection using deep learning (5, 6).

In computer vision and radiography, convolutional neural networks (CNN) are a class of artificial neural networks that are gaining a lot of popularity. CNN is used to automatically detect features from the images using a number of layers like convolution layers, pooling layers, and fully connected layers (7, 8). CNN uses successive convolution and pooling layers to classify the images. The pooling layer in the CNN reduces the dimension and classifies the object regardless of its spatial information. That means where the object is actually located in the image (9). This pooling function of CNN is both an advantage and a drawback. During the pooling function, it loses some important information that is very useful in image segmentation and object detection. To overcome this drawback, Geoffrey Hinton (10) proposed capsule network architecture.

A capsule is a cluster or group of neurons that stores information about a specific item in a picture; the information is mainly about its position, rotation, scale, etc. in a high-dimensional vector (8 dimensions or 16 dimensions), each. The capsule network architecture is divided into three parts. (1) primary capsule (convolution, reshape, and squash functions); (2) higher level capsule (dynamic routing); and (3) loss functions (margin and reconstruction loss).Capsule networks (CapsNet) (10) are basically used to overcome the loss of information that comes from the pooling operation of CNN and obtain spatial information. CapsNet's multiple convolutional layers are wrapped in capsules.

This paper utilizes transfer learning and presents a hybrid model, VCNet, for detecting the lung nodules from CT scans. Binary classification is done using the input of lung CT scans and the output is either "benign" or "malignant". A lung CT image dataset is collected from LIDC-IDRI (11) and a new hybrid model that is a combination of VGG-16 and Capsule network is developed and applied for the classification and identification of lung cancer.VGG16 is one of the finest vision model architectures based on CNN computer vision techniques. The accuracy achieved by this model for ImageNet test data is 92.7%. The model presents an improved form of AlexNet and the main architectural changes are in filter size. The 16 in VGG is used to refer that it has 16 weight layers (12).

Related Work

Lung cancer with the greatest death rate is the most prevalent and aggressive form in India. Patients with non-small cell lung cancer (NSCLC) have a 5-year survival rate of 18%. According to the 2018 GLOBOCON report (1), 11.6 percent of all lung cancer cases and 18.4 percent of all lung cancer deaths. Patients with lung cancer outnumber those with other cancers such as breast, liver, cervical, skin, and so on. Patients with pulmonary cancer can enhance their survival chances if they discover early lung cancer. Detection of cancer at last stage does not permit surgical treatment in most of the cases, so last stage lesions are treated by nonsurgical treatment like chemotherapy, Radiotherapy and immunotherapy. Computer vision methods proved an important result in lung nodule classification and detection at an early stage through CT scans. For converting the raw input into the desired features end to end learning allows direct mapping with elimination of hand –crafted features. Machine learning algorithms provide extremely good outcomes in computer vision technology and analysis of medical images. Two main classes, massive training artificial neural networks (MTANNs) and revolutionary neural networks may be performed with end-to-end training (CNNs).Nima Tajbakhsh et al. utilized both theoretical and practical approaches to compare these two classes of end-to-end learning for the detection of lung nodules and the differentiation of benign and malignant tumors in low-dose CT scans. For the analysis of the same the authors have used four MTANN architectures and two CNN architectures that all are having different depth. They used a substantial dataset for CNN training in the second phase, and their results demonstrate a smaller performance gap between MTANN and CNN. After both theoretical and experimental approach they had presented that MTANN gives better performance as compared to the CNN (13).

Goran Jakimovski et al. presented double CNN and regular CNN with a max pooling layer for identifying cancer stages through CT scans (14). One of the most difficult tasks in radiology imaging is automatically determining the precise position of the lung nodule. Hongtao Xie et al. presented the automatic detection of lung nodules using 2D CNN for the reading process of CT scans. The authors did their experiments on the LUNA-16 dataset and achieved a sensitivity of 86.42% (15). By combining information from PET and CT scans, Qin et al. (16) demonstrated a DL architecture for the noninvasive detection of lung cancer. The authors achieved a 0.92 area under the ROC curve. Nakrani et al. (17) presented a method for nodule detection using Resnet architecture in CT scans. The dataset used here is LIDC and the accuracy achieved is 95.24% (17).

Lu et al. (18) proposed an optimal methodology for detection of lung carcinoma at early stage. For good network accuracy & optimal arrangement Marine predators' algorithm is used.

Problem Statement

Many researchers have already presented various DL models for lung cancer detection, but the required accuracy on public datasets is still a big challenge for using those models for clinical purposes and also for radiologists to diagnose the cancerous nodules. Some of the researchers have achieved good accuracy in their work, but they have used either private datasets collected from hospitals or some small datasets available on the internet. In Tajbakhsh et al. (13), 95% accuracy was attained by comparing two end-to-end classes that are large artificial neural network training and convolutional neural networks. But for the implementation of the same, they used the unpublished dataset of 31 patients, including 38 scans collected from the participation of a lung cancer screening program. In (19), the LUNA-16 dataset was used to detect the lung nodules using the 3D AlexNet architecture of CNN and achieved an accuracy of 97.17%. In Jakimovski and Davcev (14), the achieved accuracy was 99.63% for lung cancer stage detection, but the authors of this paper used the private dataset of the University of South California.

To the best of our knowledge, the paper (20) implemented a hybrid model using a modified capsule network for lung disease detection and achieved an accuracy of 73%. For the detection of lung nodules, a multi-scale capsule network is proposed in (21) and achieved an accuracy of 83% for the LIDC dataset.

Based on these works the major contributions of our work are:

- A hybrid model named as VCNet is proposed by combining the features of VGG-16 and capsule network (CapsNet).
- A pre-trained VGG-16 model is used for feature extraction.
- CapsNet layers are used to handle misalignment problems with the existing deep learning models.
- Fully connected layers along with dropouts and sigmoid activation functions are also used to prevent overfitting and to build a generalized model.
- The performance of VCNet is verified on the Lung Image Database Consortium (LIDC) image collection dataset.

TABLE 2 | Model architecture.

5	Inception V3	92 MB	0.788	0.944	23,851,784

MATERIALS AND METHODS

The current investigation was performed to determine if lung CT images were benign or malignant.

Figure 2 shows a diagrammatic depiction of the proposed seven-stage technique. Stage I includes the collection of CT images of lungs from LIDC IDRI dataset. Stage-II includes image pre-processing. Stages III and IV consist of the study & implementation of pre-trained CNN models like VGG, Xception and MobileNet and calculate their performance by accuracy, precision, F1 score and recall. Study, implementation, and performance analysis of hybrid model VCNet is shown in stages

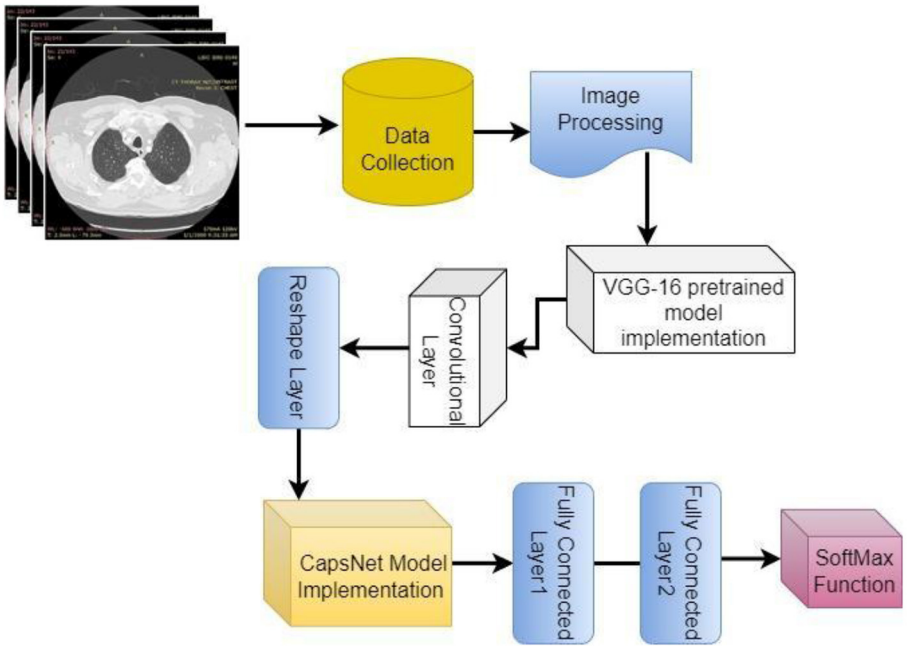

FIGURE 5 | Architecture of VCNet.

V & VI. Stage VII is the last phase, VCNet classifies CT scans as benign or malignant and analyzes their performance in terms of accuracy, precision, F1 score, and recall. All these stages are described in subsections.

Dataset Description

Dataset used here is LIDC- IDRI (11) that has a total 1,018 scans of 1,010 patients with 244,527 images. Each case in this dataset holds images of the CT scan and their corresponding XML file that contains annotations of the CT scan. Four experienced thoracic radiologists performed these annotations in two phases. In the first step, each radiologist individually categorized CT results into three classifications (nodules that are $\geq$3 mm, nodules that are $\leq$3 mm and non-nodule that are $\geq$3 mm). After that in the second step, classification is reviewed by each radiologist along with classification by another radiologist secretly. So every nodule of the dataset is assessed by all four radiologists separately. In this dataset, the diagnosis is done at two label patient levels and the nodule level. The DICOM images of the CT scan vary from 64 to 764 slices and have a resolution of 512*512*width. The average width of CT scans in this dataset is 240. Lung nodules in the LIDC-IDRI dataset are classified into four classes. (1) Unknown (No Label), (2) Benign or normal or non-cancerous (3) Primary lung cancer or Malignant, (4) Metastatic Lesion whose primary cancer was other than lung cancer.

Data Pre-processing

Preprocessing of the images is required to minimize the network overhead and computational complexity. The LIDC-IDRI dataset consists of various lung CT scan images and labeling is provided into csv file. For implementing the proposed model segregation and labeling of cancerous and noncancerous images are done based on annotations presented in csv file. Collected Dicom images are converted into jpg files using Radiant Dicom viewer 64 bit. Data augmentation methods used are rescaling, rotation, horizontal and vertical flip, and utilized ImageDataGenerator library of Keras for implementation. Rescaling is used to limit the image pixels between 0 to 1 and it helped in reducing computational complexity. Color Transformation of images (Gray to RGB) is done for better visualization. Rotation is done in a range of 10 means images are rotated from 0 to 10 degrees.

We have taken rotation range= 1 degree to randomly rotate our image between 0 and 1 degree. Rescale 1. /255 is done to transform every pixel value from range [0, 255] $\rightarrow$ [0, 1]. Color mode function of flowfrom directory of python is used to convert gray images into RGB images. For resizing the image from 512*512 to CNN input size, Keras ImageDataGenerator class is used that provides a quick and easy way to augment images.

The flow_from_directory () method of ImageDataGenerator is used to read the images directly from the directory and augment them while the neural network model is learning on the training data. The main important parameter of this method is target_size: Size of the input image. It is an attribute which converts images into size provided for the input. In our case we have taken image size 512*512, to set traget_size attribute value.

Convolutional Neural Network

Convolutional, pooling, and fully connected layers make up the three main layers of CNN design. For CNN classification and pattern recognition, the most popular architectures are LeNet, AlexNet, VGG-Net, Res-NET, ZF-Net, and SqueezNet.

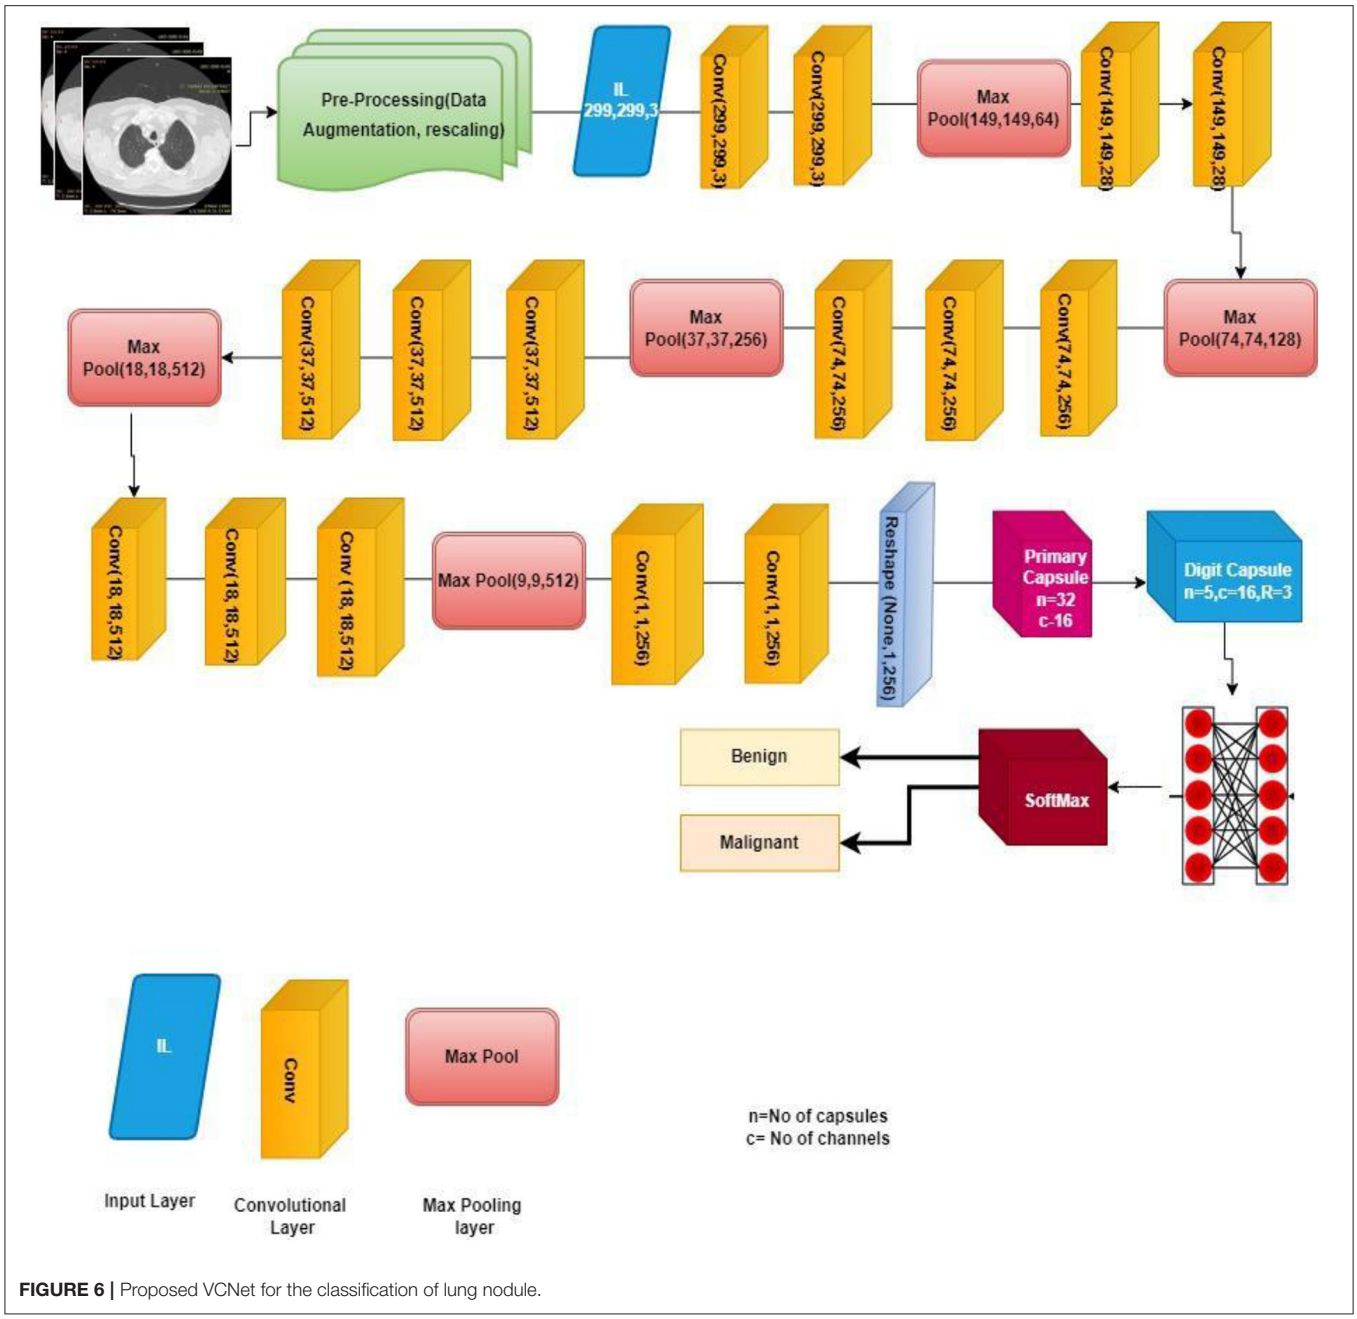

FIGURE 6 | Proposed VCNet for the classification of lung nodule.

Due to CNN's simplicity in calculation and function, the backpropagation algorithm is one of the finest learning algorithms. Back propagation differentiates during training between the algorithm predicting of labels and the ground truth labels computed by the loss function. Equation 1 gives the form of cross-entropy. Training samples are represented as inputs, and the true values of output neurons (j) are represented as inputs in the output layer (a_j^l) in this equation; n is the total number of training samples. It can be computed as:

$$C = -\frac{1}{n}\sum \times \sum_j \left(y_j \ a_j^l\right) \left(1 + y_j\right) l \, \mathrm{n}\left(1 - a_j^l\right). \quad (1)$$

Convolutional Layer

Each feature map comprises groups of neurons that together make up a feature map. Convolutional layer output is calculated by Eq. 2. Kernel (filter) size, feature maps, bias, and weight of a kernel are represented by F, m, B, and W_j, respectively. Convolutional layers have an output known as y_i, where I is an index that denotes the ith feature map in a layer known as l (2).

$$y_i^l = B_i^l + \sum_{j=1}^{ml(l-1)} F_{i,j}l \times W_j^{l-1} \quad (2)$$

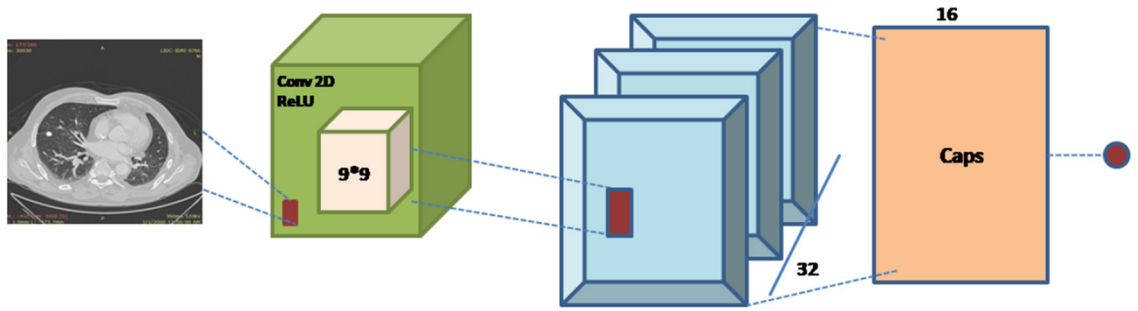

FIGURE 7 | CapsNet architecture.

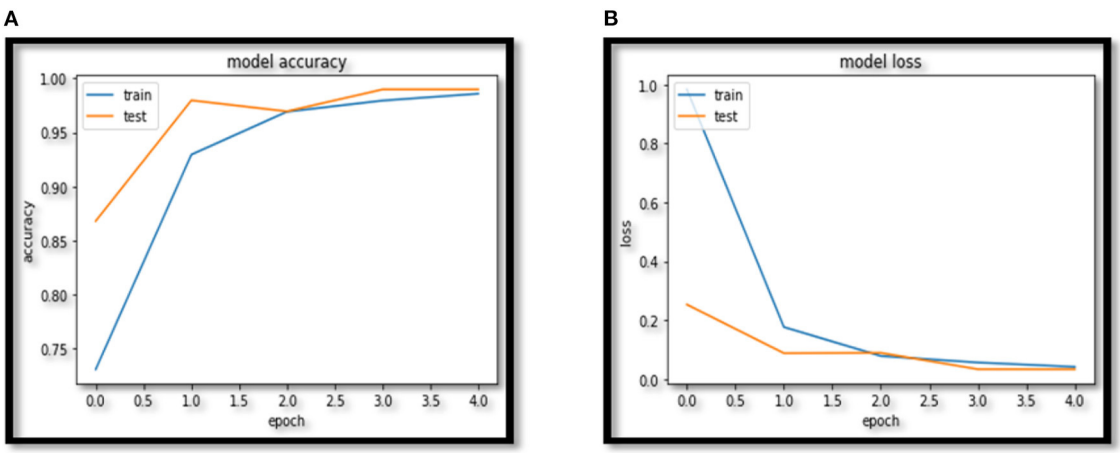

FIGURE 8 | (A) MobileNet accuracy. **(B)** MobileNet loss.

Pooling Layer

Generally, pooling layers are employed in collaboration with convolutional layers; as a result, sub-sampling decreases the input size in all depth portions and thus helps prevent over-fitting while training the network. The pooling process reduces the amount of the input, and as a result, the depth dimension is not altered. Maximum and average pooling is the most commonly used pooling technique, as shown in **Figure 3**.

There are two Equations in (3) that determine the breadth and height of the pooled-layer output.

$$B_2 = \left(\frac{B_1 + F}{S}\right) + 1 \tag{3}$$

$$H_2 = \left(\frac{H_1 + F}{S}\right) + 1 \tag{4}$$

Relu Activation

A nonlinear activation function is used in CNN instead of a local connection to determine the output of neurons. Using the improved performance, faster learning, and simple structure as a benefit, it is advantageous to use the logistic sigmoid and hyperbolic tangent activation functions (**Figure 4**). Equation (5) illustrates the Relu function. The gradient of the Relu function is zero if y is less than zero; otherwise, it is one (2).

$$f\left(y\right) = max(0, x) \tag{5}$$

Softmax Activation

Softmax is used to determine the probability of each ground truth label producing an output value between 0 and 1, then the results are transformed to perceptible values. The softmax function's formula is given by equation (6). $f\ (z)$ (22) transforms random variables (z) into meaningful values between 0 and 1 by using the softmax function.

$$f\left(z\right)_i = \frac{e^{z_j}}{\sum_{k=1}^{k} e^{z_k}} \; for \; j = 1. \tag{6}$$

Performance Metrics

To examine the developed hybrid DL model for lung cancer nodule identification and classification using various performance metrics like accuracy, precision, recall, F1-score, and support, Overall accuracy is calculated as the total true results divided by the total number of samples. The blocks are

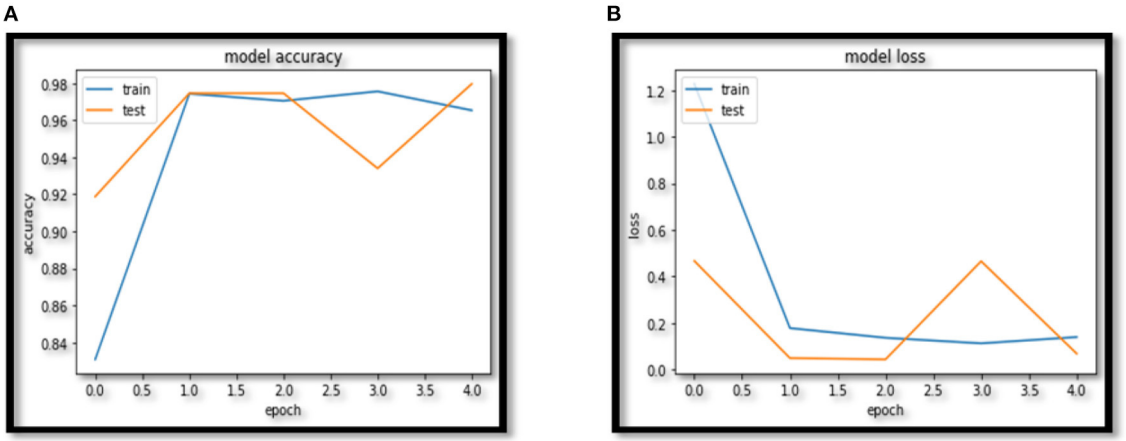

FIGURE 9 | (A) Xception accuracy. **(B)** Xception loss.

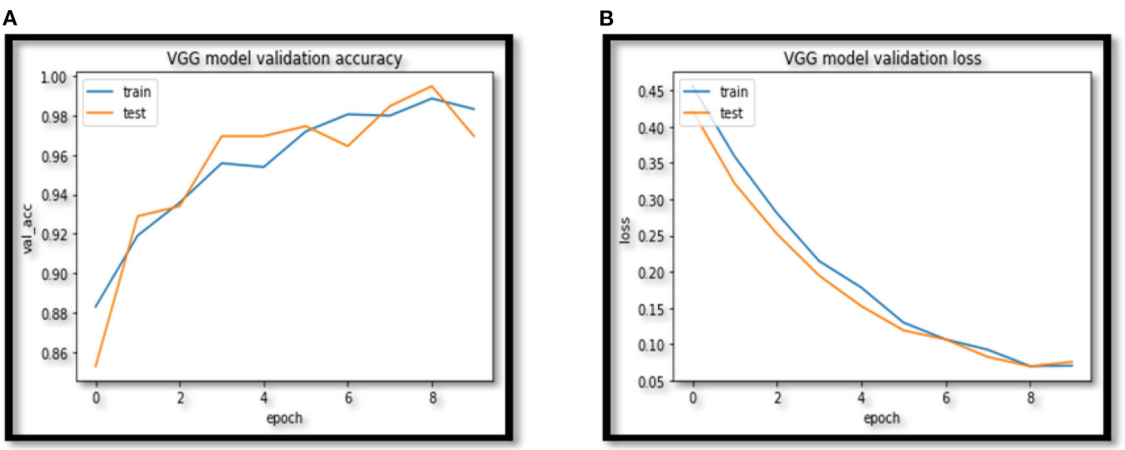

FIGURE 10 | (A) VGG accuracy. **(B)** VGG model loss.

derived from the pulmonary pictures in this study. These metrics are specified in several words like "True Positive" (TP) or "False Negative" (TN) and "False Negative" (FN). These are defined by different terminologies. TP is computed in this context as the suspected lung nodules that have been diagnosed properly as malignant. TN is determined by the number of pictures that are categorized as benign. The FN term is computed by the method that does not detect cancerous nodules. In addition, FP is determined by calculating the number of pictures not properly identified for lung cancer. Sensitivity and specificity are terms used to describe the true positive and true negative rates (23).The formulas for calculating these performance parameters are presented through Eqs 1–4.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{7}$$

$$Recall = \frac{TP}{TP + FN} \tag{8}$$

$$Precision = \frac{TP}{TP + FP} \tag{9}$$

$$F1\ Score = 2 \times \frac{Precision \times recall}{Precision + recall}. \tag{10}$$

Experimental Setup

The experiments are performed on CNN Pretrained models which are VGG-16, MobileNet and Xception on LIDC dataset. The new model VCNet is also developed and used for experimental purposes. The VCNet is designed by using a hybrid combination of VGG and Capsule Network.

Pretrained Models

We have used the following pre-trained models for the detection and classification of lung cancer using the LIDC-IDRI dataset.

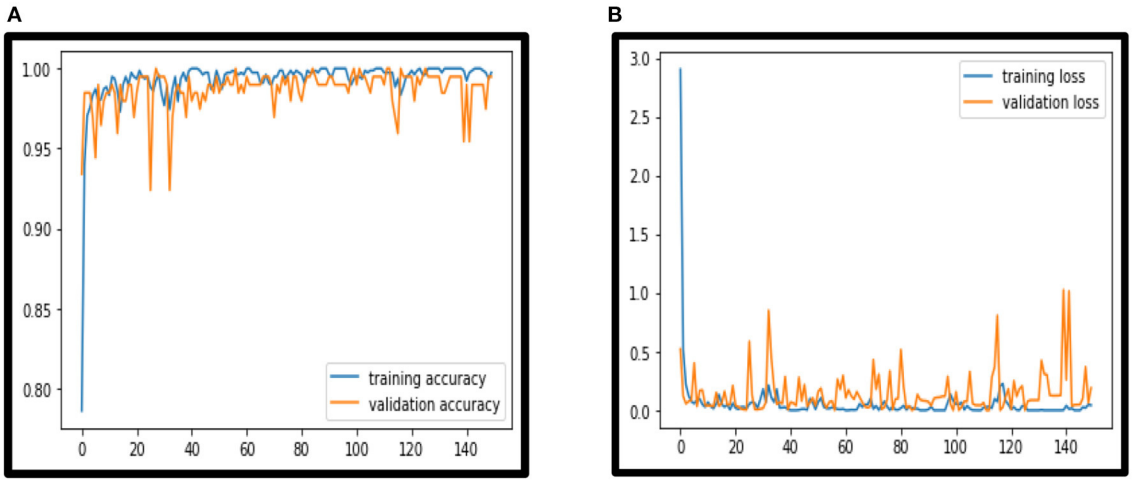

FIGURE 11 | (A) VCNet accuracy. **(B)** VCNet loss.

TABLE 3 | Comparative analyses in terms of accuracy among the proposed VCNET and the State-of-the-Art models.

Reference	Year	Image dataset	Accuracy
Jakimovski et al. (14)	2019	LONI Database	99.63%

Proposed VCNet	**2022**	**LIDC-IDRI**	**99.49%**

Mobilenet

MobileNet employs depth-wise separable convolutions, which means that instead of combining all three and flattening, it executes a separate convolution on each color channel. The input channels are filtered as a result of this. For MobileNets, depth wise convolution applies a single filter to each input channel. The depth wise convolution's outputs are then combined using an 11 convolution by the point wise convolution. In one step, a conventional convolution filters and combines inputs to create a new set of outputs. The depth wise separable convolution divides this into two layers: one for filtering and the other for combining. This factorization results in a significant reduction in computation and model size (23).

Xception

Xception is a Depth wise Separable Convolutions-based deep convolutional neural network architecture. Google researchers came up with the idea. Inception modules in convolutional neural networks are described by Google as an intermediate step between normal convolution and the depth wise separable convolution operation (a depth wise convolution followed by a point wise convolution). In this sense, a depth wise separable convolution can be thought of as an Inception module with the most towers possible. This result leads them to propose new deep convolutional neural network architecture based on Inception, but with depth wise separable convolutions in place of Inception modules (24).

VGG-16

VGG16 as a convolutional neural network architecture in their study "Very Deep Convolutional Networks for Large Scale Image Recognition." On Image Net, a dataset of over 14 million images belonging to thousands of classifications, this model obtains 92.7 percent accuracy. It employs multiple 3 × 3 filters, one after the other. VGG16 was trained on the ImageNet dataset over weeks using the Nvidia Titan Black GPU. There are 13 convolution layers, five max-pooling layers, and three dense layers in the VGG16 pre-trained architecture. Changes to the VGG-16 algorithm include a global average pooling layer and two dense layers with the ReLu and Softmax activation functions. Both dense layers have a dropout rate of 0.5 (13).

Resnet

ResNet introduced by Kaiming He in 2015, it has become key work proving that incredibly deep networks may be trained using regular SGD with additional accuracy by changing the residual module to incorporate identity mapping, as proven in this study. This network employs a VGG-19-inspired 34-layer plain network architecture, after which the shortcut connection is implemented. The design is subsequently transformed into a residual network as a result of these shortcut connections (25).

Inception V3

Inception-v3 is a convolutional neural network design from the Inception family that includes Label Smoothing, Factorized 7

× 7 convolutions, and the inclusion of an auxiliary classifer to transport label information deeper down the network, among other improvements. Inception v3 is a commonly used image recognition model that has been demonstrated to achieve an accuracy of better than 78.1 percent on the ImageNet dataset. The model represents the sum of several concepts produced over the years by numerous scholars (26).

Table 2 presents the architecture details and number of parameters used for MobileNet, Xception, and VGG-16, ResNet & Inception V3.

VCNeT Model Building and Implementation

The proposed hybrid model is implemented on the Google Colab platform by utilizing the python libraries Tensorflow and Keras. For the transfer learning pre-trained model of CNN, VGG-16 is used and modified by adding global average pooling layers and dense layers with ReLu activation function. After the VGG, a capsule network has been added with route 03. Our results show that the hybrid model VCNet performs better than the VGG model, Xception, and MobileNet architectures.

Figure 5 shows the complete architecture of the VCNet and summary of the proposed model is shown in **Figure 6**.

Implementation of Capsule Network

For the implementation of capsule network Global_Average_Pooling layer is used as an input and after that Convolution 2-dimensional layer is used to extract features with a kernel size of 9,9,512 and these features are mapped using reshape function to convert the images into one-dimensional array using reshape (1,1,3) along with squash function which is used for normalization. Lambda ?? is used after this to show that the lung image characteristics had a normal value of 0 with the default route transfer rate [−0.5: 0.5]. Calculating a margin and reconstruction loss is the most recent loss computation. This article uses the CapsNet for lung imaging data from Hinton's major architecture (26). **Figure 7** shows a basic architecture of capsule network (CapsNet) for analysis of lung nodules.

The capsule network architecture is summarized as follows:

The first Convolution layer with kernel_size = 9, filters = 512, padding = "same," strides = 9, activation = "relu," dim_capsule = 8, *n*_channels = 32, padding = "valid," strides = 2, kernel_size = 9 for the second primary capsule. *n*_class = num_capsule, dim_capsule = 16, stable of the set routings for the diagnosis capsule.

RESULT

In this paper VCNet, a new hybrid DL model is proposed for the detection of lung carcinoma using CT images. The proposed model is applied to CT images collected from the LIDC-IDRI dataset. The accuracy presented by VCNet architecture is 99.49% which is the highest among other used pretrained models. The pretrained models MobileNet, Xception, and VGG-16 achieved accuracy of 98, 97.97 and 96.95% respectively. The hybrid model built is evaluated with a validation set of pulmonary pictures. The accuracy and loss graphs of MobileNet architecture are illustrated in **Figures 8A,B**, **9A,B**, Xception architecture accuracy and loss graph, **Figures 10A,B**, VGG-16 architecture accuracy and loss graph and **Figures 11A,B** represent the accuracy and loss graph for VCNet's proposed architecture.

The findings in **Table 3** shows that suggested hybrid model VCNet were more accurate than other models in classifying lung CT images. As a consequence, the suggested hybrid VCNet attained the highest accuracy, which was 99.49 percent.

Classification matrix of different models for detection of lung nodules using LIDC IDRI dataset is presented in **Table 4**.

The total number of properly identified lung nodules and their related erroneous predictions are shown in the confusion matrix created after evaluation in **Figures 12A–D**. For the statistical analysis the performance of the hybrid model VCNet is compared with various competitive models such as CNN, MobileNet, Xception, VGG-16, ResNet and InceptionV3.

DISCUSSION

There are numerous DL models for lung cancer diagnosis; nevertheless, accuracy in public datasets is still a significant obstacle (27). Overall, the researchers' results were accurate, although some of them utilized either private hospital datasets or tiny datasets that were publicly available on the internet. 95% accuracy was obtained by comparing two big artificial neural network end-to-end classes, one of which was the last stage of convolutional neural network training and the other the final stage of artificial neural network training. The implementation of the same employed the unpublished dataset of 31 patients that had 38 scans (13).

TABLE 4 | Classification matrix of different models using LIDC dataset.

Model	Accuracy	F-Measure	Sensitivity	Specificity	AUC
CNN	95.88 ± 2.01	95 ± 1.84	96 ± 1.85	96 ± 1.92	96 ± 1.02
Xception	97.97 ± 1.02	96.87 ± 1.82	97.47 ± 1.05	97.97 ± 1.02	96.97 ± 1.02
VGG-16	96.95 ± 1.75	96.95 ± 1.55	95.95 ± 1.75	96.95 ± 1.25	95.95 ± 1.84

VCNet	**99.49 ± 0.2**	**99.12 ± 0.5**	**99.25 ± 0.5**	**99.25 ± 0.6**	**99.12 ± 0.6**

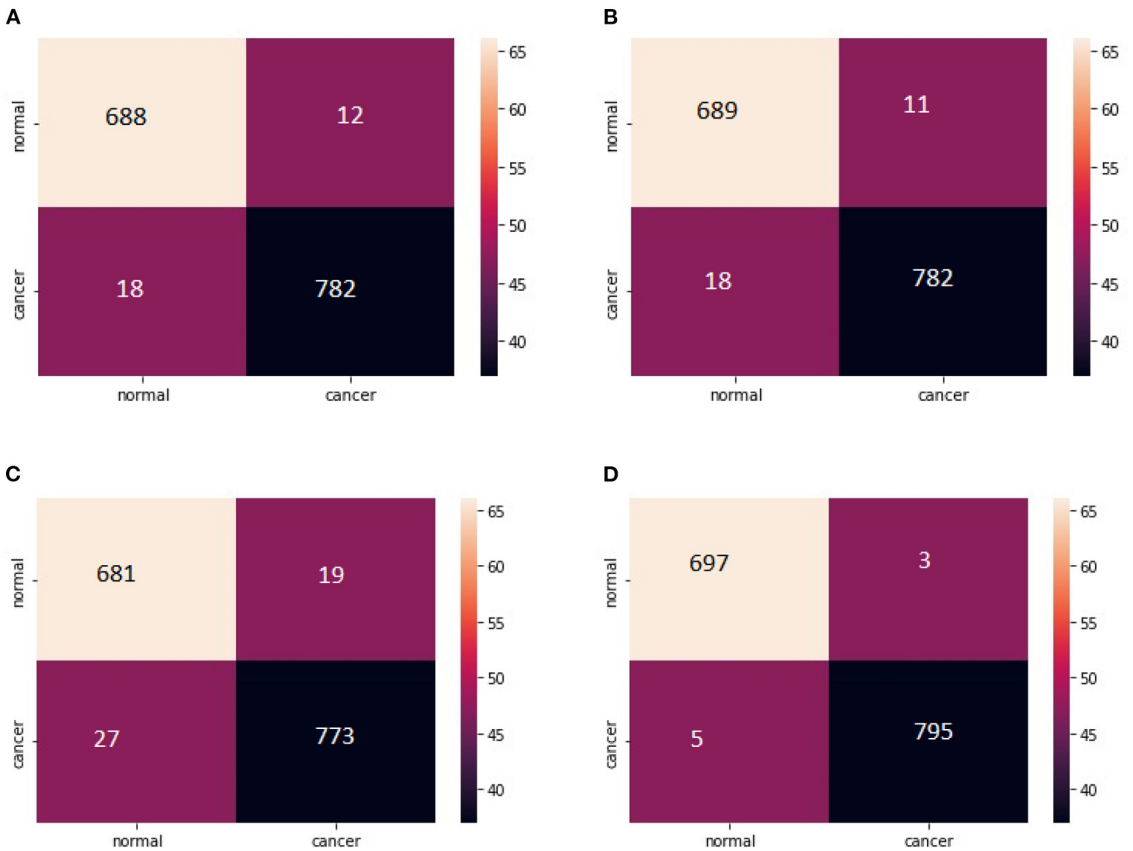

FIGURE 12 | (A) Confusion Matrix MobileNet. **(B)** Confusion Matrix XceptionNet. **(C)** Confusion matrix VGG-16. **(D)** Confusion matrix VCNet.

Detecting malignant lung nodules from the CT images takes a significant amount of time, especially if you don't have prior training in the subject. Despite recent progress in using deep learning models for lung carcinoma detection, clinical use is still difficult. For the majority of the cases, deep learning neural network models are used to identify the main nodule of the lung while ignoring the tissue that surrounds it.

In this section, the output of VCNet architecture and pre-trained models of CNN VGG-16, MobileNet and Xception on collected lung CT images are presented for classification of lung cancer nodules as normal and malignant. There were no issues applying the models because of the LIDC-IDRI dataset after preprocessing.

According to this study, 80 % of said dataset is used as a training set and the remaining 20 percent is used to evaluate the suggested VCNet architectures and pre-trained VGG-16. MobileNet& Xception architectures. **Table 4** provides a summary of the Accuracy, Precision, Recall, and F1 scores for each of the four architectures.

The model's validation accuracy and loss curves are shown in **Figures 8–11**. Using the graphs, we may conclude that no over fitting or under fitting has occurred. Training and validation accuracy and losses continue to converge, and they reach a maximum at the end of 30 epochs. On the proposed VCNet, examined in terms of validation accuracy, it was determined that the network has an error rate of $<0.1\%$ and a test accuracy of $<0.1\%$,demonstrating a good correlation between the actual and predicted values.

For lung nodules, the estimated values of Specificity and Sensitivity are near to 1 shown in confusion matrix, indicating that the model has a high true positive and true negative rate. Furthermore, the low false positive and negative rates indicate that the proposed VCNet model has a very low risk of misclassifying data. As a result, the algorithm was able to properly detect lung nodules with extremely little error.

The proposed hybrid model evaluated on the Lung Picture Database Consortium image collection dataset achieved higher accuracy as compared to current techniques MobileNet, Xception, and VGG-16. It is critical for any system in the medical sector to produce accurate findings with a little mistake, since this framework allows for clinical purposes; it can be utilized for the detection of lung nodules in lung carcinoma.

CONCLUSION

As a result of deep learning methods' impressive outcomes, in this research, CNN-based hybrid architecture, one of the effective models of deep learning in medical research, was

applied to examine lung cancer on CT scan pictures of the LIDC-IDRI dataset. Therefore, prior to implementing the model, a collection of CT scan pictures was generated from an image dataset.The proposed hybrid model is applied to CT images collected from the LIDC-IDRI dataset. The proposed VCNet architecture proposed a higher accuracy of 99.49% while the existing methods of MobileNet, Xception, and VGG-16 achieved an accuracy of 98, 97.97, and 96.95%, respectively. This proposed hybrid VCNet framework can be used for clinical purposes for nodule detection in lung carcinoma detection, which will be a very useful and time-saving method for radiologists.

Future Scope

In the future this hybrid model can be used for the detection of other types of cancer like Breast, Liver, Cervical, Brain, and Skin etc. The performance of the model can be optimized by using various optimization techniques also.

In December 2019, an outbreak of novel coronavirus pneumonia spread over Wuhan, Hubei Province, China, which then developed into a significant global health public event, giving rise to substantial economic losses. We downloaded throat swab expression profiling data of COVID-19 positive and negative patients from the Gene Expression Omnibus (GEO) database to mine novel diagnostic biomarkers. XGBoost was used to construct the model and select feature genes. Subsequently, we constructed COVID-19 classifiers such as MARS, KNN, SVM, MIL, and RF using machine learning methods. We selected the KNN classifier with the optimal MCC value from these classifiers using the IFS method to identify 24 feature genes. Finally, we used principal component analysis to classify the samples and found that the 24 feature genes could effectively be used to classify COVID-19-positive and negative patients. Additionally, we analyzed the possible biological functions and signaling pathways in which the 24 feature genes were involved by GO and KEGG enrichment analyses. The results demonstrated that these feature genes were primarily enriched in biological functions such as viral transcription and viral gene expression and pathways such as Coronavirus disease-COVID-19. In summary, the 24 feature genes we identified were highly effective in classifying COVID-19 positive and negative patients, which could serve as novel markers for COVID-19.

INTRODUCTION

In December 2019, an epidemic of novel coronary pneumonia broke out in Wuhan, Hubei Province, China, which was considered by the World Health Organization to be a serious menace to the health of citizens of the world (1). This terrible communicable epidemic is caused by infection with the severe acute respiratory syndrome type 2 coronavirus (SARS-CoV-2), a sense single-stranded RNA virus (2). As a highly contagious virus, COVID-19 swept across the globe with alarming rapidity, leading to considerable losses to human society.

So far, the effective protection strategy against COVID-19 is to strengthen immunity ability and keep social distance (3). COVID-19 diagnosis is of great essence for the identification, isolation, and treatment of infectious objects (4). Existing detection methods include antibody assays that detect serum antiviral antibodies IgG and IgM, lateral chromatography assays that detect viral antigens, and real-time reverse transcriptase-polymerase chain reaction (qRT-PCR). The current gold standard for COVID-19 diagnosis is the application of qRT-PCR to verify the presence of

SARS-CoV-2 RNA in the respiratory secretions of patients (5, 6). However, this detection method is not perfect because it is a complex test requiring a comprehensive and delicate infrastructure (5). And this method can only achieve accuracies of 30–60% in clinical application, which probably results in false-positive cases (7). More landmark diagnostic biomarkers are needed to detect COVID-19-positive patients with higher accuracy, reducing the false positive rate. Besides, exploring and developing new detection kits is of equal significance to facilitate the precise prevention and control of the epidemic.

Machine learning is applied extensively in biomedical applications, as well as COVID-19 diagnosis (8). Extreme Gradient Boosting (XGBoost) is a GBDT-based algorithm. Characterized by its high efficiency, flexibility, and portability, XGBoost is widely used in data mining, recommendation systems, and other fields (9). Zhang and GuoLiang (10) developed a machine learning algorithm for XPPA based on the XGBoost algorithm, which could be used to detect the effect of alterations in gene expression on aberrant p53 pathway activity. Athanasiou et al. (11) constructed a personalized risk prediction model for cardiovascular disease based on the XGBoost algorithm to predict the incidence of patients with cardiovascular disease. The follow-up results of 560 patients demonstrate that this predictive model has favorable performance (AUC = 71.13%), which is expected to provide new insights into clinical cardiovascular treatment. With a decoupling feature, XGBoost shows increased applicability, and it is a high-performance algorithm for modeling regarding the selection of loss functions on demand for classification and regression. Therefore, XGBoost is reliable to be applied in establishing a diagnostic, prognostic model based on patient features in clinical practice.

Here, we used the XGBoost algorithm to mine feature genes in the expression profiles of COVID-19 negative and positive samples, used a machine learning algorithm to construct MARS, KNN, SVM, MIL, and RF COVID-19 classifiers, and selected the best classifier using Iterated Function System (IFS) algorithm. Finally, the validity of this set of feature genes was verified by principal component analysis (PCA) and functional enrichment analysis, the results of which suggested the potential of the genes to be promising biomarkers for COVID-19.

MATERIALS AND METHODS

Datasets Downloading and Processing

From the GEO database (https://www.ncbi.nlm.nih.gov/geo/), the dataset GSE152075 was downloaded, which contained gene expression data from throat swab samples from 430 COVID-19-positive patients and 54 negative patients. And the data acquisition platform was GPL18573 (Illumina NextSeq 500). Genes whose mean value of gene expression was below 1 and the maximum value of gene expression was below 5 were retained. The data were normalized using the "edgR" package (12).

Model Training

To establish the link between behavioral features and classification, we implemented the XGBoost model using the machine learning algorithm XGBoost (https://xgboost.ai/). Key features were determined based on feature importance ranking and recursive elimination (9). XGBoost is a gradient advancing decision tree method whose objective function is defined as in Equation (1).

$$\$(\phi) = \sum_{i=1}^{n} loss\left(y_{i\hat{y}_i}\right) + \sum_{k=1}^{k} \Omega\left(f_k\right)(1) \quad (1)$$

In this formula, loss is the training loss, Ω (f) is the complexity of the tree, and k is the number of trees in the model. The model can be optimized by minimizing the objective function. For this reason, the additive model was used to calculate the training loss, and the Taylor expansion method was used to quickly optimize the prediction of the nth round of additive training. Greedy algorithm was used to determine the optimal complexity of the tree. In addition, we employed SMOTE for Bayesian optimization resampling of the training set due to unbalanced samples (13).

Selecting the Optimal Classifier by IFS Method

After feature selection by XGBoost, IFS method was used to identify the genes of the optimal COVID-19 classifier. IFS incremental feature selection method (14) is an algorithm proposed by Liu and Setiono (15) to find the best or closest optimal feature subset. This algorithm is based on improved information gain, which can make the equivalent exchange of information. The algorithm selects a candidate feature set using an evaluation function unrelated to the classifier, applies the classifier to the candidate feature set, and selects a feature subset utilizing the accuracy of the classifier as a criterion.

A series of COVID-19 classifiers (16) was subsequently established using the python package "sklearn" in combination with algorithms such as MARS, KNN, SVM, MIL, and RF. The IFS curve was drawn based on 10-fold cross-validation, resulting in Matthews correlation coefficient (MCC) for each classifier, which is a parameter that can effectively reflect the classifier's effectiveness (17). The classifier with the most considerable MCC value is considered as the optimal classifier, and the genes involved in it are taken as the optimal feature genes.

PCA and Sample Cluster Analysis

After the optimal COVID-19 classifier was determined, the PCA was performed on the data set using "FactoMineR" to extract the first and second principal components. PCA analysis is an unsupervised dimensionality reduction analysis method which can visually present the sample-to-sample method (18) by reducing the dimensionality of the dataset and reflecting the data to the representative dimensions PC_1 and PC_2. The effect of model classification was finally verified by pedigree cluster analysis of the samples using the "pheatmap" package (19).

GO and KEGG Enrichment Analyses

GO biological function analysis and KEGG biological pathway analysis of feature genes were performed using "clusterProfiler". GO and KEGG pathways with p-value < 0.05 were considered notably enriched (20).

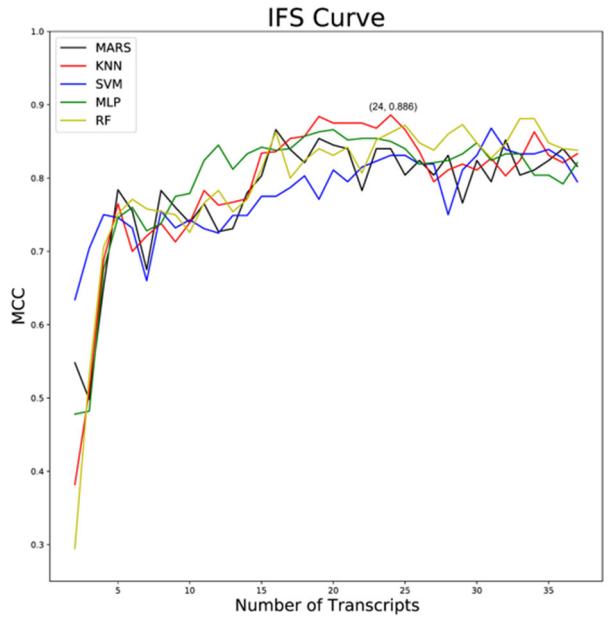

FIGURE 1 | IFS curves of MARS, KNN, SVM, MLP, and RF classifiers. Black: MARS classifier; red: KNN classifier; blue: SVM classifier; green: MLP classifier; brownish-yellow: RF classifier; horizontal ordinate indicates the number of classifier genes and vertical ordinate represents MCC coefficient.

RESULTS

XGBoost and IFS Analysis Results

A total of 15,190 genes were obtained by the normalization of the gene expression data after the preprocessing of the dataset GSE152075. Thirty-seven feature genes that were ranked according to importance were obtained by XGBoost feature selection, which could distinguish sample types (**Supplementary Table S1**). And COVID-19 classifiers such as MARS, KNN, SVM, MLP, and RF were constructed based on these 37 feature genes. Then the best classifier was selected by IFS analysis, and we found that the KNN classifier was composed of 24 feature genes (IGFBP2, KRT8, RPLP0, XAF1, RPL13, OAS2, CES1, RPL4, EEF1G, NR2F6, RPS8, RPL10A, SNX14, C5orf15, TNFRSF19, CD24, ALAS1, CEP112, C9orf24, POLR2J3, AAMP, DUOX2, EMCN, RPL3) had the highest MCC value, MCC 0.886, sensitivity 0.986, specificity 0.907, and accuracy 0.977 (**Figure 1**).

The Results of PCA Dimensionality Reduction Analysis and Sample Cluster Analysis

PCA dimensionality reduction analysis was performed on the samples according to the expression of the 24-feature genes in the optimal KNN classifier, which showed that PCA analysis could classify COVID-19 in positive patients and negative persons (**Figure 2A**). In addition, we also plotted a cluster heatmap analyzing the expression of 24 feature genes in different populations. The results showed that the 24 feature genes in the KNN classifier could distinguish COVID-19 positive patients from normal healthy people (**Figure 2B**). These findings indicated that the 24 feature genes in the KNN classifier performed well in diagnosing COVID-19-positive patients and normal healthy people, showing superior diagnostic efficacy.

The Results of GO and KEGG Enrichment Analyses

To identify the biological functions of feature genes and the signaling pathways involved, we performed enrichment analyses on the 24 feature genes. The GO analysis result showed that these genes were mainly enriched in biological functions such as viral transcription and viral gene expression (**Figure 3A**). KEGG biological pathway analysis showed gene enrichment on pathways such as Coronavirus disease-COVID-19 (**Figure 3B**). The selected feature genes were closely related to COVID-19 infection and its pathways.

DISCUSSION

Novel coronavirus pneumonia is a severe threat to global public health safety and brings enormous economic losses to human society. In this study, in order to identify new COVID-19 diagnostic biomarkers, we used the XGBoost algorithm to achieve feature selection and the IFS algorithm to determine the optimal classifier based on the throat swab expression profile data of COVID-19 positive and negative samples in the GEO database. After identifying the optimal feature genes, PCA, GO, and KEGG methods were used to verify whether the feature genes could be used as COVID-19 diagnostic biomarkers. First, we used the XGBoost algorithm to screen 37 feature genes from expression profiling data that could effectively distinguish COVID-19 positive from negative patients. Subsequently, KNN, SVM, MLP, and RF classifiers were constructed for the genes after feature selection, and the optimal classifier and its feature genes were selected based on the IFS method. Finally, we identified 24 feature genes, and based on the expression data of 24 feature genes, we performed PCA of the samples, and PCA results showed that PC_1 and PC_2 could effectively distinguish COVID-19 positive and negative samples. In addition, we performed GO and KEGG enrichment analyses of 24 feature genes, and the results showed that these feature genes were mainly gathered in biological functions such as viral transcription, viral gene expression, and pathways such as Coronavirusdisease-COVID-19. Therefore, combining all the results of bioinformatics analysis, the COVID-19 classifier of 24 feature genes was obtained in this study, while we reasonably speculated that the 24 feature genes screened in this study are expected to be novel diagnostic biomarkers for COVID-19.

Timely diagnosis of COVID-19 is essential for epidemic prevention and control, so identification of accurate diagnostic biomarkers is also an essential study for epidemic prevention and control. Feng et al. (21) constructed a machine learning diagnostic model using algorithms such as LASSO, AdaBoost, decision tree, and logistic regression based on patient clinical information to assist early COVID-19 diagnosis. The study by Kukar et al. (22) used machine learning methods to construct a

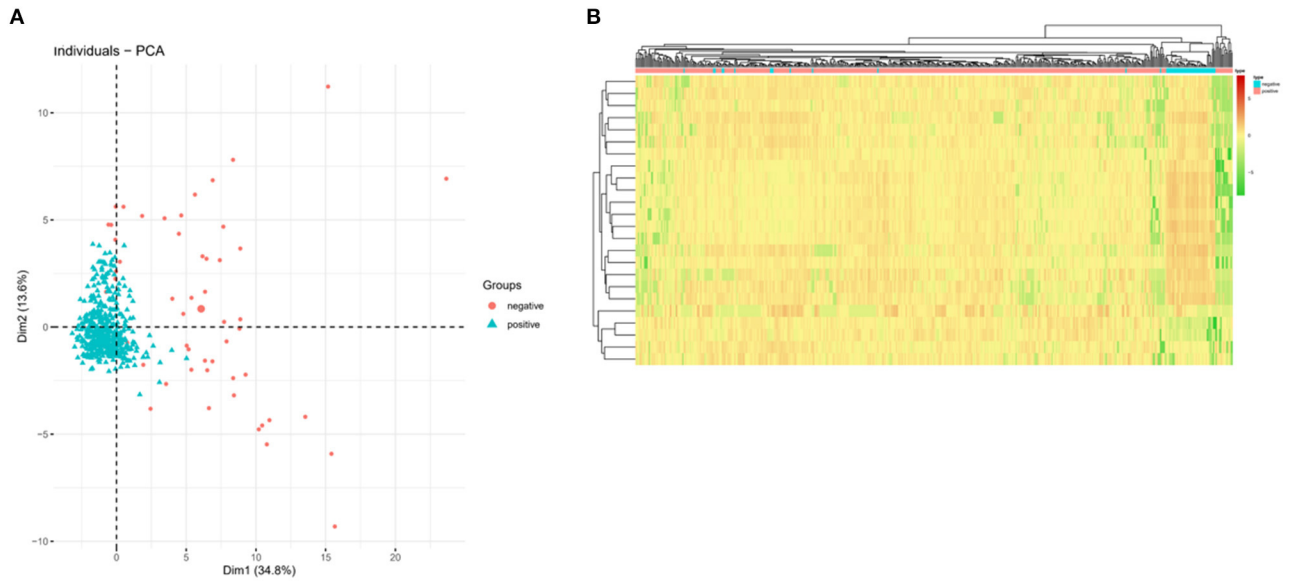

FIGURE 2 | PCA and cluster heatmap analysis based on feature genes in the KNN classifier. **(A)** PCA shows the classification performance of the KNN classifier in COVID-19 negative (red) and positive (green) populations. **(B)** Cluster heatmap showing the expression of feature genes in the KNN classifier. Red indicates high expression and green indicates low expression.

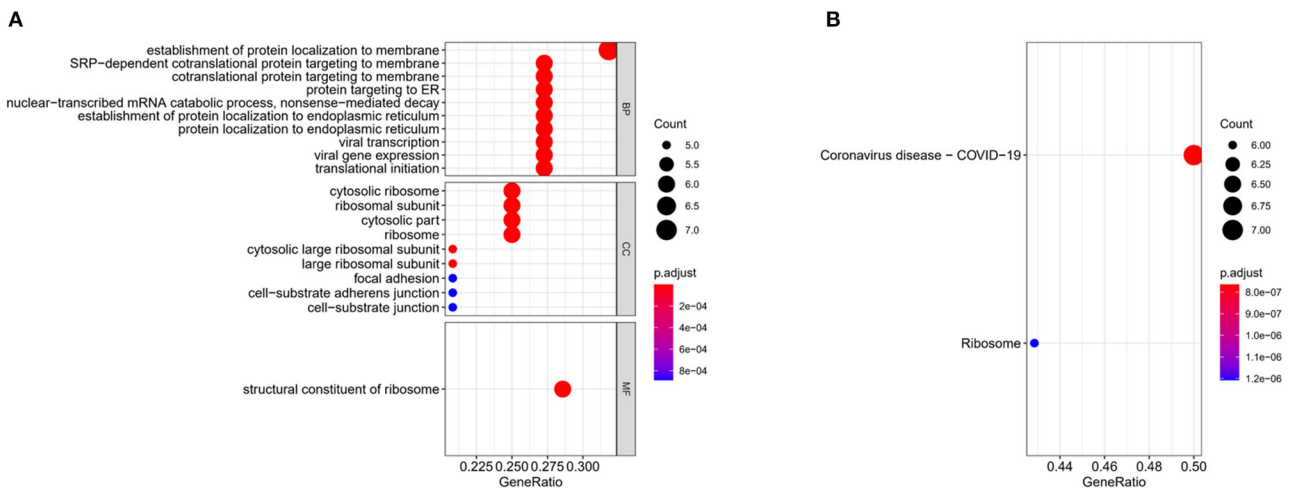

FIGURE 3 | Gene enrichment analyses. **(A)** Bubble plots for GO enrichment analysis of 24 feature genes. **(B)** Bubble plots for KEGG enrichment analysis of 24 feature genes. The bubble size in the figure indicates the gene data in teams, and the color indicates the *p*-value, and the red the color, the smaller the *p*-value.

COVID-19 diagnostic model based on blood routine parameters, which is complementary to chest CT and PT-PCR molecular diagnostics and improves COVID-19 diagnostic efficiency. Our study used the XGBoost algorithm to select feature genes in the expression profiles of throat swabs in positive patients, constructed classifiers such as MARS, KNN, SVM, MIL, and RF, and subsequently selected classifiers with optimal MCC values by the IFS method. At present, the conventional detection method of COVID-19 is nucleic acid detection, and the diagnostic biomarkers identified in this study are expected to improve the drawbacks of existing commercial nucleic acid detection kits and improve detection accuracy.

The optimal 24 feature genes, which were further analyzed by consulting the retrieved literature, we found that four genes (XAF1, OAS2, CES1, RPS8) have been reported in COVID-19. Gao et al. (23) found that XAF1 was abnormally strongly expressed in COVID-19 patients and positively correlated with the expression of ARS-CoV-2 invasion-related genes (ACE2, TMPRSS2, CTSB, and CTSL). In contrast, XAF1 was found to be associated with SARS infection by Park and Harris (24). A

recent study found that OAS2 belongs to a subset of interferon-stimulated genes, and OAS2 can be regarded as a potential candidate for a drug target in COVID-19 therapy (25). The study by Li et al. (26) found that CES1 can hydrolyze tenofovir alafenamide (TAF), and effectively hydrolyzed TAF is significant for treating respiratory virus infection. In addition, Vastrad et al. (27) identified 10 SARS-CoV-2/COVID-19 diagnostic markers such as RPS8 using bioinformatics analysis methods. Also, several ribosomal proteins (RPL family members) contributing to protein synthesis were screened out. A report went that SARS-CoV-2 infection could result in ribosome dysfunction (28), giving us a hint that RPLs were affected at molecular degree. In combination with previous reports, it can be seen that some of the 24 feature genes are closely related to COVID-19. Finally, we performed GO and KEGG enrichment analyses, and the results showed that these feature genes were mainly enriched in biological functions such as viral transcription and viral gene expression as well as pathways such as Coronavirusdisease-COVID-19. We used bioinformatics methods to screen some genes that play an essential role in COVID-19 infection, which have also been reported as COVID-19-related genes in the existing literature. Even though it takes little time and hardly any money to detect COVID-19, some critical problems remain, like false positive case which concerns the public a lot. The combined various testing methods are urgently needed to remove false positive cases. Our study comes just in handy to provide some insights for developing novel strategy for COVID-19 diagnosis, which can definitely enrich current diagnostic tools.

CONCLUSION

However, there are limitation in our study. First, this study is a retrospective study based on public databases, and no clinical samples are used to verify the performance of this classifier. Second, even if the mined genes were practically used for COVID-19 diagnosis, it is relatively costing to analyze 24 genes for one sample. Considering the limitations, we are planning to establish sample library and validate our model based on our collected samples. Overall, we mined optimal COVID-19 diagnostic biomarkers using machine learning algorithms, and our study, in combination with existing commercial nucleic acid detection kits, promises to improve COVID-19 detection accuracy.

Front. Public Health 10:869238. doi: 10.3389/fpubh.2022.869238

Early diagnosis, prioritization, screening, clustering, and tracking of patients with COVID-19, and production of drugs and vaccines are some of the applications that have made it necessary to use a new style of technology to involve, manage, and deal with this epidemic. Strategies backed by artificial intelligence (A.I.) and the Internet of Things (IoT) have been undeniably effective to understand how the virus works and prevent it from spreading. Accordingly, the main aim of this survey is to critically review the ML, IoT, and the integration of IoT and ML-based techniques in the applications related to COVID-19, from the diagnosis of the disease to the prediction of its outbreak. According to the main findings, IoT provided a prompt and efficient approach to tracking the disease spread. On the other hand, most of the studies developed by ML-based techniques aimed at the detection and handling of challenges associated with the COVID-19 pandemic. Among different approaches, Convolutional Neural Network (CNN), Support Vector Machine, Genetic CNN, and pre-trained CNN, followed by ResNet have demonstrated the best performances compared to other methods.

Keywords: machine learning, COVID-19, Internet of Things (IoT), deep learning, big data, information systems, internet of medical things, coronavirus

INTRODUCTION

The outbreak of COVID-19 in Wuhan City, Hubei Province, China, began in December 2019 through the seafood wholesale market (1). Later, on January 30, 2020, the World Health Organization (WHO) declared the prevalence of Covid-19 as an emergency pandemic worldwide (2). Many governments have declared it a dangerous pandemic and imposed full quarantine to prevent the spread of COVID-19. Several countries have reduced their growing infection by

tightening quarantine and forcing people to maintain social distance (3). Even if through complete quarantine, they failed to control the COVID-19 completely. Some countries have joined in the medical development to treat COVID-19. However, to date, there is no specific drug to treat COVID-19. However, few drugs have been suggested as potential research therapies. The proposed drug has been studied under WHO-led clinical trials (4). According to several studies, since COVID-19 is a communicable disease, the WHO has stated that complete quarantine could be the only way to prevent COVID-19 (5).

The COVID-19 outbreak has created many challenges in human life worldwide (6). The most devastating impact, increasing casualties and deaths (around the world), has made it clear the need for social and business restrictions (7). With the expansion of the COVID-19 pandemic, the world community has faced many other problems in various aspects of life, such as economic and social life, psychological wellness, political interactions, cultural activities, educational limitations, religious restrictions, and even sports events (8, 9). Such examples highlight the need for effective and intelligent systems to deal with such crises in the pandemic situation (9). Early diagnosis, prioritization, screening, clustering and tracking of patients, and production of drugs and vaccines are some of the applications that have made it necessary to use a new style of technology to involve, manage, and deal with this epidemic (10). Machine Learning (ML) and Artificial intelligence (AI) algorithms displayed promising ability in prediction and classification (11–22) including disease prediction (23–34), virus genome analysis (24, 35, 36), and medical imaging and Internet of Things (37–40). Strategies backed by artificial intelligence (A.I.) and the Internet of Things (IoT) have been undeniable to understand how the virus works and try to prevent it from spreading (9, 41). These techniques have evolved with the development of computing resources with cloud computing and recent advances in ML. These advances enable researchers to process large amounts of data and extract information. ML-based methods used in processing and modeling data on COVID-19 disease can increase efficiency and speed up results by improving computations. Several researchers have moved toward using ML-based techniques for different applications in the COVID-19 dataset, such as classification using C.T. Images (42), chest C.T. Images (43), and X-ray images (44).

Given the diversity of data, applications, and even the multiplicity of machine learning methods, it is necessary to develop a comprehensive survey study that can consider all the strengths and weaknesses in a standard and systematic study. **Table 1** presents similar survey studies developed in the field for describing their ability to convey their message on the subject reviewed. **Table 1** discusses the study's strengths to find the main research gap.

In one of the early studies, Gou et al. presented a survey to evaluate the ML-based techniques for diagnosing COVID-19 using medical data collection, image preprocessing, feature extraction, and image classification. The study evaluates Transfer, ensemble, unsupervised and semi-supervised learnings, convolutional neural networks, graph neural networks, and explainable deep neural networks. Evaluations focused on the advantages and limitations of the diagnosis techniques (45). Abumalloh et al. presented a state-of-the-art ML-based technique for handling medical image processing in the context of the COVID-19 crisis (46). Khan et al. developed a survey of the applications of A.I. for preventing the COVID-19 pandemic (47). El-Rashidy et al. conducted a review study to describe A.I.'s role in preventing the COVID-19 pandemic using the five applications, including COVID-19 diagnosis, estimation of the COVID-19 outbreak, and patient characteristics, as well as vaccine development (48). Later on, Alballa and Turaiki surveyed the recent articles on ML techniques for COVID-19 diagnosis, mortality rate prediction, and violence risk estimation (49). As can be deduced, many survey studies have been developed. But, the existence of a study that can systematically review and discuss two interrelated areas of the ML and the IoT in the form of an article has been lost from the research literature.

TABLE 1 | The description of the conducted review articles.

Reference	Highlights	Database information	Probable gap
Guo et al. (45)	ML for COVID-19 Diagnosis	NA.	Limited field of the study and lack of proper database information
Abumalloh et al. (46)	ML methods for processing the medical image in the context of the COVID-19 crisis	Eight electronic databases: Elsevier, IEEE, PubMed, Wiley Online Library, Springer, Summon, Google Scholar, and Taylor and Francis	Limited field of the study and proper evaluation
Khan et al. (47)	AI for preventing the COVID-19 pandemic	ScienceDirect, Google Scholar, and preprints from arXiv, medRxiv, and bioRxiv	Subject review interval and evaluation of methods
El-Rashidy et al. (48)	The role of A.I. in preventing the COVID-19 pandemic	Textual data, medical images, and speech data	The subject review interval
Alballa and Al-Turaiki (49)	ML techniques for COVID-19 diagnosis, mortality, and violence risk estimation	PubMed, Scopus, IEEE Xplore, and Google Scholar	Limited subject review interval

The main contribution of this study is to systematically investigate and analyze the role of ML and the Internet of Medical Things (IoMT) to address the challenges associated with diagnosis of the COVID-19 and its outbreak prediction. Here we comprehensively investigate the merits and shortcomings of the ML and IoMT tools proposed for these tasks and present a numerical and statistical analysis.

There is an urgent need to utilize existing technologies to their full potential. Internet of Things (IoT) and ML is regarded as one of the most trending technologies with great potential in fighting against the coronavirus outbreak. The IoT comprises a scarce network in which the IoT devices sense the environment and

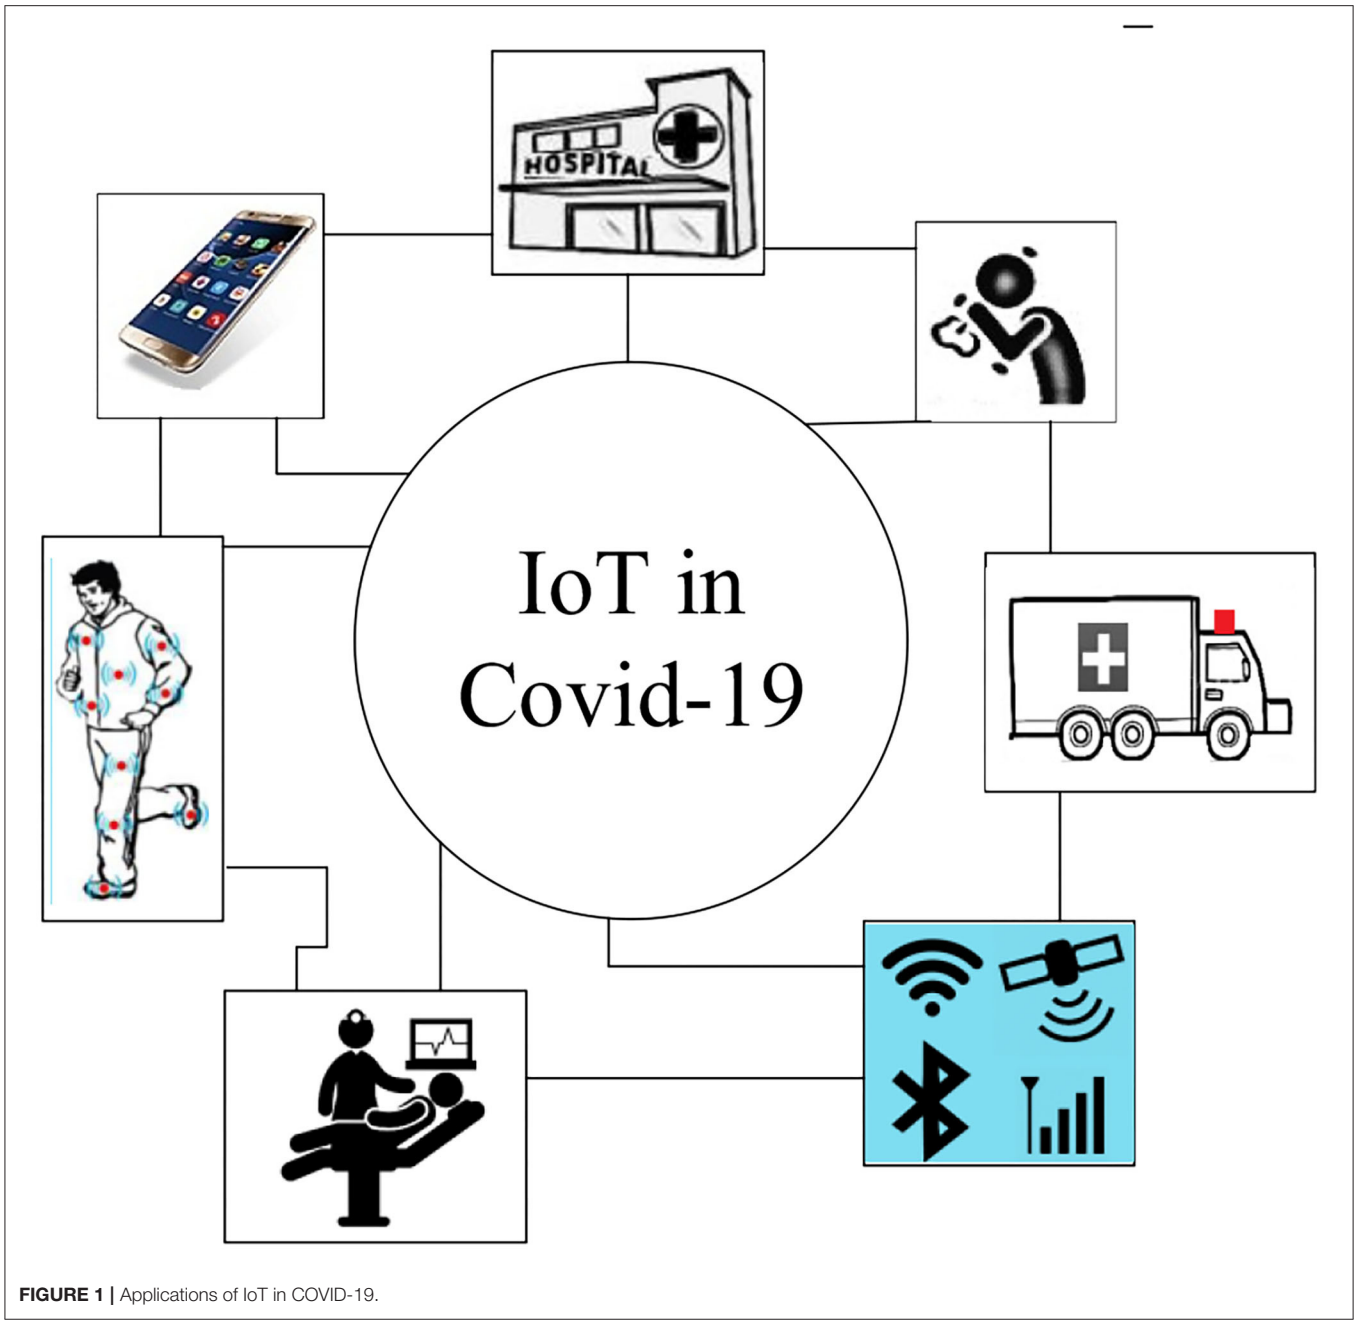

FIGURE 1 | Applications of IoT in COVID-19.

send valuable data on the internet. In this review, we examine the current status of IoT applications and ML related to COVID-19, identify their deployment and operational challenges, and suggest possible opportunities to contain the pandemic further.

The IoT provides the materials needed to help the world minimize the effects of COVID-19. The Internet of Things works with a wide range of applications to ensure compliance with health authorities' safety instructions and precautions. The Internet of Things has a scalable network with the potential to deal with the vast amount of data received from sensors used by several programs to combat COVID-19. In addition, reliable IoT networks reduce critical data delivery times, which can help provide a timely response during the global COVID-19 epidemic. Due to the prevalence of the COVID-19, the role of the Internet of Things was never as needed as it is now.

Artificial intelligence (A.I.) is one of the most important and promising technologies that help revolutionize many fields by creating a revolution. The introduction of machine learning algorithms and artificial intelligence to the Internet of Things has opened new doors in this field. Machine learning provides the opportunity to learn and extract meaningful patterns from data. Because IoT device data is collected in a database, it can easily be

TABLE 2 | The main studies for the application of IoT based techniques for handling COVID-19.

Order	Objective	Methodology/ Proposed Algorithms	Dataset	Keywords	Application	Reference
1	To aim an innovative IoT-based online solution for tracking COVID-19 outbreaks	IoT-based platform to contact and to trace the infection	5G wireless, cloud technologies, and largescale data	I.O.T.: symptom-based device-to-device (D2D) communication	Prediction and monitoring	(66)
2	To compare DL techniques to detect COVID-19	DL-based COVID-19 diagnosis technique in order to model instances for each type and to diagnosis the vulnerabilities	Data from medical IoT devices	IOT: DL algorithm, AE	Diagnostic	(67)
3	To develop an IoT-based DL platform for early detection of COVID-19	Chest X-Ray pictures for training and testing of Regional-based Convolutional Neural Networks (R.C.N.N.) through IoT-based framework	Chest X-Ray images	IoT, COVID-19, Deep learning, Region Proposal Network (RPN)	Diagnostic	(68)
4	To develop a monitoring and detection system according to real-time data from in the presence of the machine learning algorithms	SVM, ANN, Naïve Bayes, K-NN, DT, Decision Stump, 1-R, and 0-R.	Actual COVID-19 patient identifiers include: Fever, Cough, Fatigue, Sore Throat, and Shortness of Breath	Machine learning algorithms, COVID-19	Identification and monitoring	(69)
5	To investigate the IoT for diagnosis of COVID-19 patients using interconnected network	12 IoT based monitoring systems are identified and discussed.	Dataset from databases of Google Scholar, PubMed, S.C.O.P.U.S. and ResearchGate	Internet of things (IoT)	Monitoring	(70)
6	To investigate participants' health conditions and remembering the maintain physical distancing	A lightweight and low-cost IoT node using a smartphone, and fog-based ML for data handling	Vital data from participations	Internet of Things (IoT), smartphone application, Machine Learning (ML), Fuzzy system	Monitoring	(71)
7	To aim a smart edge monitoring system using smart gadgets	To diagnose coronavirus infection using gadgets, deep edge computing and IoT to detect the virus suspected H2H chain	Data from sensors	COVID-19, Edge Computing, IoT	Monitoring	(72)
8	To employ a non-contact I.R. sensor to evaluate for the body temperature	Checking the health condition	Body temperature	IoT, detection system	Detection	(73)
9	To develop a Medical Diagnosis Humanoid to provide a complete diagnostic system for COVID-19	Autonomous navigation, detection, and monitoring system	Data from six different health modules	IoT, A.I., ML, Medical Diagnosis Humanoid	Monitoring and Diagnosis	(74)
10	To develop a low-cost robotic system to diagnosis and help virus affected people	To track hand gestures using radio frequency	Hand gesture	Wireless Robot, Gesture Recognition, IoT	Diagnosis and monitoring system	(75)
11	To contribute IoT and associated sensor technologies to trace, track and mitigate COVID-19 virus by developing hardware sensor	to integrate IoT techniques and provide insight on the expected outcomes	Temperature, Location, Imaging, Pay-point data, and Social media feeds dataset	A.I., IoT, big data, data sharing, cloud computing	Diagnosis and monitoring system	(76)
12	To extract the social relationships between mobile devices by allocating the limited protective resources	To employ dynamic W.U.G. model using social IoT	Pair of real-life datasets	Social Internet of Things; susceptible-exposed-infected-removed; reinforcement learning	Detection	(77)

(Continued)

TABLE 2 | Continued

Order	Objective	Methodology/ Proposed Algorithms	Dataset	Keywords	Application	Reference
13	To develop Internet of Things to prevent the spreading of COVID-19	Investigating an infected person using IoT	NA.	Internet of Things; health care; cloud computing	Detecting and Monitoring	(78)
14	To develop a platform for biometric face detection along with COVID-19 outbreaks	IoT-based Multi-task Cascaded Convolutional Network	Face image dataset	Detection, cascaded CNN, cloud computing, IoT, edge computing,	Detection and recognition	(79)
15	To introduce a high resolution A.Q. monitoring system	A preliminary validation of the Air Heritage pervasive Air Quality monitoring concept	Air quality dataset	Smart Air Quality monitors, IoT, Artificial Intelligence, COVID-19,	Monitoring	(80)
16	To develop an IoMT architecture with respect to combat COVID-19.	IoMT platform, emerging IoMT applications, to apply within the medical environment	N.A.	COVID-19, IoMT application, security	Detection	(38)
17	To test information technology for handling the COVID-19 pandemic	A.I., block-chain, Big Data and robots, for optimally handling pandemics	Google Scholar database and Proquest	COVID-19, information technology, A.I., big data, indonesia	Detection and monitoring pandemic	(81)

used to predict the prevalence and effects of the coronavirus and how to reduce it. Data of patients with COVID-19 help predict the future behavior of the virus and regional comparison of its effects. In addition, it also helps with the possible adaptation of COVID-19 symptoms to an effective and rapid A.I. treatment.

The patient's medical record and the results obtained help to predict better treatment choices based on artificial intelligence and machine learning (ML) algorithms and lead to rapid recovery and patient monitoring. Artificial intelligence-based emergency traffic control paves the way for ambulances and other emergency service providers. BlueDot was one of the first artificial intelligence companies to predict the outbreak of the Corona virus and identify its global threat. They provided information on the mobility pattern of the virus and its potential for spread. Other A.I. companies also joined hands to work with COVID-19, including Deargen, Insilico Medicine, and S.R.I. Biosciences and Iktos, Benevolent AI, DeepMind, Nanox, Baidu, Alibaba, and EndoAngel Medical Technology Co.

Here we conclude that there is a gap in how to address the strengths and weaknesses of machine learning and IoT methods that need to be addressed. In the meantime, to close this gap, we will need to classify, determine the pros and cons, challenges and limitations, and outline ways to deal effectively with COVID-19. In line with this basic need to have a deeper insight into the applications and effects of machine learning and the Internet of Things on the COVID-19 Pandemic, we presented research to be able to study these methods in different ways and in a practical way.

Accordingly, the main purpose of this review article is to examine the ML, IoT, and the integration of IoT and ML-based techniques in the applications related to COVID-19 from the diagnosis of the disease to the prediction of its outbreak.

The study has three main sections:

- A section for describing the studies developed by IoT and IoT-ML based techniques in COVID-19 applications.
- A section for presenting the role of ML-based techniques in COVID-19 applications.
- A section for presenting the main findings, challenges, and future perspectives.

METHODOLOGY

Dataset Preparation Method

A systematic review may provide technical and practical literature for a specific topic (50). A systematic review requires a proper collection of papers on the subject. Preparing a dataset is one of the main steps in determining review work quality (50). According to the P.R.I.S.M.A. guidelines, the present study has collected the most relevant studies from W.O.S. and Scopus libraries (51). There are four steps for preparing the database using the P.R.I.S.M.A. guidelines, including (52): (1) identification, (2) screening, (3) eligibility, and (4) inclusion. In the identification step, we employed the frequently used keywords, including COVID-19, pandemic, diagnosis, detection, Prediction, Monitoring, Classification, Identification, IoT, and Machine learning to search within the article title abstract and keywords. In the first step, about 109 articles have been identified and selected from the Thomson Reuters Web-of-Science (WoS) and Elsevier Scopus. In the Screening step, the duplicate articles have been removed. Twenty-five articles (about 23%) have been removed from the dataset. Thirty nine articles (about 36%) have been eliminated due to the lack of details on the methods, datasets, full text, etc. A total of 45 cases (about 41%) have been included in the screening step. In the eligibility step, the authors team surveyed the full text of the papers, and marked the relevant articles during monitoring eligibility. In this phase,

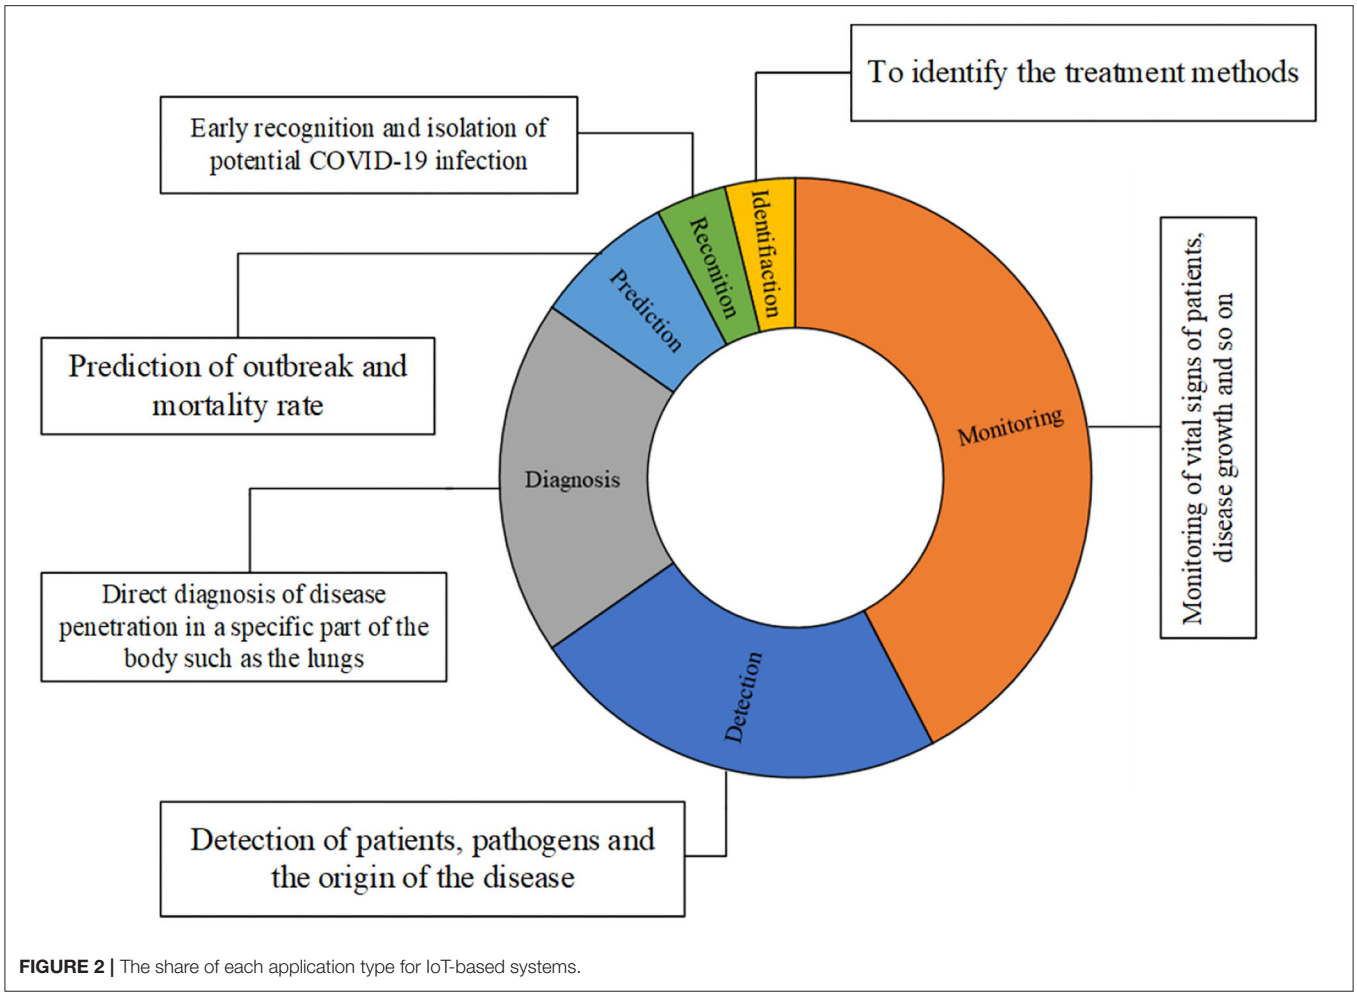

FIGURE 2 | The share of each application type for IoT-based systems.

23 cases (about 22%) have been selected for investigating the evaluation criteria and including in the dataset.

IoT for COVID-19

IoT is an interconnected set of computing tools from simple to complex that can be used in conjunction with mechanical or digital machines in the presence of humans, animals, or objects. IoT technology can easily transfer data from the source to the destination through the network without the operator's presence. This technology can be considered a special tool in human-human interaction or human-computer interaction (53, 54). An IoT platform includes the minimum equipment required, such as smart devices equipped with the web (55). These systems consist of processors, sensors, and communication hardware to collect, send, control, manage, and convert data into accessible data (55, 56). These systems connect to an IoT port used to send data to the cloud so that data can be analyzed and shared (57). These devices can operate by connecting to other related systems based on their information (58). These tools perform many of their tasks without human intervention.

Today, IoT technology in health and treatment is growing rapidly (59). The main applications of IoT in the process of treatment and intelligent health can include identification, digitization of medical information, patient transfer to the hospital, use of vital signs sensors, use of smartphones in communication, and digitization of medical processes (60, 61). Furthermore, IoT has become more popular and important due to the COVID-19 pandemic (62). Because this virus is highly contagious and has a high risk to human health, and has caused many problems for the medical staff, using non-contact methods to diagnose as soon as possible, control patients, monitor the condition of patients with acute illness, as well as maintain social distance, can be an important factor in breaking off part of the virus infection cycle (63, 64). In non-contact methods, the IoT is a leader and can solve many problems in this field (65). **Figure 1** presents the main applications of the IoT in COVID-19 era.

Table 2 presents the highlighted studies for applying IoT-based techniques to tackle COVID-19. This table represents the studies based on the main four columns. First, the objective briefly describes the main objective of each study.

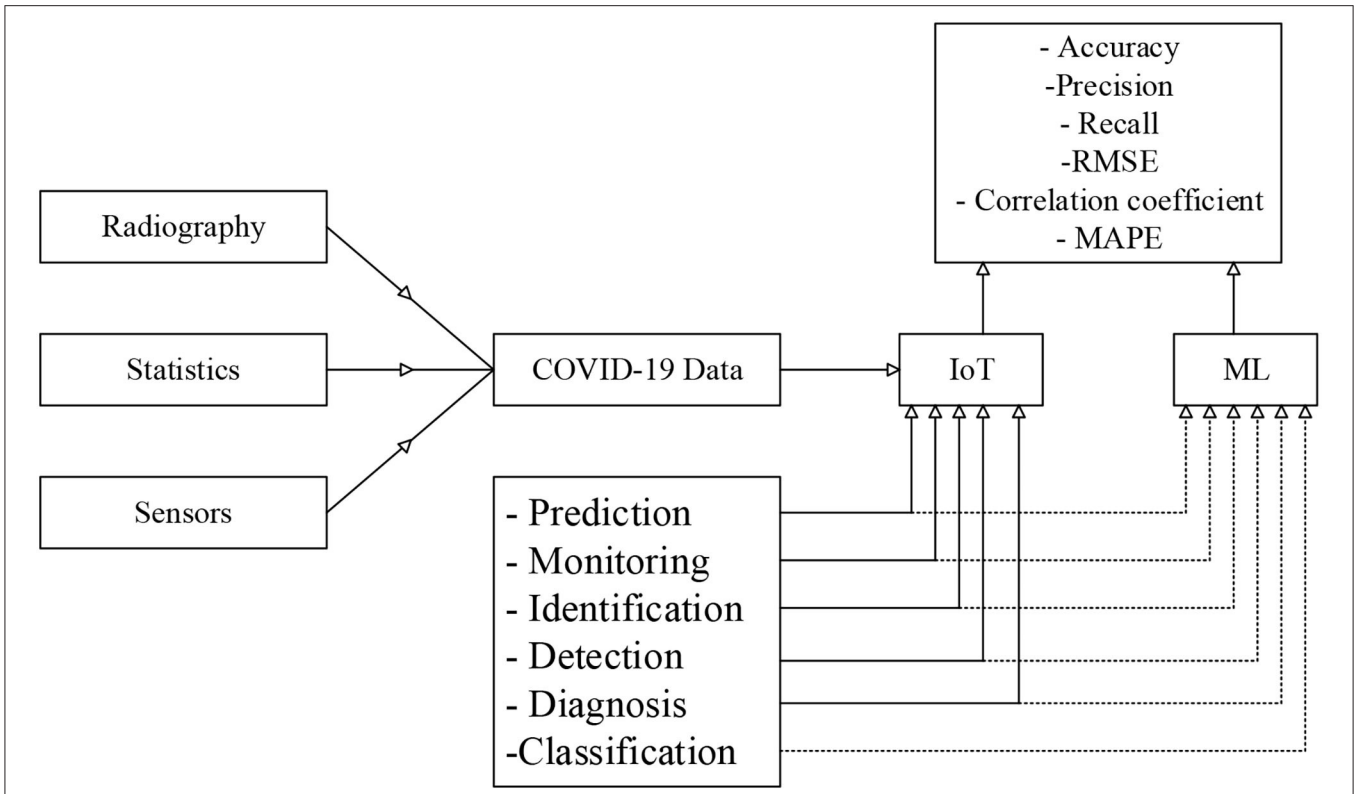

FIGURE 3 | Main contributions of the current study.

Methodology/proposed algorithm presents the main algorithm and procedure employed by each study. Keyword indicates the main points and concentration of the study and finally, the application section presents the field of the application of each method.

Figure 2 presents the contribution of different applications which are performed by IoT techniques to track COVID-19 related fields.

Figure 2 is generated based on **Table 2** to present the main applications and their portions by studies for handling IoT in

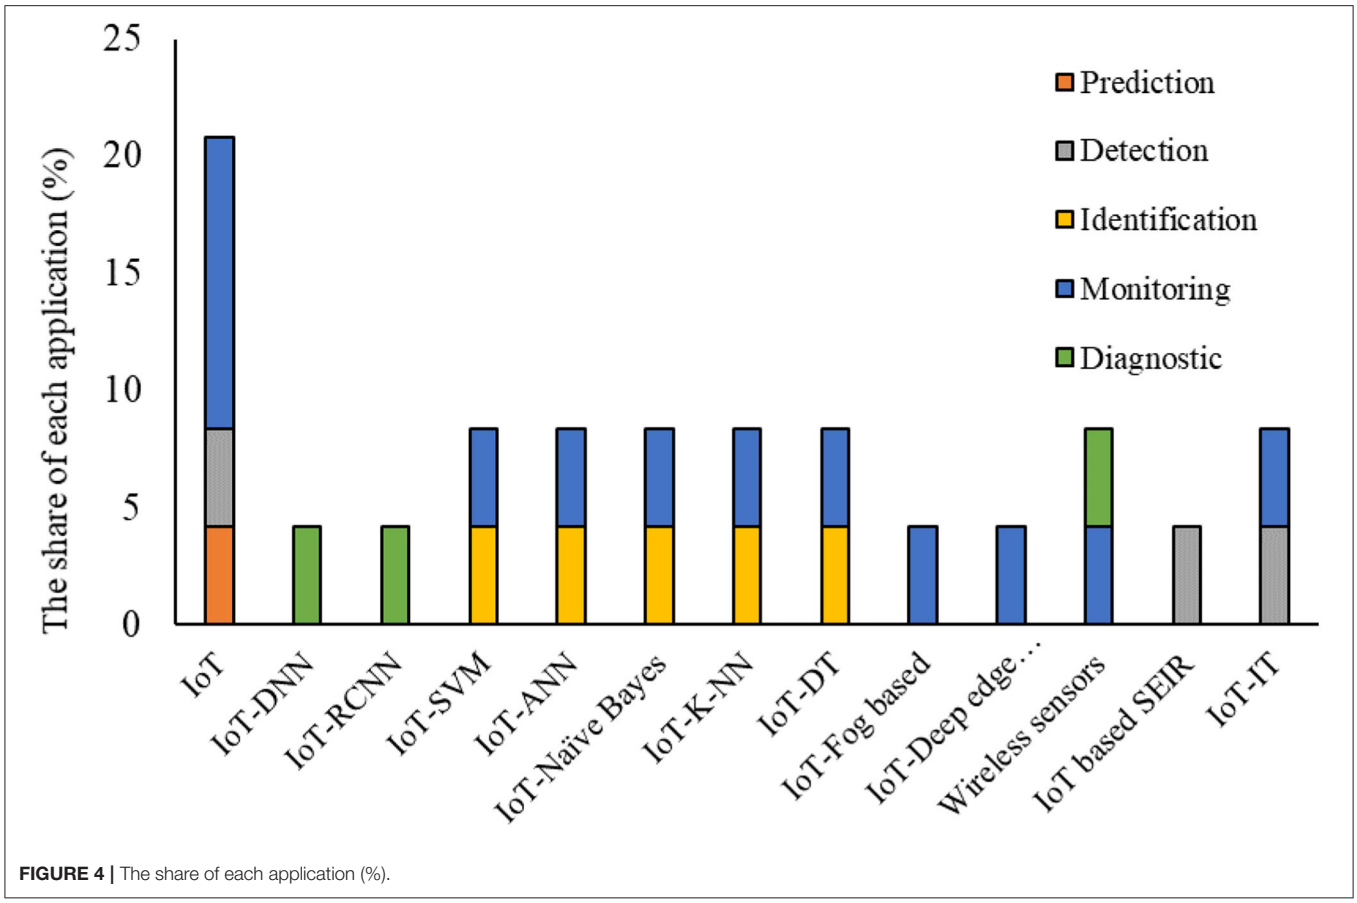

FIGURE 4 | The share of each application (%).

the COVID-19 pandemic. Monitoring, detection, and diagnosis are the main application of IoT-based techniques in tackling the COVID-19 pandemic. Monitoring can be performed in different ways. Accordingly, Roy et al. employed IoT as a real-time solution for monitoring COVID-19 outbreaks (66). Also, Otoom et al. employed IoT to provide monitoring and detection data using a real-time system to feed to the machine learning algorithms for further applications or handling (69). Singh et al. and Vedaei et al. used IoT as a tool for monitoring COVID-19 patients and their health condition in cooperating with an interconnected network (70, 71). Ashraf et al. proposed a smart edge surveillance system to monitor wearable smart gadgets which are operated according to IoT-based technology (72). Karmore et al. developed a Medical Diagnosis Humanoid to provide a complete diagnostic system for COVID-19 using IoT-based technology (74). De Vito et al. presented the outputs of a high-resolution A.Q. monitoring system based on an IoT-based technique (80).

Baskaran et al. used a non-contact infrared sensor to examine the body temperature to detect the patients with COVID-19 (73). Wang et al. exploited the social relationships in the platform of Social IoT to solve controlling issues of the COVID-19 epidemic by sharing the limited protective resources (77). Kumar et al. investigated an IoT based platform to prevent the spreading of COVID-19 (78). Kolhar et al. developed a platform of a decentralized IoT-based biometric based on a face detection platform for handling COVID-19 outbreaks (79). Aman et al. developed an architecture of IoT based framework for medical applications with respect to combat COVID-19 (38). Manalu et al. investigated the information technology to respond COVID-19 pandemic trend in accordance with the IoT technology (81).

Figure 3 presents the main contribution of these papers. According to the reviewed studies, the COVID-19 dataset can be imported from three main sources, including Radiography, statistics of health centers, and Sensors for prediction, monitoring, identification, detection, diagnosis, and classification purposes. The output of the techniques needs to be evaluated to confirm the approach performance and accuracy values. The frequently used parameters for performance analysis include Accuracy, Precision, Recall, R.M.S.E., Correlation coefficient and mean absolute percentage error. This can be considered a brief explanation of the main contribution of the present study. This study successfully presents the advantages and disadvantages of each technique for a specific task in handling the COVID-19 dataset and proposes the future perspectives. Also, this study can detect the main challenges and limitations.

There is a need to categorize the main applications of IoT and the relevance technique following COVID-19. **Table 3** presents the study's main contributions to the application of IoT and integrated IoT-ML-based techniques. Based on **Table 3**, the exact application of each of the methods used can be extracted. It is

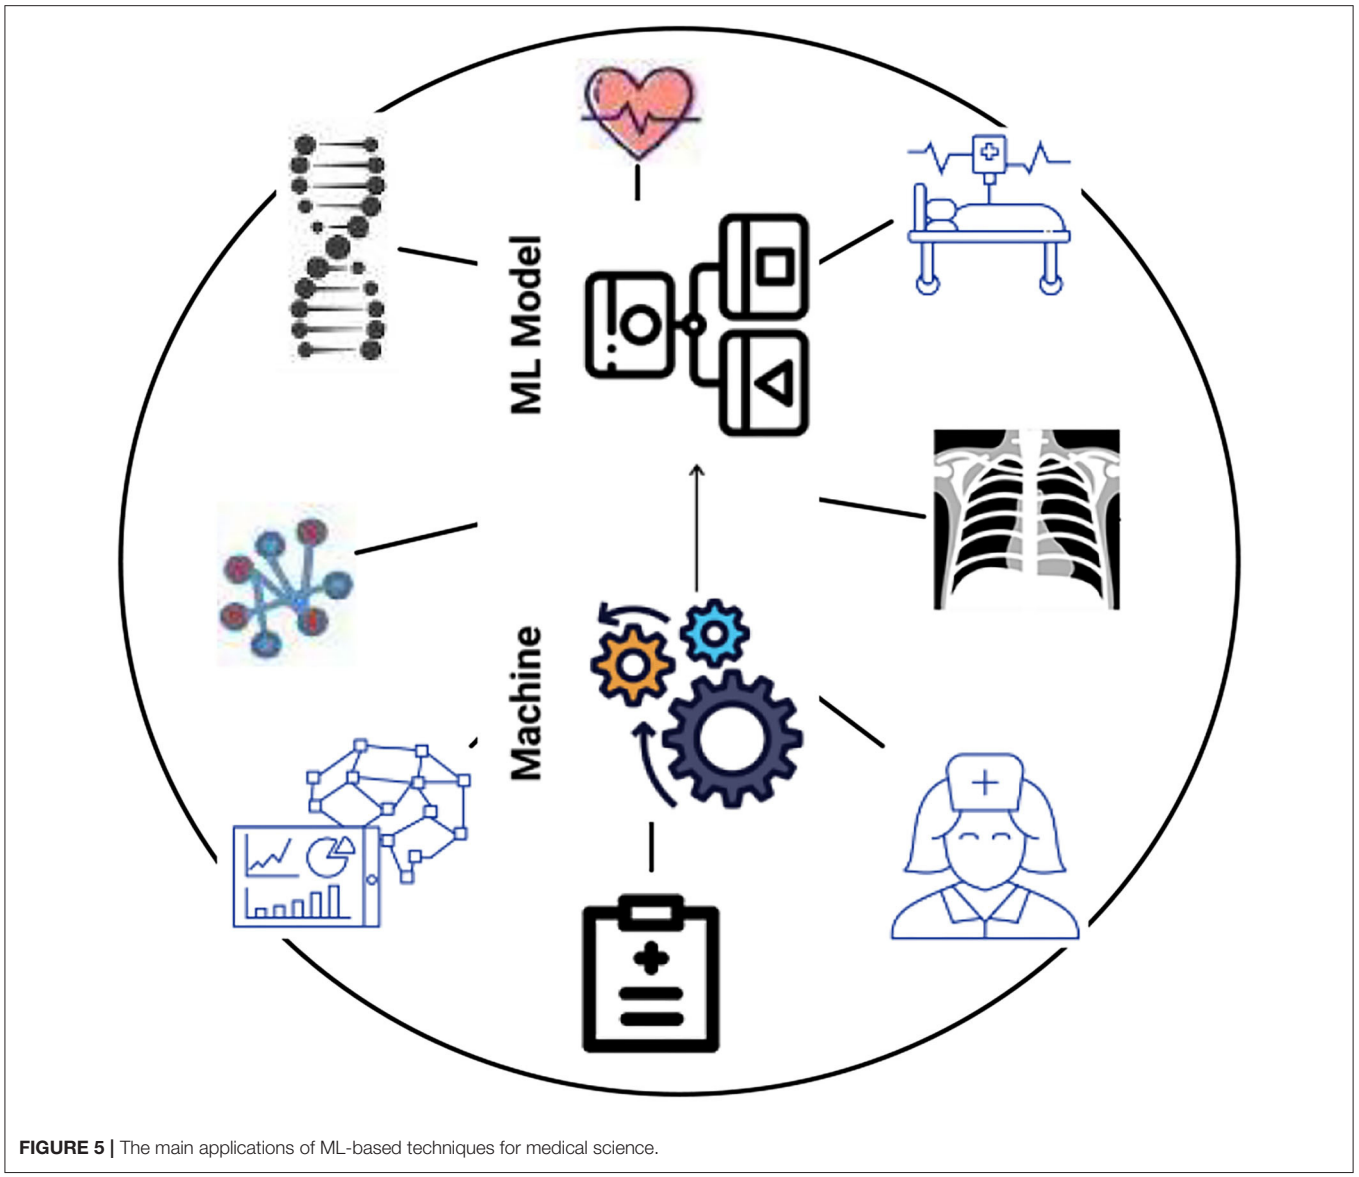

FIGURE 5 | The main applications of ML-based techniques for medical science.

also possible to find out which methodology is still available for which application can be considered a research opportunity for the future. Also, by carefully examining the different reasons for the tendency of each method to the fields shown in independent research, which can be considered necessary research and planning opportunities for policymakers in this field.

As shown in **Table 3**, IoT-based technology requires ML-based techniques to complete the task. **Figure 4** presents the share of each methodology in the applications by percentage.

As shown in **Figure 4**, IoT has been used more than other applications to monitor and detect COVID-19 cases. However, it has been less popular in the identification at the same time.

ML Techniques for Pandemic Prediction of COVID-19

Utilizing the ML platform led to reducing the adverse effects of the disease and accelerating the healing process (62). The combination of A.I. and ML has led to advances in treatment, medication, screening, prognosis, contact tracking, and the drug/vaccine development process and reduced human intervention in medical performance (82). ML is also used as a tool for managing virtual queues to prevent crowds in physical waiting rooms or long queues. In addition, it is used to predict waiting times and implement calls in a privacy manner in conjunction with the cell phone platform (83).

The ML method is widely used in data analysis by intelligently producing an analytical model. This method is a subset of artificial intelligence that analyzes data and produces a model for estimating, categorizing, optimizing, predicting, identifying problems, and decision-making (84, 85).

New computing technologies have made the problems assessed by ML-based techniques today a little different from the way they are analyzed based on past technologies (86). These techniques began to evolve from pattern recognition to

TABLE 4 | ML-based techniques for COVID-19.

Order	Aim	Method	Dataset	Key words	Application	Reference
1	To develop a mask face detection model	Deep transferring learning (ResNet50) as classifier and SVM to be compared with ensemble method	Image-based dataset	Deep transferring learning, SVM, and ensemble	Detection	(92)
2	To employ ML based platform as a healthcare application to proper decision making for COVID-19 detection	Integration of random forest, Gaussian nave bias and Generative adversarial network	Real-time processing of users' health data	Artificial intelligence, Cloud/fog computing, IoT	Detection	(93)
3	To propose an A.I. based technique integrated by C.T. scan and chest x-ray images to identify, and predict the positive infected patients	Pre-trained CNN	Chest X-ray and C.T. scan images	COVID-19, DT, X-ray images, AI	Identification and diagnosis	(94)
4	To employ a novel CNN architecture for classifying COVID-19 from chest X-rays.	CNN architecture	Chest X-ray	DL, CNN, mine data patterns	Classify and identification	(95)
5	To develop an AI based methods for fast diagnosis of COVID-19 cases	ResNet-101 in comparison with Radiology data	Chest X-ray radiography	AI, CNN, ResNet-101	Diagnosis	(96)
6	To detect COVID-19 promptly using CNN	CNN technique	Chest X-ray images	DL, CNN, Squeeze Net	Detection	(97)
7	To develop and test a new computer-aided diagnosis (CAD) to investigate COVID-19	CNN	Multi-center chest C.T. dataset	CNN, DL, CAD	Diagnosis	(40)

a comprehensive theory of the ability of computers to perform specific tasks without the need for special planning (87, 88).

In the field of medicine and treatment, ML is known as one of the most practical tools for analyzing medical data, identifying, predicting, and even treating different situations. With the advancement of medical science in today's world and the production of large volumes of medical data, there is an urgent need to analyze this data (89). **Figure 5** presents the main applications of ML-based techniques for medical science to tackle the COVID-19 pandemic. Identifying the prevalence, effective parameters in the eradication of the virus, identifying patients in the early stages, patients' pattern behaviors, and predicting outbreak and mortality rates can be considered practical and effective areas of ML-based techniques (90, 91).

Table 4 presents the highlighted studies for the application of ML-based techniques for handling COVID-19. Similar to **Tables 3**, **4** discuss them in four columns. The objective column briefly describes the main objective of each study. Methodology/proposed algorithm presents the main algorithm and procedure employed by each study. Keyword indicates the main points and concentration of the study and finally, application section presents the field of the application of each method.

According to **Table 4**, ML-based techniques are employed for detection, identification, monitoring, diagnosis, prediction, and classification purposes in the presence of the COVID-19 dataset. **Figure 6** presents the summary of each application separately. Singh and Kaur employed an ML-based platform using hybrid random forest, Gaussian Naïve Bayes, and Generative adversarial network as a healthcare application to detect COVID-19 cases (93). Vinod et al. developed a pre-trained CNN method as an ML-based technique integrated using C.T. scan and chest x-ray images to identify, detect, and predict the positive infected patients (94). Ardakani et al. developed an ML-based technique (ResNet) for fast diagnosis of COVID-19 cases compared to radiology data (96). Polsinelli et al. developed a study to detect COVID-19 promptly using CNN as a frequently used DL-based architecture (97). Nour et al. proposed an intelligence computer-aided model based on CNN with SVM classifier architecture on chest X-rays to support daily clinical applications (98). Chowdhury et al. investigated the utility of A.I. in the rapid and accurate detection of COVID-19 in the presence of chest X-ray

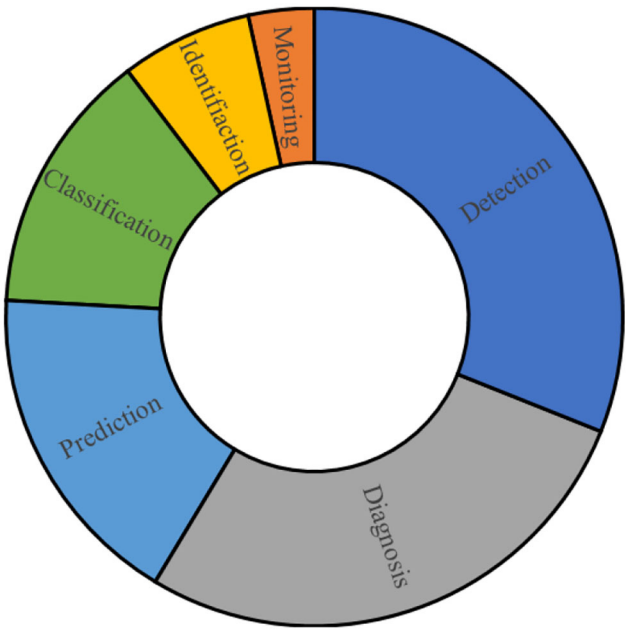

FIGURE 6 | The share of each application type for ML-based systems.

images (102). Sethi et al. employed Logistic Regression (L.R.), Multinomial Naïve Bayes, Decision Tree (D.T.), Random Forest (R.F.), SVM, and XGBoost classifiers to analyze the emotions expressed by people using social media to monitor and detect sentiment behind COVID-19 (110). Ardabili et al. developed ML-based techniques for the prediction of COVID-19 outbreaks (91). In another study, Ardabili et al. also employed a hybrid ML-based technique (Multilayered perceptron integrated by gray wolf optimizer) for the global prediction of COVID-19 cases (90). In addition, Loey et al. employed the DL-based ResNet method in the presence of an SVM-based classifier to detect a masked face (92).

According to **Figure 6**, detection, diagnosis, and prediction can be considered as the main categories of the application of ML-based methods in COVID-19. In general, one of the main sections of analyzing IoT-based and ML-Based techniques applied for a specific field is their evaluation in terms of accuracy, error, or in other word performance of the model. **Table 5** presents the evaluation criteria employed for each model.

According to **Table 5**, accuracy, followed by the recall and precision parameters has owned the highest portion of the evaluation criteria employed for analyzing COVID-19 based dataset using IoT and ML-based techniques. In the following, **Table 6** is generated from **Table 4** for indicating the share of each ML-based technique for each application and their main contributions. According to **Table 6**, ResNet as an architecture of deep learning methods followed by CNN, XGBoost, SVM, D.T., and L.R. has been used more often to tackle work with COVID-19 related data.

Figure 7 presents the share of different ML methods for different tasks to tackle the COVID-19 pandemic. As is clearly indicated in this figure, ResNet, followed by CNN, is the most common application of ML in this field. This can be due to the model's nature for handling different applications like monitoring, detection, identification, classification, and diagnosis. In comparison, other methods can do a limited number of applications.

Evaluation Criteria

Models developed using ML and IoT-ML require an evaluation step for recognizing their performance and accuracy values. According to the studies reviewed, the most effective and frequently used evaluation criteria are including Accuracy, Recall, Precision, Root mean square error (R.M.S.E.), Correlation coefficient and Mean absolute percentage error (M.A.P.E.). These criteria compare the models' output and actual values and provide a comparison score (90, 91). In the present study, we employed the criteria values reported by each study for evaluating and comparing the models. **Table 7** presents the main criteria for evaluation.

Main Findings and Evaluations

This section presents the main findings of IoT based techniques (**Table 8**) and ML-based techniques (**Table 9**). Each table includes two main columns called findings and pros. and cons.

According to **Table 8**, most of these studies lack numerical analysis for the method's performance. One of the main reasons can be the nature of the IoT technique, which goes through a practical process and shows its performance in practical applications and does not need to provide numerical statistics. In all these applications, IoT could successfully cope with the task. IoT provided a fast and efficient approach to tracking the disease spread (66). On the other hand, it can be employed as a real-time framework to minimize the impact of communicable diseases through the early detection of cases (67). In the study by Singh et al. IoT technology successfully increased patient satisfaction and reduced the readmission rate in the hospital (70). However, there is a need to integrate IoT platforms with ML-based techniques for detection purposes. In the study by Rahman et al. DL applications with IoT platforms provided promising findings to detect A.E. attacks. However, there is a need for further research, attention, and implementation of appropriate defense mechanisms, safeguards, and controls (67). Kolhar et al. employed Multi-task Cascaded Convolutional Network architecture (M.C.C.N.N.), and findings claimed that the efficiently integrated by Raspberry Pi increased the robustness of detection and recognition (79).

According to the findings given in **Table 9**, the most share of studies developed by ML-based techniques for handling COVID-19 based datasets provided performance criteria. The most share of the performance criteria, according to **Figure 8** is related to the accuracy factor. Accuracy factor is a general and normalized factor. Therefore, it can be employed for comparing the ML-based methods with different datasets. **Figure 9** presents the accuracy values for each model for comparing their performance in handling the COVID-19 dataset.

Figure 9 indicates CNN with SVM classifier, Genetic CNN, and pre-trained CNN followed by ResNet, provided highest

$Accuracy = \frac{True_p+True_n}{True_p+True_n+False_p+False_n}$	Where $True_p$ denotes the true positives, $True_n$ the true negatives, $False_p$ the false positive, and $False_n$ the false negatives.	(1)
$Recall = \frac{True_p}{True_p+False_n}$	Where $True_p$ denotes the true positives and $False_n$ the false negatives.	(2)
$Precision = \frac{True_p}{True_p+False_p}$	Where $True_p$ denotes the true positives and $False_p$ the false positives.	(3)
$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i-\hat{x}_i)^2}$	Where N denotes the total number of samples, x_i the actual samples, and $\hat{x}_i$ the predicted samples.	(4)
$Correlation\ Coefficient = \frac{Cov(x,\hat{x})}{\sigma_x\sigma_{\hat{x}}}$	Where x refers to actual samples, $\hat{x}$ to predicted samples, $Cov(x, \hat{x})$ to the covariance between x and $\hat{x}$, and σ to the standard deviation (calculated for both x and $\hat{x}$)	(5)
$MAPE = \frac{100}{N}\sum_{i=1}^{N}\lvert\frac{x_i-\hat{x}_i}{x_i}\rvert$	Where N denotes the total number of samples, x_i the actual samples, and $\hat{x}_i$ the predicted samples.	(6)

accuracy values. On the other hand, the lowest accuracy was related to single CNN followed by XGboost and K.N.N. techniques.

Challenges and Limitations

Nowadays, when the world is struggling with COVID-19 disease, every innovation and technology is used to fight this disease. Like many other areas, healthcare requires the support of new technologies such as IoT, and ML. Exploring the disease-related dataset, data preparation, prevention, and control of infectious diseases has become one of the main purposes of A.I. IoT and ML have a vital personality in better understanding, dealing with the COVID-19 crisis, and discovering the COVID-19 vaccine. ML-based technology allows computers to predict the pattern and speed of disease transmission with their intelligence and by mimicking large amounts of data. A.I. uses information from people with coronary heart disease, and improved and dead people as tracking data.

To combat the spread of the corona virus, IoT-based methods of communicating with patients provide transparency and a better understanding of how the virus is spread and strengthen

TABLE 8 | The main findings of the study for the application of IoT-based techniques.

Order	Findings	Pros. and Cons.	Reference
1	The proposed solution can identify and track the infected individual and successfully tracks all people who are in the area of disease spread	This framework integrates symptom information as a rapid and efficient approach, thus tracking the prevalence of the disease	(66)
2	DL applications are vulnerable to coronavirus attacks	The method is very vulnerable and requires further studies	(67)
3	The model provides an accuracy of 98% for detection	Combining DL and the IoT makes it easier for radiologists to control the spread of the virus	(68)
4	According to results, all the techniques, except the Decision Stump, OneR, and ZeroR provided accuracies values more than 90%	The proposed platform reduced the communicable diseases using early detection of cases and provided tracking the recovered cases, and a better understanding of the infections	(69)
5	IoT reduces clinical cost and optimizes treatment outcome of the patients	The platform improves patient satisfaction and decreases readmission rate in the hospital	(70)
6	The system can assist tracking the daily activities and decrease the risk of exposure to the COVID-19	The app announces the user to keep a physical distance of 2 m. Also, a Fuzzy-based technique evaluates the environmental risk and user health to estimate the risk of real time spreading. This platform can successfully reduce the coronavirus spread	(71)
7	The platform detects and tracks the infected person	The platform tracks COVID-19 and improves infected person and keeps the dataset for further analysis	(72)
8	The provided package enhances the testing process for increasing the efficiency of the system	This approach will increase the maximum collaboration from the employees	(73)
9	This platform is a cost-effective, safety-critical mobile robotic technology and successfully copes with diagnosis task Also the multiple diagnostic devices increases the detection accuracies	The system effectively provides a complete diagnosis and figuring out COVID-19 patients also contains multiple diagnostic devices, without any need for human interferences	(74)
10	The robot technology protect virus affected persons. The system is also recognizing the patient's Gesture and tracking the instructions	The robot collects data from patient performs tasks without image processing system	(75)
11	IoT-based technology prevent the global pandemic	Improves the control and tracking of a fast-spreading virus such as coronavirus	(76)
12	The proposed methodology is sustainable for disease tracking by an early identification of cases	This technique can successfully handles both governments and other decision-making authorities	(77)
13	This system improves the decision-making procedure	The system is connected through cloud computing and effectively supports the real-time data	(78)
14	Edge computing improved the findings on the decentralized load of face recognition	The platform enhances the robustness of detection and diagnosis	(79)
15	The proposed system could successfully cope with the task	IoT equipped ML can successfully save, and visualize monitoring the volunteers	(80)
16	This study suggests that integrated and hybrid techniques will follow up the near future, using simulation, and forecasting purposes	A higher degree of safety and privacy for humanity	(38)
17	The platform employed for the study have an effective role in the success of pandemic handling	The platform increases accessibility to the proper dataset	(81)

the treatment and research process. ML is one of the new technologies for tracking the spread of the virus and finding effective parameters in it. The ML method can successfully identify high-risk patients and predict the necessary measures to deal with possible infections to reduce the point of the effect of the disease. In addition, ML-based methods can estimate the risk of patient mortality through previous analysis. This technique improves patients' planning, treatment, and reduction and is a complementary medical tool that works with data and evidence. On the other hand, this technology improves decision-making and reduces the cost of treatment and diagnosis. At the same time, in medical imaging, ML tools help to recognize the patterns in the images and strengthen the ability of radiologists to diagnose the possibility of disease and early diagnosis of the disease.

One of the main limitations of IoT, and ML-based techniques for applications in COVID-19 is the lack of a complete dataset. This can be due to the unique development of models by limited data for a specific application within the same data field. The purpose of using IoT, A.I., or ML-based techniques is to solve a specific problem in the real world with a real application that requires the use of special hardware and equipment. There are limitations in the cost and availability of developing and equipping communication hardware in therapeutic, diagnostic, estimation, and forecasting applications for IoT technology or ML-based techniques. Also, there are limited best practices available for IoT developers. The lack of IoT edge authentication and licensing standards has led to restrictions on the application and enactment of laws, regulations, and policies in the use of this technology, and this has led to the absence of IoT-based incident response activities as the best methods. All of these limitations mean that there is still no focus on identifying ways to gain situational awareness of the security of IoT assets in a medical complex.

TABLE 9 | The main findings of the study for the application of ML-based techniques.

Order	Results	Pros. and cons.	Reference
1	The SVM classifier in the presence of R.M.F.D., S.M.F.D. and L.F.W. dataset achieved 99.64, 99.49 and 100% testing accuracy values.	The proposed model provided lowest processing time and highest accuracy	(92)
2	Recall = 0.93, Precision = 0.871 with lower processing time	The system is cost-effective by reducing processing time and sustainable by increasing the accuracy values considerably. The proposed framework can also be used to prioritize patients who require an ambulance.	(93)
3	Accuracy = 93% and recall score = 88% using chest x-ray images	The proposed method can successfully help radiologist's prompt detection of coronavirus cases	(94)
4	Accuracy (97.94 %) and AUC (98.39 %)	A channel-shuffled dual-branched CNN architecture can effectively learn salient features and increases the accuracy and precision values of the modeling	(95)
5	Sensitivity = 100%, specificity = 99.02% and accuracy = 99.51% and for radiology data, sensitivity 89.21%, specificity = 83.33% and accuracy = 86.27%	This model is low cost and is used as a complementary method during C.T. imaging	(96)
6	Accuracy = 85.03%, sensitivity = 87.55%, specificity = 81.95%, precision = 85.01% and F1-core = 86.20%	Higher classification rate by analyzing thousands of images	(97)
7	Accuracy = 94.5%, confidence interval = 95%, sensitivity = 98.4% and specificity = 98.0%	Develops a DL-based CAD scheme of chest X-ray images and improves detecting COVID-19 infected	(40)
8	Accuracy = 98.97%, sensitivity = 89.39%, specificity = 99.75%, and an F-score = 96.72%	Reduces the misdiagnosis rates, and improves evaluation rates and detects positive COVID-19 infections	(98)
9	Accuracy = 97.9%, AUC = 99.0%, and Cohen kappa score = 95.7%.	Reliable screening of COVID-19 from chest CT	(99)
10	96% of accuracy	The proposed model performance is clinically validated with expert radiologists	(39)
11	Accuracy of 99.62 and 96.70%. Average recall value of 99.63 and 96.69%, respectively, for binary and multiclass	Automated medical diagnostics for enhancing decision making rates	(100)
12	Correlation coefficient = 0.9899	providing significant variance for each criterion	(101)
13	Accuracy = 99.7%, precision = 99.7%, and sensitivity = 99.7%	Improving the speed and accuracy of COVID-19 detection	(102)
14	86% accuracy for the task of classifying	The proposed model could successfully improve the classification accuracy	(103)
15	Accuracy of 88, 91, 87 and 89% for kNN, SVM, D.T. and L.R., respectively	The proposed method can be applied anywhere, without prior training or calibration	(104)
16	F1-score of 97.9, 98.8, and 92.5%, A.U.C. of 97.4, 98.8, and 84.4% and accuracy of 97, 98.2, and 88.2%, respectively, for Cough sound, Breathing sound and voices, respectively.	To improve the COVID-19 detection through a cost-effective approach	(105)
17	$R^2 = 0.96$, RMSE = 254, MAE = 186	The proposed method could successfully estimate the number of daily cases	(106)
18	Sensitivity and specificity of 0.8645, and 0.9889.	This model provides automated and accurate segmentation of C.T. images	(107)
19	MAPEs = 0.52, 0.38, 0.05, and 0.86%, respectively for the next 6 days in Wuhan, Beijing, Shanghai, and countrywide	To minimize the errors of the prediction and to enhance the detection efficiency	(108)
20	Accuracy = 98.84%, Precision = 93%, Sensitivity = 100%, and Specificity = 97.0%	The proposed model improved classification rate in comparison with ReseNet18, ReseNet50, Squeeze net, DenseNet-121, and Visual Geometry Group	(109)
21	Accuracy for both SVM and Decision Tree could provide the maximum value by average value of 93%	Higher accuracy for perceiving the perception of people infected by COVID-19	(110)
22	R.M.S.E. and CC values for five countries including, China, Italy, U.S.A., Iran and Germany	The proposed models enhanced the forecasting rate of COVID-19 cases	(91)
23	MAPE = 13.15% and CC = 0.99	The proposed models increased the forecasting rate of COVID-19 cases	(90)

DISCUSSION

According to the reviewed studies, the COVID-19 dataset can be imported from three primary sources: radiography, health centers' statistics, and Sensors for prediction, monitoring, identification, detection, diagnosis, and classification purposes. The output of the techniques needs to be evaluated to confirm the approach performance and accuracy values. The frequently used parameters for performance analysis include Accuracy, Precision, Recall, R.M.S.E., Correlation coefficient, and mean absolute

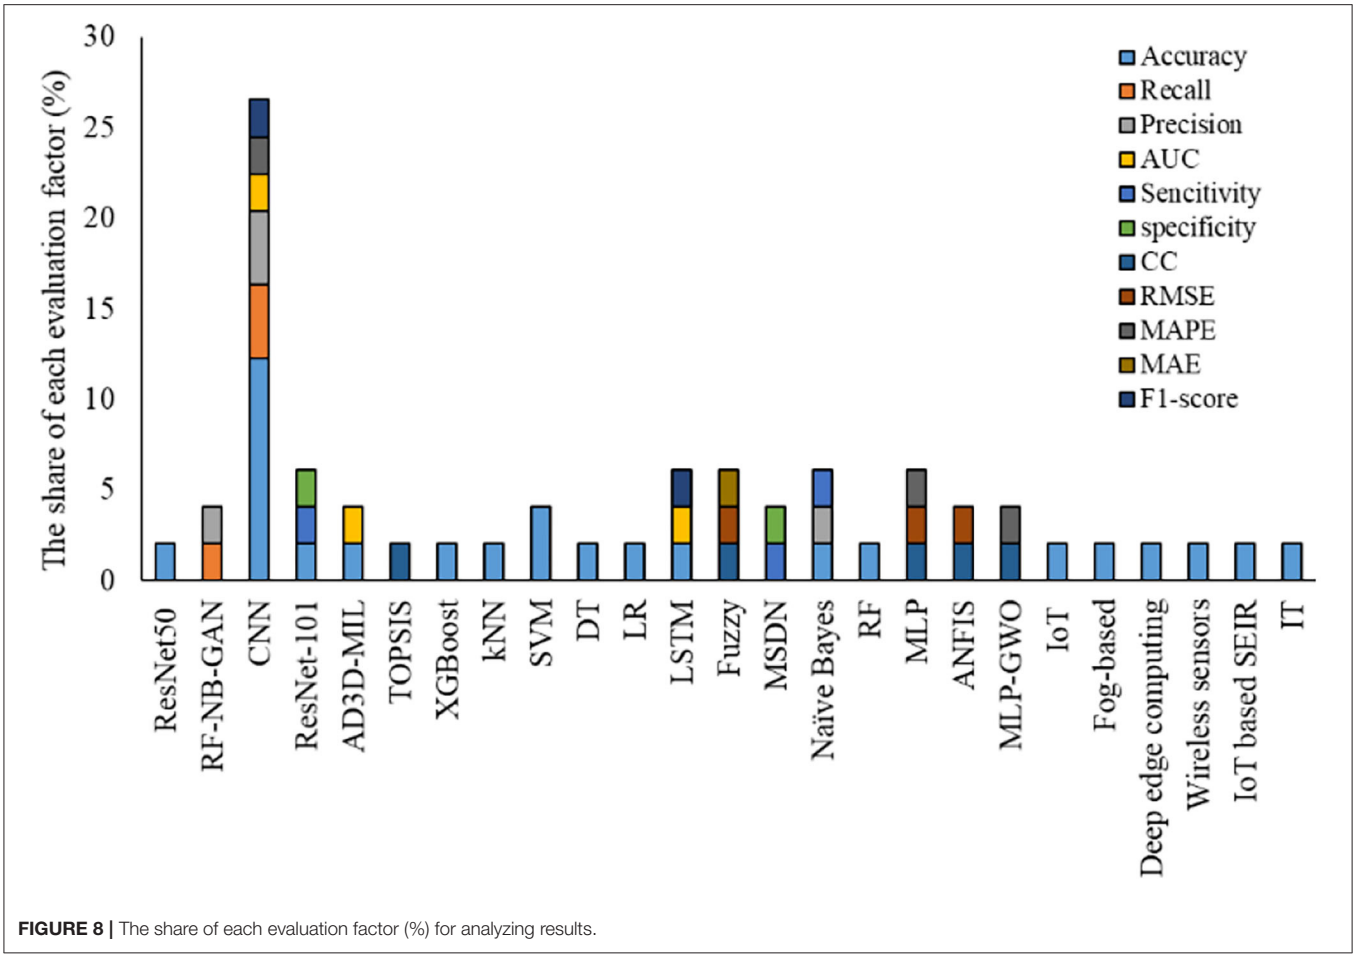

FIGURE 8 | The share of each evaluation factor (%) for analyzing results.

percentage error. This can be considered a brief explanation as the main contribution of the present study. This study successfully presents the advantages and disadvantages of each technique for a specific task in handling the COVID-19 dataset and proposes future perspectives. Also, this study can detect the main challenges and limitations.

It is also possible to find out which methodology is still available for which application can be considered a research opportunity for the future. Also, by carefully examining the different reasons for the tendency of each method to the fields shown in independent research, which can be considered necessary research and planning opportunities for policymakers in this field.

The presence of the ML platform led to reducing the adverse effects of the disease and accelerating the healing process, advances in treatment, medication, screening, prognosis, contact tracking, and the drug/vaccine development process, and reduced human intervention in medical performance as a tool for the management of virtual queues to prevent crowds in physical waiting rooms or long queues. It is used to predict waiting times and implement calls privately with the cell phone platform.

Based on the studies conducted in this study, we achieved the following results:

- IoT has been used more than other applications to monitor and detect COVID-19 cases. In contrast, it has been less popular in the identification.
- ML method is widely used in data analysis by producing an analytical model intelligently for estimating, categorizing, optimizing, predicting, identifying problems, and decision making.
- New computing technologies have made the problems assessed by ML-based techniques, began to evolve from pattern recognition to a comprehensive theory of the ability of computers to perform specific tasks without the need for special planning.
- Identifying the prevalence, effective parameters in eradicating the virus, identifying patients in the early stages, patients' pattern behaviors, and predicting outbreak and mortality rates can be considered practical and compelling areas of ML-based techniques.
- Detection, diagnosis, and prediction can be considered the main categories of the application of ML-based methods in COVID-19. In general, one of the main sections of analyzing IoT-based and ML-Based techniques applied for a specific field is their evaluation in terms of accuracy, error, or performance of the model.

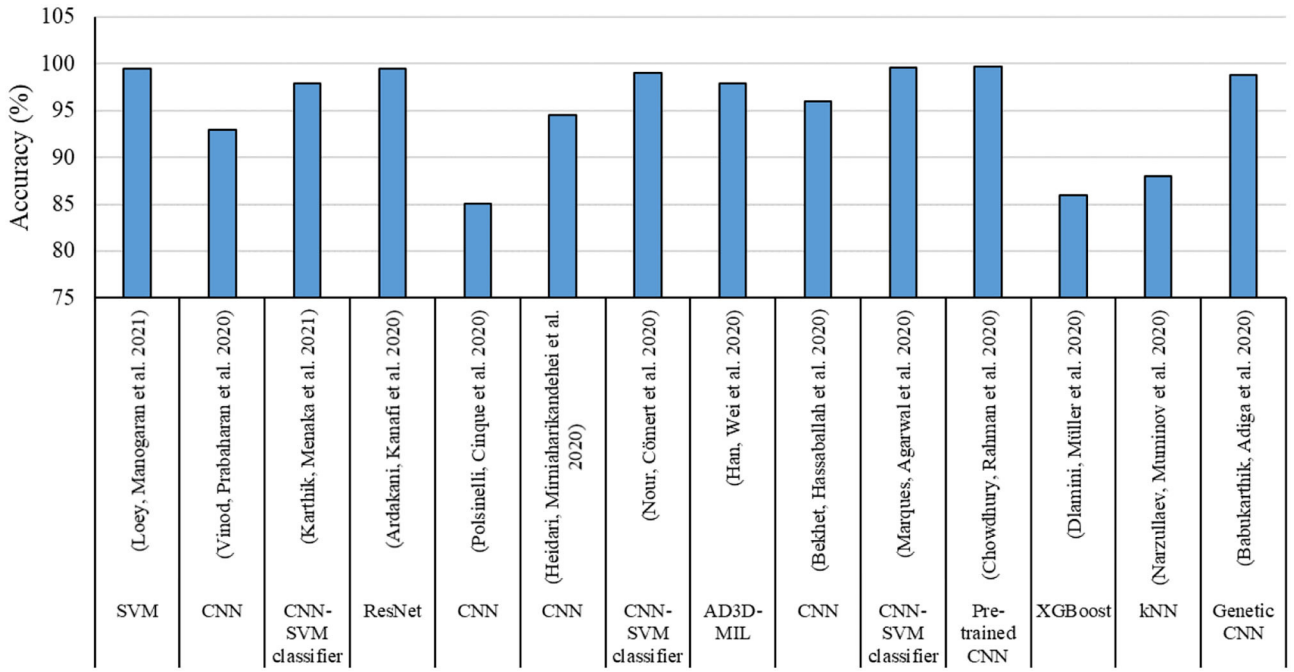

FIGURE 9 | Accuracy values.

- Accuracy, followed by the recall and precision parameters, has the highest portion of the evaluation criteria employed for analyzing the COVID-19 dataset using IoT and ML-based techniques. ResNet, as an architecture of deep learning methods followed by CNN, XGBoost, SVM, D.T., and L.R., has been used more often to tackle work with COVID-19 related data.
- Resnet follows CNN is The most common use of ML to contribute various methods for different tasks to combat Pandemic COVID-19. This trend can be due to the model's nature for handling different applications like monitoring, detection, identification, classification, and diagnosis. At the same time, other methods can do a limited number of applications.
- Models developed using ML and IoT-ML require an evaluation step for recognizing their performance and accuracy values. According to the studies reviewed, the most effective and frequently used evaluation criteria include Accuracy, Recall, Precision, Root mean square error (R.M.S.E.), Correlation coefficient, and Mean absolute percentage error (M.A.P.E.). These criteria compare the models' output and actual values and provide a comparison score (90, 91). In the present study, we employed the criteria values reported by each study for evaluating and comparing the models.
- Most of these studies lack numerical analysis for the method's performance. One of the main reasons can be the nature of the IoT technique, which goes through a practical process and shows its performance in practical applications and does not need to provide numerical statistics. In all these applications, IoT could successfully cope with the task. IoT provided a fast and efficient approach to tracking the disease spread. On the other hand, it can be employed as a real-time framework to minimize the impact of communicable diseases through the early detection of cases.
- The most share of studies developed by ML-based techniques for handling COVID-19 based dataset provided performance criteria. The most share of the performance criteria is related to the accuracy factor. The accuracy factor is general and normalized. Therefore, it can be employed for comparing the ML-based methods with different datasets.
- CNN, SVM classifier, Genetic CNN, and pre-trained CNN followed by ResNet provided the highest accuracy values. On the other hand, the lowest accuracy was related to single CNN, followed by XGboost and K.N.N. techniques.

CONCLUSION

The present study categorizes the applications of IoT, IoT-ML, and ML-based techniques to tackle COVID-19-related problems. The main applications are monitoring, detection, identification, classification, and diagnosis. Studying, comparing, and investigating these applications requires a proper judgment about the performance and effectiveness of outputs. According to a deep consideration of the evaluation criteria, it has been investigated that the accuracy, followed by the recall and precision parameters, have owned the highest portion of the evaluation criteria employed for analyzing COVID-19 based dataset using IoT and ML-based techniques.

Most of the studies lack numerical analysis for the method performance. One of the main reasons can be the nature of the IoT technique which goes through a practical process and shows its performance in practical applications. In all the applications, IoT could successfully cope with the tasks. Such that, IoT provided a fast and efficient approach to tracking the disease spread. Most of the studies developed by ML-based techniques for handling COVID-19-based datasets provided performance criteria. According to the results section, the following points can be extracted:

- IoT provided a fast and efficient approach to tracking the disease spread.
- IoT can be employed as a real-time framework to minimize the impact of communicable diseases through early detection of cases.
- The most popular performance criteria are related to the accuracy factor.
- ML-based methods are able to be used with different types of datasets.
- CNN with SVM classifier, Genetic CNN, and pre-trained CNN followed by ResNet, provided the highest accuracy values.
- A.I. is a result-oriented technology employed for proper screening, analysis, forecasting, and tracking of current and potential future patients.

Policy-making in COVID-19 disease to examine the weaknesses and strengths and vulnerabilities of society in terms of the penetration of pathogenic viruses can be considered additional measures and future studies. On the other hand, the study of collective behaviors can also be considered as a perspective to complete studies to prevent similar social harms, reduce costs incurred, and not surprise human life. The future perspective is to employ an advanced analytic ML-based platform that supports huge-data analytics. This trend moves toward smart health interconnected with innovative technologies in the sensor industry. The future is waiting for tremendous promotion in smart health.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author/s.

AUTHOR CONTRIBUTIONS

SB and SA designed the study. SA, AY, BP, AK, and AM wrote the paper. SB, AB, HA-R, MM, and AK edited the manuscript. SA, AY, and BP carried out all the analyses. SB, SA, AY, BP, and MM generated all figures and all tables. HA-R and AB were not involved in any analyses. All authors have read and approved the final version of the paper.

Mechanism of Negative Emotions of the Elderly in Normalization Period of COVID-19: A Mediated Mediation Model

*Kai Xu**

School of Educational Science, Luoyang Normal University, Luoyang, China

To explore the mechanism of negative emotions of the elderly in normalization period of COVID-19. The self-rating Depression Anxiety Stress Scale, epidemic attention scale, subjective economic status scale and physical health perception scale were used to investigate 318 elderly people in 2021. There were significant differences in negative emotions among the elderly in Henan in China with different gender, education background, medical insurance and whether they contacted suspected cases (all $P < 0.05$), but there was no significant difference on religious belief ($P > 0.05$); Attention to epidemic information was positively correlated with negative emotion ($r = 0.492$, $P < 0.01$), and negatively correlated with subjective economic status ($r = -0.138$, $P < 0.05$); Negative emotions were negatively correlated with subjective economic status ($r = -0.455$, $P < 0.01$) and health perception ($r = -0.277$, $P < 0.01$); health perception was no significant correlation with epidemic attention($r = -0.047$, $P > 0.05$) and subjective economic status ($r = -0.033$, $P > 0.05$). Bootstrap test found that epidemic attention can significantly predict negative emotion of the elderly ($\beta = 0.492$, $P < 0.001$), subjective economic status played a partial mediating role between epidemic attention and negative emotions ($\beta = 0.438$, -0.395, $P < 0.001$), and health perception moderated the first half of the mediating path ($\beta = 0.403$, $P < 0.001$, 95% CI = [0.286∼0.521]). Epidemic attention has a significant positive impact on the negative emotions of the elderly in Henan during normalization period of COVID-19, and it has effect indirectly through subjective economic status; health perception plays a moderator role in the impact of epidemic attention on subjective economic status.

INTRODUCTION

As a major public health emergency, COVID-19 is characterized by multiple transmission routes, long incubation period, strong infectivity and rapid spread. It is difficult to prevent and control the epidemic. It not only threatens people's life and physical health, but also brings various impacts on people's mental health. Due to the degenerative changes of various physical and mental functions, the elderly have become a vulnerable group in the society, which is prone to negative emotional experience, resulting in serious psychological problems (1). In this epidemic, due to the weak immune function, the elderly have become the susceptible group and high-risk vulnerable group

of this infectious disease, and most of the elderly in the critically ill group. The study also found that during the epidemic period, the incidence of depression and anxiety in the elderly increased significantly (2), and they were more prone to poor mental health and anxiety symptoms (3), which was the focus of social psychological counseling and crisis intervention during the epidemic period. At present, there are few studies on the mental health of the elderly in Chinese normalization period of COVID-19, which mainly focusing on the current situation and influencing factors of the frailty of the elderly in the community and the health management strategy of the elderly with chronic diseases (4, 5). Therefore, how to understand the law of behavior and emotion of the elderly in time and guide them to respond to public health emergencies rationally and scientifically has become an urgent topic to be studied.

In major emergencies such as the epidemic, people's mental health problems are mainly manifested in three negative emotions: stress, depression and anxiety (6). At present, there have been some researches on the mental health of the elderly during the epidemic period, but there are still deficiencies in the influence mechanism of the negative emotion of the elderly in China during the epidemic period, which needs to be further clarified. The important factor affecting people's mental health in the early stage of the epidemic is the epidemic information (7), people's cognitive uncertainty exists for a long time (8), and they tend to process negative information, which will lead to various serious negative emotional problems (9). Therefore, this study puts forward hypothesis 1:

> Epidemic concern has a significant positive impact on the negative emotions of the elderly.

Socio economic status is an important concept in the theory of social stratification. Socio economic status is the position of an individual in society and the comprehensive embodiment of his education level, occupation, income, residence and other indicators (10). The research on China's national mental health literacy found that in terms of social influencing factors, socio-economic status is the most effective factor among all variables, and its interpretation rate of Chinese mental health literacy is the highest, that is, the higher the socio-economic status, the higher the mental health literacy (11). Socio economic status is often divided into objective socio-economic status and subjective socio-economic status. The latter refers to the evaluation of their socio-economic status by the elderly compared with their peers. In the impact on the mental health of the elderly, the subjective economic status has an important impact. The higher the social class positioning, the better the mental health of the elderly (12). Therefore, this study puts forward hypothesis 2:

> Subjective economic status has a significant negative impact on the negative emotion of the elderly, and plays an intermediary role between epidemic concern and negative emotion.

Physical health perception is an individual's subjective perception and evaluation of self-health. Physical health perception level is a good indicator of health status. It can not only reflect individual health status, but also predict mortality (13). In the face of all kinds of information about the COVID-19, the elderly are more sensitive than other people. Their bodies will release a large number of signals, resulting in autonomic nervous symptoms such as elevated blood pressure, panic, suffocation, asthma, sweating, and various physical discomfort (14). The sense of physical health is closely related to negative emotions. Individuals with lower physical health perception have more negative emotions, and individuals with better physical health perception have more positive emotions (15). It can be seen that under the same conditions of epidemic concern and subjective economic status, the elderly with low physical perception will have more negative emotions, and the elderly with high physical health perception will have less negative emotions. Therefore, this study puts forward hypothesis 3:

> Physical health perception plays a regulatory role in the impact of epidemic concern on subjective economic status.

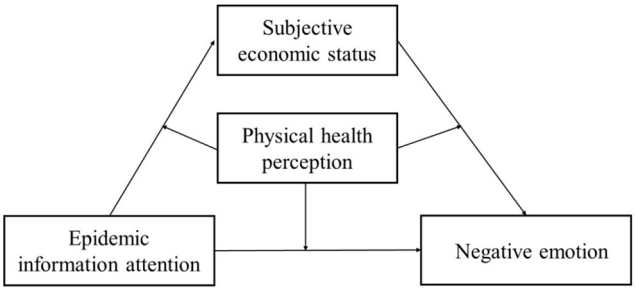

FIGURE 1 | Hypothetical model diagram of this study.

To sum up, this study proposes a moderated mediation model for the impact mechanism of negative emotions of the elderly during the COVID-19 period, as shown in **Figure 1**. Specifically, it includes the intermediary role of subjective economic status between epidemic concern and negative emotion, as well as the regulatory role of physical health perception in the direct path and intermediary path, so as to provide scientific support and thinking for effective psychological counseling and assistance to the elderly in the period of epidemic normalization.

RESEARCH OBJECT AND METHOD

Research Object

Using the method of convenient sampling, 318 elderly people were investigated in Henan Province from March to May 2021. Inclusion criteria: (1) age $\geq$ 55 years old; (2) Be conscious and able to answer questions independently; (3) Informed consent to this questionnaire and voluntary acceptance of this study. Exclusion criteria: (1) those who refuse to investigate; (2) Those with cognitive and language barriers cannot accurately understand the questionnaire items; (3) People with serious physical and mental diseases. The questionnaire adopts unified guiding language, and the elderly in their families

are investigated by Henan students from their departments and teaching departments. Since face-to-face investigation cannot be conducted during the epidemic, the online structured self-filling electronic questionnaire is adopted. After obtaining the informed consent of the elderly, the questionnaire is distributed by sharing the QR code and link of the questionnaire, which is filled in by the subjects themselves. The study passed the review of ethics of Luoyang Normal University.

Research Tool

(1) Demographic characteristics questionnaire: The contents of the questionnaire include gender, age, educational background, religious belief, whether there is medical insurance, whether there is contact with suspected cases, etc.
(2) Measurement of negative emotions: The self-rating Depression Anxiety Stress Scale (DASS-21) was developed by Lovibond et al. (16). Anxiety, depression and stress are three typical negative emotional experiences, and they are also the research hotspots of mental health in theory and clinic. Accurate and rapid diagnosis and differentiation of individual negative emotional status is the prerequisite to ensure individual mental health (17). Therefore, this study uses DASS-21 to measure mental health. Studies have confirmed that DASS-21 has good reliability and validity in the Chinese elderly (18–20). There are 21 items in the scale, which is divided into three subscales: depression, anxiety and stress. Each subscale contains 7 items. This scale adopts a 5-level score to allow the subjects to judge the consistency between their recent negative emotional experience or corresponding physiological response and the description of each item. The higher the score, the lower the level of mental health (21, 22). Diagnostic criteria for DASS-21 scores are detailed in **Table 1**.
(3) This paper adopts the epidemic concern questionnaire (23), which includes a question item ("how much do you pay attention to the epidemic situation of coronavirus pneumonia recently?"). The questionnaire adopts 5-level scoring. The higher the score, the higher the degree of concern about the epidemic.
(4) Subjective economic status scale: We used the MacArthur scale of subjective SES (24, 25) to present a 5-step ladder to the subjects, which means that the economic income is getting higher and higher from bottom to top. The subjects were asked to self-evaluate that their family economic income was at the level of the ladder, so as to represent their perceived subjective economic status.
(5) Physical health perception scale: Based on the overall physical health perception (HPQ) scale of HEO et al. (26), our survey of the elderly in China has good reliability and validity (27). The scale includes 4 items, e.g., "How would you rate your own health at present?" and "What do you think of your own health condition compared to that of other men=women of your age?". Using a five-point Likert scale, respondents were asked to answer from "bad" (1) to "excellent (5)." A high score indicated a better perception of health.

Quality Control

In order to control the quality of questionnaire collection, each IP address limit is set in the background to answer once; In order to improve the authenticity of the questionnaire, the questionnaire does not involve personal information, and there is no reward, highlighting the initiative of the respondents; In order to control the validity of the questionnaire, each question item is set as a required item. If there are unanswered questions, they cannot be submitted, so as to avoid the existence of missing values.

Statistical Method

SPSS 23.0 was used for descriptive statistics and correlation analysis, and the PROCESS 3.2 program developed by Hayes was used for moderated mediation test. The bootstrapping sampling times were 5000 and the test level was high α=0.05.

RESULTS AND ANALYSIS

Common Method Deviation Detection

Harman single factor test was used for common method deviation test (28). The results show that there are 6 factors with characteristic roots >1. The variation explained by the first factor is 26.63%, which is less than the critical standard of 40%, indicating that there is no serious common method deviation variation in this study (29).

Comparison of Negative Emotion Levels in Different Demographic Characteristics

There are significant differences in the scores of negative emotions among the elderly with different gender, educational background, whether they have medical insurance or not and whether they are exposed to suspected cases, but there is no significant difference in age and whether they have religious beliefs, as shown in **Table 2**. In terms of gender, the male elderly were significantly higher than the female elderly ($P < 0.001$); In terms of age, there was no significant difference in negative emotion scores between 55 and 65 years old group and > 65 years old group; In terms of educational background, the negative emotion of the elderly with primary school education and below is the highest, and the post test (LSD) shows that it is significantly higher than that with high school education; In terms of medical insurance, the elderly without medical insurance have the highest negative emotion score, which is significantly higher than those with partial medical insurance and complete medical insurance; In terms of whether to contact suspected cases, the negative emotions of the elderly with suspected cases were significantly higher than those without contact ($P < 0.01$).

Descriptive Statistical Analysis and Correlation Analysis

The mean value, standard deviation and correlation matrix of each variable are shown in **Table 3**. Epidemic concern was significantly positively correlated with negative emotion and negatively correlated with subjective economic status; Negative emotion was negatively correlated with subjective economic status and physical health perception; There was no significant correlation between physical health perception and epidemic

concern and subjective economic status. According to the establishment criteria of intermediary variables and regulatory variables proposed by Wen et al., if a variable has little correlation with independent variables or dependent variables, it cannot become an intermediary variable, but it can become a better regulatory variable (30). It can be seen that subjective economic status is significantly negatively correlated with epidemic concern and negative emotion, which can be used as an intermediary variable; However, there is no significant correlation between physical health perception and epidemic concern, which is a better regulatory variable.

Moderated Mediation Model Test

According to Wen et al. (31, 32), a moderated mediation model needs to meet the following four conditions: (1) The effect of independent variables on dependent variables is significant; (2) The effect of independent variables on mediator variable is significant; (3) The effect of intermediary variables on dependent variables is significant; (4) The interaction between independent variables and moderator variable has significant effect on mediator variable, or the interaction between mediator variable and moderator variable has significant effect on dependent

TABLE 3 | Correlation coefficients between variables.

Perception of physical health	15.81	3.45	−0.047	−0.277**	−0.033	—

*N = 318; *p < 0.05; **p < 0.01; ***p < 0.001.*

variables. Therefore, this article needs to test: (1) epidemic concern has a significant effect on negative emotions; (2) Epidemic concern has a significant effect on subjective economic status; (3) Subjective economic status has a significant effect on negative emotion; (4) The interaction between epidemic concern and physical health perception has a significant effect on subjective economic status, or the interaction between subjective economic status and physical health perception has a significant effect on negative emotion. The first three conditions are the test of the mediating effect of subjective economic status between epidemic concern and negative emotion, and the fourth condition is the test of the moderating effect of physical health perception on this mediating model. Before the test, according to the standardization requirements of mediation and moderating effects, this study centralizes all variables, and then multiplies the scores of physical health perception and epidemic concern, as well as the scores of physical health perception and subjective economic status as interactive items (33).

(1) Intermediary model test of subjective economic status

The first three conditions were tested by multiple stepwise regression analysis, that is, to verify the intermediary role of subjective economic status between epidemic concern and negative emotion. The results showed that in the first step regression equation, epidemic concern had a significant positive predictive effect on the negative emotions of the elderly ($\beta = 0.492$, $t = 10.058$, $P < 0.001$), indicating that epidemic concern can promote negative emotion; In the second step regression equation, epidemic concern has a significant negative predictive effect on subjective economic status ($\beta = -0.138$, $t = -2.479$, $P < 0.05$); The third step is to incorporate the independent variable epidemic concern and the intermediary variable subjective economic status into the regression equation. It is found that the subjective economic status has a significant negative predictive effect on the negative emotion of the elderly ($\beta = -0.395$, $t = -8.917$, $P < 0.001$), indicating that subjective economic status can delay negative emotions, and emotional information attention can still significantly predict negative emotions ($\beta = 0.438$, $t = 9.899$, $P < 0.001$), indicating that subjective economic status plays a partial mediating role between epidemic concern and negative emotion. As shown in **Table 4**, the first three conditions have been met.

(2) The moderator role of physical health perception in mediating model

TABLE 4 | Intermediary model test of subjective economic status.

	Physical health perception					−0.248	−5.914***	[−0.330 to −0.165]
	Epidemic concern × physical health perception					−0.099	−1.946	[−0.199∼0.001]
	Subjective economic status × physical health perception					0.055	1.287	[−0.029∼0.139]

*N = 318; *p < 0.05; **p < 0.01; ***p < 0.001.*

The fourth condition uses model 59 in the process program developed by Hayes to test the moderated mediation model, and takes physical health perception as the regulating variable into the equation. The results are shown in **Table 5**. Epidemic concern and physical health perception have significant negative prediction on subjective economic status, and their interaction items have significant positive prediction on subjective economic status ($\beta = 0.403$, $P < 0.001$), indicating that physical health perception has a moderating effect on epidemic concern → subjective economic status; Epidemic concern and physical health perception have significant negative predictive effects on negative emotions, but the interaction between epidemic concern and physical health perception and the interaction between subjective economic status and physical health perception have no significant predictive effects on negative emotions ($\beta_{\text{Interactionitem 1}} = -0.099$, $P > 0.05$; $\beta_{\text{Interactionitem2}} = 0.055$, $P > 0.05$), indicating that physical health perception has no moderating effect on epidemic concern → negative emotion, subjective economic status → negative emotion. It can be seen that physical health perception plays a moderator role in the first half path of epidemic concern → subjective economic status → negative emotion mediation model, but does not play a regulatory role in the second half path of mediation model and in the direct path of epidemic concern to negative emotion.

In order to specifically explore the moderating effect of physical health perception, add or subtract a standard deviation from the average value of physical health perception and epidemic concern score, and divide it into low physical health perception group, high physical health perception group, low epidemic concern group and high epidemic concern group. Make the slope diagram of moderating effect (as shown in **Figure 2**) to further analyze its simple effect. The results showed that in the group with low level of physical health perception, epidemic concern significantly negatively predicted subjective economic status ($t = -6.888$, $P < 0.001$); In the group with high level of physical health perception, epidemic concern significantly positively predicted subjective economic status ($t = 3.201$, $P < 0.01$). The results show that physical health perception plays a regulatory role between epidemic concern and subjective economic status.

DISCUSSION

This study found of the elderly in the COVID-19 period were very serious, the number of elderly people without depression, anxiety or stress in the COVID-19 is 0, and most of them are in serious and severe degrees, with anxiety being the most serious, followed by stress and depression, shown in **Table 6**. 44.03% of the elderly were in a state of serious depression, 94.34% of the elderly were in a state of serious anxiety, and 70.13% of the elderly were in a state of serious stress. It can be seen that the

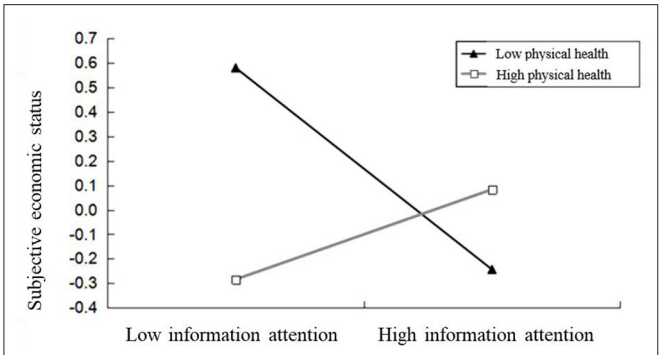

FIGURE 2 | The moderator role of physical health perception between epidemic concern and subjective economic status.

TABLE 6 | Number and proportion of people with different symptoms of depression, anxiety and stress.

	Depression	Anxiety	Stress
None	0	0	0
Mild	40 (12.58%)	0	4 (1.26%)
Medium	61 (19.18%)	4 (1.26%)	40 (12.58%)
heavier	77 (24.21%)	14 (4.40%)	51 (16.04%)
Serious	140 (44.03%)	300 (94.34%)	223 (70.13%)

elderly in the epidemic period, as a vulnerable group, are a group that needs to be cared for in social psychological counseling and crisis intervention.

Like the conclusions of other studies, the anxiety, depression and stress of the elderly men are significantly higher than those of women (2). The elderly in different age groups do not score significantly in negative emotions, because COVID-19 is a high-intensity stressful life event, which poses a major threat to the mental health of all people, and has become an important stressor causing people's psychological balance disorder (34). The elderly with primary school education and below have the highest negative emotions, which may be that the teachers with low education level lack effective information about the epidemic and lack confidence in how to prevent the epidemic, resulting in a large degree of anxiety, stress and depression. Previous studies have found that religious belief has a significant positive impact on the health status of the elderly, and its important way is to participate in religious activities. This social capital helps to alleviate the loneliness of elderly believers (35). This study found that religious beliefs have no significant impact on the negative emotions of the elderly under the epidemic. The reason for this phenomenon is that for the sake of epidemic prevention and control, gathering activities are limited, and religious worship and other activities are also greatly affected. To some extent, this finding shows that the mental health of Chinese elderly believers mainly benefits from external religious orientation rather than internal religious orientation. Different from the research of Zhou Qin and others, old-age insurance such as the new rural cooperative medical insurance, as a stable source of income, has played a positive role in improving residents' mental health, while the corresponding role of medical insurance systems such as the new rural cooperative medical system is basically not significant (36). This study found that medical insurance can greatly improve the mental health of the elderly, which is related to the special period of the epidemic. The elderly exposed to suspected cases have significant negative emotions because they are worried about being infected and are transmitted to their families.

Correlation analysis showed that epidemic concern was significantly positively correlated with negative emotion and negatively correlated with subjective economic status; Negative emotions are significantly negatively correlated with subjective economic status and physical health perception. Further analysis shows that epidemic concern has a significant positive predictive effect on negative emotions. This conclusion is consistent with the previous research results (3). The more concerned about epidemic information, the more sensitive to various information, which is more likely to lead to certain negative emotions.

The mediating effect model shows that subjective economic status plays a partial mediating role between epidemic concern and negative emotion, indicating that epidemic concern directly leads to the generation of negative emotional experience of the elderly on the one hand, and indirectly reduces the generation of negative emotional experience of the elderly through subjective economic status on the other hand. This shows that economic status is an important factor affecting the physical and mental health of the elderly in Normalization Period of COVID-19. Existing studies have also confirmed that Socio economic status is one of the fundamental factors affecting people's physical and mental health (37); the improvement of economic level will help individuals obtain better positive psychological resources, which will directly improve the mental health of the elderly and reduce the occurrence of emotional and behavioral problems (38).

The interaction between epidemic concern and physical health perception has a significant positive prediction on subjective economic status, indicating that physical health perception plays a moderating effect in the impact of epidemic concern on subjective economic status. Further simple slope analysis shows that different levels of physical health perception play different roles in the relationship between epidemic concern and subjective economic status: the older people with low-level physical health perception pay more attention to the epidemic, the lower their subjective economic status, and the lower their attention to the epidemic, the higher their subjective economic status; Different from the elderly with high-level physical health perception, the lower their attention to the epidemic, the lower their subjective economic status. The more they pay attention to the epidemic, the higher their subjective economic status. According to the theory of limited cognitive resources, people's cognitive resources are limited, which makes people have to allocate limited resources to different activities or different aspects of the same activity (39). When the elderly are weak and ill, they will continue to pay attention to their health, so that their cognitive resources have been occupied. Therefore, those who allocate more cognitive resources to obtain epidemic information are often those with poor economic conditions.

Compared with those with good economic conditions, they are more likely to perceive the threat of the epidemic to their health; Correspondingly, the cognitive resources of healthy elderly people do not focus too much on their own physical health. They pay more attention to the external world. The more types of activities they participate in, the better their health will benefit. These are closely related to economic conditions (40). Therefore, those who pay more attention to epidemic information are often those with better economic conditions.

CONCLUSION

To sum up, this study found that subjective economic status and physical health perception play a regulatory intermediary role between epidemic concern and negative emotions, which is of great significance to prevent and reduce the occurrence of psychological crisis and effectively carry out psychological counseling for the elderly during the epidemic period. Firstly, the intermediary role of subjective economic status suggests that we can start from the aspects of medical insurance, ensuring the living standard of low-income people and increasing income; Secondly, the differential moderating effect of physical health perception suggests that different targeted strategies should be adopted in prevention and intervention. For the elderly with low physical health, we should focus on life security and physical health maintenance, while for the elderly with good physical health, we should release effective epidemic information to guide them to actively participate in epidemic prevention and control.

Sharma S, Gupta S, Gupta D, Rashid J, Juneja S, Kim J and Elarabawy MM (2022) Performance Evaluation of the Deep Learning Based Convolutional Neural Network Approach for the Recognition of Chest X-Ray Images. Front. Oncol. 12:932496. doi: 10.3389/fonc.2022.932496

Recent advancement in the field of deep learning has provided promising performance for the analysis of medical images. Every year, pneumonia is the leading cause for death of various children under the age of 5 years. Chest X-rays are the first technique that is used for the detection of pneumonia. Various deep learning and computer vision techniques can be used to determine the virus which causes pneumonia using Chest X-ray images. These days, it is possible to use Convolutional Neural Networks (CNN) for the classification and analysis of images due to the availability of a large number of datasets. In this work, a CNN model is implemented for the recognition of Chest X-ray images for the detection of Pneumonia. The model is trained on a publicly available Chest X-ray images dataset having two classes: Normal chest X-ray images and Pneumonic Chest X-ray images, where each class has 5000 Samples. 80% of the collected data is used for the purpose to train the model, and the rest for testing the model. The model is trained and validated using two optimizers: Adam and RMSprop. The maximum recognition accuracy of 98% is obtained on the validation dataset. The obtained results are further compared with the results obtained by other researchers for the recognition of biomedical images.

Keywords: biomedical images, convolutional neural network, deep learning, chest X-rays, optimizers

1 INTRODUCTION

Fungi, bacteria, or viruses fill the lungs with fluid, which is the main reason for the infection of the lungs. This infection which is known as Pneumonia causes effusion of the pleural as well as inflammation in the air sacs. Pneumonia is the cause of 15% of the deaths in children who are below the age of 5 years (1). Pneumonia is more prevalent in underdeveloped or developing 'countries with scanty medical resources. This disease can be fatal if not diagnosed and treated early. It can cause the failure of the respiratory system or inflammation can be uncontrolled. For its diagnosis: Magnetic

resonance imaging (MRI), radiography (X-ray), or computed tomography (CT) is frequently used, whereas radiography or X-ray is most commonly used as it is an inexpensive and non-invasive examination. Chest X-ray is the radiology test in which the chest is exposed to radiation to produce an image of the internal organs of the chest. Once the chest X-ray is produced then the radiologist interprets the organs of the chest by looking at the image produced. An automated system is required which can detect the Pneumonia for the X-ray image as manual chest X-ray examination is prone to variability (2). Sometimes the X- rays are not very clear, which makes it difficult for the radiotherapist to identify the features that help in the detection of disease. Therefore, a deep learning-based CNN model is required that can automatically recognize the healthy and pneumonic lungs from the Chest X-ray images (3). Deep learning and machine learning in the field of Artificial Intelligence that is being used in various fields like visual recognition, natural language processing (NLP), self-driving cars, fraud detection, news aggregation, and so on. Deep Learning based Models work similar to that of a human brain, by using data as the input so that it can be processed through various layers for its recognition. These models can find the hidden features that are sometimes not possible to detect by radiologists. CNN is the main tool of deep learning models which can automatically find the various features of the images which makes the recognition of images possible for different classes.

Figure 1 shows the X-ray images of the lungs for the healthy and Pneumonic chest. **Figure 1A** is the healthy X-ray whereas **Figure 1B** is the Pneumonic X-ray. It can be seen that the pneumonic X-ray has white spots called infiltrates.

The paper is structured as: A review similar to the related work is given in Section 2; while Section 3 represents the methods used in this paper. The results obtained are depicted in Section 4 which is followed by the conclusion in Section 5. The contributions of the proposed work are given below:

- A CNN based model is developed which can be used for the recognition of chest X-ray images of the lungs.
- A model is evaluated to find the suitable optimizer, number of epochs as well as the learning rate (LR) which can work well on the available dataset.
- A Comparison of the proposed work with other developed models for the recognition of biomedical images.

2 RELATED WORK

Detect Pneumonia using chest X-ray images is a problem for many years (4, 5). Sometimes the chest X-rays are not clear enough to identify the 'features' that help in the diagnosis of the disease. Various machine learning, as well as deep learning models, are being used for the detection and classification of pneumonia. In machine learning techniques, various features are required to be manually extracted whereas features are automatically extracted by employing deep learning techniques for detection and classification. In this section, an attempt has been made to present the work that has been done for the recognition of biomedical images using Machine Learning as well as Deep Learning techniques. Chandra et al. (6) have employed a machine learning technique to detect pneumonia. First, the lung regions are segmented from the X-ray, and later eight statistical features are extracted from the regions which are used for classification. Once the features are extracted, various classifiers are implemented for classification like the random forest, logistic regression, and multilayer perceptron (MLP) technique. The model is evaluated on 412 images and the accuracy obtained is 95.39%. Yue et al. (7) have extracted six features from the 52 CT scanned images for the detection of pneumonia. An AUC (area under the curve) of 97% is achieved. Similarly, Kuo et al. (8) have also manually extracted various features for the detection and classification of Pneumonia. The extracted features are applied to various classification models such as decision tree, support vector machine (SVM), and logistic regression. The maximum accuracy obtained is 94.5% using the decision tree.

Features are manually extracted in machine learning techniques (9, 10) whereas features are automatically extracted in deep learning techniques (11, 12). Tuncer et al. (13) has also employed a machine learning-based technique, which has further imposed the fuzzy tree transformed technique on

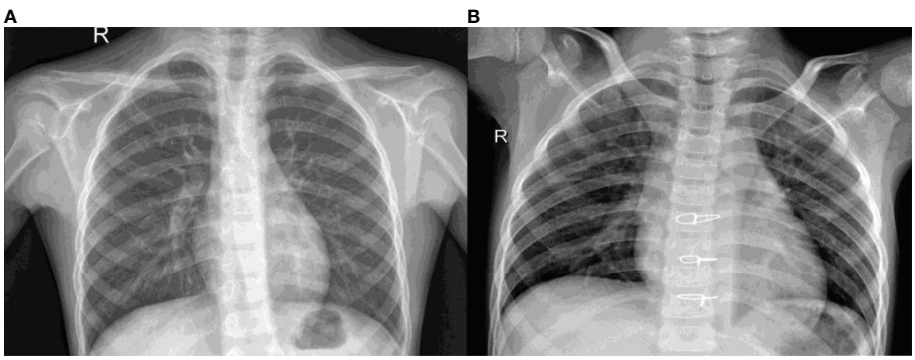

FIGURE 1 | X-ray images of the lungs **(A)** Healthy chest X-ray **(B)** Pneumonic chest X-ray.

the images. Then, various features are extracted with the help of multi-kernel local binary pattern, and later various classifiers are employed. Obtained accuracy is 97.01%. Various deep learning techniques are being employed for the detection and classification of chest X-rays.

Sharma et al. (14) implemented a CNN based model for the classification of pneumonia in Chest X-rays. The data augmentation technique is also employed to increase the data. Obtained accuracy is 90.68%. Similarly, Stephen et al. (15) also employed CNN based model by incorporating a data augmentation technique and obtained an accuracy of 93.73%. Rajpukar et al. (16) have also implemented a Deep learning-based DenseNet-121 CNN model for classifying pneumonia from Chest X-ray images. F1 score of only 76.8% is achieved. The model has not perform well due to the unavailability of the patient's history. It has been found that various machine learning and deep learning models have been implemented for recognition. Manual extraction of features is a cumbersome task as required in machine learning models, but features are not required to be manually extracted in deep learning models, which makes them easier to implement. In this work, we have obtained a recognition accuracy of 98% using a 12 layered customized CNN model with the help of RMSprop Optimizer. A suitable optimizer has also been obtained for the available dataset. The prepared model has also been evaluated using Adam Optimizer while other parameters are kept the same.

3 PROPOSED APPROACH

CNN based model is proposed for the recognition and classification of the Chest X-ray images. Publically available Kaggle dataset of X-ray images is used for recognition. The proposed Methodology of the work is given in **Figure 2** below. It can be seen from the figure that an X-ray image is given as input to the CNN model. First, the image is resized to 64X32 and then it will pass through some different layers (convolution, pooling, and flattening) after dividing into training and validation datasets. In the end, the obtained image will be passed through the output class which will predict the class of that image i.e. Pneumonic or Healthy image.

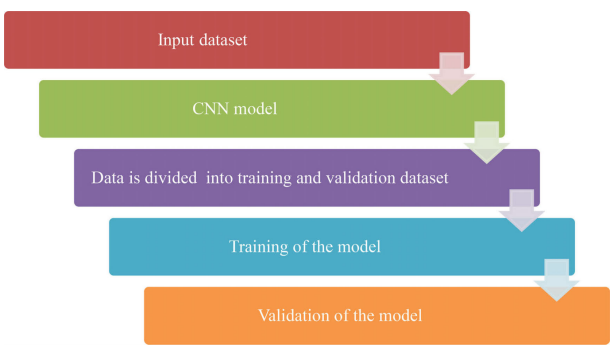

FIGURE 2 | Methodology of the proposed work.

3.1 Input Dataset

Kaggle dataset is used for classification and recognition. Data preprocessing is not required as the dataset is already available in a clean and pre-processed format. The dataset consists of two classes of chest X-ray images where each class has 5000 images of Healthy and Pneumonic Chest X-rays. 4000 images of each class are used to train the model, and 1000 images of each class are used to test the model. Few of the dataset images for Healthy and Pneumonic Chest X-rays can be observed in **Figure 3**.

3.2 Data Augmentation

To increase the number of images for each class, a data augmentation technique is employed. As data augmentation helps in improving the performance of the model a model is trained on different examples of the dataset. Flipping and Rotation of the existing dataset are carried out to enhance the dataset. **Figure 4** is showing the flipped and rotated images of the dataset.

3.3 Proposed Convolution Model

A total of 10000 images of healthy and pneumonic chest X-rays have been taken and each class has 5000 samples.

All the samples are passed through the set of three main layers of the CNN model: convolution, pooling and then the fully connected layer. The basic block diagram of the proposed model is shown in **Figure 5**. CNN model has been the biggest contributor in the field of image analysis and computer vision. CNN model or ConvNet can learn the features of various images which are used for their classification and recognition. The convolution layer helps in obtaining the feature maps from the images which are the extraction of various features. Automatic feature extraction takes place using a convolution layer. The pooling layer helps in retaining the important features while it also helps in dropping off the features which are least important for the recognition. This layer helps reduce the image size. The fully connected layer at the end helps in obtaining the output as classes. The architecture of the CNN model is shown in **Figure 6**. The X-ray image is given as input to the first layer of the model, i.e. convolution layer with 32 filters and the size of each filter is 3x3 which will help in obtaining 32 feature maps. These are given to the next layer: the Maxpooling layer with a filter pool of size 2x2 and a stride with the size (2, 2). All Maxpooling layers used in the model have the same size. In the next convolution layer, the number of filters is increased from 32 to 64 with the same size 3x3 as used earlier, which is again followed by a max-pooling layer. The number of filters in the next convolution layer increases to 128 which is followed by the max-pooling layer, and the last convolution layer has 256 filters (17, 18). In the end, a flattening layer is introduced so that the obtained pooled feature maps can be fed to the array of the neural network (19, 20). Two dense layers are introduced after the flattening layer which is followed by an output layer.

4 RESULTS AND ANALYSIS

In this section, results obtained for the recognition of chest X-rays are shown. The CNN model is trained using 80% of the data for the recognition of healthy and pneumonic chest X-rays. Once the model is trained, then it is validated using the rest of the

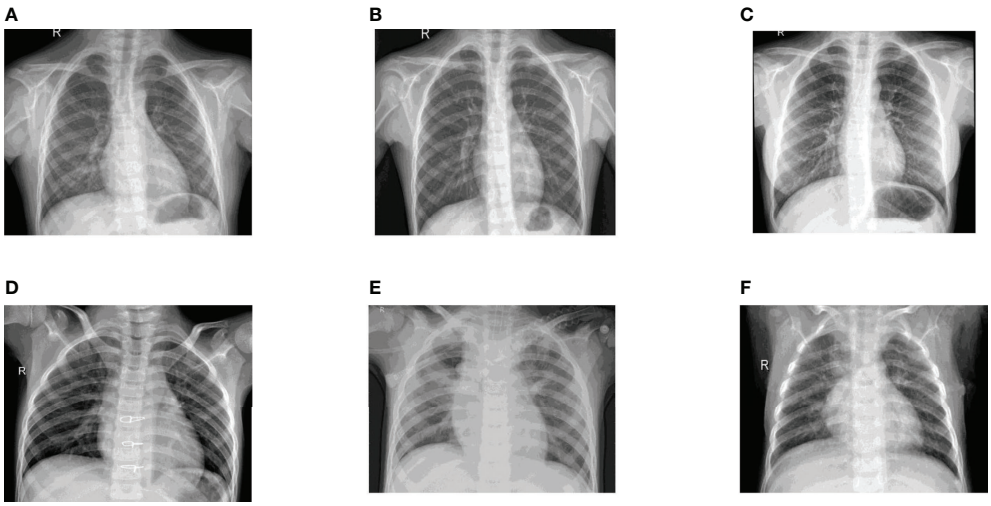

FIGURE 3 | Dataset Images: **(A)** Healthy Chest X-ray 1, **(B)** Healthy Chest X-ray 2, **(C)** Healthy Chest X-ray 3, **(D)** Pneumonic Chest X-ray 1, **(E)** Pneumonic Chest X-ray 2 and **(F)** Pneumonic Chest X-ray 3.

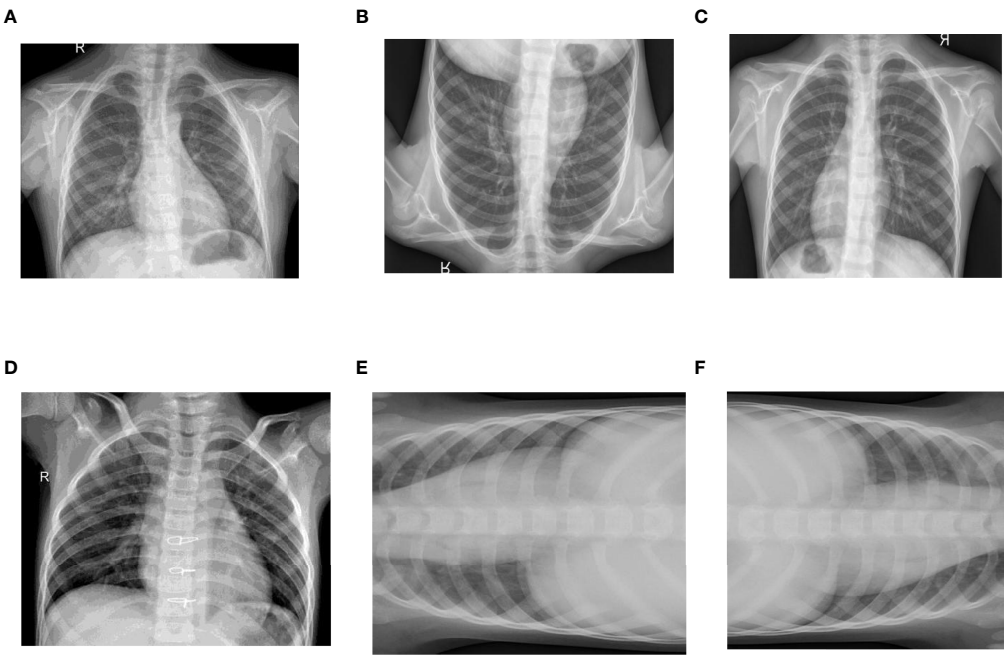

FIGURE 4 | Data Augmentation of Images: **(A)** Original Healthy Chest X-ray, **(B)** Healthy Chest X-ray Flipped Vertically, **(C)** Healthy Chest X-ray Flipped Horizontally, **(D)** Original Pneumonic Chest X-ray, **(E)** Pneumonic Chest X-ray rotated 90 degrees left and **(F)** Pneumonic Chest X-ray rotated 90 degrees right.

images. The model is trained using RMSprop as well as Adam optimizer with an LR of 0.01 and the number of epochs used is 30. The model has not perform well with the other optimizers as compared to the two selected optimizers. Even, when the number of epochs are increased from 30, the model's performance started to deteriorate or either remained the same. Therefore, the model performed at its best with the selected optimization parameters. All the results are obtained on the Google Colab, which is a free Jupyter environment that runs on the cloud.

4.1 Result Analysis Using RMSprop Optimizer

The model has been trained and validated with the help of RMSprop Optimizer where the number of epochs using which the model is trained is 30, LR used is 0.01 and Batch size of 4 is

FIGURE 5 | Block diagram of the CNN Model.

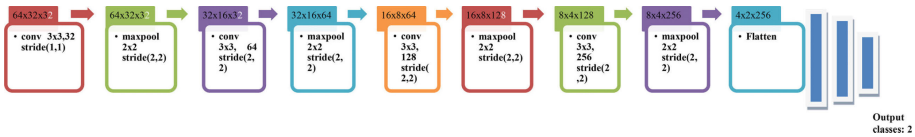

FIGURE 6 | Layered Architecture of the CNN Model.

used. The model is validated with the help of various parameters such as accuracy, loss, recall, area under the curve (AUC) and precision (19, 21).

4.1.1 nTraining and Validation: Accuracy and Loss Curves

Figure 7 is showing the results obtained on the training as well as the validation dataset. A maximum validation accuracy of 98% is obtained on the 29th epoch. In **Figure 7A**, Validation accuracy (22) is below 60% on the 1st epoch and increases till 3rd epoch to around 84% and then decreases on 4th epoch and again increases on the next epoch (23–25). The highest validation accuracy obtained is 98% on the 29th epoch, and it is 97% on the last epoch. Training accuracy also started at around 80% in the 1st epoch and going close to 90% in the last epoch. **Figure 7B** is showing the curve for the training and validation dataset. Validation loss is around 1.61 in the 1st epoch and is decreasing till the 5th epoch to 0.13 but again increasing in the 6th epoch to 1.74. The value obtained for validation loss is 0.06 on the last epoch but the minimum validation loss obtained is 0.05 on the 29th epoch itself. Training loss is 0.50 in the 1st epoch and decreases to close to a value of 0.30 in the last epoch.

4.1.2 Confusion Matrix Parameters Analysis

Performance metrics are used for the recognition of patterns and the classification of images. These parameters are important in building a perfect model which can give more accurate and precise results. Maximum validation precision, maximum validation recall, and maximum validation AUC obtained are 0.05, 98%, 98% and 99% on the 29th epoch.

The best results for the available dataset using the proposed CNN model are obtained on the 29th Epoch. **Figure 8A** shows the curve of precision for the training and validation dataset. The value of precision for the validation data is below 0.60 on the 1st epoch, increasing till the 3rd epoch and later decreasing and then increasing. The maximum value of the precision is 0.98 on the 29th epoch, while 0.97 on the last epoch. The value of precision for the training dataset is around 0.80 on the 1st epoch and goes close to 0.90 on the last epoch. The parameter convergence plot for Recall is shown in **Figure 8B**. Recall for the validation dataset is below 0.60 on the 1st epoch and 0.97 on the last epoch. The maximum value for the recall is 0.98 on the 29th epoch. The value of recall for the training dataset is 0.80 on the 1st epoch and close to 0.90 on the last epoch. The AUC for the validation and training dataset is shown in **Figure 8C**. The highest value of AUC achieved is around 0.99 on the 29th as well as 30th epoch, while the minimum value of AUC is 0.77 on the 2nd epoch and it started at 0.78 on the 1st epoch. The AUC for the training data is around 0.87 on the 1st epoch and is going close to 0.96 on the 30th epoch.

4.2 Result Analysis Using Adam Optimizer

Here the model is trained and validated using Adam Optimizer (19, 20). The number of epochs using which the model is trained is

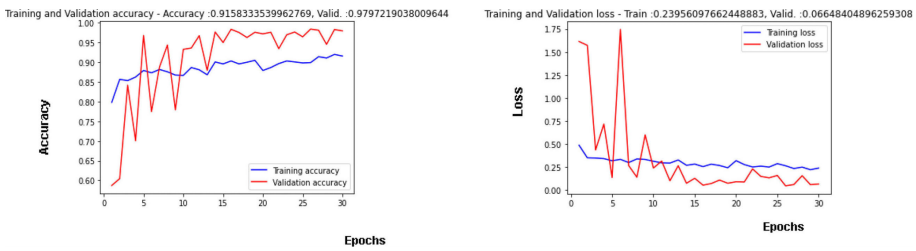

FIGURE 7 | Training and Validation Curves using RMSprop Optimizer: **(A)** Accuracy, **(B)** Loss.

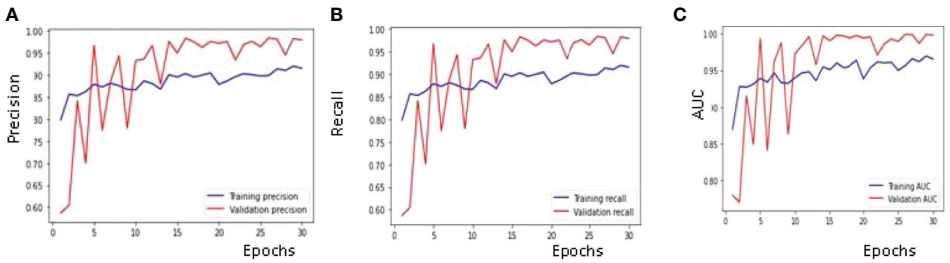

FIGURE 8 | Confusion Matrix Parameter Curves using RMSprop Optimizer: **(A)** Precision, **(B)** Recall and **(C)** AUC.

30, the LR used is 0.01, and a batch size of 4 is used. The model is validated with the help of various parameters like accuracy, loss, Recall, Area under the curve (AUC) (19, 26), and precision (22, 27).

4.2.1 Training and Validation: Accuracy and Loss Curves

Figure 9 is showing the results obtained on the training as well as the Validation dataset. The maximum validation accuracy of 97% is obtained on the 29th epoch. It can be observed from **Figure 9A** that the validation accuracy is below 60% in the 1st epoch and increases till the 4th epoch to around 94% and then decreases in the 5th and 6th epoch and again increases in the next epoch. The highest validation accuracy obtained is 97% on the 29th epoch and it is 94% on the last epoch. Training accuracy also started at around 80% in the 1st epoch and is below 90% till the last epoch. **Figure 9B** is showing the loss curve for the training and validation dataset. The validation loss is around 2.2 in the 1st epoch and is decreasing till the 5th epoch to 0.47 but again increasing in the 6th epoch to 1.25. The value obtained for validation loss is 0.15 on the last epoch but the minimum validation loss obtained is 0.08 on the 29th epoch itself. Training loss is around 2 in the 1st epoch and decreases to close to a value of 0.80 in the last epoch.

4.2.2 Confusion Matrix Parameters Analysis

Maximum validation precision, maximum validation recall, and maximum validation AUC obtained are 98%, 98% and 99% on the 29th epoch. The best results for the available dataset using the proposed CNN model are obtained on the 29th Epoch. **Figure 10A** is shows the curve of precision for the training and validation dataset. The value of precision for the validation data is below 0.60 on the 1st epoch, increasing till the 5th epoch and later decreasing and then increasing. The maximum value of the precision is 0.98 on the 29th epoch, while 0.94 on the last epoch. The value of precision for the training dataset is around 0.80 on the 1st epoch and goes close to 0.87 on the last epoch. The parameter convergence plot for Recall is shown in **Figure 10B**. Recall for the validation dataset is below 0.60 on the 1st epoch and 0.94 on the last epoch. The maximum value for the recall is 0.98 on the 29th epoch. The value of recall for the training dataset is 0.80 on the 1st epoch and close to 0.87 on the last epoch. The AUC for the validation and training dataset is shown in **Figure 10C**. The highest value of AUC achieved is around 0.99 on the 29th and it is 0.98 on the 30th epoch while the minimum value of AUC is 0.67 on the 1st epoch. The AUC for the training data is around 0.87 on the 1st epoch and is going close to 0.93 on the 30th epoch.

4.3 Results Comparison of Adam and RMS Optimizer

The parameter values obtained by using two optimizers: RMSprop and Adam are shown in **Table 1**. The table shows the results for various validation parameters such as accuracy, loss, precision, recall, and AUC (25). A model is trained and validated using 30 epochs, it can be seen that the maximum accuracy is obtained on the 29th epoch using both the optimizers. RMSprop has achieved the maximum accuracy of 98% with a minimum loss of 0.05 while Adam optimizer has obtained the

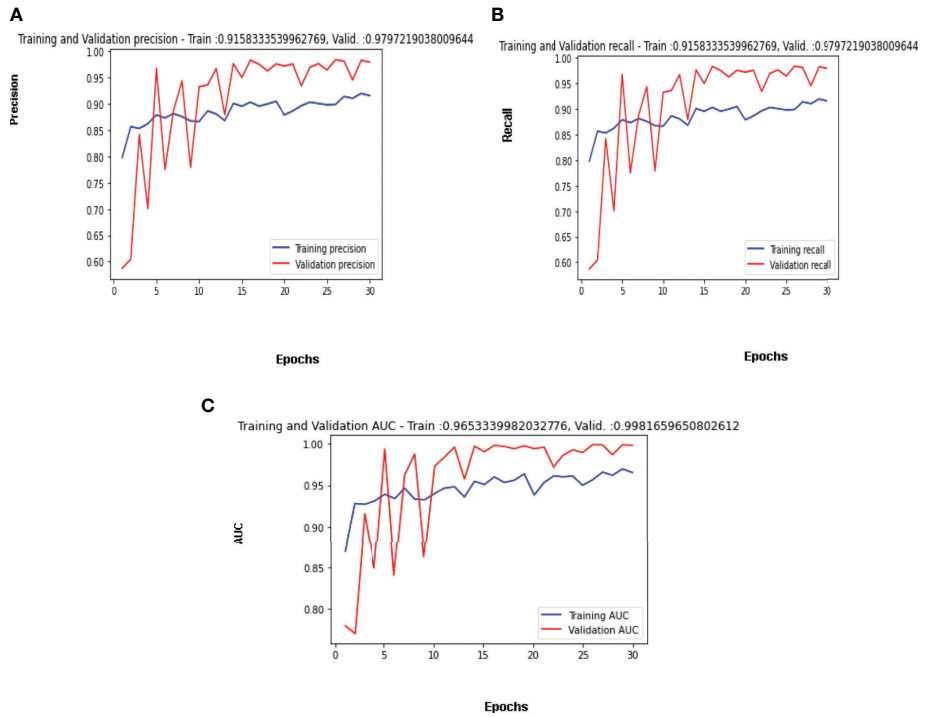

FIGURE 10 | Confusion Matrix Parameter Curves Using Adam Optimizer: **(A)** Precision, **(B)** Recall, and **(C)** AUC.

TABLE 1 | Results obtained on the Validation dataset using two optimizers: RMSprop and Adam.

Optimizer	Epoch	Accuracy	Loss	Precision	Recall	AUC
	1	0.58	1.61	0.58	0.58	0.78
	2	0.60	1.57	0.60	0.60	0.77
	3	0.84	0.43	0.84	0.84	0.91
	4	0.70	0.71	0.70	0.70	0.84
	5	0.96	0.13	0.96	0.96	0.99
RMSprop	6	0.77	1.74	0.77	0.77	0.84
	7	0.88	0.26	0.88	0.88	0.96
	28	0.94	0.15	0.94	0.94	0.98
	29	0.98	0.05	0.98	0.98	0.99
	30	0.97	0.06	0.97	0.97	0.99
	1	0.58	2.29	0.58	0.58	0.67
	2	0.73	0.50	0.73	0.73	0.87
	3	0.92	0.25	0.92	0.92	0.97
	4	0.94	0.20	0.94	0.94	0.98
Adam	5	0.81	0.47	0.81	0.81	0.89
	6	0.61	1.25	0.61	0.61	0.81
	7	0.96	0.10	0.96	0.96	0.99
	28	0.97	0.09	0.97	0.9722	0.9944
	29	0.97	0.08	0.98	0.9815	0.9953
	30	0.94	0.15	0.94	0.9450	0.9883

maximum accuracy of 97% with a minimum loss of 0.08. The results for the average accuracy of the validation and loss are also depicted in **Table 2**. Average Validation loss and Accuracy using RMSprop optimizer is 0.33 and 90% while 9.22 and 85% using Adam Optimizer. The graph representation for the same is given in **Figure 11**.

4.4 Comparison of the Proposed Work With the Existing Models

Table 3 shows a comparison of the proposed work with existing models which have been used for the recognition of biomedical images. The table shows the values of parameters obtained for the recognition of biomedical images. It can be observed in the

TABLE 2 | Comparison of the average validation loss and accuracy obtained by two optimizers.

Parameter/Optimizer		RMSprop	Adam
Average	Validation Loss	0.33	9.22
Average	Validation Accuracy	0.90	0.85

Proposed Model	Chest X-ray	• Automatic Feature Extraction • Deep Learning based CNN Model	Accuracy:98%

table that the highest recognition accuracy obtained by the proposed work is 98% by employing CNN based deep learning model in which automatic feature extraction takes place while others have achieved less accuracy.

5 CONCLUSION

As Pneumonia is a life-threatening disease that occurs due to an infection in the lungs if not detected at an early stage. Chest X-ray is the most common method for the diagnosis of the disease. Radiotherapist manually observes the features from the Chest X-ray which can help in the identification of the Pneumonia. A CNN model is proposed for the recognition of chest X-rays which are classified into 2 classes: Healthy X-rays and pneumonic X-rays. A CNN model employing two optimizers: RMSprop and Adam are used for recognition. Kaggle dataset is used for the recognition having 5000 samples of images for each class. From the obtained results, it has been observed that the RMS prop optimizer with an LR of 0.01 has helped in obtaining the maximum validation accuracy of 98% while the Adam optimizer has achieved the maximum validation accuracy of 97%. In terms of the average validation values obtained using two optimizers, it has been found that the highest average accuracy and the lowest average loss of 90% and 0.33 are also achieved using RMSprop Optimizer for the available dataset. Huge data are being taken into consideration for recognition and classification. The future direction could be to think about reducing the processing time of the data. Selective information processing is the solution, which means processing the required part of the image only instead of the whole image.

It can be concluded from the obtained results that RMSprop has outperformed Adam Optimizer for the recognition of the available dataset.

Age-related Macular Degeneration (AMD) is a kind of irreversible vision loss or disease caused by retinal pigment epithelial cells and neuroretinal degeneration, which has become the main cause of vision loss and blindness of the elderly over 65 years old in developed countries. The main clinical manifestations are cognitive decline, mental symptoms and behavioral disorders, and the gradual decline of daily living ability. In this paper, a feature extraction method of electroencephalogram (EEG) signal based on multi-spectral image fusion of multi-brain regions is proposed based on artificial neural network (ANN). In this method, the brain is divided into several different brain regions, and the EEG signals of different brain regions are transformed into several multispectral images by combining with the multispectral image transformation method. Using Alzheimer's disease (AD) classification algorithm, the depth residual network model pre-trained in ImageNet was transferred to sMRI data set for fine adjustment, instead of training a brand-new model from scratch. The results show that the proposed method solves the problem of few available medical image samples and shortens the training time of ANN model.

Keywords: artificial neural network, age-related macular degeneration, Alzheimer's disease, relevance, correlation

INTRODUCTION

Alzheimer's disease (AD) is a kind of neurodegenerative disease, which is mainly characterized by memory disorder, cognitive disorder and language disorder, and is the most common cause of senile dementia (1). The latest survey report released by the International Association of AD shows that a new AD case will appear every 3 s around the world. The exact etiology and pathogenesis of AD are not clear, so there is no complete cure for AD. Once suffering from AD, it will cause destructive damage to the physiological structure of the brain. For example, various brain regions will gradually shrink. Because this injury is irreversible, the life expectancy of patients diagnosed with AD is only about 7 years (2). Therefore, how to control the progress of AD is extremely important.

Age-related macular degeneration (AMD) is the main cause of blindness in the elderly, especially irreversible visual loss. Cognitive function is an important part of the higher cerebral cortex, which is composed of memory, attention, calculation, orientation, executive ability, and so on. AD is the most common disease type of cognitive dysfunction. The prevalence of AMD and cognitive dysfunction increases with age, which has a great impact on people's life, study and work (3, 4). Literature (5) found that the score of the simple mental state examination scale in AMD group was lower than that of the matched control group without AMD, such as age, sex, and years of education, and the prevalence of AD in AMD patients was higher than that in the control group (40.7 vs. 20.4%, $p = 0.03$). Literature (6) a large-scale prospective study of AD, AMD, and control group showed that there was no significant difference between AD group and control group. Some studies have found that AMD and AD are not only common in epidemiology, but also common in molecular aspects (7–10). It is speculated that oxidative stress may be the earliest feature of AD, and the level of heme oxygenase-1, a sensitive marker of oxidative stress, was found in the brain tissues of AD and patients with mild cognitive impairment. Literature (11) found that aggregated Aβ is not only the activator of complement system in brain, but also the activator of microglia, which leads to the increase of oxidative stress. It has been found that microglia activation also exists around drusen and subretinal space, causing damage to brain and eyes. Literature (12, 13) in a population-based prospective cohort study, it was found that the newly diagnosed dry and wet AMD group was more likely to suffer from AD or Alzheimer's disease ($p = 0.044$) than the control group with no AMD at all and matched age, sex, and entry time. Compared with wet AMD patients, the relationship between dry AMD patients and AD is more obvious.

In the deep learning algorithm, convolutional neural network and deep neural network are used to classify electroencephalogram (EEG) signals of AMD and NC. Literature (14) classifies resting EEG signals of AD patients, patients with mild cognitive impairment and normal people by combining convolutional neural network with multilayer feed-forward perceptron, and finally obtains the best accuracy of 85% for the second classification and 82% for the third classification. Literature (15) classified the resting EEG signals of patients with AD, patients with mild cognitive impairment, and normal people by using convolutional neural network, and finally got the best accuracy of 89.8% for the second classification and 83.3% for the third classification (16). In the visual working memory paradigm, features are extracted from patients' task EEG signals, and then multi-kernel SVM is used for classification. Finally, the maximum classification accuracy is 91.76 and 82.23%, respectively, under the stimulus of 0-back and 1-back tasks.

Artificial neural network (ANN) is a complex network system, which consists of a large number of simple basic elements-neurons connected with each other, and performs information parallel processing and non-linear transformation by simulating the way of human brain nerve processing information (17). ANN can simulate many basic functions and ways of thinking of the brain, and acquire external knowledge through learning and store it in the network. ANN has been widely used in economy, engineering, medicine, biology, and other fields, and has become a unique information processing discipline. Compared with digital computers, ANN is closer to the human brain in terms of composition principle and functional characteristics. "Instead of executing operations step by step according to a given program, ANN can adapt itself to the environment and summarize laws!" Complete some operation, identification or process control (18). Based on the basic theory of ANN, this paper proposes an AD classification algorithm based on transfer learning and deep residual network. Migrate the pre-trained depth residual network model in ImageNet to sMRI data set for fine-tuning, instead of training a brand-new model from scratch; The results show that the proposed method solves the problem of few available medical image samples.

CORRELATION MECHANISM BETWEEN AMD AND AD

Although AMD and AD are degenerative diseases of different tissues, because retina is an integral part of central nervous system, there may be a correlation between the pathology and pathogenesis of these two diseases.

Pathophysiological Research

Some studies have found that AMD and AD are not only common in epidemiology, but also common in molecular aspects (19). For example, the characteristic senile plaque of AD and the marker drusen of AMD have common active ingredients, the most important of which is Aβ, both of which contain and (20).

In addition, a study showed that the defects of electroretinogram were eliminated in a dose-dependent manner by administering antibodies targeting and terminals to mice. The decrease of Aβ level in retinal pigment epithelial deposits and the preservation of retinal pigment epithelial structure were related to anti-q antibody immunotherapy and visual protection. These observations are consistent with the decrease of amyloid and the improvement of cognitive function in AD mice treated with anti-Aβ antibody (21).

Relevance Mechanism

Chronic Inflammatory Reaction

Inflammatory reaction is the rapid response of cells to danger, with the aim of initiating immune response. In the short term, inflammatory reaction is beneficial, but a long-term chronic inflammatory reaction is harmful to the body. Long-term inflammation is related to the development of various chronic diseases, such as autoimmune diseases and neurodegenerative diseases (22). Amyloid protein and lipofuscin increase with age in normal eyes and brain, which activate inflammasome, complement system and autophagy lysosome and accelerate the progress of diseases (23). The studies have found that microglia activation also exists around drusen and subretinal space (24), which causes damage to brain and eyes. These phenomena are both the causes and consequences of Aβ formation. In this way, an irreversible positive feedback mechanism of pro-inflammatory cytokines and protease secretion occurs, which drives the progress of the disease (25).

Oxidative Stress

In the brain and eyes, the function of physiological cells needs oxidative stress, but when it exceeds a certain threshold, it will be cytotoxic. However, the human body has an antioxidant system to rebuild the internal balance: the dysfunction of this system may contribute to AD pathophysiology. It is speculated that oxidative stress may be the earliest feature of AD, and the level of heme oxygenase-1, a sensitive marker of oxidative stress, was found in the brain tissues of AD and patients with mild cognitive impairment. It has also been found that autophagy and lysosomes also participate in the oxidative stress process in the eyes of patients with AMD and the brains of patients with AD (26). In a word, excessive oxidative stress and dysfunction of mitochondria and lysosomes seem to be common pathophysiology in the pathogenesis of AMD and AD.

RESEARCH METHOD

Artificial Neural Network

Neural network is composed of a large number of neurons connected with each other. The processing ability of a single neuron is not strong, but after a large number of neurons are interconnected into a network, its processing ability is greatly improved. Neural network is a model obtained by abstracting and simplifying biological neural network on the basis of simulating the basic characteristics of brain. In neural networks, the storage of knowledge and information is characterized by the interconnected and distributed physical connections among neurons, while learning and recognition are the dynamic changes of the weighting coefficients of connections among neurons.

It is the basic information processing unit of ANN operation, and the neuron model contains 3 basic elements: synapse, adder and activation function. **Figure 1** shows the neuron model, where the input is signal and represents the synaptic weight of neuron .

The neuron in **Figure 1** can be described by the following equations:

$$u_j = \sum_{i=1}^{n} \left(w_{nj} x_n\right) \tag{1}$$

$$y_j = \phi\left(u_j + b_j\right) \tag{2}$$

At present, according to different problems, different ANN models are proposed, and each algorithm is different. Common network models include BP neural network model, Hofield neural network model, linear neural network model, and Kohonen self-organizing model. These ANNs are not suitable for all the problems, so we must choose the appropriate ANNs according to the different problems to be solved. BP neural network and radial basis function neural network are often used in medical diagnosis and prediction, and perceptron model is mainly used for classification in clinic.

Multi-Brain Multispectral Image Fusion Algorithm

A large number of studies have shown that there are differences in EEG signals between AMD and Normal Control (NC), which are generally manifested in five brain regions. The five brain regions are frontal lobe, parietal lobe, left temporal lobe, right temporal lobe, and occipital lobe (27). For example, in frontal lobe, there are differences between theta frequency band and delta frequency band between AMD and NC group. In parietal lobe, AMD and NC have different phase coupling in the cross-frequency band between alpha frequency band and beta frequency band. In this study, EEG signals of five brain regions were converted into multispectral images by multispectral image conversion method. Multispectral images representing different brain regions are obtained by using the method of multispectral image transformation alone in five brain regions.

In this study, the EEG signals of five brain regions were transformed into five multispectral images by the method of multispectral image conversion. Each brain region contains more electrodes, and if all the electrodes are used, the amount of calculation will be greatly increased. Therefore, some electrodes are selected from each brain region, and the EEG signals of these electrodes are converted into multispectral images.

In this study, pixel-level weighted average image fusion algorithm is used to fuse multispectral images of multiple brain regions. The fusion formula of the weighted average fusion method is shown in formula (3):

$$Y = \sum_{n} A_n X_n \tag{3}$$

In formula (3), A_n represents the corresponding weight, $\sum_n A_n = 1$, X_n represents the corresponding pixel, and Y represents the generated new pixel.

Because the multispectral image formed in this study is a 40*40*3 color image, each pixel X is composed of 3 values (RGB 3 primary colors), namely $X = (X_R, X_G, X_B)$. According to the above weighted average fusion formula, the following formula is obtained.

$$\begin{aligned} Y_R &= \sum_{n} A_n X_R \\ Y_G &= \sum_{n} A_n X_G \\ Y_B &= \sum_{n} A_n X_B \end{aligned} \tag{4}$$

That is, for the pixels in each image, the corresponding R, G, and B are taken for weighted average fusion, and finally the corresponding pixels of the new multispectral image are generated.

$$Y = \left(\sum_{n} A_n X_R, \sum_{n} A_n X_G, \sum_{n} A_n X_B\right) \tag{5}$$

In this study, the pixel-level weighted fusion method of image fusion algorithm is used to fuse these 5 images to form a new image, as shown in **Figure 2**.

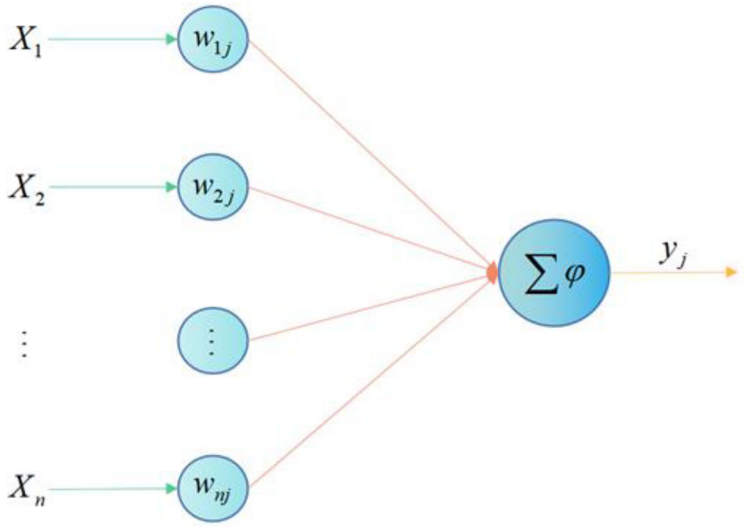

FIGURE 1 | Neuron model.

The feature extraction method of EEG signal based on multispectral image fusion of brain regions is a combination of multispectral image transformation method and image fusion method. Firstly, the EEG signals of each brain region are extracted according to the electrode position (28). Secondly, the multi-spectral image transformation method is used to transform the EEG signals of each brain region into multi-spectral images of the characteristics of each brain region. Finally, the image weighted average fusion algorithm is used to fuse the multispectral images of the five brain regions to form the fused multispectral image as shown in **Figure 2**.

Multi-brain multispectral image fusion;

Input: EEG of task EEG.

Output: multispectral images of multiple brain regions and fused multispectral images.

BEGIN

(1) $X_i = EEG(i)$. //The electrode signals of the 5 selected brain regions are extracted, in which the values of i are e, d, ZN, YN, and z, which respectively represent frontal lobe, parietal lobe, left temporal lobe, right temporal lobe and occipital lobe.

(2) $Y_i = FFT(X_i)$. //Fourier transform was carried out on EEG signals of each brain region.

(3) $Z_j = Y_i(j)$. //The values of j are alpha, beta, and theta, which means extracting signals of 3 frequency bands.

(4) $Z_j = square(Z_j)$. //Take the sum of squares for the signals of the three frequency bands respectively.

(5) Local_2d = AEP(Local_3d). //According to AEP method, the electrode 3d coordinates are converted into 2d coordinates.

(6) $D_i = Conver_to_image(Z_{theta}, Z_{theta}, Z_{beta} = R, G, B \mid$ Local _2d, Clough-Tocher$)$. //The features of the sum of squares of the three frequency bands of each electrode are transformed into images according to the 2d coordinates of the electrodes, and the surrounding pixels are filled up by Clough-Tocher interpolation method. The images formed by the three frequency bands are used as RGB channels of color images, and a color multispectral image is formed.

(7) $Output(D_i)$. //Outputting multispectral images of five brain regions.

(8) $D = \sum_i W_i D_i$. //Image-level weighted average fusion method, that is, adding corresponding pixels, in which the weight sum is 1, that is, $\sum_i W_i = 1$.

(9) $Output(D)$. //Output a new multispectral image after fusion.

END

Group Diagram Construction

The key to construct population map is to select the phenotypic measure that best explains the similarity between imaging data or the similarity between subject tags. In the ANN method, there are h sets of phenotypic information $M = \{M_h\}$ (such as gender and age of the subjects), and the adjacency matrix W of the population graph is defined as:

$$W(v, w) = sim(A_v, A_w) \sum_{h=1}^{H} \gamma(M_h(v), M_h(w)) \quad (6)$$

This formula represents the edge weight between the tested v and the tested w, which consists of 2 parts: $sim(A_v, A_w)$ represents the similarity of brain network features between the tested, and increases the edge weight between the most similar nodes; γ represents the similarity between phenotypic information.

Specifically, feature similarity is defined as:

$$sim(A_v, A_w) = \exp\left(-\frac{(\rho(x(v), x(v)))^2}{2\sigma^2}\right) \quad (7)$$

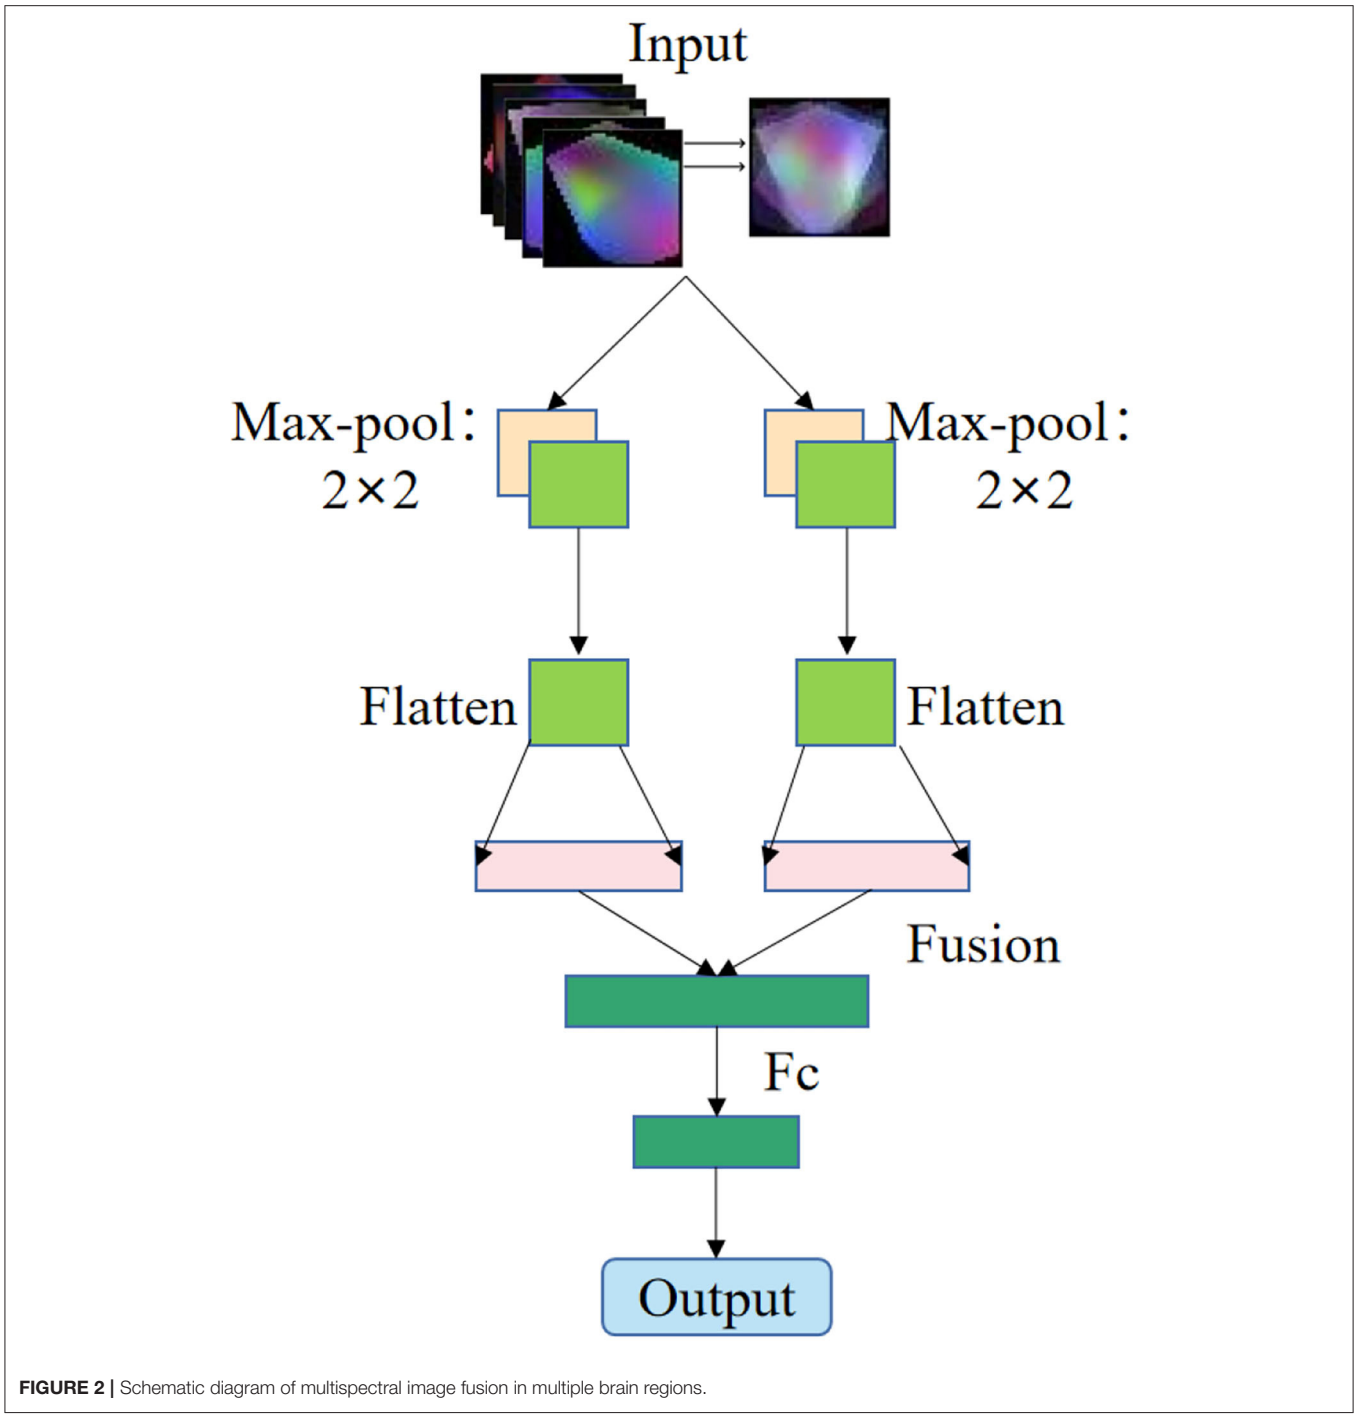

FIGURE 2 | Schematic diagram of multispectral image fusion in multiple brain regions.

Where, $\rho\left(x\left(v\right),x\left(v\right)\right) \in (0,1)$ is the similarity distance between two subjects, and the more similar the two groups are, the closer the similarity distance is to 1; σ is the kernel width, so the neighborhood range can be customized.

The idea of this feature similarity measure is that subjects belonging to the same class (healthy or ill) have more similar networks than subjects from different classes, that is, larger sim values. The definition of phenotypic information similarity can be divided into quantitative type and qualitative type (29). For qualitative phenotypic information with gender as an example, the Kroneckerdelta formula is used to defineγ. For example, if two subjects have the same gender, the weight of the edge between two nodes will increase.

For quantitative phenotypic information with age as an example, if the difference between them is less than the present value, it is considered to be similar, and the edge weight between

two nodes is set to 1; otherwise, it is considered that the information is not similar, and the edge weight is 0. γ is defined by a unit step function with threshold θ, which includes:

$$\gamma\left(M_h\left(v\right), M_h\left(w\right)\right) = \begin{cases} 1, & \left(\left|M_h\left(v\right), M_h\left(w\right)\right| < \theta\right) \\ 0, & \text{Otherwise} \end{cases} \tag{8}$$

Finally, the similarity of eigenvalues is multiplied by the similarity of phenotypic information, which is integrated into the total edge weight to obtain the final group adjacency matrix, that is, the graph structure. This definition of similarity reflects strong similarity in the same test.

AD Classification Algorithm

The Residual Neural Network (ResNet) was proposed by He et al. (30). The depth ResNet consists of a group of residual blocks, each of which consists of convolution layer, batch normalization layer and active function rectification linear unit. ResNets can be regarded as multiple basic blocks connected in series with each other. This shortcut can skip each basic block in parallel and then connect it to the output of the stack layer. It is easier to optimize the residual mapping than to optimize the original, unreferenced mapping.

Based on the special design of deep ResNet, the problems such as gradient explosion and gradient disappearance are effectively suppressed, so that the network can be fully trained, the number of network layers is deepened, and the performance of parameter optimization space is improved. Because the pre-trained ResNet-20 model accepts an image input size of $214 \times 214 \times 4$, we convert each sMRI slice image into a size of $214 \times 214 \times 4$, and then subtract the average intensity value from the corresponding single image channel to normalize the image. Then, we will migrate the ResNet-20 model pre-trained in ImageNet to the data set for fine-tuning.

In addition, because the number of parameters in the fully connected layer is too large to be trained, we removed the original fully connected layer and retrained a fully connected layer $F\left(e\right)$ whose length depends on the number of categories, and e represents the number of categories.

In order to prevent over-fitting, we also added a dropout layer with a loss rate of 0.1. p_{ave} indicates that average pooling is used in this paper. The softmax function used in the training process is shown in the following formula:

$$\text{softmax}\left(\mathrm{F}_j\right) = \frac{\exp^{\mathrm{F}_j}}{\sum_{k=1}^{e} \exp^{\mathrm{F}_k}}, j = 1, 2, \cdots, e \tag{9}$$

We use the cross-entropy loss function to measure the performance of the classification model, and its output is a probability value between 0 and 1. Cross entropy loss increases with the distance that the predicted output deviates from the actual label. If the number of classes is two, the binary cross entropy loss is calculated as follows:

$$L\left(y, p\right) = -\left(y \log p + \left(1 - y\right) \log\left(1 - p\right)\right) \tag{10}$$

If $e > 2$, the classification cross entropy loss is calculated as follows:

$$L\left(y, p\right) = -\sum_{\mathrm{c}=1}^{\mathrm{e}} \mathrm{y}_{\mathrm{o,c}} \log\left(p_{\mathrm{o,c}}\right) \tag{11}$$

Where y is the actual value and p is the predicted value. The optimization algorithm for updating parameters is RMSprop (root mean square propagation), and the learning rate is set to 0.0001. The flow chart of AD classification algorithm based on transfer learning and deep residual network is shown in **Figure 3**.

RESULT ANALYSIS AND DISCUSSION

In this study, k-fold cross-validation method ($K = 5$) is used to evaluate the model, but the problem of this study belongs to classification. For the algorithm proposed in this study, the generalization performance of the model will be evaluated by selecting the functions of calculation accuracy, recall rate, F1 value, AUC value, average validation accuracy and average validation loss. Among them, for the new algorithm proposed in this study and its comparative experiments, all evaluation indexes are used, while for some basic experiments, only verification accuracy is used as the only evaluation index.

Experimental Results of EEG Feature Extraction Method Based on Multispectral Image Fusion in Multiple Brain Regions

Figure 4 shows the graph of the average verification accuracy of multispectral image experiments in multiple brain regions. YN stands for right temporal lobe, ZN stands for left temporal lobe, Z stands for occipital lobe, D stands for parietal lobe, 18 stands for 18 brain regions commonly used in related research, E stands for frontal lobe, and All stands for all brain regions selected by the above five regions.

It can be seen from the figure that the curve representing All is the highest, and the accuracy reaches the highest point around the 30th epochs, which can remain stable, but the curve fluctuates. In other cases, the curves representing E, 18 and D are slightly lower than All, and the accuracy reaches the highest point around the 35th epochs and remains stable. While the curves representing z, ZN and YN are low, and the accuracy reaches the highest point around the 50th epochs and remains stable.

Figure 5 shows the graph of the average verification loss function of multispectral image experiment in multiple brain regions.

It can be seen from **Figure 5** that the curve representing All is the lowest, and the loss function value can reach the lowest around the 30th epochs, but the curve fluctuates greatly. In other cases, the curves representing f, 18 and p are slightly higher than All, and the loss function value reaches the lowest point around the 50th epochs and remains stable. While the curves representing o, LT and RT are higher, and the loss function value reaches the lowest point around the 55th epochs and remains stable.

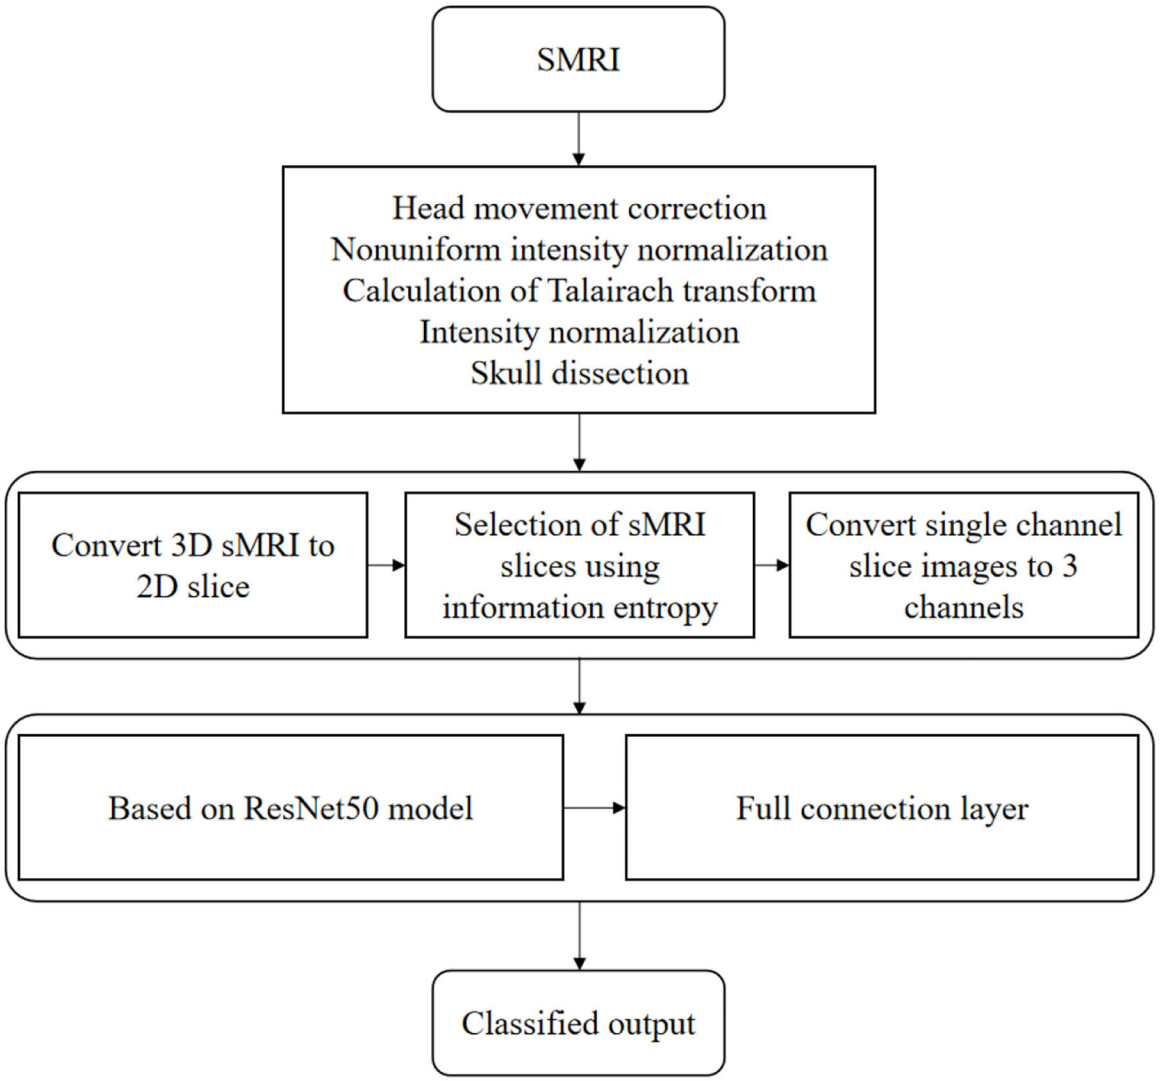

FIGURE 3 | AD classification algorithm flow chart.

Figure 6 shows the average verification accuracy rate, average recall rate, average F1 value and average AUC value of this experiment.

Figure 6 shows that the frontal lobe has the highest value among the 5 multi-spectral image classification performance indexes, which are 97.24% of the average verification accuracy, 97.80% of the average recall rate, 97.60% of the average F1 value and 99.01% of the average AUC value.

In addition, among the seven brain regions, the multispectral image classification performance index of ALL brain regions is in the best position, and the average verification accuracy rate, recall rate, F1 value and AUC value are 97.96, 97.82, 97.88, and 98.35%, respectively.

It can be concluded that the fused multispectral image can complement the information contained in the multispectral image of multi-brain region, so that the fused image has richer feature information, thus improving the classification accuracy. At the same time, the research results of this paper have surpassed the classification performance of previous AMD EEG studies.

In the future, many different image fusion technologies can be used to fuse multispectral images, and the positive and negative relationships among brain regions can also be considered, so as to refine the fusion of multispectral images with multiple brain regions, and the amount of data can be increased by increasing the number of subjects, so as to further verify the rationality of this method.

AD Classification Algorithm Analysis

All the classification models proposed in this paper are trained and tested in NVIDIA GeForce GTX 1060 GPU system based on Keras. One advantage of Keras is that it can easily and quickly prototype and run seamlessly on GPU. In this paper, transfer learning is introduced, only some layers of the pre-trained ANN model are trained, and the amount of data used in

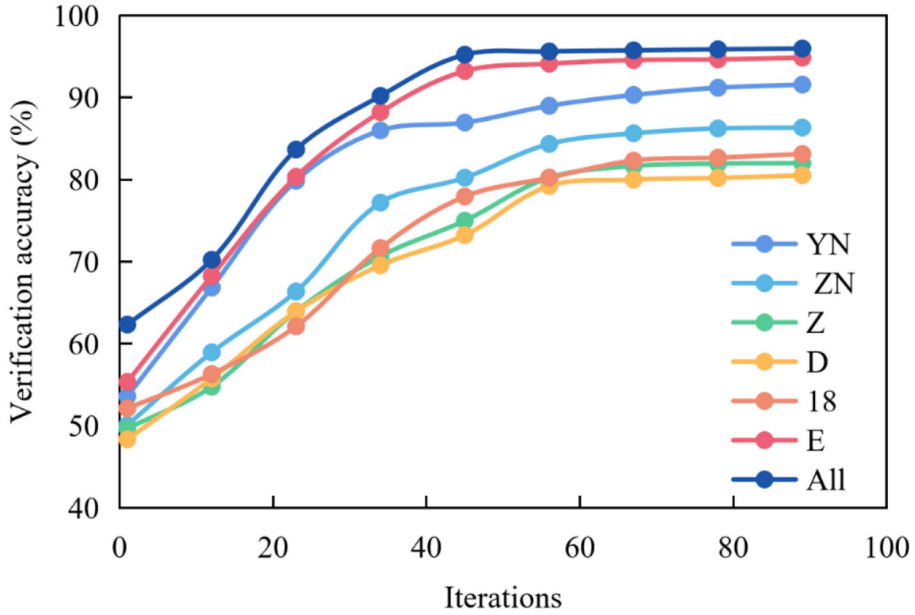

FIGURE 4 | Average verification accuracy curve of multispectral image fusion in multiple brain regions.

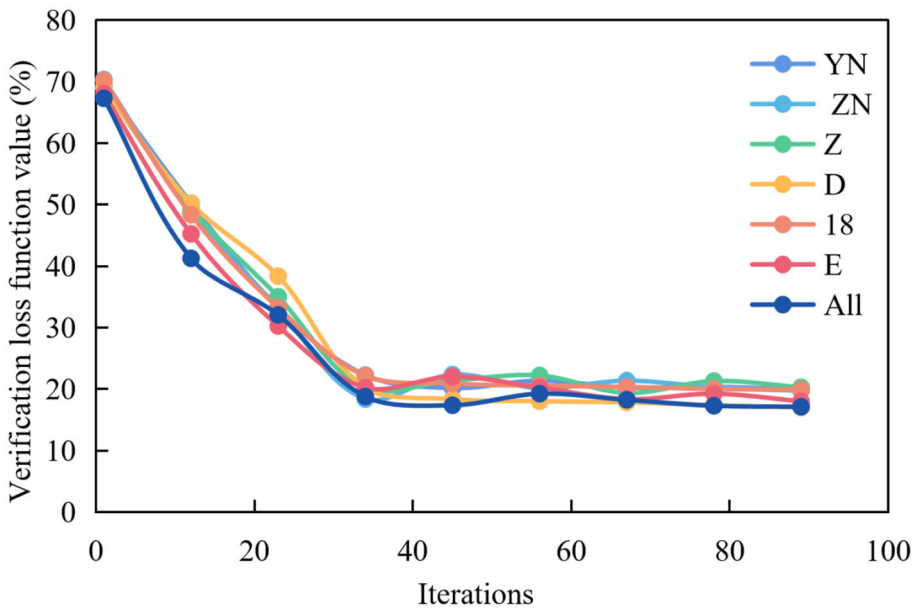

FIGURE 5 | Average verification loss function curve of multispectral image fusion in multiple brain regions.

this experiment is small, so this experiment can be completed in this GPU system.

In order to record the experimental results conveniently, we call our method ResNet-20_TL. The classification results of AD, NC, and AMD by the method proposed in this paper are shown in **Figure 7**.

For binary classification, the accuracy, sensitivity and specificity of the model trained in this paper are 97.66, 90.25, and 96.33% in AD/AMD classification, 90.01, 86.35, and 91.24% in AD/AMD classification, and 92.35 and 82.35% in NC/AMD classification, respectively. For ternary classification, the classification accuracy, sensitivity and specificity of the proposed method are 87.69, 73.21, and 85.46%, respectively.

It can be seen from **Figure 7** that AD and NC are the easiest categories to judge, while AMD is easy to be confused with AD

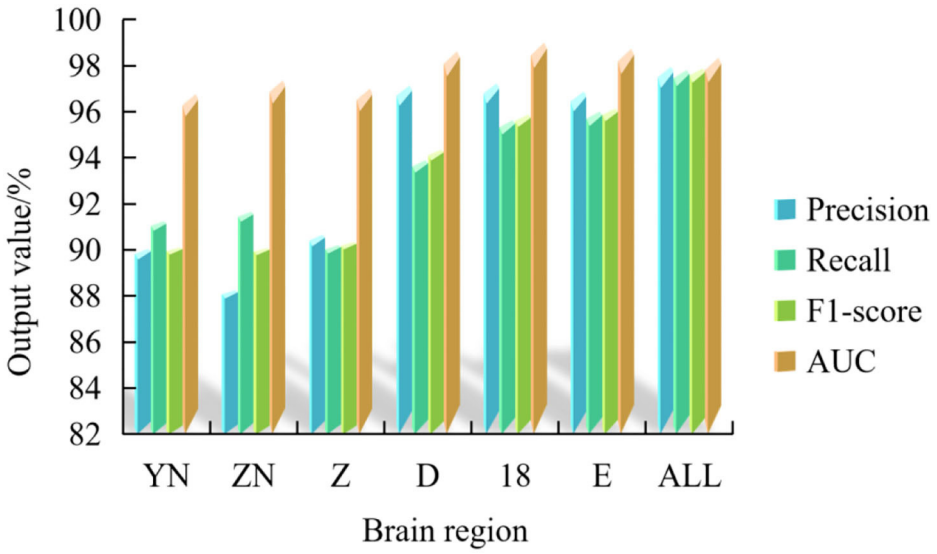

FIGURE 6 | Average accuracy rate, recall rate, F1 value and AUC of multispectral image fusion experiments in multiple brain regions.

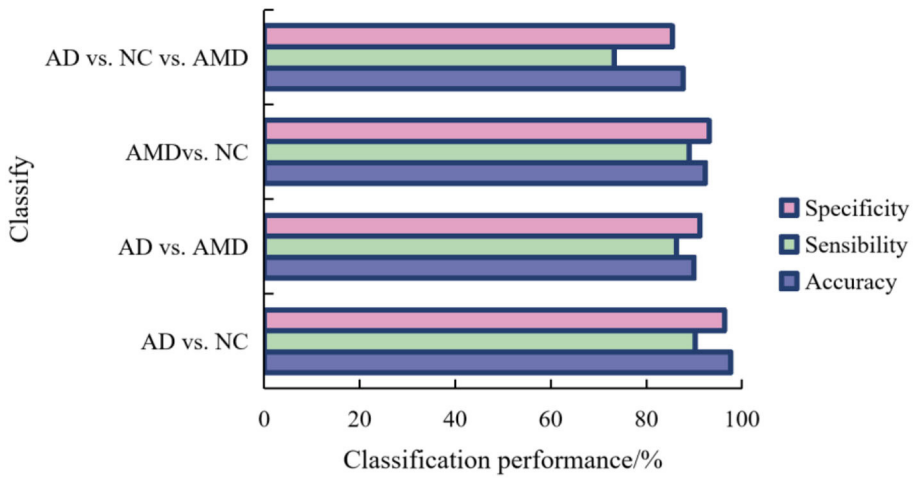

FIGURE 7 | PerformaNCe of ResNet-20_TL model in AD, NC, and AMD classification.

and NC. this is because the brain structure of the subjects in different stages of the disease changes to different degrees, the brain tissue of the subjects in AD shrinks seriously, and the brain of the subjects in NC is in a normal state, so the difference in scanned sMRI images is larger, and the proposed method is easier to extract discriminatory features, thus improving the classification performance.

It can also be seen from **Figure 7** that compared with binary classification, the accuracy and specificity of AD/NC/AMD classification are lower than 90%, and the sensitivity is lower, mainly because AMD is the intermediate stage between AD and AMD, which leads to the "distance" between features being not obvious enough, so it is not easy to distinguish, which leads to the unsatisfactory accuracy of ternary classification.

In addition, in order to prove the ability of migration learning, we also trained ResNet-20 network from scratch, which is represented by ResNet-20_scratch. For ResNet-20 model trained from scratch, 20 epochs were trained, and the batch was still 64. The adaptive learning rate was used, and the parameters were optimized by RMSProp.

In order to compare the classification performance of ResNet-20_TL model and ResNet-20_scratch model more intuitively, we use a column chart to show it, as shown in **Figure 8**. Obviously, the fine-tuned ResNet-20 model has better performance in each classification task than the ResNet-20 model trained from scratch.

In addition, facing the classification tasks of AMD/NC, AD/NC, AMD/AD, and AD/AMD/NC, the AUC comparison

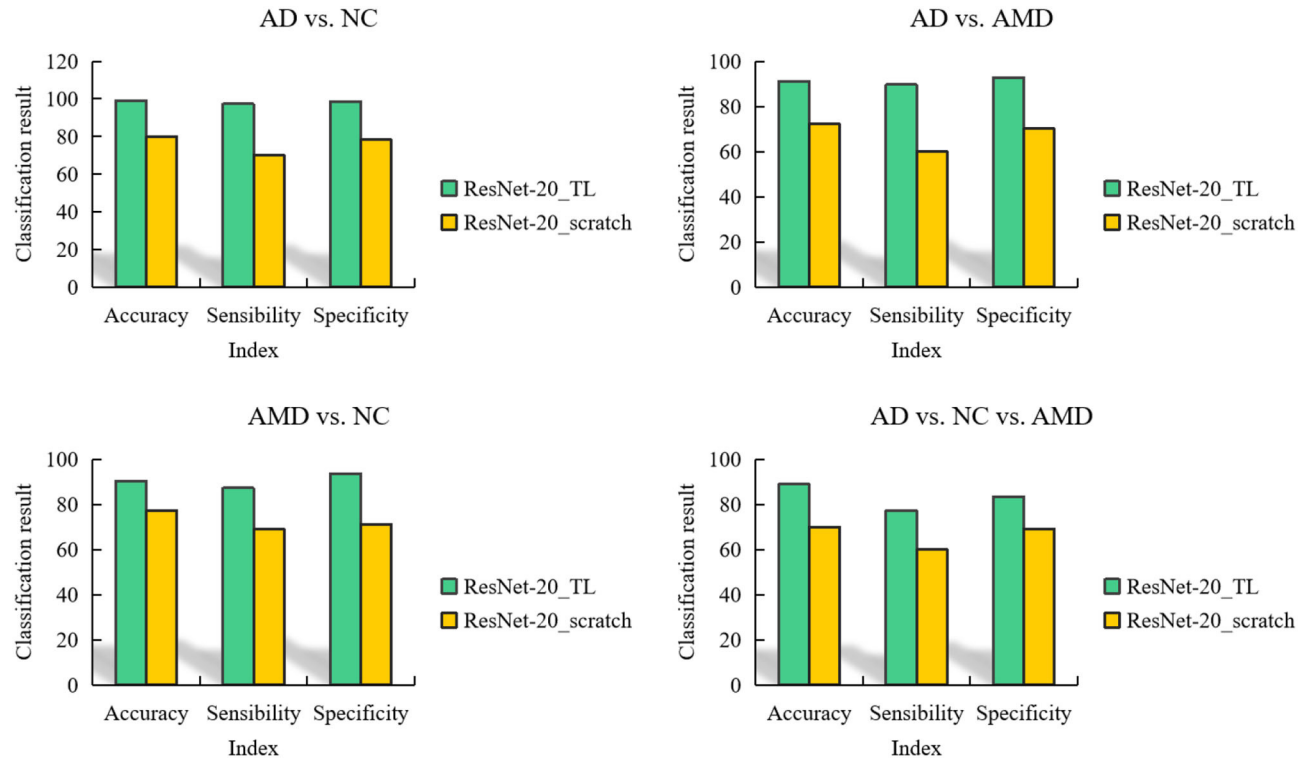

FIGURE 8 | Comparison of classification results obtained by 2 ANN models in 4 classification tasks.

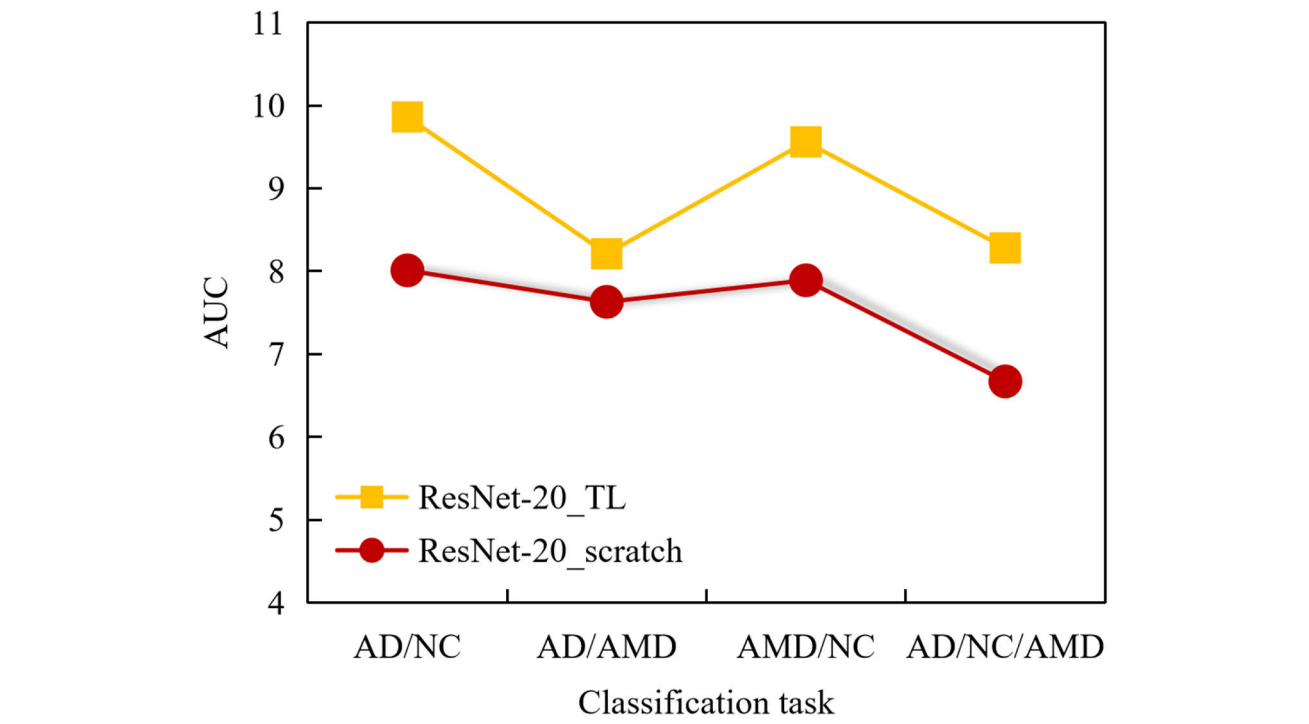

FIGURE 9 | AUC comparison curves of 2 ANN models in classification tasks AMD/NC, AD/NC, AMD/AD, and AD/AMD/NC.

diagram of the area under the curve obtained by the 2 ANN models is shown in **Figure 9**.

It can be seen from **Figure 9** that the AUC value of ResNet-20_scratch model trained from scratch is higher than 0.8 in AD/NC classification, and the AUC value of the other 3 classification tasks is lower than 0.8, and the AUC value of AD/NC/AMD classification is as low as 0.71, which indicates that the auxiliary diagnosis performance of ResNet-20_scratch model is not outstanding enough, and there is room for further improvement.

On the whole, the AUC values obtained by ResNet-20_scratch model in 4 classification tasks are lower than those obtained by ResNet-20_TL model, which also proves the effectiveness of the proposed method. It can be seen from the figure that the AUC of the 4 classification tasks obtained by ResNet-20_TL model is higher than 0.8, and the AUC value of AD/NC classification is up to 0.97, which shows that the ResNet-20_TL model proposed in this paper can help doctors to complete the diagnosis of AD subjects and NC subjects accurately.

CONCLUSION

With the increase of AD or AMD in the world, as the early stage of AD, the accurate diagnosis of AMD has become a hot spot in the field of scientific research. In the diagnosis research of AMD, there is still a problem that the classification accuracy is not high enough. ANN has a wide application prospect in many disciplines, such as forensic science. At present, a new upsurge of ANN research is being set off at home and abroad, and new networks with different architectures are constantly coming out, among which BP network, Hopfield network, stochastic neural network, self-organizing neural network, associative memory neural network and CMAC model are more mature. Experiments show that the EEG feature extraction method based on multispectral image fusion in multiple brain regions can obviously improve the classification accuracy of task EEG signals between AMD and NC. Based on the pre-trained ResNet-50 network, the proposed method is evaluated in ADNI data set, and the detailed experimental results are given. The results show that the classification accuracy of the proposed method is better than that of the network model trained from scratch.

In the future, we can consider the positive and negative factors that affect the relationship between brain regions when fusing multispectral images for multiple brain regions, so as to obtain multispectral images that express brain features more accurately. We can try to use 3D convolution neural network to train the above data set.

Cancer is a major public health issue in the modern world. Breast cancer is a type of cancer that starts in the breast and spreads to other parts of the body. One of the most common types of cancer that kill women is breast cancer. When cells become uncontrollably large, cancer develops. There are various types of breast cancer. The proposed model discussed benign and malignant breast cancer. In computer-aided diagnosis systems, the identification and classification of breast cancer using histopathology and ultrasound images are critical steps. Investigators have demonstrated the ability to automate the initial level identification and classification of the tumor throughout the last few decades. Breast cancer can be detected early, allowing patients to obtain proper therapy and thereby increase their chances of survival. Deep learning (DL), machine learning (ML), and transfer learning (TL) techniques are used to solve many medical issues. There are several scientific studies in the previous literature on the categorization and identification of cancer tumors using various types of models but with some limitations. However, research is hampered by the lack of a dataset. The proposed methodology is created to help with the automatic identification and diagnosis of breast cancer. Our main contribution is that the proposed model used the transfer learning technique on three datasets, A, B, C, and A2, A2 is the dataset A with two classes. In this study, ultrasound images and histopathology images are used. The model used in this work is a customized CNN-AlexNet, which was trained according to the requirements of the datasets. This is also one of the contributions of this work. The results have shown that the proposed system empowered with transfer learning achieved the highest accuracy than the existing models on datasets A, B, C, and A2.

Keywords: breast cancer (BC), deep learning (DL), learning rate (LR), machine learning (ML), transfer learning (TL), convolutional neural network (CNN)

INTRODUCTION

Medical imaging is a valuable tool for detecting the existence of various medical diseases and analyzing investigational outcomes. The use of biomedical imaging in cancer treatment is crucial. Cancer is a major public health issue in the modern world. According to the World Health Organization (WHO), cancer in 2018 caused 9.6 million deaths, and a probable 10 million deaths were caused by cancer in 2020 (1). Cancer tumors are caused by the uncontrollable growth of cells in the breast. One of the most frequent malignancies in women is breast cancer. BC is estimated to attack more than 8% of women at some point in their life. BC can start in any part of the breast. The majority of BC begins in the lobules or ducts. However, BC can be detected early, allowing patients to obtain proper therapy and so increase their chances of survival.

Imaging technologies such as magnetic resonance imaging (MRI), diagnostic mammography (2) (X-rays), thermography, and ultrasound (sonography) can help analyze and identify breast cancer (3). Ultrasound images are used in this proposed study. Breast cancer is classified as benign and malignant. Benign tumor cells only grow in the breast and do not split throughout the other cells. A malignant tumor is made up of cancerous cells that have the ability to expand uncontrollably, spread to other areas of the body, and infect other tissues. Because cancer cells vary in size, shape, and location, automatically detecting and localizing cancer cells in BC images are a huge difficulty. Machine learning (ML) (4) approaches have found widespread use in a variety of domains, including educational prediction, pattern recognition, image editing, feature reduction, defect diagnosis, face identification, micro-expression recognition, NLP, and medical diagnosis. Its greatest potential has been discovered in the diagnosis of breast cancer (5).

Many researchers have proposed numerous strategies for the automatic classification of cells in breast cancer detection in recent decades (6). By identifying nucleus traits, cancerous cells of breast cancer can be classified as benign and malignant. However, the system's efficiency and accuracy decrease as a result of the complexity of typical machine learning procedures such as pre-processing, segmentation, feature extraction, and others. Traditional ML problems can be solved using the recently developed DL technique. With exceptional feature representation, this technique can perform picture classification and object localization challenges. The transfer learning approach used a natural-image dataset such as ImageNet and then applied a fine-tuning technique to solve this problem. The main benefit of transfer learning is that it improves classification accuracy and speeds up the training process.

First, network parameters were pre-trained using the data and used in the required domain, and then the system restrictions were changed for improved performance. This study used a model for the classification and detection using TL. The proposed model has two components. The first component is training, and the second component is testing. BC classification can be done using a CNN pre-trained such as the ResNet50, VGG 16, VGG 19, and Inception V2 Res Net. In this work, we have done the job of BC classification and detection by using the AlexNet model. AlexNet is a powerful model that can achieve high accuracies on even the most difficult datasets. AlexNet is a leading architecture for any object identification task and classification, and it has a wide range of applications in the artificial intelligence field of computer vision. Some previous studies used the AlexNet, but in this work, we used a customized AlexNet model which has not been used before in previous studies. In the customized AlexNet, the first and last three layers of the architecture are modified, and newly modified layers are the image input layer, fully connected layer, classification layer, and softmax layer, although the remaining layers remain fixed. The customized model has all of the features for image processing that it learned during the process of training. The main goal of this project was to detect and classify breast cancer, reduce training time, increase accuracy, and enhance classification performance.

There are many previous studies on breast tumors using various types of models, but with some limitations, breast cancer has limited studies due to the lack of publicly available benchmark datasets. This proposed system worked on three datasets A, B, C, and A2, A2 is dataset A with two classes with a total number of 10,336 images, which is a good dataset. This study is the first to compare three common datasets and suggest the use of customized transfer learning algorithms for breast cancer classification and detection on multiple datasets. By using the customized AlexNet, we achieved the optimum accuracy. This work used ultrasound images and histopathology images, the sample images of ultrasounds are shown in **Figure 1**, and the sample images of histopathology are shown in **Figure 2**.

This study is divided into five sections. Section 2 is the literature review, section 3 is the proposed system model, section 4 is the simulation and results, and section 5 is the conclusion of this work.

LITERATURE REVIEW

Diagnosis of BC disease is a challenge for researchers. To solve this problem of breast cancer, various models and techniques such as ML, DL, and TL are used. Researchers used datasets based on mammography (X-rays), magnetic resonance imaging (MRI), ultrasound (sonography), and thermography to diagnose breast cancer disease.

Fractal dimension (FD) is the best indicator of ruggedness for regular elements, according to their findings. Breast lumps are uneven and can vary from malignant to benign; as a result, the breast is one of the best places to apply fractal geometry. The support vector machine, on the other side, is a new categorization technique. They (2) employed two techniques, FA: SVM and Box Count Method (BCM) in distinct operations that produced good results in respective sectors. The BCM is used to extract features. The retrieved feature "FD" assesses the difficulty of the 42-image input dataset. The generated FD is then processed using the SVM classifier which is used to classify malignant and benign cells. Their highest accuracy is 98.13%.

Breast cancer is a major disease among women between the ages of 59 and 69. They (4) also showed that finding tiny tumors early improves predictions and reduces death rates

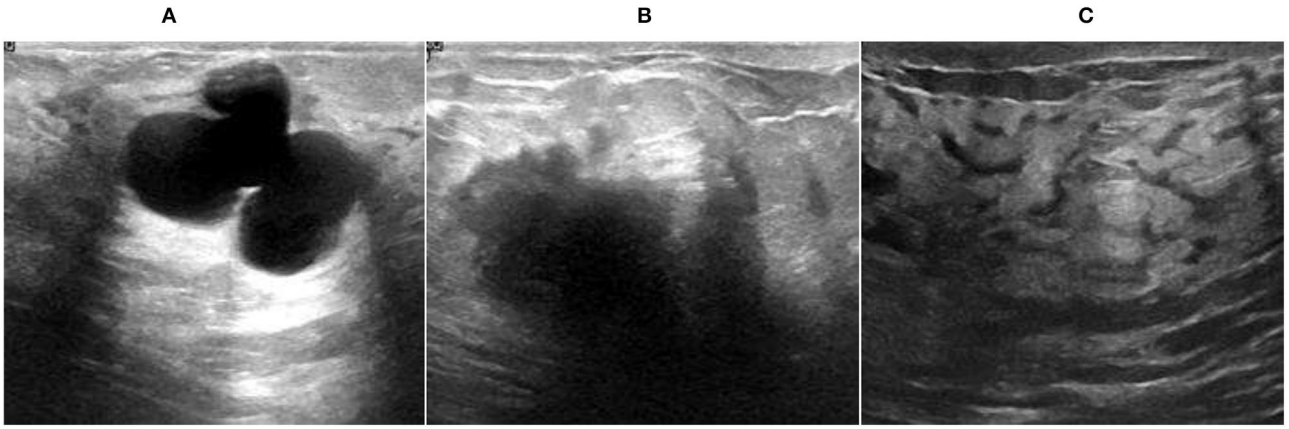

FIGURE 1 | Ultrasound image samples: **(A)** benign, **(B)** malignant, and **(C)** normal.

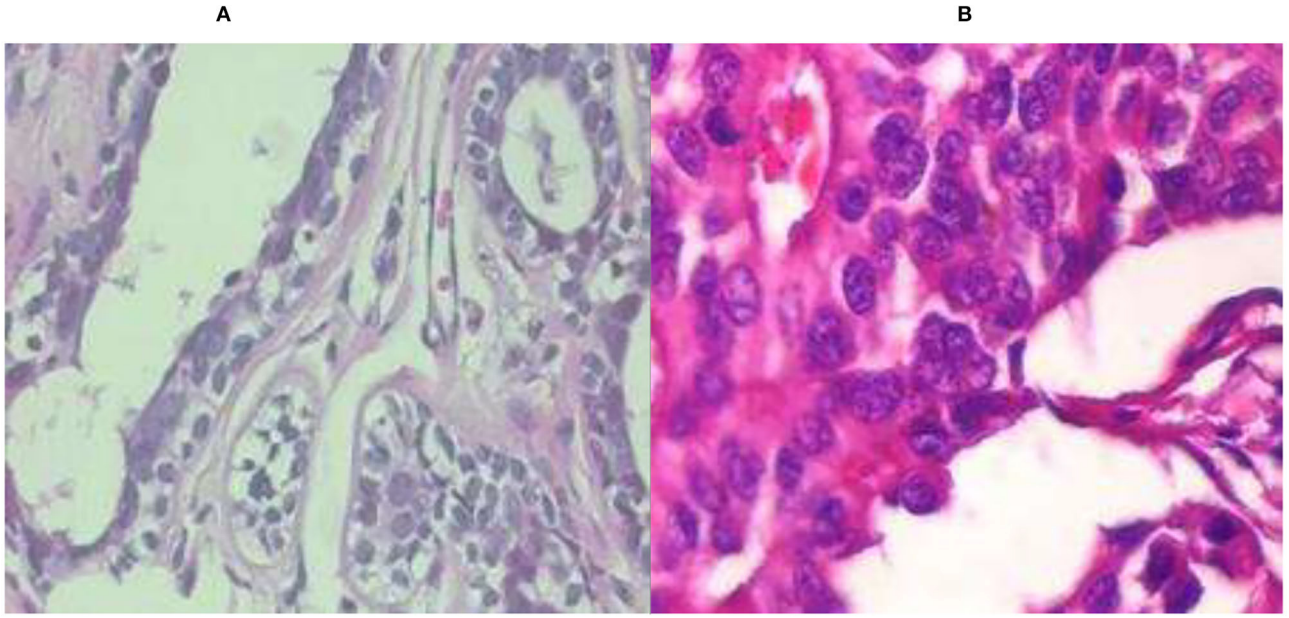

FIGURE 2 | Histopathology image samples: **(A)** benign and **(B)** malignant.

significantly. Mammography is a useful screening diagnostic method. However, due to tiny changes in tissue densities within mammography pictures, mammography interpretation is challenging. This is particularly true for solid tissues of the breast, and according to this study, screening is more appropriate in greasy breast tissue than in solid breast tissue. Their research focuses on BC detection, as well as danger issues and breast cancer assessments. Their research also focuses on the early diagnosis of BC using 3D MRI mammographic technologies and the classification of mammography pictures using ML.

Their research (5) proposes a heterogeneous efficient machine learning strategy for the early detection of breast cancer. The suggested method follows the CRISP-DM process and employs a stack to construct the collaborative model, which involves three algorithms: KNN, SVM, and decision tree. This meta-classifier's performance is compared to the separate presentations of DT, SVM, and KNN and other particular classifiers NB, SGD, LR, ANN, and a homogeneous collaborative model of (KNN, SVM, DT) and (RF). Using chi-square, the top five characteristics such as glucose, resist in, HOMA, insulin, and BMI are calculated. At K = 20, the proposed collaborative model has the best accurateness of 78% and the smallest log loss of 0.56, denying the null hypothesis. The one-tailed *t*-test, which delivers a lesser consequence at $\infty = 0.05$, yields a *P*-value of 0.014.

In this paper (7), they tested the presentation of using conveyed features from a pre-trained model on a dataset of

1,125 breast ultrasound cases. Their dataset is composed of 2,392 regions of interest (ROIs). Each ROI was marked up as cystic, malignant, or benign. Using a convolutional neural network (CNN) (6) from each ROI, features were taken out and used to train (SVM) classifiers. For comparison, classifiers were also trained before retrieving tumor features. CNN-extracted feature-trained classifiers were pretty similar to human-designed feature-trained classifiers. The SVM (8) which was trained on both human-designed features and CNN-extracted features had a 90% accuracy rate in the classification task. The accuracy of the SVM trained on CNN features was 88%, compared to 85% for the SVM trained on features that are human-designed in the task of determining malignant or benign. Deep learning (DL) methods currently in use rely on large datasets. It is worth noting that the study's dataset is not available to the general public.

In this work (8), they look at the potential uses of machine learning for brain problems. They show why machine learning is generating so much interest among researchers and clinicians in the field of brain disorders (9) by highlighting three main applications: predicting sickness onset, assisting with diagnosis, and predicting longitudinal outcomes. They explore the hurdles that must be solved for a successful translational implementation of machine learning in routine psychiatric and neurologic care after exhibiting various applications.

This paper (10) used two datasets of breast ultrasound from two different systems. The first set of data is called breast ultrasound images (BUSI). There is a total of 780 photographs in the BUSI dataset (normal 133, malignant 210, and 437 benign). B dataset has 163 pictures (110 benign and 53 malignant). They used a generative adversarial network (GAN) technology for data augmentation. Researchers can access their BUSI dataset for free. In addition, DL algorithms are applied in this study for breast ultrasound classification. They compare the performance of two alternative methods: a CNN-AlexNet approach and a transfer learning technique with and without augmenting. Their network is trained with a 0.0001 learning rate and 60 epochs. They achieved the accuracies of 94% on BUSI data, 92% on dataset B, and 99% on augmentation.

In this paper (11), they introduce a publicly available collection of 7,909 breast cancer histopathology images. Both benign and malignant images are included in the dataset. The aim connected with this dataset is to automatically classify these photographs into two categories which would be a useful computer-aided diagnosis tool for the clinician. The accuracy ranges from 80 to 85% indicating that there is still space for improvement. In their work to evaluate the feature collection, they used multi-classifiers KNN, SVM, quadratic linear analysis, and RF.

The use of DL techniques for breast ultrasound lesion identification is proposed in this study (12), and three alternative methods are investigated: patch-based Le Net, transfer learning (13), and U-Net approach with the AlexNet model. Two conventional ultrasound picture datasets were obtained, and two separate ultrasound devices are compared and contrasted in this study. Dataset A contains 306 photographs (246 benign and 60 malignant), while dataset B has a total of 163 images (110 benign and 53 malignant). They employed grayscale ultrasound pictures that were divided into 28 × 28 patches. RMS Propagation with LR of 0.01 and 60 epochs is used to train the network. They used the AlexNet model to attain a maximum accuracy which is 91% for dataset A and 89% for dataset B.

Based on two methodologies cross-validation and 80–20, a DL model based on the TL methodology is built in this study (14) to proficiently help in the automatic identification and identification of the breast cancer suspicious area. Deep learning architectures are designed to solve certain problems. Transfer learning applies what one has learned while working on one problem to another. They used six evaluation metrics to assess the proposed model's performance. To train this model, they used a learning rate of 0.01 and 60 epochs. Transfer learning is effective in detecting breast cancer by categorizing mammogram images of the breast with general accuracy, sensitivity, specificity, precision, F-score, and accuracy of 98.96, 97.83, 99.13, 97.35, 97.6.%, and 95%, respectively.

They (15) investigate a quantitative solution to a machine learning problem in this paper. They used transfer learning to train a set of hybrid traditional neural networks based on Azevedo et al. (15) work. Their mission was to tackle BCDR's difficulty in identifying full-image mammograms as malignant or benign. Data collected in this study were used throughout our research to illustrate the regions of the mammograms that the networks were targeting while measuring various performance indicators. They also indicate that some designs perform much better than others depending on the task. According to their findings, the greatest accuracy is 84%.

They (16) demonstrate in their study that the early detection and classification of breast cancer are critical in assisting patients in taking appropriate action. Mammography images, on the contrary, have low sensitivity and efficiency for identifying breast cancer. Furthermore, MRI has a higher sensitivity for detecting breast cancer than mammography. A novel Back Propagation Boosting Recurrent Widening Model (BPBRW) with a Hybrid Krill Herd African Buffalo Optimization (HKH-ABO) method is created in this study to diagnose breast cancer at an earlier stage utilizing breast MRI data. The system is initially trained using MRI breast pictures. Furthermore, the proposed BPBRW with HKH-ABO mechanism distinguishes between benign and malignant breast cancer tumors. Additionally, Python is used to simulate this model. They demonstrate that their model has a 99.6% accuracy rate.

They (17) constructed four distinct predictive models and offered data exploratory techniques (DET) to increase breast cancer detection accuracy in this study. Prior to the models, researchers dug deep into four-layered critical DET, such as feature distribution, correlation, removal, and hyperparameter optimization, to find the most robust feature categorization into malignant and benign classifications. On the WDBC and BCCD datasets, the proposed approaches and classifiers were tested. To evaluate each classifier's efficiency and training time, standard performance metrics such as confusion matrices and K-fold approaches were used. With DET, the models' diagnostic capacity improved, on polynomial SVM achieving 99.3% accuracy, LR 98.06, KNN 97.35, and EC 97.61% accurateness with the WDBC database.

Their (18) goal was to create a hierarchical breast cancer system model that would improve detection accuracy and reduce breast cancer misdiagnosis. To categorize breast cancer tumors and compare their performances, the dataset was subjected to ANN and SVM. The SVM utilizing radial features produced the best accuracy of classification of 91.6%, whereas the ANN obtained 76.6%. As a result, SVM was used to conclude about the importance of breast screening. The second stage involved applying transfer learning to train AlexNet, InceptionV3, and ResNet101. AlexNet scored 81.16%, ResNet101 scored 85.51%, and InceptionV3 scored 91.3 %, according to the data.

They (19) present a framework based on the notion of transfer learning in their research. In addition, a variety of augmentation procedures, including multiple rotation combinations, scale, and shifting, were implemented to prevent a fitting problem and create consistent outcomes by expanding the number of screened mammography pictures. Their proposed solution was tested on the Screening mammography Image Analysis Society (MIAS) database and achieved an accuracy of 89.5% using ResNet50 and 70% utilizing the NASNet-Mobile network. Pre-trained categorization networks are much more efficient and effective, making them more suitable for diagnostic imaging, especially for short training datasets, according to their suggested system.

They (20) used machine learning-based algorithms to help the radiologist read mammography pictures and classify the tumor in an acceptable amount of time in this study. They extracted a number of features from the mammogram's region of interest, which the physician manually labeled. To train and create the suggested structural classification models, these properties are added to a classification engine. They tested the suggested system's accuracy using a dataset that had never been encountered before in the model. As a result, this research discovered that a variety of circumstances can affect the results, which they ignored after investigating. After merging the selection of features optimization approaches, this study advises employing the optimized SVM or Nave Bayes, which provided 100% accuracy.

Their (21) research focuses on employing TL with fine-tuning and on training the CNN with areas derived from the IN breast and MIAS datasets to apply, evaluate, and compare architectures such as AlexNet, Google Net, Vgg19, and Resnet50 to classify breast lesions. They looked at 14 classifiers, each of which corresponded to benign or malignant microcalcifications and masses, as several previous studies have done. With the CNN, they obtained the best results. With an AUC of 99.29%, an F1 score of 91.92%, accuracy of 91.92%, precision of 92.15%, sensitivity of 91.70%, and specificity of 97.66% on a balanced database, Google Net is the better model in a Cad model for breast cancer.

The effectiveness of BC categorization for malignant and benign tumors was evaluated utilizing several machine learning algorithms (k-NN, RF, and SVM) and aggregation methods to calculate the prediction of BC survival by applying 10-fold cross-validation. Their research (22) used a dataset from WDBC that included 23 selected variables evaluated by 569 people, of whom 212 had malignant tumors and 357 had benign tumors. The analysis was done to look at the characteristics of the tumors using the mean, worst values, and standard error. There are 10 properties for each feature. According to the results, AdaBoost has the maximum accuracy for 30 features (98.95%), 10 mean features (98.07%), and 10 worst features (98.77%) with the lowest error rate. To obtain the best accuracy rate, their recommended approaches are categorized using 2-, 3-, and 5-fold cross-validation. When all approaches were compared, AdaBoost ensemble methods had the highest accuracy, with 98.77% for 10-fold cross-validation and 98.41 and 98.24% for 2- and 3-fold cross-validation, respectively. Nonetheless, 5-fold cross-validation revealed that SVM generated the highest accuracy rate of 98.60% with the least error rate.

Breast cancer affects a large number of people all around the world. Mammography is a key advancement in breast cancer detection. It is difficult for doctors to recognize due to its intricate structure. Their (23) research suggests using a CNN to detect cancer cells early. By separating malignant and benign mammography pictures, detection and accuracy can be greatly improved. The Break His $\times$400 database comes from Kaggle, and the architectures NASNet-Large, DenseNet-201, Big Transfer (M-r101x1x1), and Inception ResNet-V3 perform admirably. M-r101x1x1 has a maximum accuracy of 90% among them. The most important goal of their research is to use selected neural networks to accurately classify breast cancer. This research could help to enhance the systematic diagnosis of early-stage breast cancer.

Despite the fact that there are several scientific studies on the categorization and identification of cancer tumors using various types of models but with some limitations. Breast cancer has limited studies due to the lack of publicly available benchmark datasets. In their work (14), they have used multiple methods such as ResNet50, inception V3, Inception V2 Res Net VGG 19, and VGG 16 but their dataset is too small and they just work on one single dataset and their maximum accuracy is 98.96. In this work (10), they used two different datasets using transfer learning. Datasets are good, but their maximum accuracy is 94% on the BUSI dataset and 92% on dataset B. In this work (12), they also used two different datasets by using CNN multiple models, and they achieved a maximum accuracy with AlexNet, 91% on dataset A and 89% on dataset B. In their work (11), they used a good and large dataset but they also achieved a maximum accuracy is 80–85%. **Table 1** shows the comparison of previous studies in terms of accuracy and limitations. Previous studies (4, 5, 7, 10–12, 14) have some limitations like less number of images in the dataset, less accuracy, hand-crafted features required, lack of diverse datasets, no publically available dataset, and an imbalanced number of images in datasets.

The following are the primary contributions of this work:.

- This work used three different datasets of breast cancer and compare their results on the same model.
- Improving the accuracy of classification and detection by customizing the model AlexNet.
- Model proposed achieved the maximum accuracy results using transfer learning approaches.

PROPOSED MODEL

In order to assess and identify diseases in medical images, machine learning techniques were applied. Many ML (24) and DL (25) approaches have been widely employed in medical image processing in recent years to detect and evaluate items in medical images. The use of DL techniques to detect breast cancer at an early stage aids medical practitioners in determining its therapy. Breast cancer has been diagnosed early using a variety of DL and transfer learning approaches. DL methods are useful tools for detecting the disease early. **Figure 3** shows the application-level representation of the suggested system model.

As we know that in deep learning, few steps are very important: first is data acquisition, data pre-processing, and then the training of the datasets. As we know that if the data are image-based, then the deep learning methods give more accurate results as compared to the machine learning, which is the reason we used deep learning-based solution. There are various kinds of deep learning models like CNN and KNN, as we know that computational resources are also required to compute such kinds of problems like processing power. In further deep learning if we have less computational resources like this one, then we used transfer learning instead of the other deep learning models that is why here we used transfer learning to save the computing power resource optimization. In transfer learning, we used a pre-trained model AlexNet, and we customized this model according to our problem which saves computing power. After that, we stored it in the cloud so that we can use this pre-trained model.

The detailed proposed system model is shown in **Figure 4**. The projected method for breast cancer identification and classifications contains two major components. The first component is pre-processing and training, and the second is testing. Based on deep learning techniques, the proposed system model accepts images to help in the classification and early detection of diseases in various stages. Previous research and the Kaggle repository were used to collect the training data, which consisted of ultrasound and histopathology images and the data were collected in raw form. The raw data were handled by the pre-processing layer, which converted the images according to the requirement of the model which is 227*227 for AlexNet and customized the pre-trained model AlexNet for transfer learning.

The second layer is training, and for training, this study used pre-processed images of the training layer [227*227] and import the customized trained model. The model must be retrained if the learning conditions are not met; otherwise, the trained model is saved in the cloud. The intelligent trained model detects and classifies breast cancer into three categories: benign, malignant, and normal. If the patient is normal, no need to visit the doctor, and if the patient is having symptoms of benign or malignant system, refer her to the doctor for the treatment of BC. **Table 2** shows the pseudocode of the proposed algorithm.

Dataset

In general, a dataset should be provided to construct a healthcare system employing deep learning. Three separate datasets of breast images are used in this investigation. This study referred to datasets as datasets A, B, and C. Dataset A is collected from (10, 26), dataset B is collected from (11, 27), and dataset C is collected from (28). Dataset A includes medical images of breast cancer obtained by an ultrasound scan. The images in this dataset A are divided into three categories: normal, benign, and malignant. Dataset B contains histopathology pictures of malignant and benign breast cancers, and images were taken as part of a clinical investigation. Dataset C images are also histopathology images. Dataset C is divided into two categories: malignant and benign. We also used dataset A with two classes, benign and malignant, and called it as dataset A2. The number of images in all datasets is shown in **Table 3**.

After data collection, pre-processing of images is done. This pre-processing is critical for removing the limitations of abnormality observation and dimension of images according to the AlexNet model. The quality of the images can be increased, and the results can become more precise. Splitting is an important part of a model for training and testing. This proposed model is done by splitting datasets randomly into 80% for the training set and 20% for testing.

Transfer Learning

Transfer learning is a technique that involves training a CNN model to learn features for a wide range of domains. The proposed TL method is based on AlexNet. The images of the breasts are in grayscale. To make model training easier, pre-processing actions like resizing images into 227*227 were taken. This study divided the dataset into training and testing groups randomly, so the models were able to identify significant elements in each image and get a perfect score on the test set. The

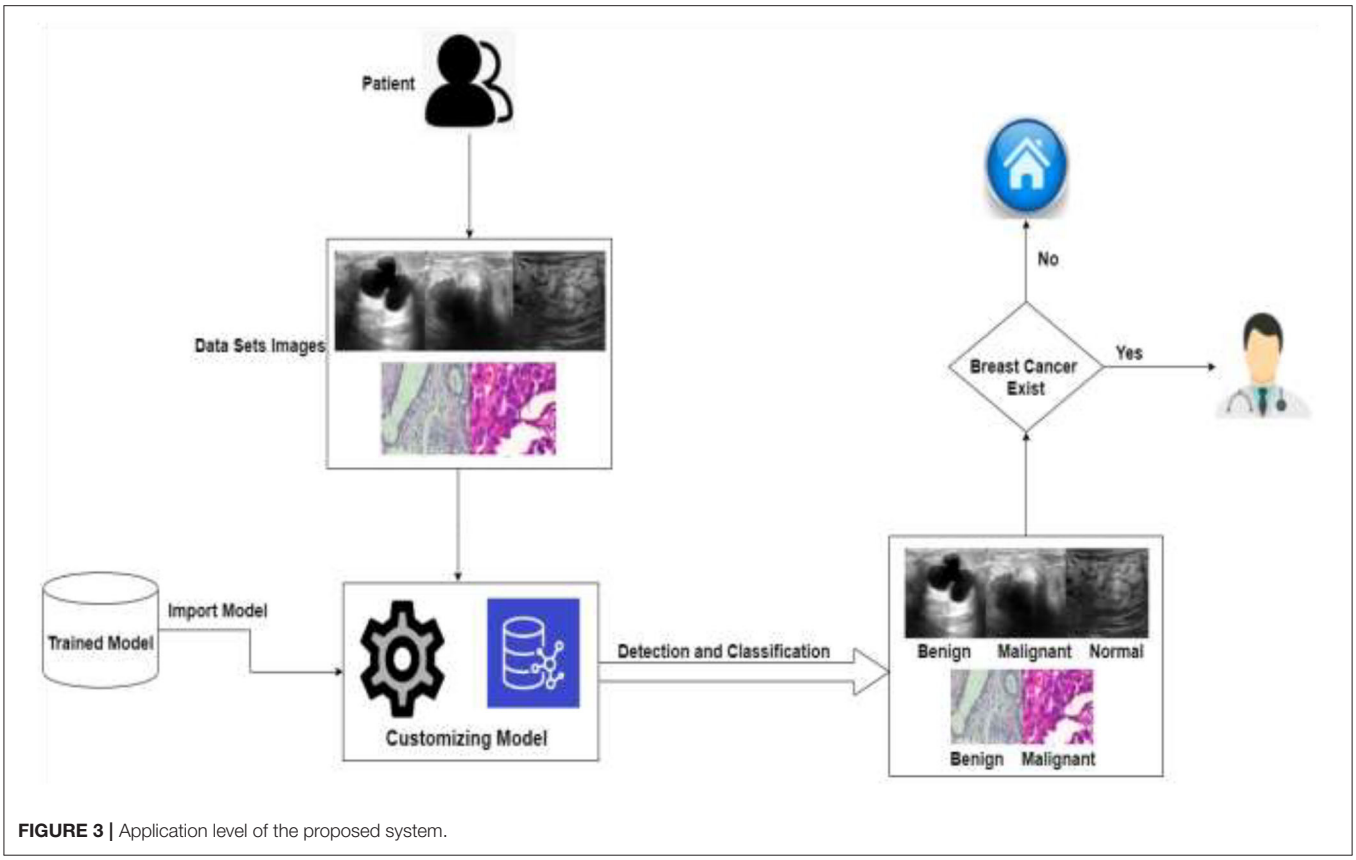

FIGURE 3 | Application level of the proposed system.

AlexNet model was used to train all datasets (A, B, and C). The model that has been trained is kept and reused.

This proposed methodology customized the AlexNet model. AlexNet is an eight-layer network with learnable parameters in which three are fully connected layers and five are convolutional layers with max pooling. ReLU is a non-linear initiation function that exists in each layer. Images from the pre-processed layer are read by the network's input layer. The fully connected layers learn disease features to categorize images into specific classes. Early convolutional layers extract common features from pictures by using filters such as detection of edges and preserving the spatial connection between pixels, but later convolutional layers using filters extract general features from images such as detection of edges.

This CNN (29) network was modified to our needs, and the pre-processed images were then loaded into the proposed AlexNet transfer learning model (30). According to the problem, the first and last three layers of the architecture are modified and newly modified layers are the image input layer, fully connected layer, softmax layer, and classification layer, although the remaining layers remain fixed. This customized network is used for TL. The first layer will set the dimension into 227*227, and the last three layers are set up according to the labels of the output class and they can categorize the images into their respective groups. The output's size, which is divided into numerous types, is the input parameter for fully connected layers. The fully connected layer in the proposed model will connect three classes: benign, malignant, and normal. Softmax layers are used to apply softmax functions to the input. A fully connected layer learns the class's precise features to differentiate across classes. So, fully connected layers are altered according to dataset classes. To identify images in distinct class labels, this projected network is trained on breast cancer labels of multi-class.

Learning rate and number of epochs are two of the parameters that can be used as training options. The learning rate and epochs are used to train the network. The training was done on various epochs such as 10, 30, and 50, and it was discovered that the ideal epoch was 50, with a learning rate of 0.0008. For training, the stochastic gradient descent with momentum (SGDM) technique of optimization is used. Newly edited layers use these training settings for the breast cancer dataset. The CNN layers are accountable for extracting the general features of images and then for the classification and identification of new datasets by reusing these learning parameters. Models that have been customized and trained are placed on clouds and can be reused. Pre-processed images are passed to the customized model AlexNet during the validation stage. The customized model has all of the features for image processing that it learned during the process of training, so it assesses the images and classifies them into normal, benign, and malignant diseases. After the classification and detection of breast cancer if the patient is normal, no need to visit a doctor, and if the patient has symptoms of disease, then refer to a doctor.

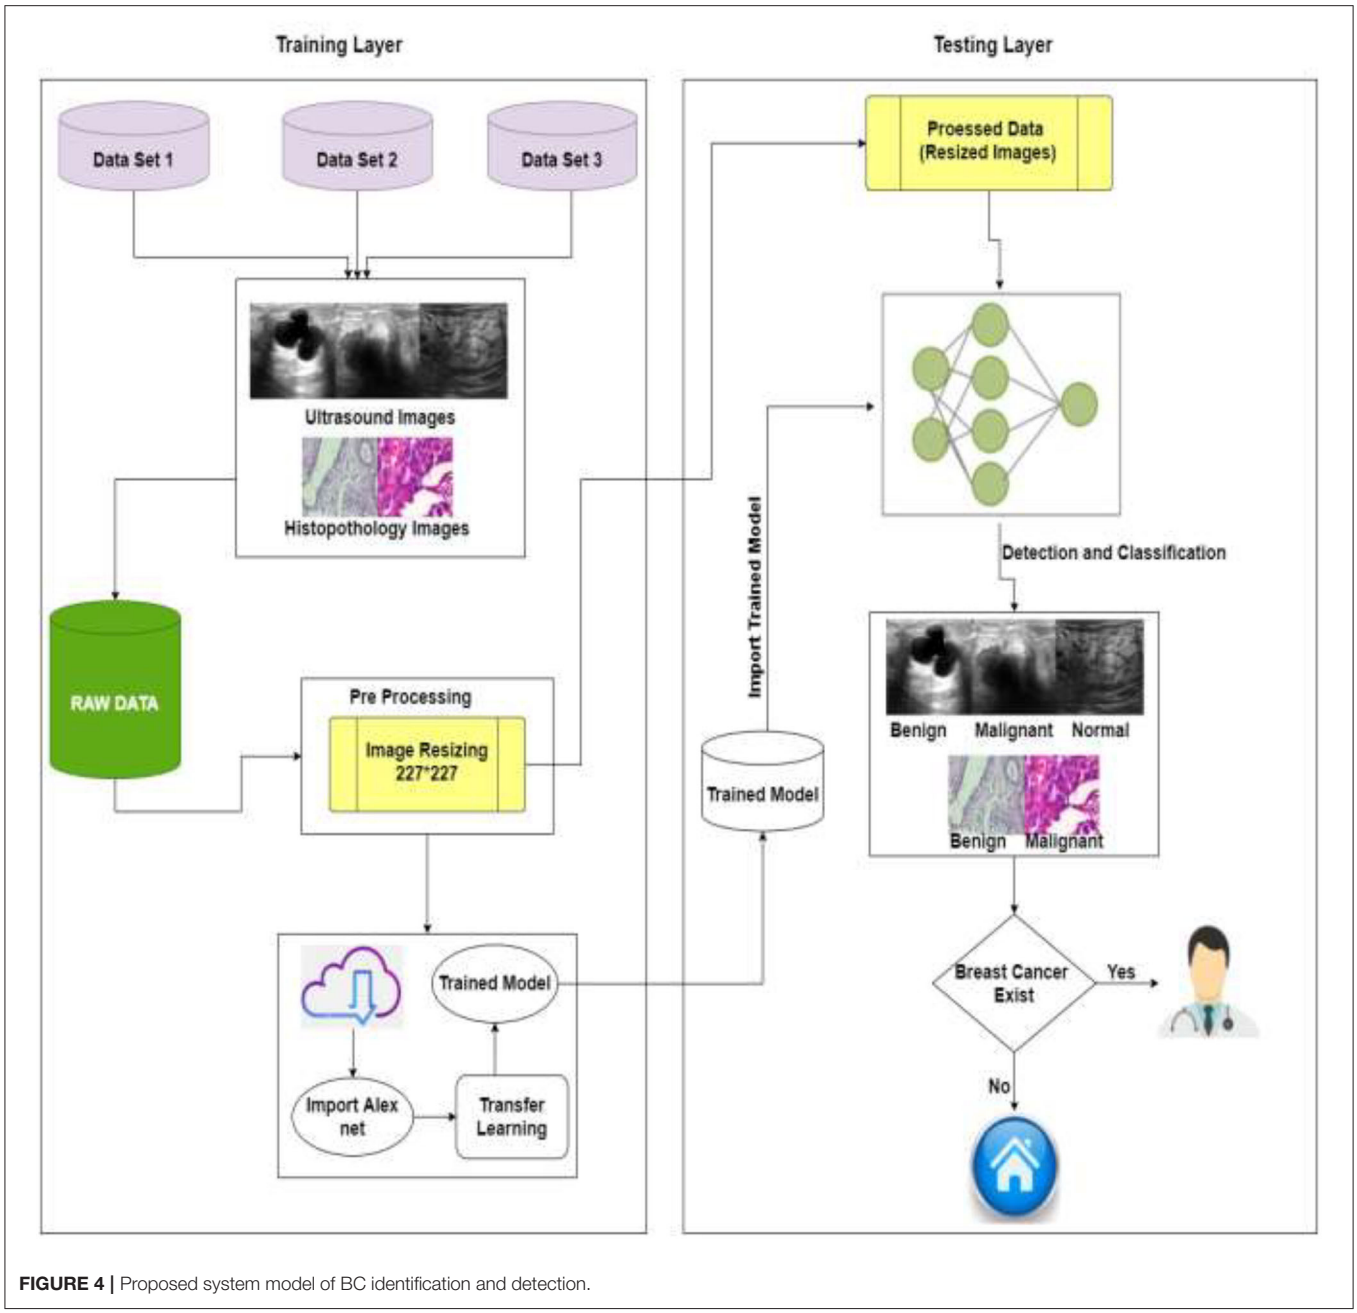

FIGURE 4 | Proposed system model of BC identification and detection.

SIMULATION AND RESULTS

Breast cancer is caused by the uncontrollable growth of cells in the breast. One of the most frequent malignancies in women is breast cancer. BC is estimated to attack more than 8% of women at some point in their life. However, BC can be detected early, allowing patients to obtain proper therapy and so increase their chances of survival. There are many previous studies on breast tumors using various types of models, but with some limitations, breast cancer has limited studies due to the lack of publicly available benchmark datasets. In this study, we worked on three datasets (A, B, C, and A2, A2 is dataset A with two classes) with a total number of 10,336 images which is a good dataset. This study is the first to compare three common datasets and suggests the use of customized transfer learning algorithm AlexNet for breast classification and detection on multiple datasets. **Table 14** shows that previous studies do not give accurate results that is why we need a better solution to diagnose breast cancer with more accuracy. Some previous studies used AlexNet, but in this work, we used customized AlexNet model that is not used before in previous studies. The customized model has all of the features for image processing that it learned during the process of training. By using customized AlexNet, we achieved good results that are shown in this section of this study.

In this section, multiple tests were carried out to investigate the performance of this model on datasets A, B, and C. Benign, malignant, and normal were used to categorize the datasets. AlexNet (31) was used to create the proposed model for detecting and classifying breast cancer. The categorization and findings are done in MATLAB 2020a. Evaluation metrics are used to assess produced results. In the training phase, for training, 80% of the dataset is utilized while for testing 20% is used. Transfer learning is applied on AlexNet and compared in form of accuracy (Acc), sensitivity (Sen), specificity (Spe), false-negative ratio (FNR), Miss classification rate (MCR), false-positive ratio (FPR), true positive (TP), false positive (FP), true negative (TN), and false negative (FN) (24, 25). These assessment measures are used to quantify a predictive model's performance.

For binary classes of datasets A2, B, and C.

$$Acc = \frac{C_P/G_P + C_N/G_N}{G_P + G_N} * 100 \quad (1)$$

$$MCR = \frac{C_N/G_P + C_P/G_N}{N} * 100 \quad (2)$$

$$Sen = \frac{C_P/G_P}{C_P/G_P + C_P/G_N} * 100 \quad (3)$$

$$Spe = \frac{C_N/G_N}{C_N/G_N + C_N/G_P} * 100 \quad (4)$$

$$FPR = \frac{C_N/G_P}{C_N/G_N + C_N/G_P} * 100 \quad (5)$$

$$FNR = \frac{C_P/G_N}{C_P/G_P + C_P/G_N} * 100 \quad (6)$$

The proposed system classifies datasets A, B, and C into two and three classes, namely benign, malignant, and normal. This work trained datasets on multiple epochs like 10, 30, and 50, and the

best accuracy of the proposed model is 99.4% for dataset "A," 96.7% for dataset B, 99.1% for dataset C, and 100% for dataset A2 on 50 epochs and 0.0008 learning rate. The model proposed for classification and identification of the BC provided improved accuracy as compared to the earlier work of dataset A (10), their accuracy was 94% of dataset B (11), their accuracy was 80% to 85% and no previous work on dataset C, and the proposed model also achieved 100% on dataset A with two classes (dataset A2).

The algorithm is trained on multiple parameters. Transfer learning-based parameters are utilized for training this model and to get the required output in the proposed system. On 10, 30, and 50 epochs to attain optimal accuracy and loss rate, this study trained the model multiple times. **Table 4** shows the dataset A classes (benign, malignant, and normal accuracy, respectively, 98.9, 100, and 100% and miss rate, respectively, 1.1%, 0.0%, and 0.0%), dataset B classes (benign and malignant accuracy, respectively, 96.0 and 97.0% and miss rate, respectively, 4.0 and 3.0%), dataset C classes (benign and malignant accuracy, respectively, 99.1 and 99.1% and miss rate, respectively, 0.9 and 0.9%), and dataset A2 classes (benign and malignant accuracy, respectively, 100 and 100% and miss rate, respectively, 0.0 and 0.0%) on 50 epochs.

Table 5 shows the accuracy and miss rate of dataset "A" on 10, 30, and 50 epochs. Accuracy is 70.5%, miss rate is 29.5% on 10 epochs, accuracy is 96.8%, miss rate is 3.2% on 30 epochs, and accuracy is 96.8%, miss rate is 3.2% on 50 epochs. **Table 6** shows the miss rate and accuracy of dataset B on 10, 30, and 50 epochs. Accuracy is 77.5%, miss rate is 22.5% on 10 epochs, accuracy is 95.6%, miss rate is 4.4% on 30 epochs, and accuracy is 96.7%, miss rate is 3.3% on 50 epochs. **Table 7** shows the accuracy and miss rate of dataset C on 10, 30, and 50 epochs. Accuracy is 96.0%, miss rate is 4.0% on 10 epochs, accuracy is 97.3%, miss rate is 2.7% on 30 epochs, and accuracy is 99.1%, miss rate is 0.9% on 50 epochs. **Table 8** shows the accuracy and miss rate of dataset A2 on 10, 30, and 50 epochs. Accuracy is 89.1%, miss rate is 10.9% on 10 epochs, accuracy is 96.1%, miss rate is 3.9% on 30 epochs, and accuracy is 100%, miss rate is 0.0% on 50 epochs.

Figure 5 represents the proposed system's labeled pictures of BC according to the dataset "A" classes benign, malignant, and normal. **Figure 6** represents according to the dataset B classes benign and malignant. **Figure 7** represents according to the dataset C classes benign and malignant. **Figure 8** represents according to the dataset A2 classes benign and malignant.

Table 9 shows the confusion matrix of breast cancer classification dataset "A" on 50 epochs. The total number of photographs used for 50 epochs was 780 of dataset "A" with 624 images used for training and 156 images used for testing. A total of 86 images of benign were used for classification in which 86 were classified as benign, 42 images of malignant were used in the classification in which 42 were classified as malignant, and 28 images of normal were used in the classification in which 27 were classified as benign and 1 as benign.

Table 10 shows the confusion matrix of breast cancer classification dataset B on 50 epochs. The total number of photographs used for 50 epochs was 7,783 of dataset A with 6,226 images used for training and 1,557 images used for testing. A total of 508 images of benign were used for classification in which 476 were classified as benign and 32 as malignant, and 1,049 images of malignant were used for classification in which 1,029 were classified as malignant and 20 as benign.

Table 11 shows the confusion matrix of breast cancer classification dataset C on 50 epochs. The total number of photographs used for 50 epochs was 1,126 of dataset C with 225 images used for training and 901 images used for testing. A total of 109 images of benign were used for classification in which 108 were classified as benign and 1 as malignant, and 116 images of malignant were used for classification in which 115 were classified as malignant and 1 as benign.

Table 12 shows the confusion matrix of breast cancer classification dataset A2 on 50 epochs. The total number of photographs used for 50 epochs was 647 of dataset A2 with 518 images used for training and 129 images used for testing. A total of 87 images of benign were used for classification in which 87 were classified as benign and 0 as malignant, and 42 images of malignant were used for classification in which 42 were classified as malignant and 0 as benign.

Figure 9 represents the training accuracy plot which is made up of iterations and epochs and displays the results for 50 epochs of dataset "A." The precision was initially modest, but as the number of epochs increased, it gradually improved. The proposed system is trained at a learning rate of 0.0008 and a total number of six repetitions for each epoch. The chart depicts the

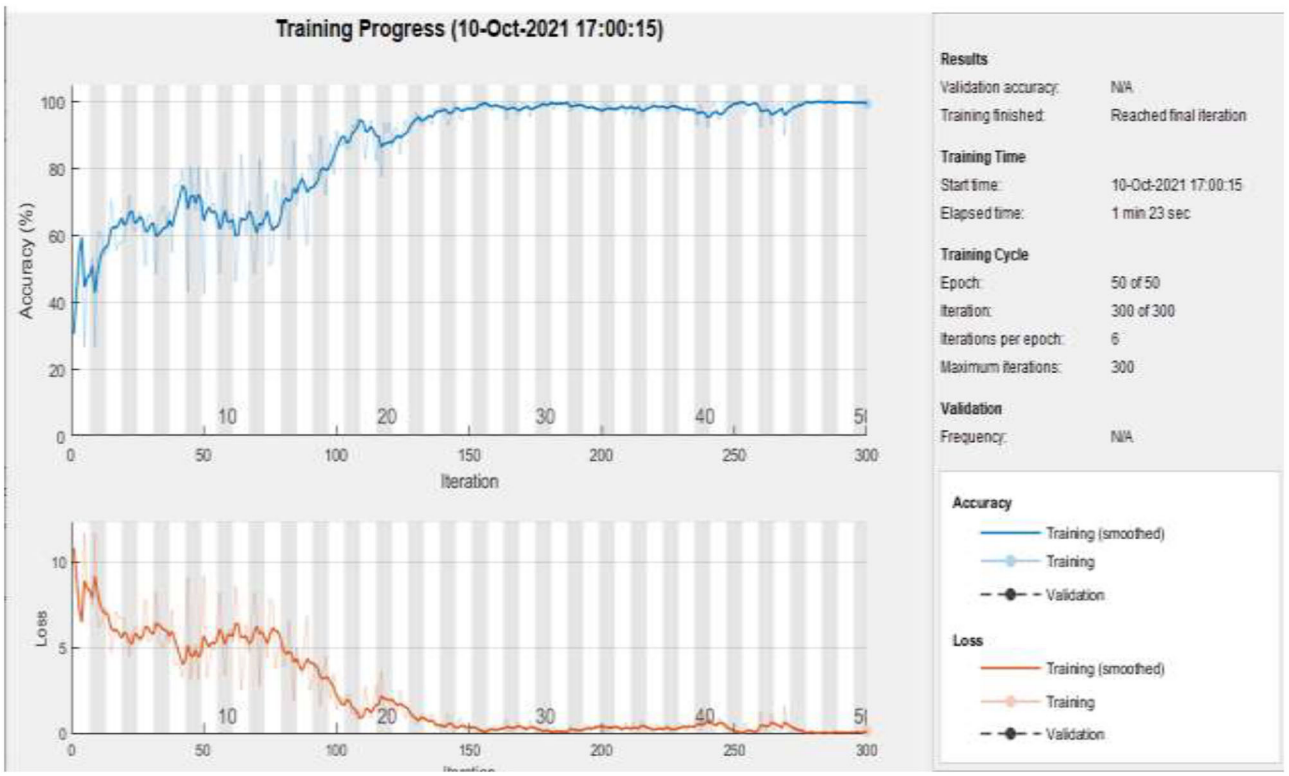

FIGURE 9 | Training of dataset A at 50 epochs.

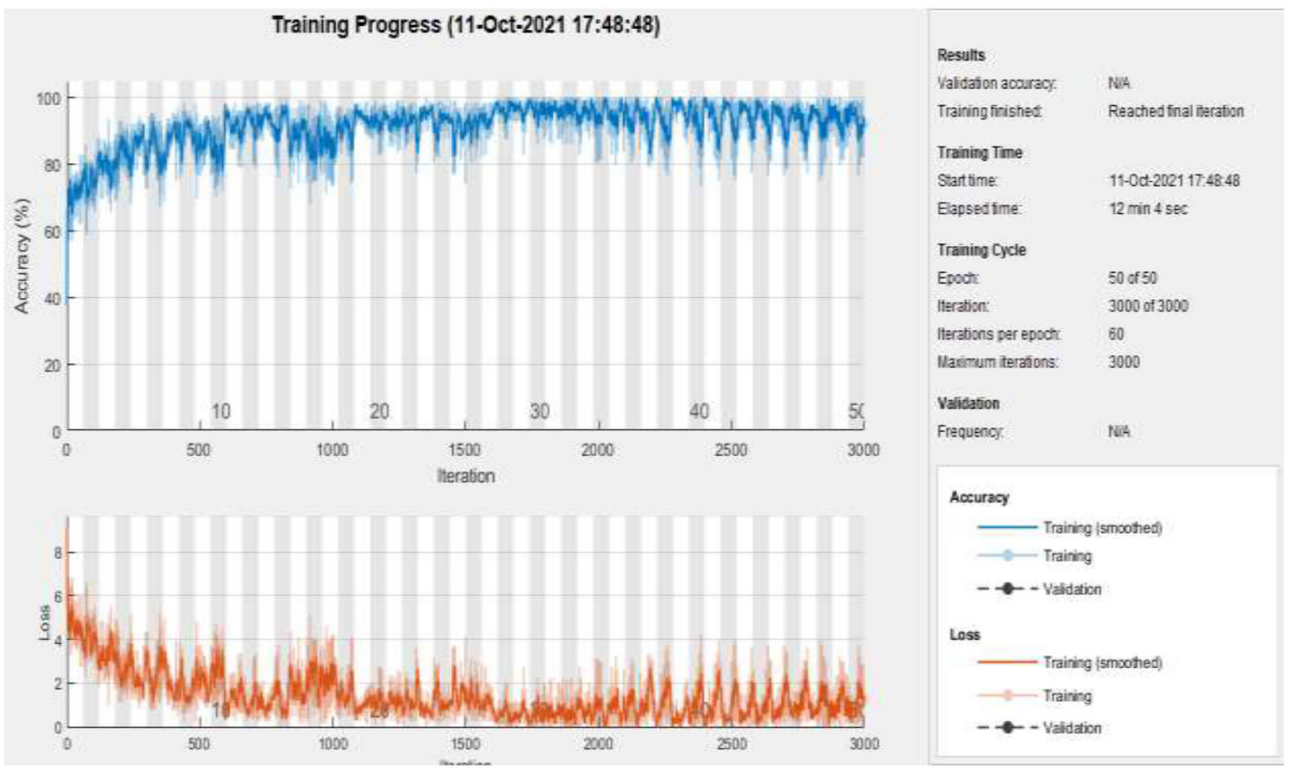

FIGURE 10 | Training of dataset B at 50 epochs.

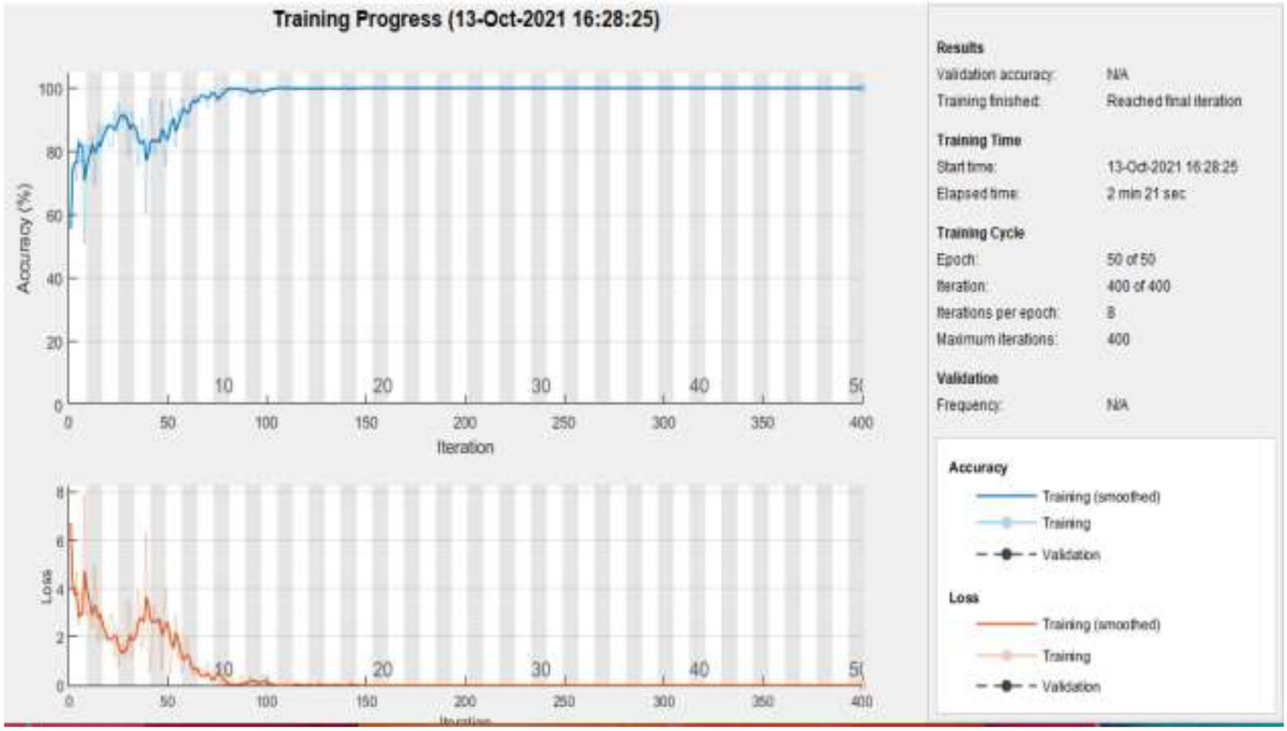

FIGURE 11 | Training of dataset C at 50 epochs.

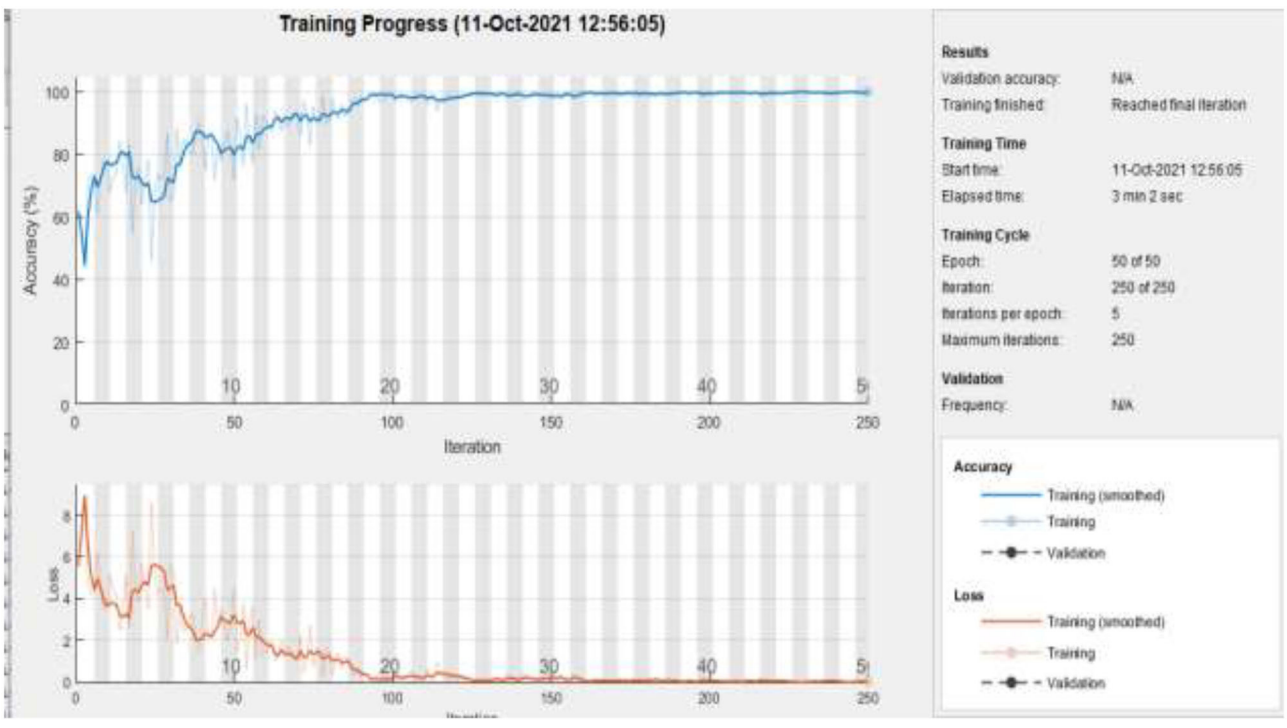

FIGURE 12 | Training of dataset A2 at 50 epochs.

percentage of accuracy for training that began at 1 epoch and ended at 50 epochs.

Figure 10 represents the training accuracy plot which is made up of iterations and epochs and displays the results for 50 epochs of dataset B. The precision was initially modest, but as the number of epochs increased, it gradually improved. The proposed system is trained at a learning rate of 0.0008 and a total number of 60 repetitions for each epoch. The chart depicts the percentage of accuracy for training that began at 1 epoch and ended at 50 epochs.

Figure 11 represents the training accuracy plot which is made up of iterations and epochs and displays the results for 50 epochs of dataset C. The precision was initially modest, but as the number of epochs increased, it gradually improved. The proposed system is trained at a learning rate of 0.0008 and a total number of eight repetitions for each epoch. The chart depicts the percentage of accuracy for training that began at 1 epoch and ended at 50 epochs.

Figure 12 represents the training accuracy plot which is made up of iterations and epochs and displays the results for 50 epochs of dataset A2. The precision was initially modest, but as the number of epochs increased, it gradually improved. The proposed system is trained at a learning rate of 0.0008 and a total number of five repetitions for each epoch. The chart depicts the percentage of accuracy for training that began at 1 epoch and ended at 50 epochs.

The proposed model gives the more precise results as shown in **Table 13**, and it gives TP of class benign 86 from 87, malignant 42 from 42, and normal 26 from 27. The proposed model gave precise results which are shown in **Table 14**; on dataset "A," it gives 99.35% accuracy and 1.149 % FNR for class benign, 100% accuracy and 0.0 % FNR for class malignant, and 99.35% accuracy and 0.0 % FNR for class normal. **Table 15** shows that the proposed model gives 96.66% accuracy and 4.03% FNR on dataset B, 99.11% accuracy and 0.9174%

TABLE 13 | TP, FP, FN, and TN of dataset A.

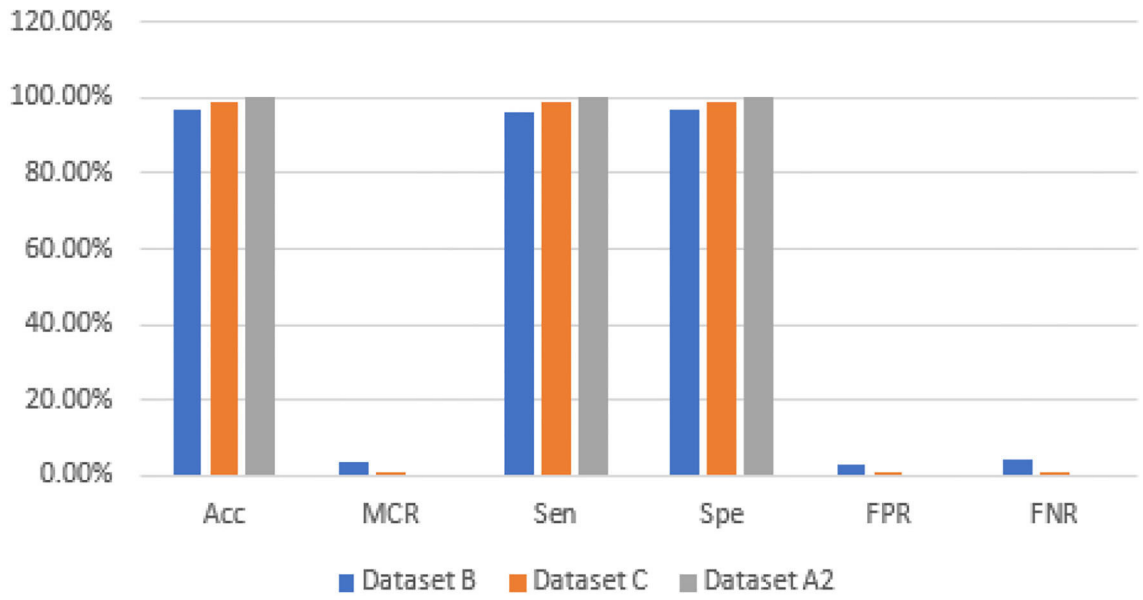

FIGURE 14 | Statistical measures of datasets B, C, and A2.

FIGURE 15 | Accuracy and miss rate in contrast with previous studies.

FNR on dataset C, and 100% accuracy and 0.0% FNR on dataset A2.

The graphical representations of the statistical measures of dataset "A" are shown in **Figure 13**, and the graphical representations of the statistical measures of datasets B, C, and A2 are shown in **Figures 14**, **15**. Multiple methods for detecting BC have been utilized in the past. In the identification of a disease for a given class, the proposed methodology attained good accuracy. As a result, early disease diagnosis can assist medical experts in providing treatment to prevent breast cancer spread. **Table 15** shows the comparison of the suggested system model's performance with the literature work in terms of accuracy and miss rate. The proposed model obtained an accuracy and miss rate of 99.4% and 0.6%, respectively, on dataset "A," accuracy and miss rate of 96.66 and 3.34%, respectively, on dataset B, accuracy and miss rate of 99.11 and 0.89%, respectively, on dataset C, and accuracy and miss rate of 100% and 0%, respectively, on dataset A2. These results show that the proposed model achieved accuracy more than the previous models such as AlexNet, VGG 16, Inception, Res net, and NASNet (10) on dataset BUSI and B, SVM (11), AlexNet (12) on dataset A and B, Inception V3, Res net 50, VGG 16, VGG 19, and Inception V2 Res net (14).

CONCLUSION

The early detection and classification of breast cancer help to prevent the disease's spread. The use of transfer learning AlexNet on breast cancer classification and detection was examined in this work. Deep learning and transfer learning approaches are adapted to the specific properties of any dataset. The proposed model used the customized AlexNet technique on three datasets, A, B, C, and A2, A2 is the dataset A with two classes. This proposed model empowered with transfer learning achieved the best results by using the customized AlexNet. Dataset A has a maximum accuracy of 99.4%, whereas dataset B has a maximum accuracy of 96.70%, dataset C has a maximum accuracy of 99.10%, and dataset A2 has a maximum accuracy of 100%. In future work, we will apply fusion on these datasets for optimum results. We will also apply other CNN algorithms and our model of machine learning on these datasets.

Breast cancer (BC) was the most common malignant tumor in women, and breast infiltrating ductal carcinoma (IDC) accounted for about 80% of all BC cases. BC patients who had bone metastases (BM) were more likely to have poor prognosis and bad quality of life, and earlier attention to patients at a high risk of BM was important. This study aimed to develop a predictive model based on machine learning to predict risk of BM in patients with IDC. Six different machine learning algorithms, including Logistic regression (LR), Naive Bayes classifiers (NBC), Decision tree (DT), Random Forest (RF), Gradient Boosting Machine (GBM), and Extreme gradient boosting (XGB), were used to build prediction models. The XGB model offered the best predictive performance among these 6 models in internal and external validation sets (AUC: 0.888, accuracy: 0.803, sensitivity: 0.801, and specificity: 0.837). Finally, an XGB model-based web predictor was developed to predict risk of BM in IDC patients, which may help physicians make personalized clinical decisions and treatment plans for IDC patients.

INTRODUCTION

As one of the most common malignancies, breast cancer (BC) accounted for 30% of all cancers in women (1). The incidence of BC continued to increase at a rate of ∼0.5% per year, which was attributed at least in part to the continued decline in fertility and increased body weight (2). In the cancer statistical report, the number of BC patients exceeded 2.1 million, and infiltrating ductal carcinoma (IDC) was the most common one among different types of BC (3, 4). Early diagnosis provides a favorable prognosis and better overall survival for BC patients. In North America, early screening for BC significantly increased the 5-year survival rate to over 80% for BC patients (5). In recent years, BC patients still had a high incidence of distant metastatic recurrence, which was an important indicator for poor prognosis. Recent studies have suggested that age, menopausal status, T, N stages, histological grade and HR/HER2 status were risk factors for BM in BC patients (6–8). For distant metastases, bone was the most common site, and more than 60% of BC patients developed bone metastases (BM) (9). Another study indicated over 20% of patients developed BM within an average follow-up duration of 8 years. And further survival prognostic modeling showed a 40-month median survival time for patients with BM (10). In addition, BC patients with BM

often developed secondary clinical complexities that took up significant medical resources (11). Early diagnosis of BM from BC will help in the timely prevention and treatment of complications and increase the quality of life for BC patients.

Currently, precision medicine has preceded four concepts: predictive, personalized, preventive and participatory (12). The technology of big data analytics is becoming a clinical imperative (13). This means that we need to use advanced technology to analyze large amounts of medical data to provide recommendations for individualized treatment. Many studies have used machine learning (ML) techniques to study clinical risk factors associated with cancer metastases for early detection (14–16). It is known that the most common type of pathology in BC is IDC (4). But few studies focused on incorporating machine learning to predict the risk of BM from IDC patients.

In this study, we attempted to develop a predictive model to predict the BM risk in IDC patients based on machine learning, and to assist clinicians in implementing more rational clinical decisions as well as to enable patients to receive earlier treatment. Our contribution includes:

- Machine learning algorithms were used instead of traditional statistical regression methods to process data on clinical characteristics of IDC patients to identify patients at high risk for BM.
- This paper compared various algorithms that could be used to process patient data and identified XGB as the best method for processing the data. Further, the hyperparameters of the XGB algorithm were fine-tuned using a random search method to improve performance.
- We performed importance analysis of the features included in the model using the permutation importance method, and these features were further analyzed and understood from a clinical medicine perspective in the discussion section.
- This study proposed a machine learning based solution that could assist clinicians in making individualized diagnoses of BM for IDC patients.

The rest of the paper was organized as follows: the materials and methods section provided a detailed documentation of the materials and methods used, as well as the dataset description, statistical analyses, data pre-processing, feature engineering, classification algorithms used and evaluation metrics. Results of the experiment are discussed in Section Results and then further discussed in Section Discussion. Conclusions, limitations and future work section concluded the results and provided limitations and the future direction of the current work.

MATERIALS AND METHODS

Study Population

The training and internal test set data was derived from the Surveillance, Epidemiology, and End Results (SEER) database, and the external test set data was derived from the First Affiliated Hospital of Nanchang University in China. A data set of 311,408 IDC patients was included from the SEER database (2010–2017) and sliced into a training set and an internal test set randomly in a ratio of 7:3. An external validation set included data from 1,243 IDC patients of our hospital (2010–2017). The exclusion criteria for clinical data were as follows: (1) unknown information of T, N stage, race, laterality, breast subtype, grade and marital status. (2) Other cases with unknown primary tumor and metastatic status. The detailed exclusion criteria were shown in **Figure 1**. Information of all variables was complete for these patients.

Data Selection

We selected nine variables from the SEER database and our hospital that may affect BM in patients with IDC, including age at diagnosis, race, sex, grade, T, N stage, breast subtype, laterality and marital status. All cases included in this study were staged using the 7th edition of the AJCC TNM staging system and the relevant guidelines of the SEER project.

Statistical Analyses

The statistical analyses in this study were all performed by Python (version 3.8, Python Software Foundation) and SPSS (version 26, IBM, USA). Data from SEER were randomly sliced into training and internal test sets in a ratio of 7:3 using python. The training set was used to construct the models, and the internal test set and external test set were used for model validation and evaluation. A heat map was drawn to determine the association among the variables. A univariate analysis was performed to compare variables between patients with and without BM. For categorical data, the chi-square test was used, and for continuous non-normally distributed data, the Wilcoxon rank-sum test was used. Variables with a $P < 0.05$ in univariate analysis were enclosed within the construction of machine learning models and multivariate logistic regression was performed to identify the risk factors of BM from IDC patients.

Data Pre-processing and Feature Engineering

Category variables such as T and N stages were processed using label encoding methods. The univariate analysis was used to screen for meaningful combinations of features for predicting the risk of IDC patients with BM. Correlation analysis was used to analyze the correlation among the selected features. Feature importance analysis was performed on the variables based on the Permutation Importance principle (17, 18).

Evaluation Metrics

The purpose of this study was to accurately predict the clinical outcome of a specific patient based on multiple variables. So the predictive power and accuracy of the model were important. Thus, to evaluate the model, we considered the area under the receiver operating characteristic curve (AUC), accuracy, sensitivity (recall rate) and specificity score in the study. The following terms were used in the equations: TP (True Positive); TN (True Negative); FP (False Positive); and FN (False Negative).

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

$$sensitivity\ (recall\ rate) = \frac{TP}{TP + FN}$$

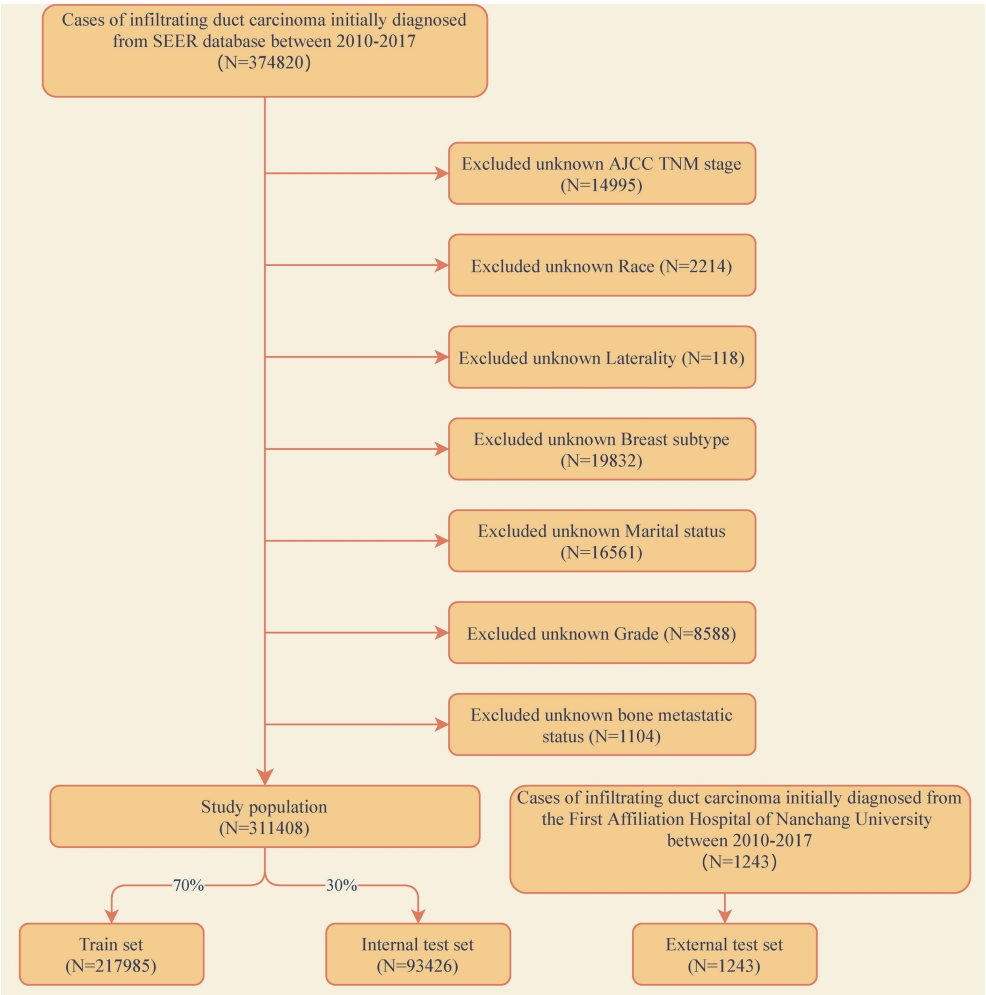

FIGURE 1 | Flow diagram of the study population selected from the Surveillance, Epidemiology, and End Results (SEER) database and the First Affiliated Hospital of Nanchang University. According to the inclusion and exclusion criteria, a total of 311,408 patients of SEER were included in this study, and they were randomly cut into the training and internal test sets in a 7:3 ratio. Data from the First Affiliated Hospital of Nanchang University (n = 1,243) as an external test set.

$$specificity = \frac{TN}{TN + FP}$$

Model Establishment

All the algorithmic models were built based on scikit-learn (version 0.24.2). The random oversampling method in imbalanced-learn (version 0.9.1) was used to deal with the imbalance of data distribution.

In this study, we used six different machine learning algorithms: Logistic regression (LR), Naive Bayes classifiers (NBC), Decision tree (DT), Random Forest (RF), Gradient Boosting Machine (GBM) and Extreme gradient boosting (XGB) (19–24). The ML algorithms were trained and adjusted to predict the BM in IDC patients. Random search method in scikit-learn was used to adjust the hyperparameters of the model. Then, the predictive performance of the ML models was evaluated in internal 10-fold cross-validation of the train set, internal and external test sets and the AUC, accuracy, sensitivity (recall rate) and specificity score were evaluated. Then, we selected the best-performing model to build a web predictor.

RESULTS

Demographic Baseline Characteristics

A total of 311,408 cases who were first diagnosed with IDC in the SEER database from 2010 to 2017 were included. Of these cases, 7,949 (2.55%) complicated with BM and 303,459 (97.45%) without BM. All demographic and clinicopathological characteristics of these patients were demonstrated in detail in **Table 1**. All cases were randomly divided into a training set (n = 217,985) and an internal test set (n = 93,426) in a ratio of 7:3. Data for the external test set were derived from IDC patients firstly diagnosed in our hospital from 2010 to 2017 (N = 1,243). The details of the training and test sets were shown in **Table 2**.

Univariate Analysis and Multivariate Logistic Regression Analysis

According to the univariate analysis, patients' age, gender, race, grade, T, N stage, breast subtype and marital status were significantly associated with BM in patients with IDC ($P < 0.05$; **Table 3**). Variables with a $P < 0.05$ in the univariate analysis were selected for multivariate logistic regression analysis, in order to identify the risk factors of BM in IDC patients. According to these results, age, race, grade, T, N stage, breast subtype, and marital status were found to be independent factors for BM (**Table 3**).

Correlation Analysis of Features

To identify the effect of these features on prediction, correlation tests between each other were performed. Correlation analysis among dataset features provides information about the degree of interaction among features. The heat map showed the relevance of these features on the prediction of ML algorithm (**Figure 2**). The figure showed a positive correlation among T-stage, N-stage and pathological grade. This was consistent with clinical experience that poorly differentiated tumor tissue was poorly demarcated from surrounding normal tissue, which meant it was more aggressive.

Relative Feature Importance on Prediction

The feature importance of each ML model for predicting BM was illustrated in **Figure 3**. Permutation importance principle was used to analyze the relative feature importance on the variables in each ML model. The basic idea of the principle was: (1) Train the model. (2) Disrupt the data in one of the columns and use that dataset for prediction, evaluating the decrease in prediction accuracy to reflect the importance of that feature variable. (3) Restore the validation dataset and repeat the second step to analyze the other feature variables. Although the relative feature importance in different ML models varied slightly, T, N stage, breast subtype, grade, and marital status were the top-ranked variables in most models. In contrast, the race was the last one in most models. But it also contributed to the model. In the XGB model, the relative feature importance was sorted in descending order by T, N stage, breast subtype, grade, marital status, laterality, age, sex, and race.

Model Performance

The prediction performance of all models was compared with the internal 10-fold cross-validation of the training set, internal and external test sets, as shown in **Figures 4–6** and **Table 4**. In the

internal test set, the XGB model was the best performer with an AUC of 0.857, an accuracy of 0.787, a sensitivity of 0.787 and a specificity of 0.791. In the external test set, the XGB model showed a relatively better performance with an AUC of 0.888, an accuracy of 0.803, a sensitivity of 0.801 and a specificity of 0.837 (**Table 4**). Finally, we used the highest-performing model to create a web predictor.

Web Predictor

Based on the XGB model, a ML algorithm for optimal predictive performance, the web predictor mentioned above was developed to predict the risk of BM in IDC patients. We can predict the BM risk in IDC patients simply by setting variables in the sidebar of the website (**Figure 7**) (https://share.streamlit.io/liuwencaincu/breast-cancer/main/breast.py).

DISCUSSION

Breast cancer was the most common malignant tumor in women, and IDC accounted for about 80% of all BC cases (3). BC patients who had BM were more likely to have poor prognosis and bad quality of life (25), and earlier attention to patients at a

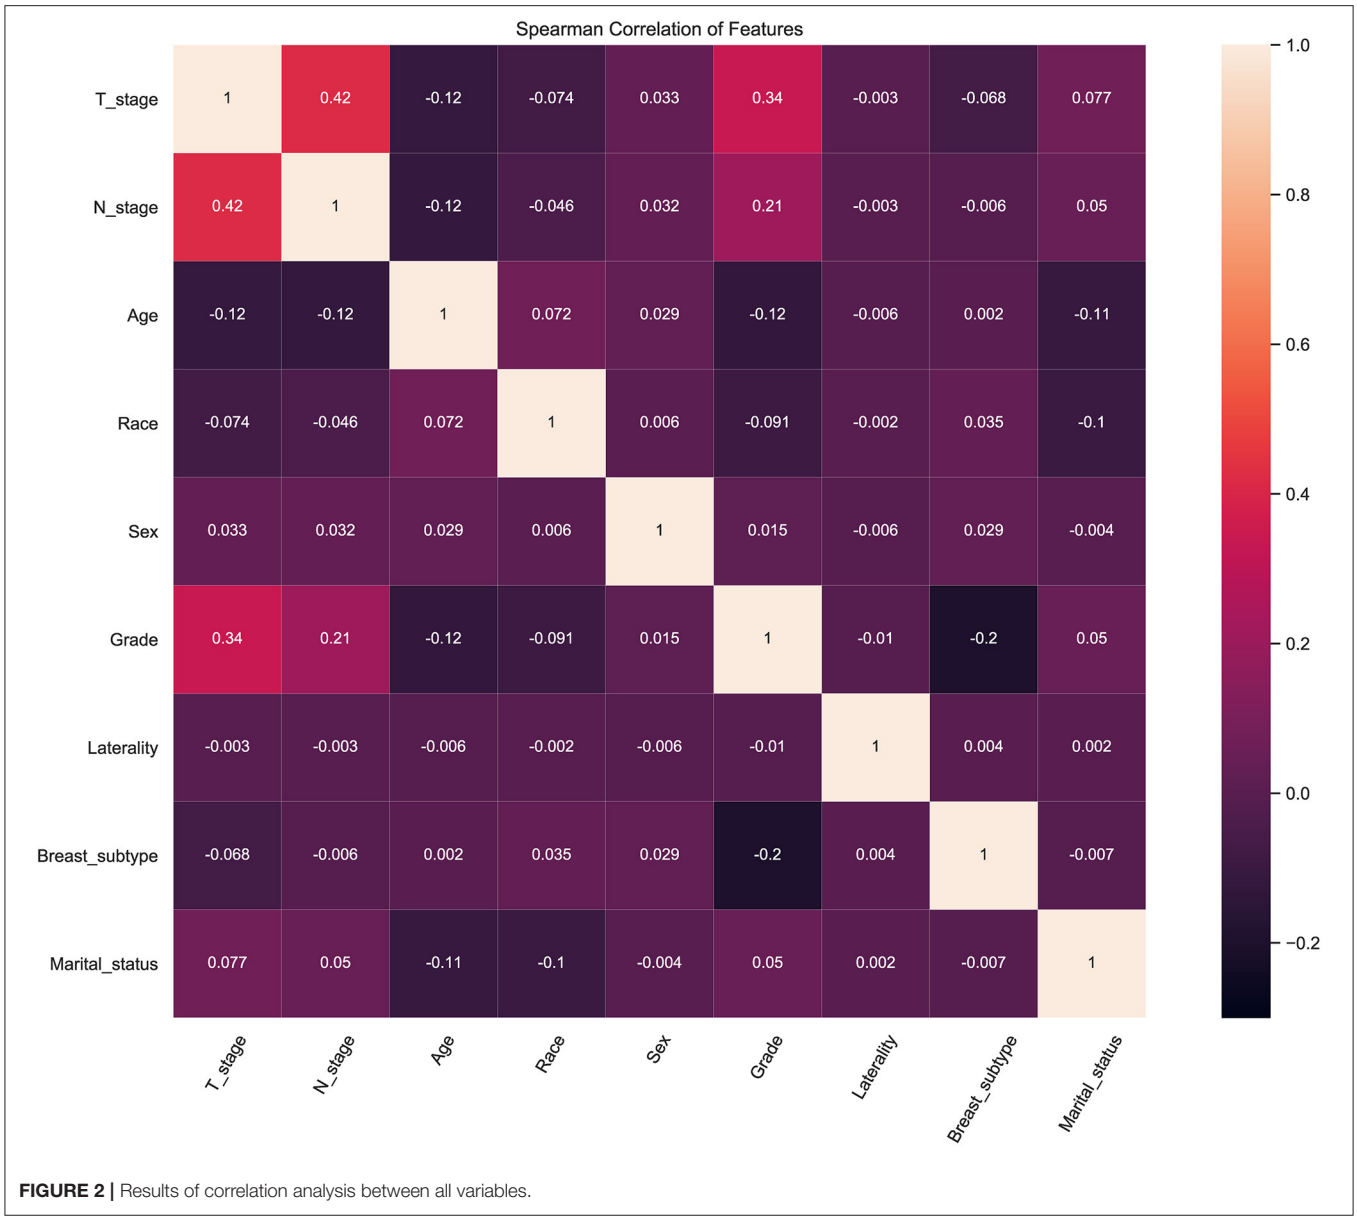

FIGURE 2 | Results of correlation analysis between all variables.

high risk of BM was important. However, metastatic BC was a highly heterogeneous disease, and bone was the most common site of distance metastasis from BC (3, 5, 26). A decline in quality of life was common among patients with BC who suffered from BM. And the risk of skeletal-related events significantly increased following BM in BC patients, such as pain, fracture and hypercalcemia (27, 28). The life expectancy of patients with BC benefitted from early detection and systemic therapy. Therefore, the prognosis of patients with late detection was often poor against a background of increasing incidence of BM.

Bone scintigraphy is often used to distinguish BC patients likely to develop BM. However, this method may not be suitable for early screening due to the expense and radiation damage associated with bone imaging. To help address these potential problems, we built a predictive model using ML technologies to predict BM in IDC patients and identify patients at a high risk of BM.

Presently, new techniques in ML and artificial intelligence (AI) help us succeed in translational research in many fields (29–31). Given the success of ML techniques in other fields, coupled with the large amount of data available in healthcare, ML techniques will have a promising future in the medical field (32–34). In particular, the emergence of electronic medical records (EMR) has generated a large accumulation of clinical data sets, including clinical diagnoses and laboratory data. ML in the medical field can lead to accurate diagnosis and personalized patient care (35). Since the outbreak of the COVID-19, scientists have used ML techniques to develop a variety of predictive and diagnostic models based on big clinical data from patients to help health care professionals work together to address the pandemic

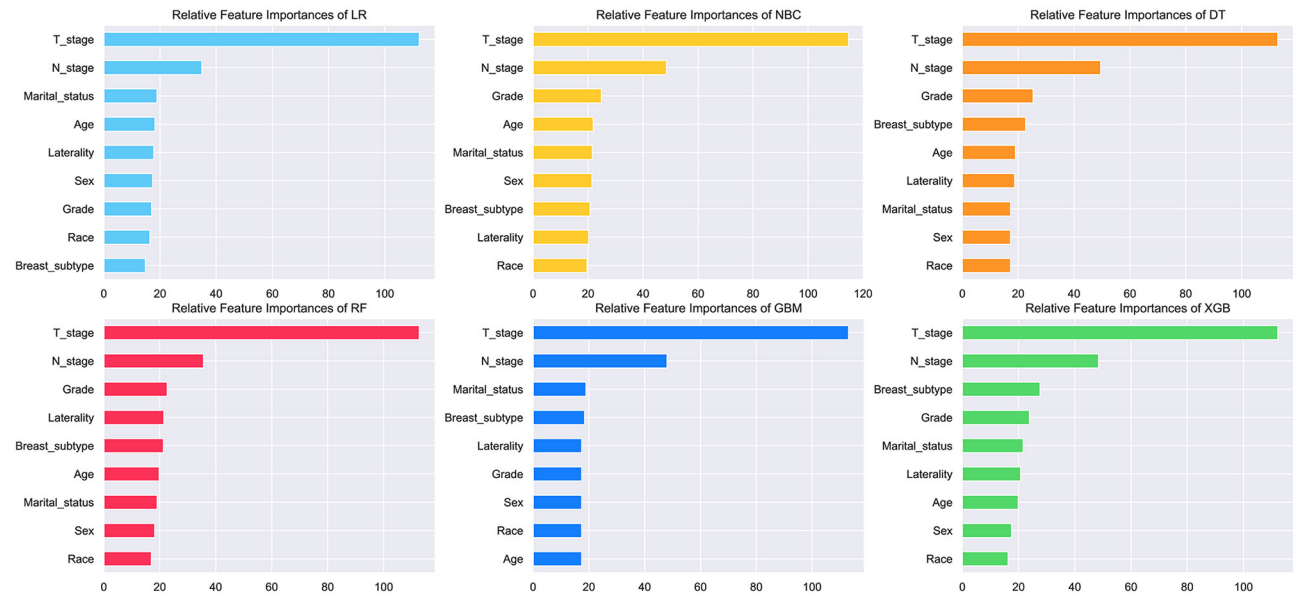

FIGURE 3 | Relative feature importance of different models. The plot showed the ranking of the relative importance of features in all models.

(36–38). Statistical and comprehensive reviews of ML in medical diagnosis by Bhavsar et al. (35, 39) suggested that ML techniques can help medical professionals reduce diagnostic errors, improve healthcare services, and cut treatment costs. And in the cancer metastases field, some clinical prediction models in predicting the risk of BM based on ML algorithms have been developed to assist clinicians in personalizing patient diagnosis (40, 41).

This study was novel in using ML algorithms to predict the risk of BM in IDC patients. To our knowledge, researchers in the medical field have only used traditional linear statistical models to predict the risk of BM in IDC patients, and few studies applied ML techniques to them (42). A ML model based on XGB algorithm was developed to accurately predict the risk of BM, outperforming other models developed in this study. The model

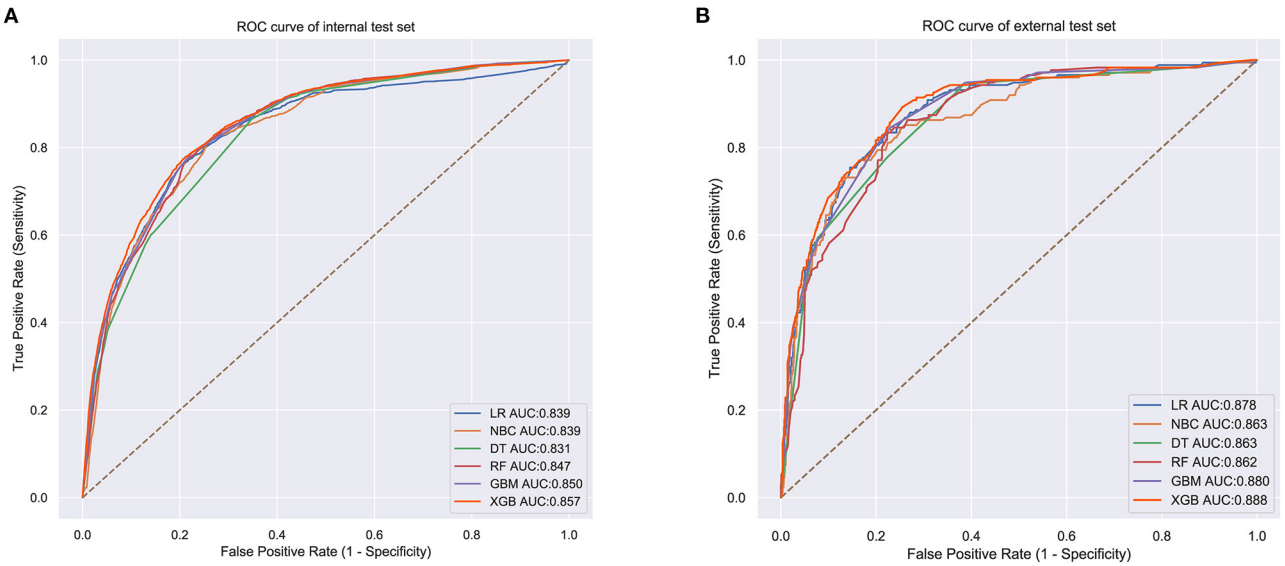

FIGURE 5 | (A) Internal test ROC curve of different machine learning models. **(B)** External test ROC curve of different machine learning models.

established in this study had great discrimination and showed satisfactory specificity and sensitivity.

In this study, several models were constructed and validated to predict BM risk in patients with IDC using current ML methods, and logistic regression analysis demonstrated that age, race, grade, T, N stage, breast subtype, and marital status were independent risk factors for BM. After analyzing the performance of six ML algorithms, we found that the XGB method performed the best (AUC-0.888). The XGB algorithm added a regular term to the objective function to control the complexity of the model and avoid overfitting, while supporting column sampling to enhance the stability of the model (19). This may be part of the reason why it achieved the best performance in our study. To increase the practicality of this model implementation, we created an online web calculator for calculating individual BM probability in IDC patients.

Previous study indicated that age and race were investigated broadly as risk factors for BC metastasis (43). It was reported that white women were less likely to have BM from BC than black women (44). In our study, blacks also had a higher incidence of BM than those of Whites, American Indians and Asia-Pacific people. Chen et al. and Wang et al. found that elderly women were more likely to develop BM from BC (45, 46). In the present study, we found that advanced age was a risk factor for BM in patients with IDC.

Tumor size was positively correlated with the chance of BM. Yazdani et al. found that tumor size was a risk factor of BM from BC and a larger tumor size increased the likelihood of BM (47). In this study, patients with N3 stage were significantly more likely to develop BM than patients with other stages. And the average N stage in patients with BM was higher than that of the non-metastatic population. Yazdani et al. reported that more cancerous axillary lymph nodes increase the risk of BM (47). Colleoni et al. also found that there was the highest frequency of BM in patients who had four or more cancerous axillary lymph nodes (48). In addition, patients with higher-grade IDC had a higher risk of BM than those with grade I (Well differentiated) in this study. One reason for this may be that poorly differentiated tumor tissue was poorly demarcated from surrounding normal tissue, which meant it was more aggressive.

Additionally, it has been found that different breast subtypes showed different trends of BM. Previous study indicated that the incidence of BM was higher in patients with HR+/HER2- (Luminal A) and HR+/HER2+ (Luminal B) (49). In the current study, we found patients with HR+/HER2+ (Luminal B) were more likely to develop BM than those with other subtypes of BC.

Another risk factor for BM in our model was marital status. Unmarried patients had a higher risk of BM than those who were married. Zhao et al. and Gao et al. reported that marital status was a prognostic factor influencing the survival of metastatic BC patients (50, 51). Thus, we believed that the lifestyle habits and psychological factors of unmarried women may influence the distance metastasis of IDC patients.

As far as we know, this study was the first attempt to use ML algorithms to predict the risk of BM for IDC patients. Although some previous prediction models for BC based on the SEER database have been developed, it verified just from the SEER database and whether it can be used in different regions was not clear (26, 45). In addition, these studies only used nomogram as a visualization tool and did not provide a web predictor. External test of the model was important to validate the stability of the model for different regional populations. Therefore, in this study, we used data from the SEER database to build a prediction model based on the XGB algorithm and validated it with a cohort from China. Through our predictive model, we can predict the risk of BM in patients with IDC in the early

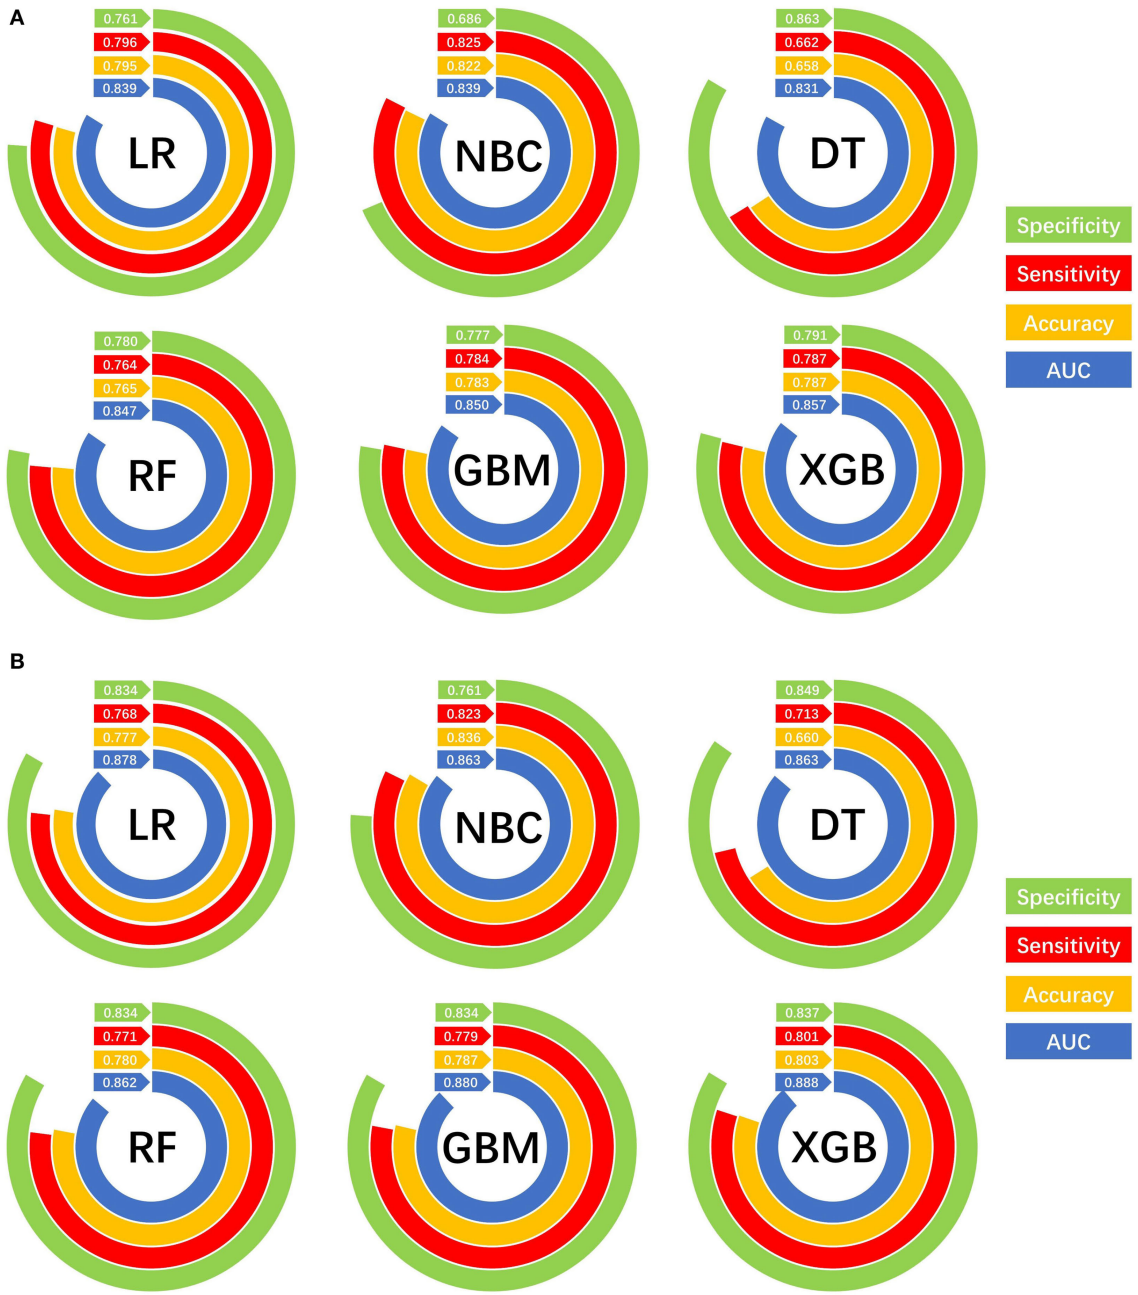

FIGURE 6 | Prediction performances of different machine learning models. **(A)** Internal validation of different machine learning models. **(B)** External validation of different machine learning models.

stage, indicate the related risks before the progression to the late stage, and accept the corresponding treatment regimen as soon as possible, which can significantly improve the prognosis of IDC patients. Furthermore, we developed a web predictor based on the model to predict the risk of BM in IDC patients. Clinicians can easily enter information about the patient's relevant variables into the model on the web page, and the model will calculate the patient's risk of developing BM. Nowadays, precision medicine has preceded four concepts: predictive, personalized, preventive and participatory. Due to the ML model we built, we can predict the risk of BM to a particular patient. The rapidity and accuracy of the prediction output allowed clinicians to make personalized decisions for their patients and could be used as a basis for clinicians to explain their decisions to patients and involved them in their treatment choices. From the clinician's point of view, substantial advances in ML had potential implications in clinical practice, including diagnosis, risk stratification and prognosis, treatment planning, and advances in precision medical methods

(52). Of course, they always had the final decision when it came to interpretation based on their domain expertise.

CONCLUSIONS, LIMITATIONS, AND FUTURE WORK

Overall, this study used ML algorithms to construct and validate a clinical prediction model for predicting the risk of BM in patients with IDC based on large samples. Among all these algorithms, XGB performed the best. And we built an easy-to-use web calculator based on the XGB model, which can help physicians to individualize the diagnosis and treatment of BM in IDC patients.

Although our model achieved good results in prediction, there were still some limitations in it. First, it was a retrospective study, which needed to be further verified by prospective study. Second, only one external validation set was used to validate the model, and further efforts were required to validate the performance of the model in a more diverse population. Third, the SEER database just recorded the initial diagnosis of a patient, which meant that further information was lack and we were unable to access this information for further analysis.

For future work, we will focus on prospective and diverse population validation of the models to verify the performance and stability. These models are then expected to be integrated into applications that assist clinicians in medical decision-making. This can be a step toward a semi-autonomous diagnostic system that can assist clinicians in making individualized diagnoses of BM for IDC patients.

DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: https://seer.cancer.gov/.

ETHICS STATEMENT

We received permission to access the research data file in the SEER program from the National Cancer Institute, US. Approval

was waived by the Local Ethics Committee, as SEER data is publicly available and de-identified. This study was approved by the Ethics Committee of the First Affiliated Hospital of Nanchang University, and cases from the First Affiliated Hospital of Nanchang University signed a written informed consent form.

AUTHOR CONTRIBUTIONS

W-CL and J-ML designed the study. W-CL, S-NW, W-LT, A-AL, and B-LS performed analysis and generated the figures and tables. W-CL, M-XL, and S-NW wrote the manuscript. Z-LL and J-ML critically reviewed the manuscript. All authors have read and approved the manuscript.

FUNDING

This work was supported by the Department of Science and Technology Program of Jiangxi Province, China (No. 20203BBG73045).

ACKNOWLEDGMENTS

We thank Mr. Wenxing Qian of Department of Computer Science, Beijing Jiaotong University for his assistance in algorithm and Ms. Yixin Lai of School of Pharmacy, Tongji Medical College, Huazhong University of Science and Technology for her assistance in literature search.

Zhang Z, Zhanghuang C, Wang J, Mi T, Liu J, Tian X, Jin L and He D (2022) A Web-Based Prediction Model for Cancer-Specific Survival of Elderly Patients Undergoing Surgery With Prostate Cancer: A Population-Based Study. Front. Public Health 10:935521. doi: 10.3389/fpubh.2022.935521

Objective: Prostate cancer (PC) is the second leading cause of cancer death in men in the United States after lung cancer in global incidence. Elderly male patients over 65 years old account for more than 60% of PC patients, and the impact of surgical treatment on the prognosis of PC patients is controversial. Moreover, there are currently no predictive models that can predict the prognosis of elderly PC patients undergoing surgical treatment. Therefore, we aimed to construct a new nomogram to predict cancer-specific survival (CSS) in elderly PC patients undergoing surgical treatment.

Methods: Data for surgically treated PC patients aged 65 years and older were obtained from the Surveillance, Epidemiology, and End Results (SEER) database. Univariate and multivariate Cox regression models were used to identify independent risk factors for elderly PC patients undergoing surgical treatment. A nomogram of elderly PC patients undergoing surgical treatment was developed based on the multivariate Cox regression model. The consistency index (C-index), the area under the subject operating characteristic curve (AUC), and the calibration curve were used to test the accuracy and discrimination of the predictive model. Decision curve analysis (DCA) was used to examine the potential clinical value of this model.

Results: A total of 44,975 elderly PC patients undergoing surgery in 2010–2018 were randomly assigned to the training set (N = 31705) and validation set (N = 13270). the training set was used for nomogram development and the validation set was used for internal validation. Univariate and multivariate Cox regression model analysis showed that age, marriage, TNM stage, surgical style, chemotherapy, radiotherapy, Gleason score(GS), and prostate-specific antigen(PSA) were independent risk factors for CSS in elderly PC patients undergoing surgical treatment. The C index of the training set and validation indices are 0.911(95%CI: 0.899–0.923) and 0.913(95%CI:

0.893–0.933), respectively, indicating that the nomogram has a good discrimination ability. The AUC and the calibration curves also show good accuracy and discriminability.

Conclusions: To our knowledge, our nomogram is the first predictive model for elderly PC patients undergoing surgical treatment, filling the gap in current predictive models for this PC patient population. Our data comes from the SEER database, which is trustworthy and reliable. Moreover, our model has been internally validated in the validation set using the C-index,AUC and the and the calibration curve, showed that the model have good accuracy and reliability, which can help clinicians and patients make better clinical decision-making. Moreover, the DCA results show that our nomogram has a better potential clinical application value than the TNM staging system.

Keywords: nomogram, SEER, prostate cancer, surgery, elderly, CSS

BACKGROUND

The global incidence of prostate cancer (PC) is second only to lung cancer, and it is also the second leading cause of cancer death among men in the United States (1). PC is a heterogeneous disease with a variable natural history (2). With the introduction of serum prostate-specific antigen(PSA) testing in the late 1980s, the age at diagnosis of PC was nearly 10 years earlier, so surgeons can now provide more prompt surgical intervention early in tumor development without waiting for advanced stage (3).

PC has a variety of treatment options, including active surveillance (AS), surgical resection, radiotherapy (RT), chemotherapy, local ablation therapy (cryotherapy, high-intensity focused ultrasound), etc. Surgery is the primary treatment modality for PC, including radical prostatectomy (RP) and local tumor resection. However, while up to half of the patients with PC require only active surveillance at initial diagnosis, most men are willing to undergo aggressive local surgical treatment. Radical prostatectomy is associated with improved cancer-specific mortality(CSM), metastasis-free survival, and the need for palliative care, and surgical resection may be more beneficial for PC patients than radiotherapy (4). Xia et al. demonstrated that men undergoing radical prostatectomy had an increased life expectancy by 1.8 months compared to active surveillance (5). The above studies suggest that patients with PC treated with surgery may have a better prognosis. However, some studies suggest that surgery does not have much benefit in the prognosis of PC patients. The ProtecT trial reported the results of several extensive cohort studies suggesting that active surveillance could be safely used in carefully selected low-risk PC patients (6, 7). Elisabeth M et al. also found that surgical resection and radiotherapy did not benefit much from survival in patients with low-risk PC (4). We found that the current study is controversial regarding the impact of surgical treatment on the prognosis of PC patients. Based on this, we are eager to develop a model that can predict prognostic factors in PC patients undergoing surgery.

The traditional tumor-node-metastasis (TNM) cancer staging system of the American Joint Committee on Cancer (AJCC) has been used as a prognostic criterion for the vast majority of solid tumors. However, it does not include many important factors related to PC survival, such as age, prostate-specific antigen, Gleason score(GS), surgical, chemoradiotherapy, etc. In recent years, the nomogram prediction model has been considered one of the most accurate ways to predict tumors (8). Currently, nomograms based on the SEER database have been increasingly used to predict the prognosis of PC patients. Joao Ricardo Alves et al. constructed a nomogram predicting extracapsular extension in prostate cancer patients (9). In addition, researchers have developed nomograms that can predict lymph node metastases in patients with intermediate-risk prostate cancer, bone metastases in patients with newly diagnosed prostate cancer, survival in patients with prostate cancer spinal metastases, and survival in patients with metastatic prostate cancer undergoing radical prostatectomy (10–13). The incidence of PC is closely related to age. Data report that older men over 65 years old account for more than 60% of PC patients (14), and more than 90% of PC cancer-specific deaths (CSS) occur in this age group (15). Therefore, finding prognostic factors associated with CSS in surgically treated elderly PC patients has important clinical implications for reducing patient mortality. Unfortunately, however, to our knowledge, no nomogram has been developed for elderly PC patients undergoing surgical treatment. Therefore, our study aimed to use data from the SEER database to develop a nomogram for elderly PC patients undergoing surgical treatment that can accurately predict the relevant factors affecting patients' CSS to better assist clinicians and patients in making clinically aided decisions.

PATIENTS AND METHODS

Data Source and Data Extraction

Data from patients diagnosed with PC between 2010 and 2018 were extracted from the SEER database, and our study targeted patients aged 65 years and older and undergoing surgical treatment. The SEER database is a national cancer database covering approximately 30% of the population and containing 18 cancer medical centers. No ethical approval and patient informed consent is required because the SEER database data are publicly available and hidden patient information. The research methodology used in this study follows the research guidelines published in the SEER database.

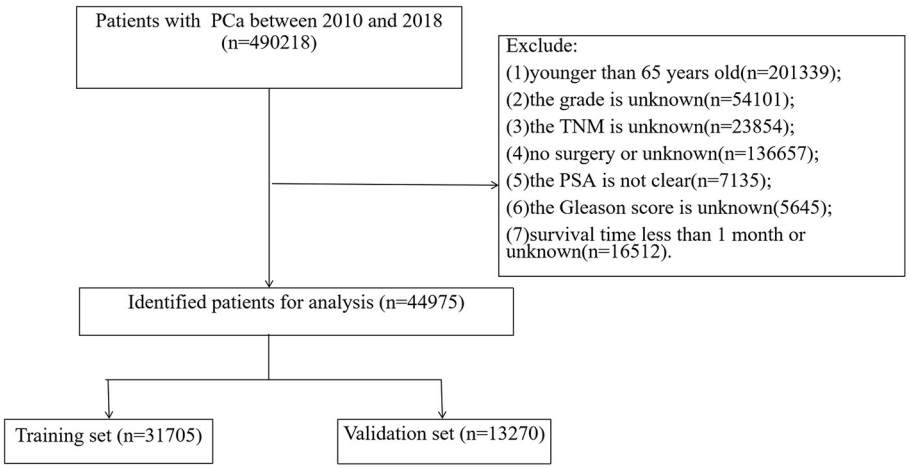

FIGURE 1 | Flowchart for inclusion and exclusion of elderly PC patients undergoing surgery treatment.

The variables in the SEER database include demographic characteristics [age, race, marital status), tumor grade (grade I, II, III, and IV)], TNM stage, surgical method (local tumor resection, radical prostatectomy), radiotherapy, chemotherapy, prostate-specific antigen, Gleason score, survival status, cause of death and survival time. Patient ethnicity was classified as white, black, and other types. Inclusion criteria: (1) patients aged 65 years and older, (2) a pathological diagnosis of PC, and (3) patients undergoing surgical treatment. Exclusion criteria: (1) patients younger than 65 years old, (2) tumor grade is unknown, (3) TNM stage is unknown, (4) no surgical treatment or surgical method is unknown, (5) prostate-specific antigen is unclear, (6) Gleason score is unknown, (7) survival time is < 1 month or survival time is unknown. The flowchart of patient inclusion and exclusion is shown in **Figure 1**.

Development and Validation of the Nomogram

All patients were randomized into the training set (70%) and the validation set (30%) for nomogram development and internal validation. Univariate and multivariate Cox proportional regression models were used to identify independent risk factors for patients in the training set. The nomogram was established based on the restivariate Cox regression analysis, and results were used to predict CSS at 3-, 5-, and 8-year in surgically treated elderly PC patients. In addition, the nomograms were calibrated at 3-, 5-, and 8-year, and these assessments used 1,000 autonomous samples. The accuracy and discrimination of the model were tested by the consistency index (c-index) and the area under the subject operating characteristic curve (AUC).

Clinical Application

The decision analysis curve (DCA) is used to assess the clinical value of the nomogram. We also calculated the risk for each patient from the nomogram. All patients were divided into high-risk and low-risk groups using the cutoff value of the subject operating characteristic curve (ROC). The Log-rank test and the Kaplan-Meier (K-M) curves examined the differences in survival between high-risk and low-risk patients. In addition, we analyzed differences between surgery and radiotherapy in high-risk and low-risk groups.

Statistical Analysis

Means and standard deviations were used to describe continuous variables such as age. Chi-square or non-parametric U tests were used for comparison between groups. Other classifications were described by frequency (%), and the differences between the groups were compared using the chi-square test. The Cox regression model analyzed the patient prognostic factors, and the patient survival differences were analyzed by the log-rank test and the K-M curve. Statistical analyses were performed using the R software version 4.1.0 and SPSS26.0.The R package includes "survival," "ggDCA," "DynNom," and "RMS" P values <0.05 were considered statistically significant.

RESULTS

Clinical Features

A total of 44,975 PC patients from 2010 to 2018 were included in our study from the SEER database who were all over 65 years old and were treated surgically, including the training set ($N = 31705$) and the validation set ($N = 13270$). The mean age of all patients was 70.0 ± 4.73 years, and most patients were white (82.7%) and married (76%). The tumor grade was mainly at grade II (42.2%) and grade III (48.9%). The T stage was dominated by T2 (48.6%), followed by T1 (22.6%) and T3 (26.5%), and minimal T4 (2.38%). All patients were mainly N0 (95.1%) and M0 (98.3%). Most patients underwent radical prostatectomy (83.2%), and fewer patients underwent local tumor resection (16.8%). Only 0.5% of the patients received chemotherapy. The majority of the patients (90.6%) did not receive radiotherapy. The Gleason score was mainly 7 (50.6%), and no significant difference between patients with Gleason scores$\leq$6 (24.2%) and Gleason score$\geq$8 (25.2%). 73.6% patients with prostate-specific antigen <10 ng/ml,

17.8% with prostate-specific antigen 10–20 ng / ml and only 8.58% with prostate-specific antigen> 20 ng/ml.There was no significant statistical deviation in the clinical characteristics of both groups, and the results are shown in **Table 1**.

COX Regression Analysis

A univariate Cox regression model was used to analyze and screen influencing factors associated with survival in the training set. The results showed that age, marriage, grade Grade III, TNM stage, surgical method, chemotherapy, radiotherapy, prostate-specific antigen, and Gleason score were the prognostic factors affecting patient survival. Then, a multivariate Cox regression analysis was used to screen for independent risk factors associated with patient survival. The results showed that age, marriage, TNM stage, surgical method, radiotherapy, chemotherapy, prostate-specific antigen, and Gleason score were independent risk factors affecting patient CSS. All of the results are shown in **Table 2**.

Development and Validation of the Nomograms

We constructed a feasible nomogram based on a multivariable Cox regression analysis model to predict CSS at 3-, 5-, and 8-year in elderly PC patients undergoing surgery (**Figure 2**). Age, TNM stage, surgical method, prostate-specific antigen, and Gleason score are the most significant factors influencing CSS in elderly PC patients undergoing surgical treatment. In addition, radiotherapy, chemotherapy, and marriage also have some effects.

We used internal cross-validation to validate the model's accuracy and discriminability. The C-index for the training and validation sets is 0.911(95%CI: 0.899–0.923) and 0.913(95%CI: 0.893–0.933, respectively), indicating that the prediction model of the nomogram has a good recognition ability. The calibration curves of the training and validation sets show that the predicted values of the nomogram are highly consistent with the actual observations (**Figure 3**), indicating that the nomogram has good accuracy. AUC was used to detect the discrimination of the nomogram, AUC at 3-,5-and 8-year was 92.9, 91.7, and 88.3 in the training set, and in the validation set, AUC at 3-,5-, and 8-year was 91.9,91.1 and 91.7, respectively (**Figure 4**).

Clinical Application of the Nomogram

DCA responds to the clinical value of the nomogram, and our results showed that it has good clinical potential value in both the training group and the validation set (**Figure 5**). Furthermore, we calculated the risk value for each patient based on the nomogram and calculated the optimal cutoff value using the ROC curve. Patients were classified into high-risk (total score 114.33) and low-risk (total score <114.33). The K-M curve showed that the survival rate of patients in the low-risk group was significantly higher than that in both the high-risk group and the high-risk group (**Figure 6**). The high-risk group of patients with 3-, 5-, and 8-year survival rates were 97.7%, 93.1%, and 88.6%, respectively. The low-risk group's 3-, 5- and 8-year survival rates were 99.8%, 99.6%, and 99.1%, respectively. Although most of the high-risk group patients underwent radical prostatectomy, the patients undergoing local tumor resection had higher survival rates. Almost all patients in the low-risk group underwent radical prostatectomy, so there was no significant difference in patient

survival (**Figure 7**). We found that the survival rate of patients in the high-risk group receiving radiotherapy was lower than those who did not, considering that most older patients in the high-risk group had comorbidities and side effects of radiotherapy. In contrast, the survival rate of patients receiving and without radiotherapy in the low-risk group was not significantly different (**Figure 8**).

DISCUSSION

Although the traditional TNM stage is widely used in cancer management, multiple factors affect the prognosis clinically, and the TNM stage does not include these clinical factors. The prostate-specific antigen and Gleason score are critical factors for the prognosis of PC patients. Therefore, the most commonly used risk stratification scheme, D'Amico, combines clinical-stage, prostate-specific antigen, and Gleason score (16). Patients were divided into three risk levels: low risk (clinical stage T1-T2a, prostate-specific antigen≤10 ng/mL and Gleason score≤6), medium risk (T2b or <10 ≤prostate-specifc antigen 20 ng/mL or Gleason score 7), or high-risk disease (stage T2c or prostate-specific antigen> 20 ng/mL or Gleason score≥8). Although the D'Amico risk assessment protocol included prostate-specific antigen and Gleason score compared with the TNM stage, it still ignores the impact of age, ethnicity, marriage, surgical style, and chemoradiotherapy on the survival of PC patients.

The SEER database contains data from 18 medical centers analyzing prominent samples representative of populations from different regions. The SEER database contains patient demographic characteristics (age, race, marital status), tumor grade, TNM stage, treatment mode, and prognostic information, including survival status, cause of death, and survival time. The nomogram is a convenient and reliable statistical prediction tool that also uses multiple clinical variables different from the TNM stage to predict the prognosis of cancer patients (17). The nomogram can provide an individualized prediction of CSS through a comprehensive analysis of these clinicopathological factors. Nomogram meets the requirements of the integrated model. It promotes personalized medicine to facilitate clinicians' use for prognosis prediction using the SEER database. Previous virus studies have developed nomograms for predicting the OS and CSS of multiple databases. Moreover, it has shown promising clinical potential value in renal cancer, endometrial stromal sarcoma, glioma, nephroblastoma, and other cancers (18–20).

It is well known that the chance of genetic mutations inducing cancer increases with age. Studies have shown that age has a crucial role in the survival rate of various cancers (21). PC is no exception, and its incidence was significantly associated with age. PC was more frequent in older men, and the median age of diagnosis was 66 years (22). Multiple predictive models for the PC also showed that age is an independent risk factor for the prognosis of PC patients (15). Our results also show that age is an essential factor affecting patient prognosis. In addition, we found that age was linearly associated with poorer prognostic outcomes in elderly patients older than 65 years, with no significant cutoff value.

It has been reported in much literature that marriage benefits the prognosis of most cancer patients due to more social and financial support after marriage, as well as partner psychological comfort to patients (23). Our results show that marriage is also a protective factor for elderly PC patients undergoing surgery. Previous literature has reported the prevalence of PC among different ethnic groups, and the prognosis was also significantly associated with race (24). However, our study found that race was not an independent risk factor for elderly PC patients undergoing

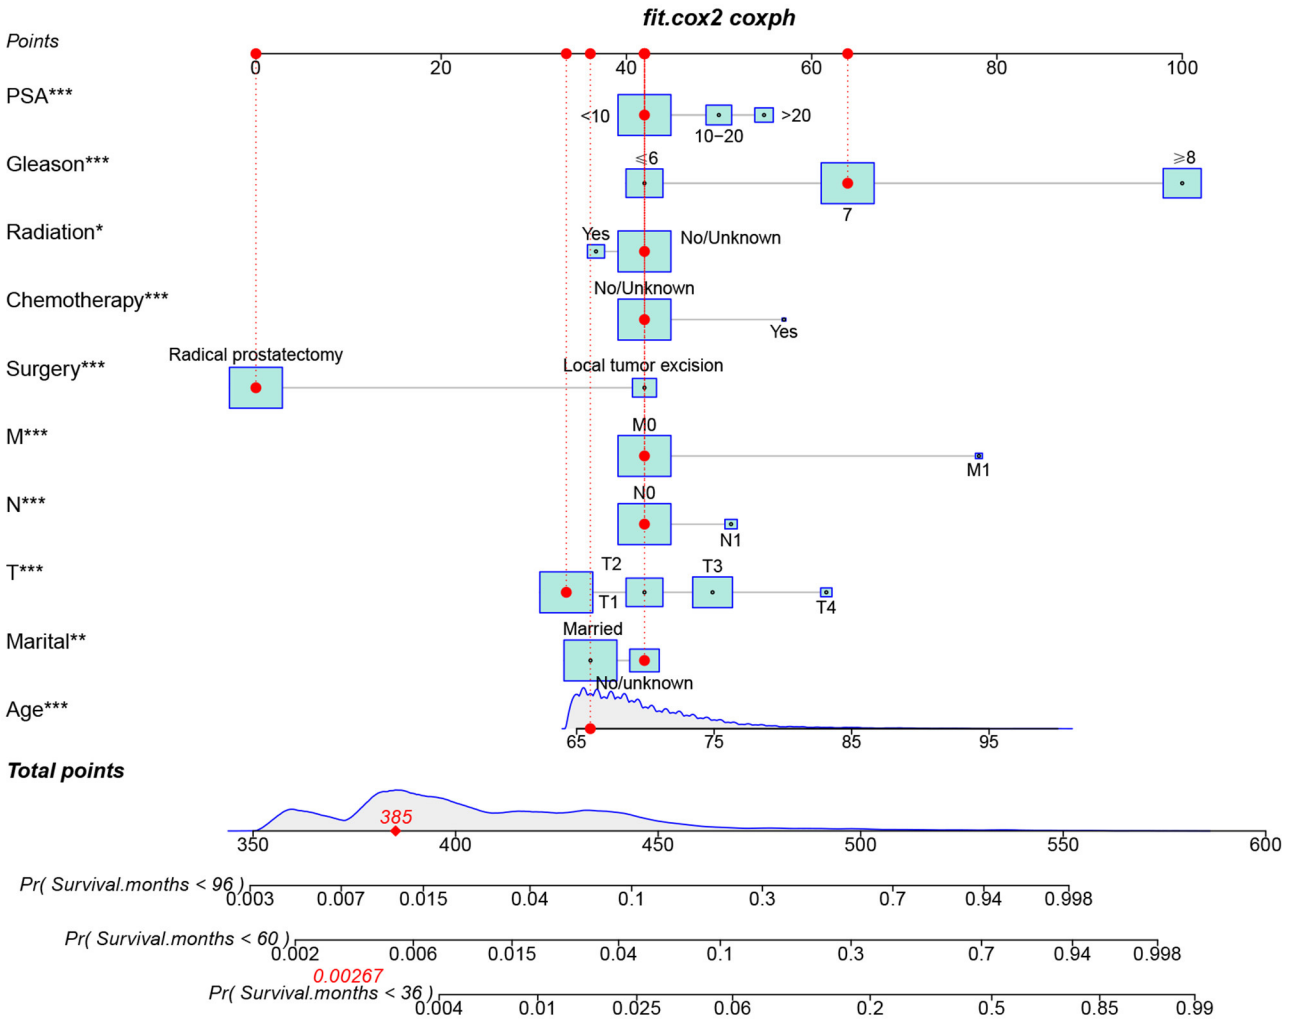

FIGURE 2 | The nomogram for predicting 3-, 5-, and 8-year CSS in elderly PC patients undergoing surgery treatment.

surgery. We considered that this might be related to differences in financial ability and medical level among different ethnic groups, leading to selection bias in treatment modalities.

Prostate-specific antigen screening began in the late 1980s, leading to a sharp increase in PC incidence over a short period (25). In 2012, the US Preventive Services Working Group (USPSTF) reported that prostate-specific antigen screening reduced the risk of PC death, and the USPSTF recommended including prostate-specific antigen in PC screening (26). The impact of screen-detected active treatment for PC on long-term survival compared to active surveillance is unknown but is associated with sexual dysfunction and dysuria (27). A secondary analysis of two randomized clinical trials by Martin et al. showed that increased prostate-specific antigen levels after treatment might be associated with a worse prognosis for locally advanced PC in men (28). The D'Amico risk assessment scheme divided prostate-specific antigen into three grades, prostate-specific antigen $\leq$10 ng/mL, 10–20 ng/mL, $>$ 20 ng/mL. Our prediction model also divided prostate-specific antigen according to this standard. The results showed that the higher the prostate-specific antigen expression level, the worse the patient prognosis, consistent with previous studies (29). Meanwhile, the Gleason score serves as an important tool for predicting the prognosis of PC patients. Our prediction model also divides it into three grades according to the D Amico protocol, Gleason score$\leq$6, Gleason score 7, and Gleason score$\geq$8. Our results showed that the Gleason score of most elderly PC patients undergoing surgical treatment was 7, the worst prognosis for Gleason score$\geq$8, and the best prognosis for Gleason score$\leq$6, which is also supported by previous studies (30, 31).

PC treatment mainly includes active surveillance, surgical resection, radiotherapy, chemotherapy, ADT, and other comprehensive treatment methods. Surgical resection mainly includes radical prostatectomy and local tumor resection. Radiotherapy and radical prostatectomy are evidence-based treatments for non-metastatic PC and can reduce PC mortality

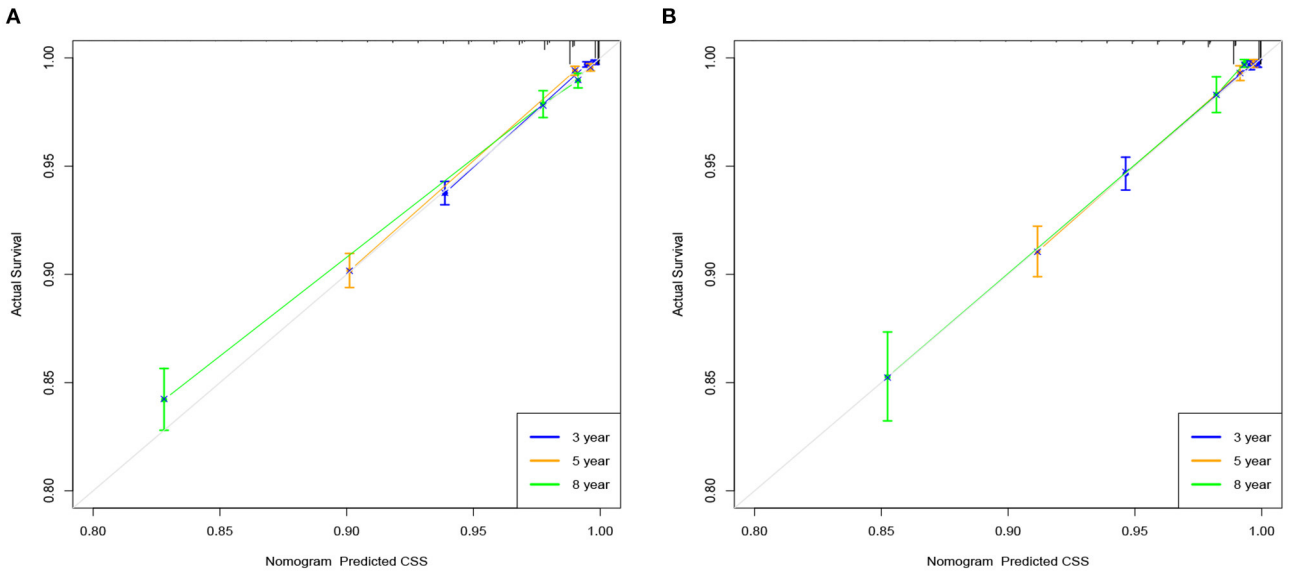

FIGURE 3 | Calibration curve of the nomogram in the training set **(A)** and validation set **(B)**. The horizontal axis is the predicted value in the nomogram, and the vertical axis is the observed value.

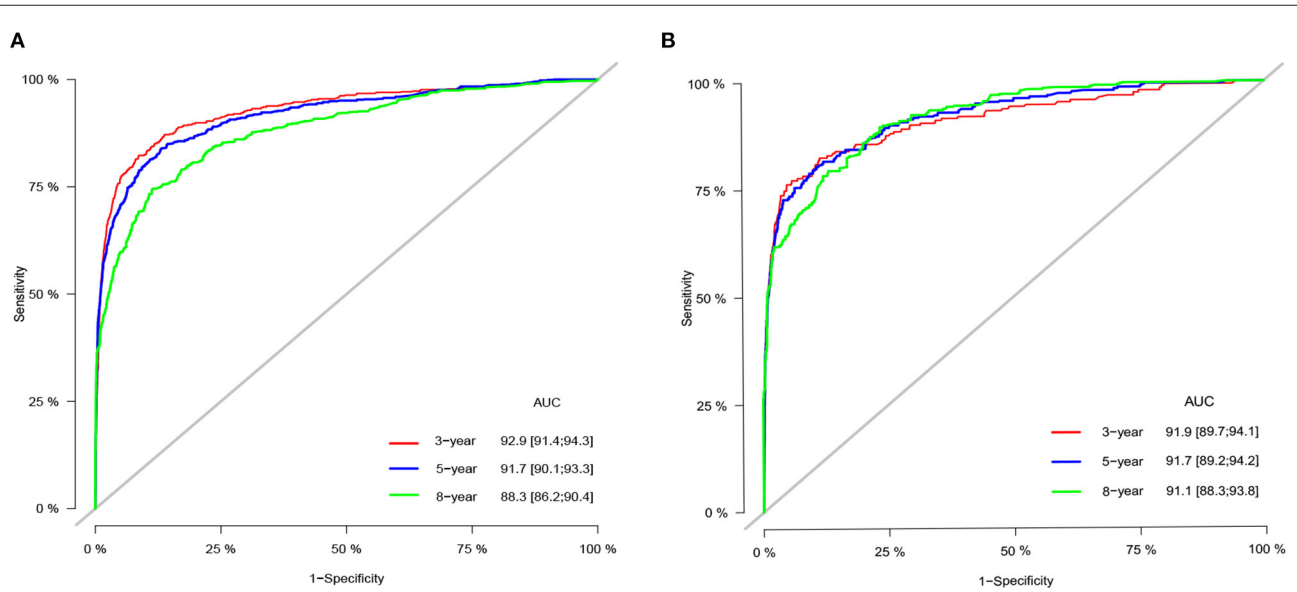

FIGURE 4 | AUC for predicting 3-, 5-, and 8-year CSS in the training set **(A)** and validation set **(B)**.

compared with non-therapeutic randomized clinical trials (32). A ProtecT randomized controlled trial by David E Neal et al. showed that 90% of localized patients did not die of PC within 10 years. Whether through active surveillance, surgery, or radiotherapy, active surveillance had fewer side effects on sexual and bladder function but a greater risk of tumor spread (33). The study by Freddie C Hamdy et al. confirmed that surgery and radiotherapy were associated with a lower incidence of disease progression and metastasis than active surveillance (34). A randomized trial conducted by Lars Holmberg et al. showed that radical prostatectomy significantly reduced CSS in early-stage PC patients but showed no significant difference between surgery and observation waiting for OS (40). Anna Bill-Axelson et al. confirmed that radical prostatectomy was associated with reduced mortality in PC, but adjuvant local or systemic therapy may be more beneficial in men with extracapsular tumor growth; they also concluded that radical prostatectomy showed no benefit in

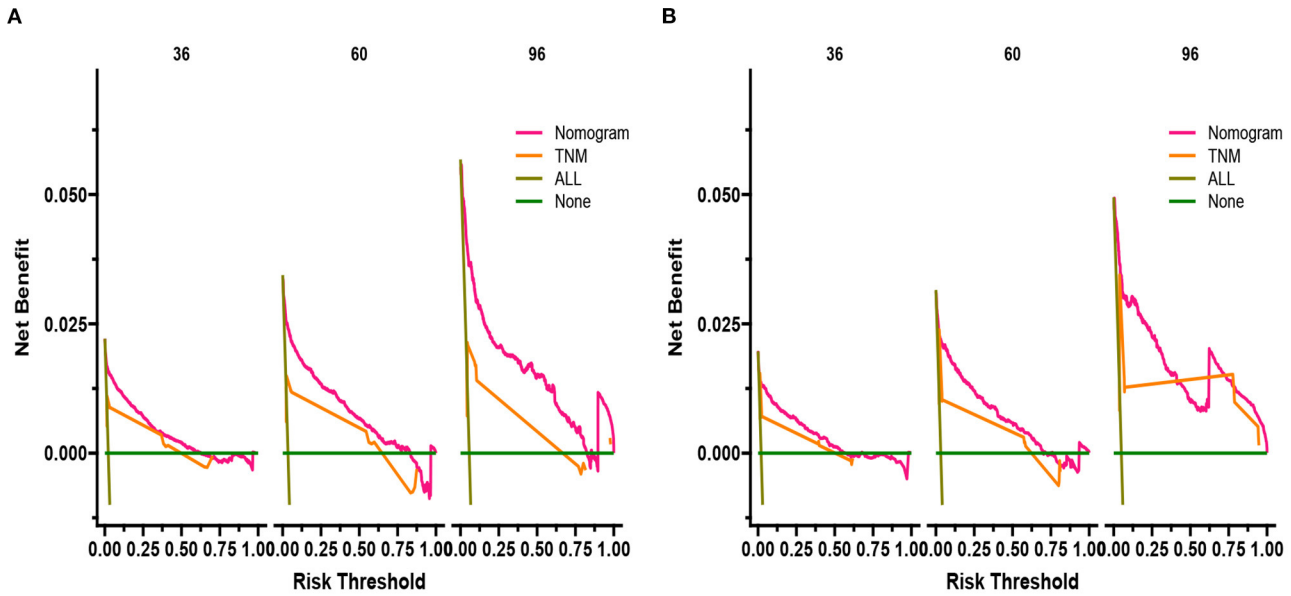

FIGURE 5 | DCA of the nomogram in the training set **(A)** and the validation set **(B)**. The Y-axis represents a net benefit, and the X-axis represents threshold probability. The green line means no patients died, and the dark green line means all patients died. When the threshold probability is between 0% and 100%, the net benefit of the model exceeds all deaths or none.

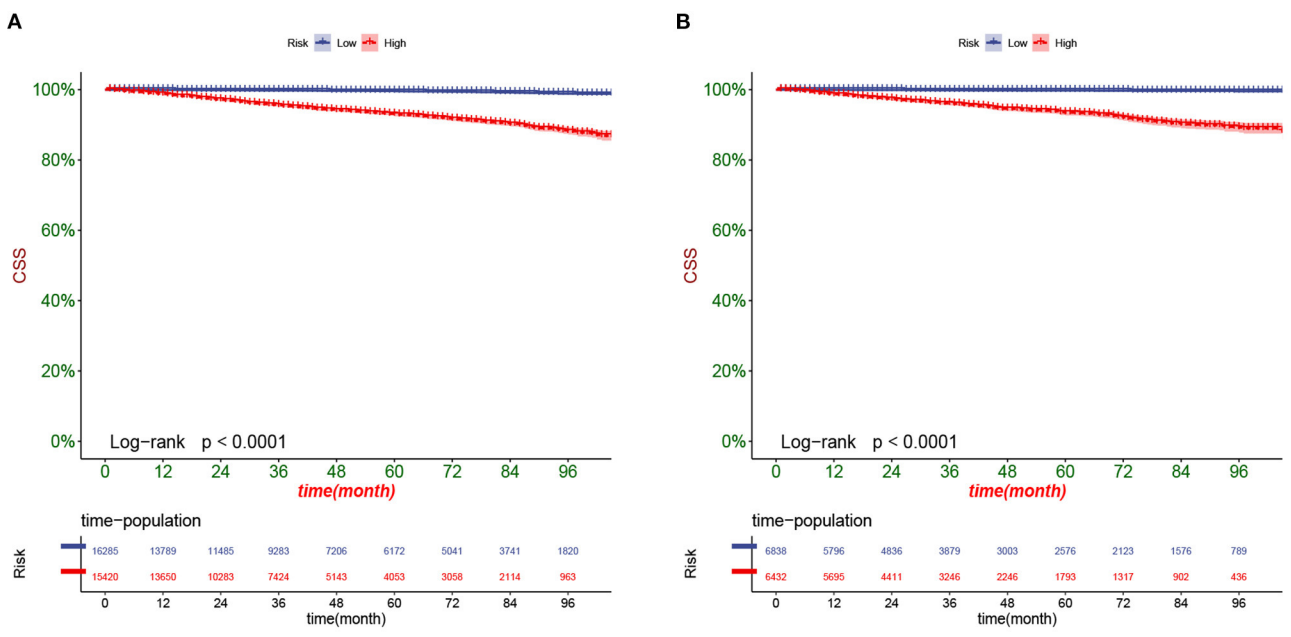

FIGURE 6 | Kaplan-Meier curves of patients in the low-risk and high-risk groups in the training set **(A)** and validation set **(B)**.

elderly PC patients over 65 years (35). After nearly 20 years of follow-up of men with localized PC, Timothy J Wilt et al. found that surgery was not associated with significantly reduced mortality and a higher frequency of adverse events than active surveillance (36). The above studies show that different treatment modalities' outcomes differ significantly for different types of PC patients. Our results showed that radical prostatectomy is associated with a better prognosis than local tumor resection; postoperative radiotherapy achieves a better prognosis than patients without radiotherapy. However, our nomogram shows that chemotherapy is associated with a worse prognosis. We consider why patients receiving chemotherapy often relapsed or

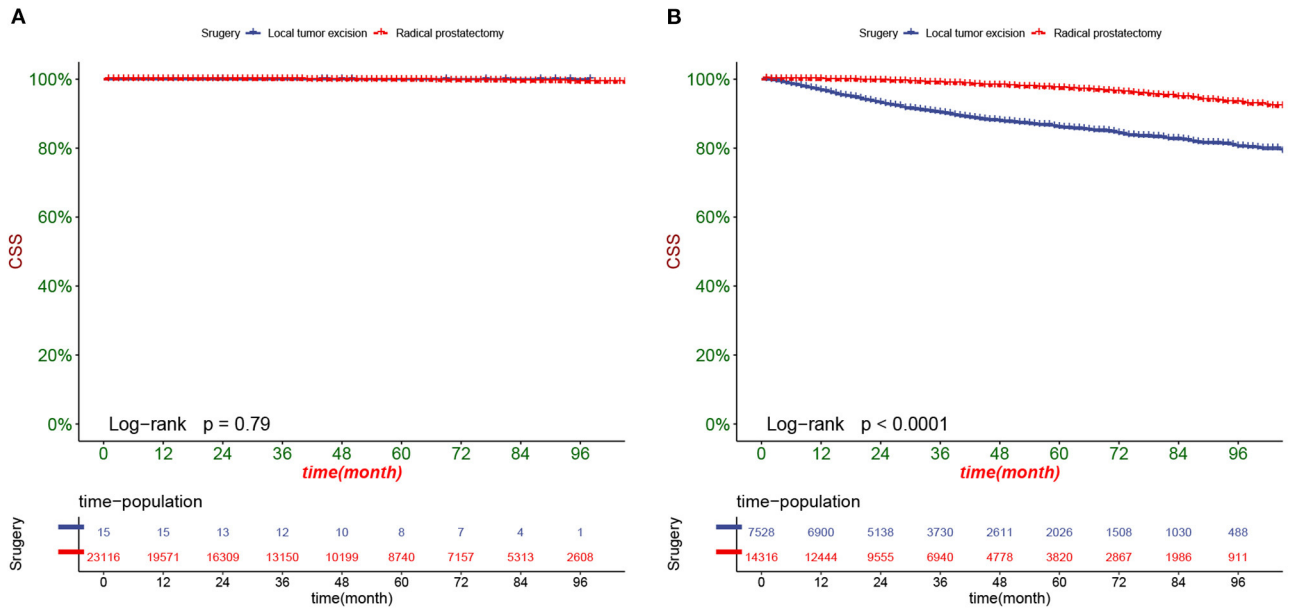

FIGURE 7 | Kaplan-Meier curves of patients with different surgery in the low-risk group **(A)** and high-risk group **(B)**.

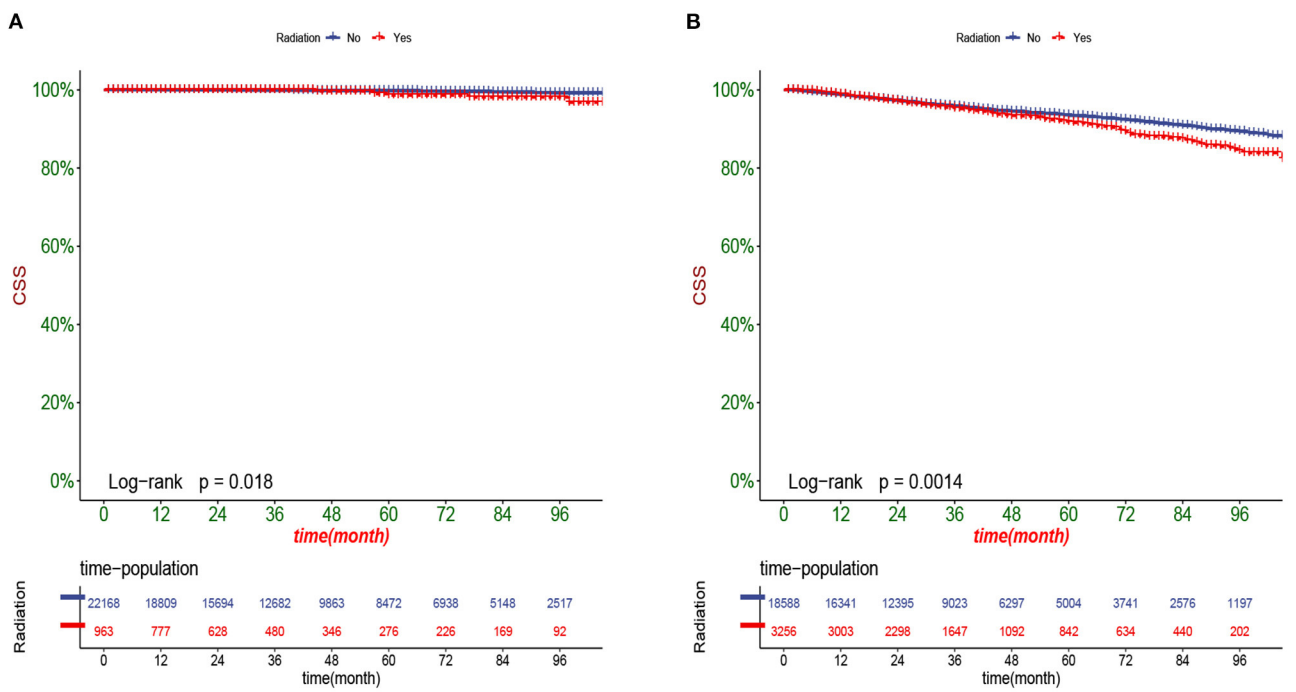

FIGURE 8 | Kaplan-Meier curves of patients with or without radiotherapy in the low-risk group **(A)** and high-risk group **(B)**.

have distant metastasis and have a worse prognosis. At the same time, the small number of people receiving chemotherapy results in biased results.

The nomogram based on the SEER database has good accuracy, but this study has some shortcomings. First, there is a lack of essential information, such as ADT, which is one of the primary treatment modalities for PC; however, there is a lack of data related to ADT in the SEER database, so our model also lacks the relationship between ADT and prognosis. Moreover, PSA is an important indicator related to prognosis for PC patients.

However, it was not included in the SEER database until 2010, so we can only choose data after 2010 to build a predictive model, resulting in a smaller sample size for us to choose. Second, our nomogram could not include all related prognostic variables such as BMI, smoking, alcohol consumption, Etc. leading to some limitations in our results. Finally, our study was retrospective, which may lead to an unavoidable risk of selection bias. Although our results have some limitations, our nomogram still includes key prognostic variables and has been internally validated to show good accuracy, so the results are not significantly biased. Second, our nomogram shows good potential clinical application value, which can help doctors and patients to make clinical decision-making.

CONCLUSION

Our study explored the clinicopathological factors affecting CSS in elderly PC patients undergoing surgical treatment. We found that age, marriage, prostate-specific antigen, Gleason score, surgical mode, chemoradiotherapy, and TNM stage were independent risk factors affecting CSS in patients. We established a nomogram that could predict the CSS in elderly PC patients undergoing surgical treatment. The model has been internally validated with good accuracy and reliability. It showed better potential clinical application value than the TNM staging system; it can help clinicians and patients make clinical decisions. However, our study is retrospective, which may lead to an unavoidable risk of selection bias. Future prospective studies with large and multicenter samples are needed to validate the nomogram further.

DATA AVAILABILITY STATEMENT

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/**Supplementary Material**.

AUTHOR CONTRIBUTIONS

ZZ and CZ designed the study. ZZ, JW, JL, LJ, and XT collected and analyzed the data. ZZ drafted the initial manuscript. CZ, TM, JL, and DH revised the article critically. CZ, JL, and DH reviewed and edited the article. All authors approved the final manuscript.

Intelligent automatic sleep staging model based on CNN and LSTM

Lan Zhuang[1], Minhui Dai[2,3], Yi Zhou[3] and Lingyu Sun[2,3]*

[1]Staff Hospital, Central South University, Changsha, China, [2]Teaching and Research Section of Clinical Nursing, Xiangya Hospital of Central South University, Changsha, China, [3]Department of Ophthalmology, Xiangya Hospital, Central South University, Changsha, China

Since electroencephalogram (EEG) is a significant basis to treat and diagnose somnipathy, sleep electroencephalogram automatic staging methods play important role in the treatment and diagnosis of sleep disorders. Due to the characteristics of weak signals, EEG needs accurate and efficient algorithms to extract feature information before applying it in the sleep stages. Conventional feature extraction methods have low efficiency and are difficult to meet the time validity of fast staging. In addition, it can easily lead to the omission of key features owing to insufficient a priori knowledge. Deep learning networks, such as convolutional neural networks (CNNs), have powerful processing capabilities in data analysis and data mining. In this study, a deep learning network is introduced into the study of the sleep stage. In this study, the feature fusion method is presented, and long-term and short-term memory (LSTM) is selected as the classification network to improve the accuracy of sleep stage recognition. First, based on EEG and deep learning network, an automatic sleep phase method based on a multi-channel EGG is proposed. Second, CNN-LSTM is used to monitor EEG and EOG samples during sleep. In addition, without any signal preprocessing or feature extraction, data expansion (DA) can be realized for unbalanced data, and special data and non-general data can be deleted. Finally, the MIT-BIH dataset is used to train and evaluate the proposed model. The experimental results show that the EEG-based sleep phase method proposed in this paper provides an effective method for the diagnosis and treatment of sleep disorders, and hence has a practical application value.

KEYWORDS

EEG signal, convolutional neural network, long-term and short-term memory, sleep stage, multichannel, feature fusion

Introduction

People spend one-third of their time sleeping every day, and sleep is an important and necessary physiological process of the human body. Sleep quality will seriously affect people's physical and mental health. The acceleration of the pace of life in modern society and the increase of life pressure have also affected people's sleep quality, causing many people to suffer from sleep diseases (1). Clinical medicine analyzes and judges sleep quality by monitoring patients' sleep status, so as to achieve the purpose of treating or preventing sleep diseases. The collection of sleep data is the basis of sleep quality analysis.

At present, the research on automatic sleep staging has made some progress. The sleep staging process requires professionals to receive a lot of training and accumulate on-site experience, which is a complex and cumbersome process. Therefore, it is necessary to combine sleep with artificial intelligence to automatically and effectively evaluate sleep stages. Sleep is the most important physiological process related to human health. With the acceleration of people's pace of life and the increase in stress, the incidence rate of sleep disorders is also increasing. At present, patients tend to be younger. Therefore, the research on sleep has attracted extensive attention from scholars. From a clinical point of view, sleep staging is an important basis for monitoring sleep quality and detecting sleep-related diseases. Nowadays, people all over the world have difficulty sleeping or even insomnia, and more and more diseases are caused by sleep problems. Studies have shown that sleep quality plays a very important role in the regeneration of memory neurons. Poor sleep quality or insufficient sleep will damage memory to some extent. In addition, some studies have proved that sleep disorder has been identified as one of the earliest potential biomarkers for the progression of Alzheimer's disease, and monitoring sleep changes is helpful for early intervention of dementia (2). Therefore, how to correctly stage sleep is an important basis for monitoring sleep quality and diagnosing sleep-related diseases. It has important practical significance and application value to improve sleep quality or diagnose sleep disorders through artificial intelligence. The convolutional neural network is a feedforward neural network, including an input layer, an output layer, convolution layer, and pool layer (3). Its special network structure can effectively reduce the complexity of the neural network. It has achieved great success in many fields, particularly in image recognition. At present, CNN has been successfully applied to many specific projects, such as original EEG data, target recognition, and handwritten character recognition. It also occupies a place in many fields, such as analyzing visual images, speech recognition, and predicting human traffic (4). As we all know, CNN has the characteristics of shared weight structure and transformation invariance. CNN consists of input and output layers and multiple hidden layers. The hidden layer can be a convolution layer, a pooling layer, or a full connection layer. Compared with other traditional algorithms, CNN uses relatively less preprocessing. This means that CNN can learn from the manually designed filter in the traditional algorithm. Its main advantage is that it can replace prior knowledge and artificial design feature engineering (5). Therefore, this study aims to study a new automatic sleep classification method based on EEG signals, including signal preprocessing, feature extraction, and classification and recognition. The main research content of this paper is to realize the automatic segmentation of sleep by using signal processing method and pattern recognition theory, and establish an automatic sleep staging system with high accuracy and fast calculation speed to provide more effective and convenient sleep staging methods for medical researchers, and reduce the workload of clinical diagnosis.

The specific contributions of this study include the following:

(1) Based on EEG signals and a deep learning network, this paper proposes an automatic sleep staging method based on multi-channel EEG, and CNN-LSTM is used for supervised learning of sleep staging on original EEG and EOG samples.
(2) The EEG signals are filtered and extracted, respectively, and the features are extracted by CNN and LSTM in parallel. The two features are fused for classification.
(3) By introducing an electro-oculogram and fusing the modal information between EEG and EOG, the classification accuracy of each stage is improved.
(4) When decomposing EEG signal and using the method proposed in this paper and the characteristics of rhythm wave, relative energy, and complexity for automatic sleep staging, by using the information complementarity between different modes, the calculation time of feature extraction can be reduced, the error can be reduced, and the accuracy of automatic staging can be improved.

The remainder of this paper is organized as follows. Section Related work discusses related work, followed by the composition of brain waves in EEG and signal detection in Section EEG signal. Sleep staging criteria and specific sleep stages are discussed in Section Sleep stage. Section CNN-LSTM sleep stages algorithms presents CNN-LSTM sleep stages algorithms, Section Contrast experiment and result analysis details the contrast experiment and result analysis, and Section Conclusion and future work provides a conclusion with a summary and future research direction.

Related work

Sleep experts can determine the quality of sleep by recording electrical activity through sensors connected to different parts of the body. A set of signals collected by these sensors is called polysomnography (PSG). A series of physiological signals were recorded, including EEG, EOG, EMG, and ECG. EEG signals often contain a lot of information about physiological activities (6). It is an extremely complex bioelectrical signal. It provides important analytical reference information for neurology, medicine, and other disciplines. It can accurately reflect the activity of the brain and is gradually widely used in sleep research. Each person has different characteristics and amplitudes of EEG signals in different sleep states, which reflects the different and complex functions of the brain in different stages (7). The classification of different characteristics of different sleep stages is called sleep stage. It is not only

the standard for judging sleep quality, but also the basis for diagnosing some brain diseases. It has important clinical significance and broad application prospects for the treatment of sleep disorders (8). The early classification standard of sleep stage is the R&K standard, which was proposed by Rechtchaffen and Kales in 1968. The human sleep process is divided into three types: wake, non-rapid eye movement sleep (NREM), and rapid eye movement sleep (REM) (9). According to expert standards, polysomnography (PSG) is divided into stages every 30 s. Professional sleep data evaluation can only be carried out in the hospital, and then experts judge each paragraph according to the classification criteria through visual observation. It is very cumbersome, time-consuming, and prone to subjective errors (10). An 8-h PSG data requires professional doctors to spend 2–4 h on sleep staging, which is very inefficient. Therefore, the development of automatic sleep staging is of great significance. Automatic staging is the research of feature extraction and classification of EEG data collected by using signal processing, pattern recognition, and computer technology. Compared with manual staging, it saves time and effort. It can not only improve the efficiency of data judgment and classification, but also reduce the misjudgment caused by doctors' subjective factors in the process of staging (11, 12).

In order to avoid the misjudgment of subjective consciousness caused by the manual recognition of the sleep stage by experts, more and more scholars are committed to the research of automatic sleep staging. Sleep data staging belongs to the category of pattern recognition (13). In recent years, with the rapid development of pattern recognition methods, a large number of classification methods have been found and used, accompanied by continuous changes and improvements. Common recognition methods are as follows: Decision Tree (DT), Artificial Neural Networks (ANNs), Linear Discriminant Machine (LDM), and Support Vector Machine (SVM) (14, 15). An interpretable machine learning algorithm was used to evaluate the interrater reliability (IRR) of sleep stage annotation among sleep centers by Liu et al. (16). Intracenter and intercenter assessments were conducted on 679 patients without sleep apnea from six sleep centers in China's Taiwan. Bandyopadhyay and Goldstein (17) provided a concise overview of relevant terminology, definitions, and use cases of AI in sleep medicine. They conclude that artificial intelligence is a powerful tool in healthcare that may improve patient care, enhance diagnostic abilities, and augment the management of sleep disorders. Bozkurt et al. (18) proposed a new approach to sleep staging, which is one of the diagnostic procedures for the disease. An artificial intelligence-based sleep/awake system detection was developed for sleep staging processing. Photoplethysmography (PPG) signal and heart rate variable (HRV) were used in the study. Zhu et al. (19) adapted edge AI to develop a lightweight automatic sleep staging method for children using single-channel EEG. The trained sleep staging model will be deployed to edge smart devices so that the sleep staging can be implemented on edge devices which will greatly save network resources and improve the performance and privacy of the sleep staging application. Cesari et al. (1) conducted this study to evaluate interrater reliability between manual sleep stage scoring performed in two European sleep centers and automatic sleep stage scoring performed by the previously validated artificial intelligence-based Stanford-STAGES algorithm. Abbasi et al. (20) proposed an internet of things and ensemble-based automatic sleep stage classification in this study. Twelve EEG features, from nine bipolar channels, were used to train and test the base classifiers, including a convolutional neural network, support vector machine, and multilayer perceptron. Eldele et al. (21) proposed a novel attention-based deep learning architecture called AttnSleep to classify sleep stages using single-channel EEG signals. This architecture started with the feature extraction module based on a multi-resolution convolutional neural network (MRCNN) and adaptive feature recalibration (AFR). Prochazka et al. (22) devoted to the analysis of multi-channel biomedical signals acquired in the sleep laboratory. The goal of the study was to visualize the features associated with sleep stages as specified by an experienced neurologist in their adaptive classification. Delimayanti et al. (23) demonstrated the utilization of features extracted from EEG signals *via* FFT to improve the performance of automated sleep stage classification through machine learning methods. Gao et al. (24) developed a novel program called GI-SleepNet, a generative adversarial network (GAN)-assisted image-based sleep staging for mice that is accurate, versatile, compact, and easy to use. Loh et al. (25) proposed a deep learning model based on a one-dimensional convolutional neural network (1D-CNN) for CAP detection and homogenous 3-class classification for sleep stages: wakefulness (W), rapid eye movement (REM), and NREM sleep. The proposed model was developed using standardized EEG recordings. Manzano et al. (26) presented the first approximation using a single channel and information from the current epoch to perform the classification. The complete Physionet database has been used in the experiments. The main research objective of this paper is to realize the research on EEG sleep automatic staging by using signal processing method and deep learning theory, and establish an automatic sleep staging system with high accuracy and fast calculation speed to provide a more effective and convenient sleep staging methods for medical researchers, reduce the workload of clinical diagnosis, and reduce the error rate.

EEG signal

The brain is mainly responsible for controlling and regulating the thinking and conscious activities of the human body. EEG is a random signal reflecting the electrical activities of brain tissue. The cerebral cortex of the brain is the highest

center of the nervous system regulating body movement, which is responsible for the cognitive and emotional functions of the brain. Various human activities and senses can find corresponding regions in the cerebral cortex, and each region has its specific role and function. Neuron cells in the cerebral cortex are the reason why human beings have complex activities as advanced organisms. The condition for complex activities is that each neuron cell can communicate through dendritic connections, which makes human activities have countless possibilities (27).

Scientific research shows that EEG signal is formed by a large number of neuronal cells. It is a non-linear mixture of multiple cells connected by non-linear coupling. From the perspective of chaos theory, the human brain is a complex non-linear dynamic system. EEG signal has the following characteristics: weak signal and strong noise; high complexity of signal components; prominent frequency characteristics; non-linearity; and non-stationarity.

Composition of brain waves

The root cause of EEG is the response of neurons in the cerebral cortex to electrical activity. The signals generated by the potential activity of nerve cells can be obtained by placing electrodes on the scalp. The amplitude, frequency, and phase of the waveform contained in the EEG have certain characteristics. The bandwidth of EEG is 0.5–100 Hz, and the 0.5–30 Hz portion of spontaneous EEG is considered in clinical medicine. According to the frequency characteristics, it can be divided into four basic rhythm waves and non-basic waves. The regular waves in the sleep process are rhythm waves, and the irregular waves are non-basic waves. There are four kinds of rhythm waves:

(1) δ wave: 0.5–4 Hz, amplitude 20–200 μV. δ wave is the wave with the lowest frequency in the brain, which is obvious in the forehead. It appears more often in the EEG of infants or people with intellectual disabilities, and it will not occur in normal people when they are awake; however, this wave can be produced when adults are in extreme fatigue, deep sleep, and deep anesthesia. When the cortex is inhibited, δ rhythmic waves appear.
(2) θ wave: 4–8 Hz, amplitude about 20–150 μV. θ wave is a low-frequency rhythmic wave in the human brain. It is the main EEG activity in teenagers aged 10–17 years. It is obvious in temporal and parietal areas. Similar to δ wave, it occurs only when the brain nerve is in a sleepy, depressed, or frustrated state, and it does not occur when normal people are awake, mtf(Modulation Transfer Function) wave, if someone is awake, the signal contains a lot of θ wave, should be paid attention to, its brain may have lesions, which will lead to disease.
(3) α wave: 8–13 Hz, amplitude $<$100 μV. α wave is the most obvious waveform with a high frequency in adult EEG. It has a stable existence in the state of closed and relaxed eyes, but it disappears immediately after being stimulated by the outside world. The α wave represents human logical reasoning and creative thinking, which are not available to other animals. The α wave is a basic waveform of health and an important rhythmic wave reflecting various indexes of the brain.
(4) β wave: 13–30 Hz amplitude of 5–20 V. The frequency is 13–30 Hz. β wave is in the range of 20–30 Hz β two waves. β wave is the fastest rhythmic wave in the brain, which is mainly concentrated in the frontal and central regions. β waves are the manifestation of the excited state of the cerebral cortex and can also be used as the characteristics of brain awakening. It can be detected when people are moving, thinking, reading, or watching movies.

There are three types of common non-fundamental waves as follows:

(1) K-complex wave: there is no exact frequency range, and is composed of a positive and negative sharp waves. It first appears negative and then positive, and the transient time is $>$0.5 s. The K-complex wave usually appears together with the spindle wave, which are fused together to determine the S2 phase. The K-complex wave is obvious in the top and central regions.
(2) Sawtooth wave: the frequency range is 2–7 Hz. The waveform is like a sawtooth shape. Its existence generally represents the beginning of a dream, that is, sawtooth waves generally exist when the human body is in a light sleep state or dreaming.
(3) Spindle wave: the frequency is 12–14 Hz, and the amplitude is the largest and constantly changing in EEG. At first, it is the lowest, the highest in the center, and then gradually decreases to the lowest. It is obvious in the parietal and midline regions of the brain. The spindle wave is the main characteristic waveform during light sleep.

EEG detection

The EEG signal detection and recording equipment are composed of amplifier, electrode, display, etc. Electrodes are used to measure brain epidermal potential. Special electrodes need to be selected to measure EEG. In fact, the electrodes that can be used to measure brain potential include a tubular electrode, deep electrodes, disk electrodes, and so on. Different electrodes are designed to meet the different noise signals generated in the acquisition process of EEG signals. The conditions for selecting electrodes are as follows: small drift can reduce the noise interference of EEG; the polarization potential

is stable, indicating good reproducibility; small photoelectric effect ensures that the electrode is not affected by light and is not easy to aging; and good mechanical properties mean long electrode life. Considering the above factors, the disk electrode is the most commonly used electrode for EEG measurement.

Sleep stage

Sleep staging criteria

The EEG changes during sleep. According to different eye, EEG, and EMG signals, a sleep grading system can be designed to respond to different sleep levels. The R&K staging standard proposed in the 1960s is widely used in the world. Sleep is divided into six periods: wake, non-rapid eye movement (NREM, including I, II, III, and IV), and rapid eye movement (REM). This standard is of great significance to study sleep staging, which was once called the "gold standard." Later, researchers found that the characteristics of sleep stages III and IV were not obvious. Therefore, in 2007, the American Society of Sleep Medicine merged the two stages III and IV in the R&K standard, divided the total sleep period into five stages, and set the latest sleep staging standard (AASM standard), which is of epoch-making significance. The sleep staging standard selected in this paper is the AASM standard. Figure 1 presents the sleep staging criteria according to AASM.

Specific introduction to sleep stages

According to the AASM standard, the sleep process is divided into five stages: waking stage (W), rapid eye movement stage (REM), light sleep phase I (N1), light sleep phase II (N2), and deep sleep phase (N3). Each sleep stage will be briefly discussed below.

Waking stage (W period): adults are generally awake for about two-thirds of the time in a day. At this stage, eye movement is obvious, which is the characteristic of frequent blinking. During the awake period, the EEG shows an uninterrupted alpha wave (frequency 8–13 Hz, amplitude 20–100 μV).

Light sleep phase I (N1): this phase often occurs when the awake state changes to other sleep states, or when there is more body movement during sleep, generally accounting for about 5–10% of the whole night's sleep. The duration of each occurrence is short, often only 1–7 min. The characteristics of this period are as follows: the content of the alpha wave decreases (<50%), and the content of the theta wave (frequency is 4–8 Hz and the amplitude is 20–150 μV) will slowly increase.

Light sleep phase II (N2): this phase occupies a longer time than light sleep phase I during the whole night, generally accounting for 44–55% of the sleep duration. This period is characterized by the gradual emergence of two new characteristics of EEG signals: sleep spindle wave and K-complex wave. These waveforms are most obvious in the EEG-type detection of the central electrode. At this stage, the θ waves of EEG signals increase and gradually appear at the same time as the δ wave (frequency is 0.15–4 Hz and amplitude is 20–200 μV).

Deep sleep period (N3): when people enter deep sleep, that is, when the sleep stage is in N3, the repair functions of the body and the visceral function are the strongest. At this stage, the cerebrospinal fluid in the brain will regularly clean the "biological waste" in the brain, which is very important for stabilizing mood, restoring energy, and adjusting mental state. This stage accounts for about 10–20% of the total sleep time. It is the deepest stage in the sleep process. The approximate frequency range of EEG signals at this stage is 0.5–2 Hz, and δ waves slowly increased, accounting for more than 20% of the waves.

Rapid eye movement (REM): this accounts for 20–50% of the total sleep process. The biggest feature of the REM phase is rapid eye movement, which is similar to the EEG signal of the N1 phase, and the REM sawtooth phase occurs. At this stage, α waves increased but showed an irregular pattern, and were accompanied by rapid eye movement.

CNN-LSTM sleep stages algorithms

This paper will construct the automatic sleep stages model based on CNN and LSTM algorithms, train the model, and evaluate its classification performance through experiments.

Deep neural networks

Convolutional neural network (CNN)

A convolutional neural network (CNN) is a feedforward neural network, and it is featured with weight sharing and local reception. A typical CNN structure is shown in Figure 2. The convolution neural network is constructed by imitating the visual perception mechanism of biology, which can carry out supervised learning and unsupervised learning. The sharing of convolution kernel parameters in the hidden layer and the sparsity of inter-layer connections enable the convolution neural network to learn grid-like topology features with less computation. The function of the convolution layer is to extract the features of the input data. It contains multiple convolution kernels. Each element of the convolution kernel corresponds to a weight coefficient and a bias vector, which is similar to a neuron of a feedforward neural network. Each neuron in the convolution layer is connected to multiple neurons in the area

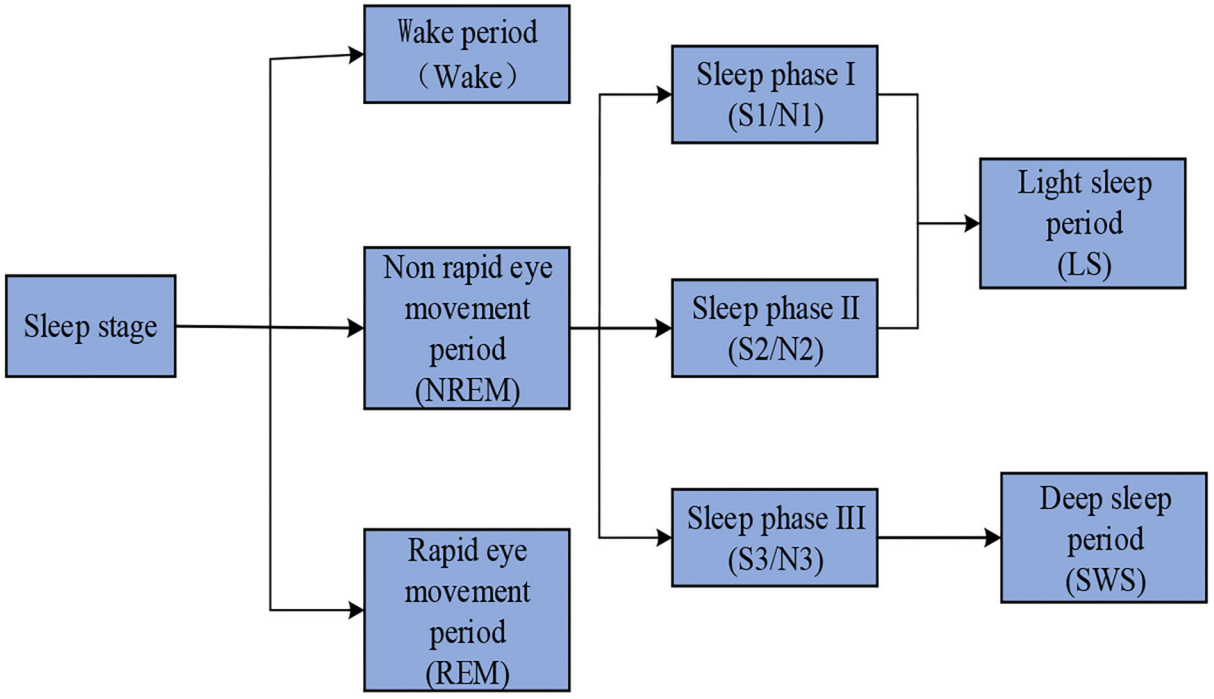

FIGURE 1
AASM sleep staging criteria.

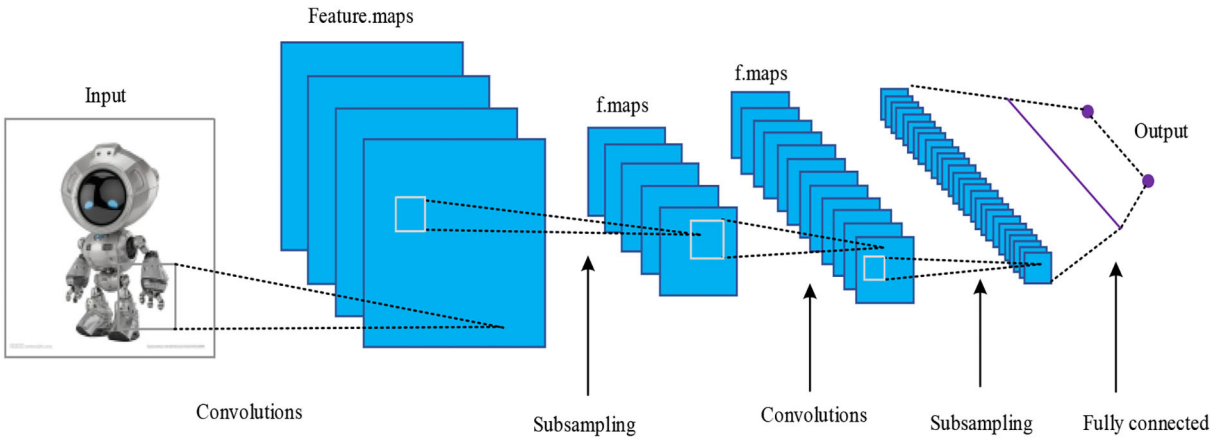

FIGURE 2
Typical CNN structure.

close to the previous layer, and the size of the area depends on the size of the convolution kernel.

In the structure, the output of the convolutional layer is locally connected to the input of the last layer, and it can be acquired by sliding the window gradually according to the step length. The corresponding local features with each parameter of the convolution kernel are multiplied and the weight of the kernel is kept unchanged, that is, weight sharing. Usually, in every convolutional layer, there are several convolution kernels and different features can be extracted. Through convolution, image features can be obtained, and after that, the classifiers can be trained according to these features directly, but such computation is huge and over-fitting occurs easily. Therefore, the addition of a pooling layer after the convolutional layer can shrink the feature map matrix and reduce the computation amount while enhancing the anti-jamming capability for feature

identification, e.g., image deformation and distortion. Through local connection, weight sharing, and pooling, CNN greatly reduces the complexity of the network.

The convolutional neural network is frequently used in the processing of images and discrete signals, and its network structure mainly includes the input layer, the convolutional layer, the pooling layer, the full-connected layer, and the output layer.

(1) Convolutional layer

The convolutional layer is the most important layer in CNN, and it extracts efficient high-level feature information from the data of the input layer and inputs the regions divided by sliding windows, and conducts convolution operations with the kernel parameters. During each computation, the kernel window translates at the fixed step length in the input layer until the entire input participates in the convolution operation. Then with the activation function, add non-linear factors and construct the feature map. The output of the computation is also called feature mapping. Assume the input to be a two-dimensional tensor I and a two-dimensional convolution kernel K, CNN uses the cross-correlation function which is basically the same as the convolution operation and does not reserve the convolution kernel.

$$\begin{aligned} S(i,j) &= (I * K)(i,j) \\ &= \sum_m \sum_n I(m,n) K(i-m, j-n) \\ &= \sum_m \sum_n I(i+m, j+n) K(m,n) \end{aligned} \tag{1}$$

In essence, CNN's convolution operation gets the local features from the weighted sum of local input through the convolution kernel and its convolution operation is as follows:

Convolution operation has strengths, such as sparse connection and parameter sharing. In the networks which connect all layers with a full-connected layer, each input and output cells are combined and connected, resulting in huge computation and easy over-fitting, exploding and vanishing gradient, and other issues. However, both the size and quantity of the convolution kernels are much fewer than the input nerve cell, and they can significantly reduce the number of weight parameters and have the characteristics of sparse weight. Besides, every weight factor in the convolution kernel has translated convolution operation with all neurons of the last layer, reducing the dense matrix operation in the full-connected layer and increasing the efficiency of reverse update of network parameters through weight and parameter sharing.

(2) Pooling layer

The pooling layer processes the output of the last layer through pooling functions, such as the maximum, mean, and L^2 norm. It comprehensively takes into account the neighbor value of each position in the output of the last layer, conducts further feature localization processing on the original feature map, and maps it into another feature space. The pooling layer can reduce the scale of input, maintain the output of the features in the last layer, and effectively lower the dimensions of features so as to enhance the computational efficiency of the network.

(3) Full-connected layer

Full-connected layer maps the feature map output from previous layers into a feature vector and reduces the impact of spatial location on object identification. As the full-connected layer is based on dense matrix operation, it has low computational efficiency, and it is easy to contribute to over-fitting; therefore, Dropout is often used to increase the sparsity of the full-connected layer and reduce the feature redundancy among neurons.

LSTM network

A recurrent neural network (RNN) is a neural network that is suitable to be used in the processing of sequence data. RNN increases the lateral ties among cells, making it preserve the information state of the context windows when analyzing time sequence data, and it has been widely applied in natural language processing and machine vision which includes serial input. In practical applications, it mainly includes long short-term memory (LSTM) and gated recurrent cell (GRU).

This paper mainly uses LSTM to acquire the time sequence features of sleep EEG. LSTM introduces logic control gates, and they are responsible for the memory and update of the history state. The input gate is responsible to control the impact of the input x_t on the current LSTM cell state c_t, and the forgotten gate controls the impact of the state c_{t-1} of the last moment on c_t. The cell structure of LSTM is shown in Figure 3.

The expressions among the LSTM forgotten door f_t, input door i_t,output door o_t, and state vector $\tilde{c}_t$ within the cell can be given by:

$$f_t = \sigma\left(W_f \cdot \left[h_{t-1}, x_t\right] + b_f\right) \tag{2}$$

$$i_t = \sigma\left(W_t \cdot \left[h_{t-1}, x_t\right] + b_t\right) \tag{3}$$

$$\tilde{c}_t = \tanh\left(W_c \cdot \left[h_{t-1}, x_t\right] + b_c\right) \tag{4}$$

$$c_t = f_t \times c_{t-1} + i_t \times \tilde{c}_t \tag{5}$$

$$o_t = \sigma\left(W_o \cdot \left[h_{t-1}, x_t\right] + b_o\right) \tag{6}$$

$$h_t = o_t \times \tanh(c_t) \tag{7}$$

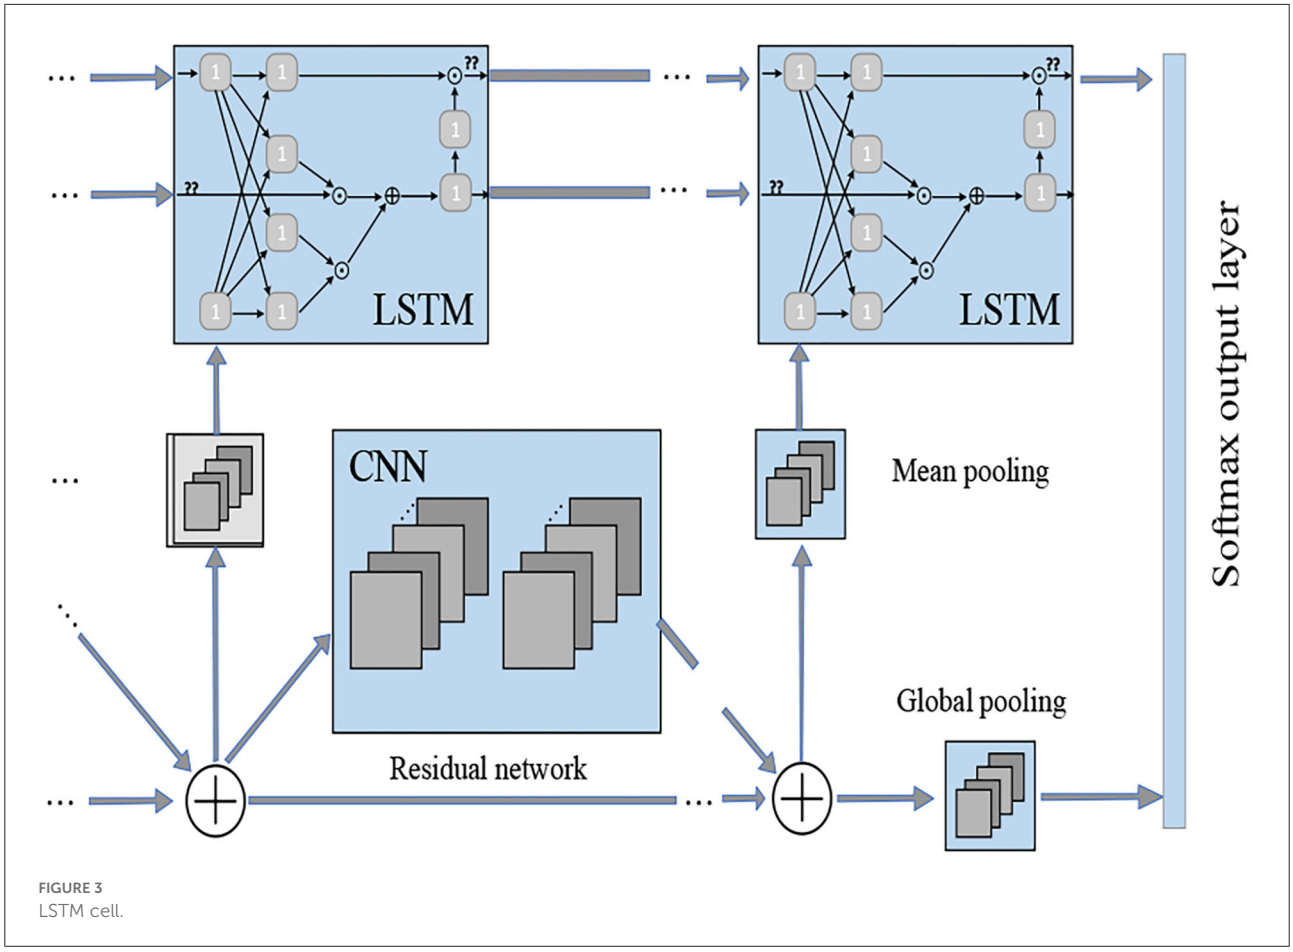

FIGURE 3
LSTM cell.

where $W_\bullet$ is the weight matrix, $b_\bullet$ is the bias vector, σ is logistic sigmoid function, and tanh is the hyperbolic tangent mapping activation function.

Building of automatic sleep stages model based on neural network

CNN-LSTM automatic sleep stages model

The identification CNN-LSTM activity can be done by introducing the LSTM model on the basis of the CNN model, and it uses CNN to process feature extraction and LSTM to process long-time sequence data. CNN has a two-layered structure: one is the feature extraction layer and its structure adopts the ReLU function as the activation function of the convolutional network, and the other is the feature mapping layer and its structure uses the sigmoid function as the activation function. It takes the pre-processed activity sequence as the input of the model and sets the convolution kernel with a length of l. After convolution operation, it gets the new feature sequence with a length of $le = (n - l + 1)$, which is shortened through the maximum pooling process, and finally obtains the extracted activity feature vector $v = (v_1, v_2, \ldots, v_g)$. As the extension of the recurrent neural network, LSTM can better solve the strong data dependency problem in time sequence. The specific model of the LSTM model in activity identification is indicated in Figure 4.

Figure 4 shows the structure of how the single LSTM neuron processes data dependencies. Therefore, LSTM replaces the full-connected layer of CNN and takes the activity feature vector $x = \{v_1, v_2, \ldots, v_g\} = \{x_1, x_2, \ldots, x_g\}$ obtained as the LSTM input with each feature vector corresponding to an activity label A_i. LSTM determines the reservation of cell state according to the control among its input gate, forgotten gate, and output gate, maintains the relationship between the data with strong dependencies, and solves long-term dependency problems in order to accurately identify the activities. $c(t-1)$ represents the unit state of the last moment, and the philosophy of LSTM is that the state of the current moment t depends on the state of the same neuron in the last moment $t-1$. $h(t)$ can be defined as the output state of the hidden layer at the current moment, and it can be given by

$$h(t) = \log h(t-1) \bullet x(t) \tag{8}$$

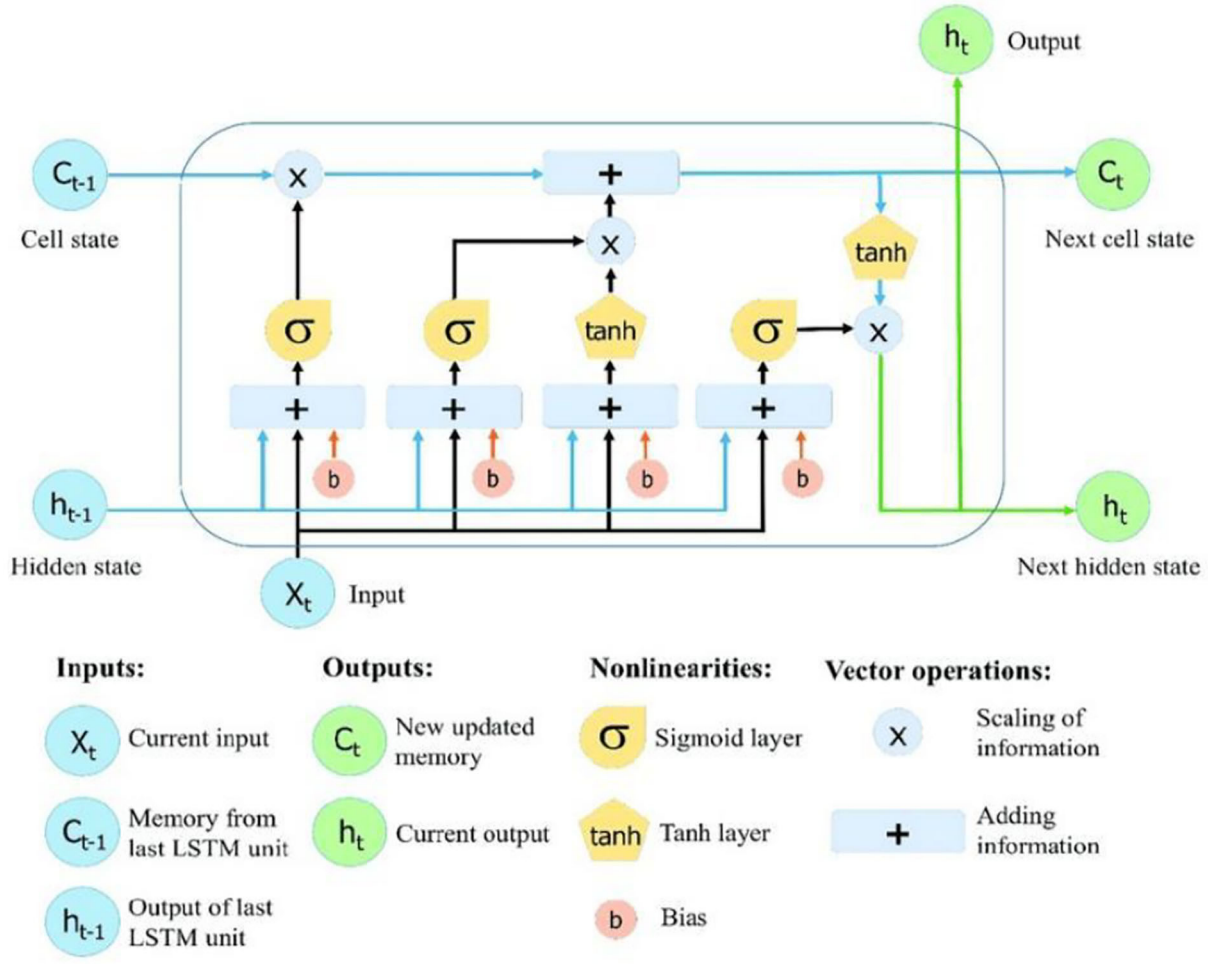

FIGURE 4
Single LSTM neuron processing data dependencies.

where $x(t)$ represents the input data of neuron at moment t and $h(t-1)$ means the LSTM output of the last moment, i.e.,.. The values after forgotten threshold, input threshold, and output threshold can be calculated by:

$$f(t) = \sigma\left(W_{(f)} \bullet x(t) + U_{(f)} \bullet h(t-1) + b_{(f)}\right) \quad (9)$$

$$i(t) = \sigma\left(W_{(i)} \bullet x(t) + U_{(i)} \bullet h(t-1) + b_{(i)}\right) \quad (10)$$

$$o(t) = \sigma\left(W_{(o)} \bullet x(t) + U_{(o)} \bullet h(t-1) + b_{(o)}\right) \quad (11)$$

where $f(t)$, $i(t)$, and $o(t)$ represent the output state of the corresponding thresholds, respectively. W and U are the weights of each branch, and b is the bias of each threshold. The activation sigmoid function of input gate decides what information to update, and tanh layer creates a new cell state, which can be given by:

$$\tilde{c}(t) = \tanh(W(c) \bullet x(t) + U(c) \bullet h(t-1) + b(c)) \quad (12)$$

Meanwhile, the old cell state will be updated to the new cell state $c(t)$, which can be given by:

$$c(t) = f(t) \bullet c(t-1) + i(t) \bullet \tilde{c}(t) \quad (13)$$

The sigmoid function of the output gate determines what information to output and obtains the output $h(t)$ of the current hidden layer through the tanh function, as suggested by Formula (14):

$$h(t) = o(t) \bullet \tanh\left(c(t-1)\right) \quad (14)$$

In the entire LSTM computation process, the output $h(t-1)$ of the hidden layer of the neuron at moment $t-1$ and $x(t)$ are the input of the neuron at moment t. The input of the neuron in the input layer produces the neuron output $h(t)$ under the action of activation function, and the memory state $c(t-1)$ of the neuron cell at moment $t-1$ forms that memory state $c(t)$ at moment t. In the learning process, Formulas (5) and (7) show that the activation function tanh affects $c(t)$, and the affected $c(t)$ has point multiplication with the output state $o(t)$ after the control of the output threshold to get the output $h(t)$ of the hidden layer at moment t. The Softmax activation function normalizes the value of the weight α of the hidden layer, gets the multiplication product and sum of the weight $\alpha(i)$ in the hidden layer with the output $h(t)$ of the hidden layer at the current moment, and obtains the final feature expression $y(t)$ of the activity identification samples so as to get the respective probabilities of the activities in the sample set, as shown in Formula (15).

$$y(t) = \sum \alpha(i)h(t) \tag{15}$$

Therefore, the interaction among the LSTM input gate, output gate, and forgotten gate decides whether the information should be preserved or abandoned in order to solve the problem of strong data dependencies. This cycle is repeated and after the iteration of one batch (one-time training samples), the accuracy is calculated as the difference between the expected and actual activities.

Model structure of automatic sleep stage algorithm

This paper builds the automatic sleep stage algorithm model, mainly including the model structure, size of convolution kernel, and so on. Sleep EEG screens and produces IMF through EMD, and it can effectively present the rhythm wave form and frequency feature of EEG. Therefore, the CNN structure is used to get the time-frequency domain features of each group of IMF, and these features will help with the decision-making of the model on sleep stages and are used to improve the performance of the CNN-LSTM model.

To better simulate the stages of sleep, CNN input includes the EEG and EOG signals which are not processed in the classification stage, and takes a digital matrix as the input. The proposed model in this paper adopts four two-dimensional convolution layers and uses rectified linear unit (ReLU) as the activation function. For each two-dimensional convolution layer, it uses dropout to avoid over-fitting, resulting in neurons being closed or abandoned at a 20% probability. Every convolution layer is followed by one maximum pooling layer before two full-connected layers. The first connected layer has 4,096 cells, and the second one has 1,500 cells. Both layers also adopt dropout to avoid over-fitting and lead to closed or abandoned neurons at a 50% probability. The last is a full-connected layer with a size of 5, and it chooses ReLU as its activation function. All activation functions used in the convolution layers are ReLU with a negative slope of 0.

In EEG-CNN automatic sleep stage model, the input is a 30-s EEG signal with a sampling rate of 200 Hz, and it is represented in a 5 * 6,000 matrix form. Here 5 means that it adopts the data of five channels, and each EEG sample signal is built alternatively in the order of input layer, Cov, Dropout, Pool until FC1 and FC2, and output. This paper divides EEG and EOG signals of the sleep stages of all types into a test set and training set. To be specific, 20% of all datasets are randomly selected as the test set, and the remaining are selected as the training set in each training stage. When using CNN at a fixed-length time sequence, the output of the convolution directly correlates with the input, the number of convolution layers, and their step lengths. If the output of the last convolution layer is too big, then the majority of the weights will be located in the full-connected layer. CNN connects with LSTM in a parallel manner, and it is used to learn the time sequence features of the output features of two networks. The network output is five sleep stages divided by the AASM sleep staging rule. Figure 5 represents the neural network model of sleep stages.

In Figure 5, the output dimension and core size of each layer are as follows: input layer: 300 × 2; 1st LSTM layer: 300 × 64; 2nd LSTM layer: 64; 1st convolution layer: 296 × 64,5; 1st pooling layer: 98 × 64,3; 2nd convolution layer: 94 × 32,5; 2nd pooling layer: 31 × 32,3; flatten: 992; concatenate: 1,056; 1st full-connected layer: 64; 2nd full-connected layer: 32; and Softmax: 5.

Every convolution layer in this model includes three operations: convolution operation, batch normalization, and activation function non-linearization. Batch normalization acts behind convolution operation, and it is used to re-adjust the distribution of the output in the last layer. It standardizes the input of each hidden layer and prevents the gradient diffusion caused by network deepening. The input layer of the CNN-LSTM designed in this study has 300 * 2 dimensions. It extracts time sequence features through LSTM, captures profound local correlation information through parallel CNN structure, fuses the convolution features and time sequence features into the full-connected layer, and outputs the multi-classification result from the Softmax layer. The size of batch processing used in this experiment is set to 20. It selects ReLU as the activation function, which is a piecewise linear function and has unilateral inhibition, making the neurons have sparse activation and play the part of automatic decoupling, and increase the convergence speed. The function $f(x)$ can be given by:

$$f(x) = \max(0, x) \tag{16}$$

Then, the full-connected layer maps the high-dimensionality and high-level features obtained from the previous model into

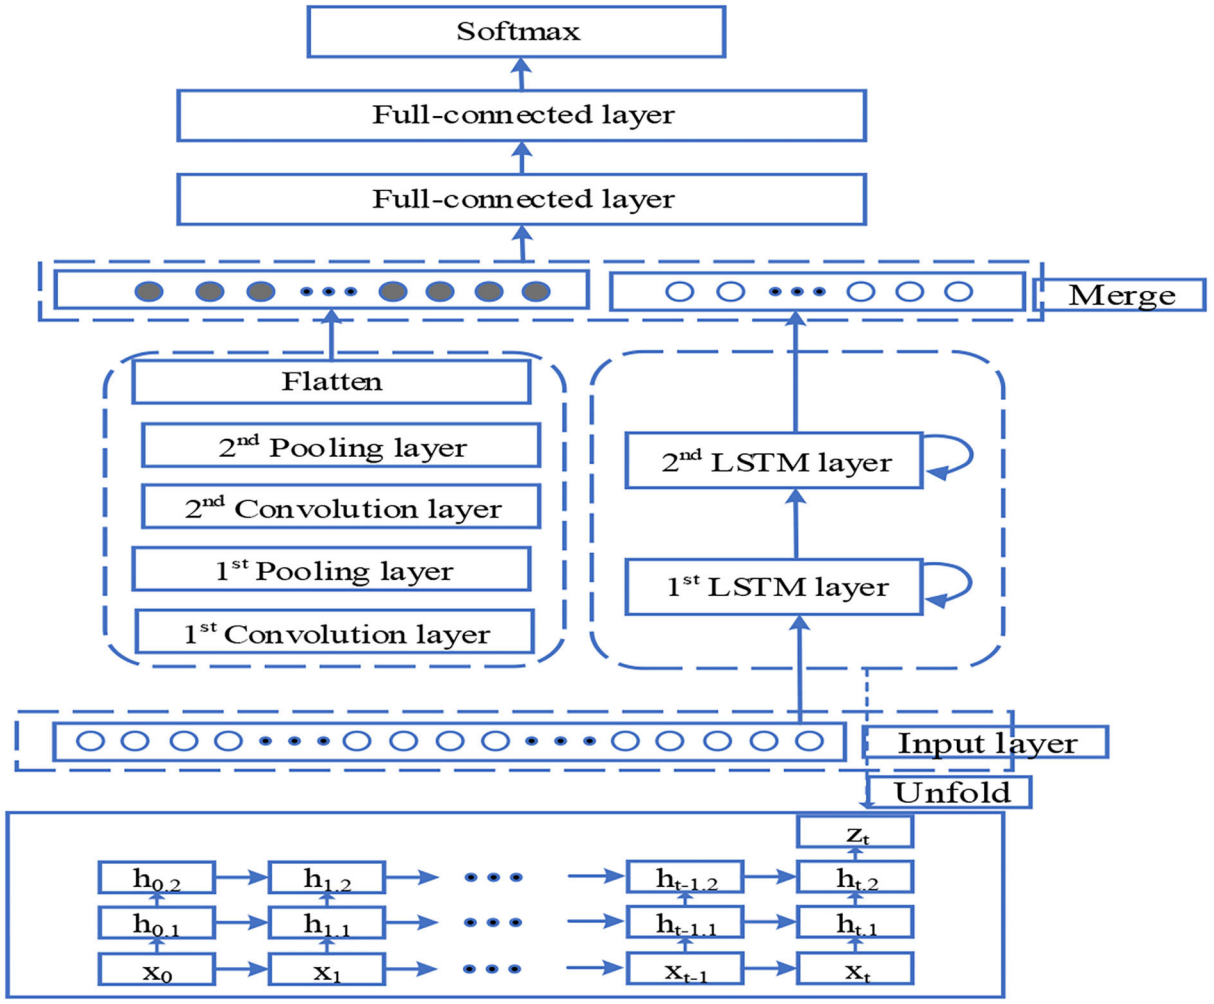

FIGURE 5
Neural network model of sleep stages.

the label space with five sleep stages. This model finally uses the Softmax classifier, into which the full-connected layer inputs the five real numbers obtained by multiplying the input feature vector and weight matrix and adding the bias input. The Softmax layer converts it into the probability of the corresponding five sleep stages, and the model judges the staging result according to the maximum probability.

Contrast experiment and result analysis

Performance evaluation index

Recall (REC), Precision (PRE), F1 (F1-Score, F1), and ACC (Accuracy) are employed to evaluate the classification performance of the proposed model. ACC is defined as the proportion of the number of samples of the prediction pair to the total number of samples. PRE indicates how many of the predicted positive samples are really positive samples. REC indicates how many positive examples in the sample are correctly predicted. They are common indicators in the statistical analysis. MF1 refers to the mean value of all F1 values in each sleep stage. ACC stands for the percentage of the classification of accurate sleep stages to all sleep stages. REC, PRE, F1, ACC, and MF1 are calculated with the following formulas respectively:

$$PRE = \frac{TP}{TP + FP}, REC = \frac{TP}{TP + FN} \quad (17)$$

$$F1 = 2\frac{PRE * REC}{PRE + REC} \quad (18)$$

$$ACC = \frac{\Sigma_{C=1}^{C} TP_C}{N} \tag{19}$$

$$MF_1 = \frac{\Sigma_{C=1}^{C} F1_C}{C} \tag{20}$$

where TP_c is the number with accurate prediction in all classes and N is the total number of samples in all 30 s. $F1_c$ is the score of $F1$ of a certain class, and C is the number of sleep stages. TP is true positive, FN is false negative, and FP is false positive.

Training process

The experiment uses the data of 30 subjects in the MIT-BIH dataset, totaling 60 all-night sleep data. In the experiment, the use of LSTM enables the extraction of the features in a time sequence. In order not to interrupt the time sequence of the sleep stages, a division is made to the data with each subject as the unit. Table 1 presents the division of the subjects in the training set and test set.

The training set is made of the sleep data of 24 people for two nights, totaling 48 nights. The number of samples in each sleep stage in the training set is listed in Table 2.

The test set comprises the sleep data of two nights of six people, totaling 12 nights. The samples of each sleep stage are presented in Table 3.

In the training process, evaluate and validate the automatic sleep stage model apart from establishing the test set for the data of six persons, which is totally independent of the training set. Divide the sleep data of 24 persons in the training set into 12 on average, each of which includes the sleep data of four nights. In the 10th round of training, extract and use a ground subset as the validation set.

In the pre-training phase, randomly resample the data in W, N1, N3, and REM stages and perform under-sampled processing in the N2 stage, making the number of samples from six sleep stages every night not to exceed 200 after resampling and under-sampling. The total generations of data training have 100 epochs. A stochastic gradient descent optimizer is used and the initial learning rate is 0.015, which decays 0.1-fold after iterations and training of 20 generations. Set the batch as 10.

Experiment result and analysis

Hilbert transform focuses on extracting the local characteristics of the signal. HHT amplitude spectrum and marginal spectrum can obtain the time-frequency distribution characteristics of each IMF and the global energy distribution of each frequency. They are distributed in a narrow-band frequency, and the central frequency has a certain distance. It can be seen that the energy of IMF in a local frequency band is relatively concentrated, and the energy proportion of the high-frequency component is relatively small. The multi-resolution characteristics of HHT make the frequency and energy characteristics of this part of the signal more obvious. In order to study the energy distribution characteristics of each sleep period, the data of subjects for 10 days are randomly selected from the MIT-BIH dataset. Forty-five EEG signals are taken from each sleep period every day, and a total of 450 EEG signals are taken during all sleep periods. The instantaneous frequencies of the first four IMF components after empirical mode analysis are calculated, the frequency points are counted, and the probability density histogram is drawn, as shown in Figure 6.

This experiment adopts the EGG in MIT-BIH dataset as the input research subject of the model and performs automatic sleep stage model training on the training method and the divided dataset. The goal of the model is to classify sleep into five stages: W, N1, N2, N3, and REM according to AASM rules. In the training steps, the loss and accuracy curves of the training set and test set are shown in Figures 7, 8.

As shown in the performance curves of the training process, the loss function can converge quickly, and the total accuracy reaches 90.6% when the data finishes 100 iterations. But for the test set, its loss function value vibrates greatly. The study shows that with multi-channel EEG and EOG, it is viable to classify the sleep stages with the CNN-LSTM in this study and that EOG data should not be ignored in the study of automatic staging. The training is end-to-end and needs no professional knowledge to select any signal preprocessing method, which is a strength. Neural networks can independently learn the features of each stage and is the most suitable method for classification tasks. From the features of convolutional networks, the convolution layer can learn the excellent filter. Table 4 presents the comparison of performance between the proposed model and other models.

Sors et al. (2018) (30)	Convolutional neural networks	96.86	35.42	89.41	85.52	82.56	89.33
Ours	Multi-channels EEG & EOG CNN-LSTM	90.73	59.78	90.55	83.22	87.38	90.60

It can be seen from Table 4 that the proposed model shows quite good performance and better staging accuracy than other models, which demonstrates the generalization ability of the proposed model. As shown in the results, the multi-channel EEG and EOG model, adopted in this study, is better than the existing multi-channel models. Although other models show excellent performance, the performance of the proposed model is better than other models. From the staging results of different models, it can be concluded that the proposed model has significant advantages.

Conclusion and future work

In this study, an intelligent automatic sleep staging model based on CNN and LSTM is proposed. As sleep is an extremely complicated process, it is difficult to obtain high accuracy using automatic staging methods (31, 32). The proposed automatic sleep staging method, which is based on EEG, still needs improvement, mainly in the following aspects: (1) The impact of other physiological parameters should be considered. As sleep is a complex process, physiological parameters, such as electrocardio, myoelectricity, electro-oculogram, and breath, have a certain influence on sleep (33). Hence, more parameters should be introduced into the study of sleep stages, which can further increase the accuracy of automatic sleep staging. (2) More feature parameters and experiment samples need to be used to extract more feature parameters (34), including time domain, frequency domain, and non-linear features. Multi-channel data should be selected and more features and data need to be used to make a comprehensive study of sleep stages.

In the future work, we will further explore the application of neural network technology to the automatic sleep staging task, improve the overall accuracy, and provide a theoretical basis for the application of various neural networks to sleep staging.

Data availability statement

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

Author contributions

LZ and MD designed the experiments and research project. YZ performed the experiments and analyzed the data. LS wrote the paper. All authors contributed to the article and approved the submitted version.

Funding

This work was supported in part by the National Science Foundation of China (Grant No. 61772190).

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Background: Currently, the clinical prediction model for patients with osteosarcoma was almost developed from single-center data, lacking external validation. Due to their low reliability and low predictive power, there were few clinical applications. Our study aimed to set up a clinical prediction model with stronger predictive ability, credibility, and clinical application value for osteosarcoma.

Methods: Clinical information related to osteosarcoma patients from 2010 to 2016 was collected in the SEER database and four different Chinese medical centers. Factors were screened using three models (full subset regression, univariate Cox, and LASSO) *via* minimum AIC and maximum AUC values in the SEER database. The model was selected by the strongest predictive power and visualized by three statistical methods: nomogram, web calculator, and decision tree. The model was further externally validated and evaluated for its clinical utility in data from four medical centers.

Results: Eight predicting factors, namely, age, grade, laterality, stage M, surgery, bone metastases, lung metastases, and tumor size, were selected from the model based on the minimum AIC and maximum AUC value. The internal and external validation results showed that the model possessed good consistency. ROC curves revealed good predictive ability (AUC > 0.8 in both internal and external validation). The DCA results demonstrated that the model had an

excellent clinical predicted utility in 3 years and 5 years for North American and Chinese patients.

Conclusions: The clinical prediction model was built and visualized in this study, including a nomogram and a web calculator (https://dr-lee.shinyapps.io/osteosarcoma/), which indicated very good consistency, predictive power, and clinical application value.

KEYWORDS

osteosarcoma, SEER, multicenter study, nomogram, web calculator, prediction model

Background

Osteosarcoma, the most frequent primary malignancy of bone, accounting for approximately 35% of bone malignancy (1), originates from malignant mesenchymal cells (2), which produce osteoid and/or immature bone (3). Surgery combined with peri-operative chemotherapy is the current treatment while local therapy alone is insufficient (4). The presence or absence of metastases has become an important prognostic factor. Studies have shown that the 5-year survival rate for primary focus without metastases is more than 65% (5–7). Certain variables cannot explain the complicated survival rate. For diagnosis and treatment option, the American Joint Committee on Cancer (AJCC) system (8) and Enneking system (9) are popular. Factors of these systems can imply survival duration with treatment option roughly, but it is limited. A prediction model for survival is urgent for further prognosis prediction and instructive therapy selection (10, 11).

Osteosarcoma incidence remains low relative to other tumors (12). Therefore, a sufficient number of subjects are quite challenging. The Surveillance, Epidemiology, and End Results (SEER) database is an authoritative cancer statistics database in the United States that records morbidity, mortality, and incidence information for millions of patients with malignancies. Currently, although there have been relevant studies on osteosarcoma based on the SEER database, these prediction models showed a lower power (almost AUC < 0.8) or have no external data validation (13–15).

In this study, we built models based on osteosarcoma patients' data in the SEER database using three models, and the apt model was visualized. The validation data set from four different regional medical centers in China presented great power and credibility of the apt model. The nomogram and the web calculator were visualized, possessing good consistency and clinical application value.

Abbreviations: AJCC, The American Joint Committee on Cancer; AIC, Akaike's Information Criterion; AUC, area under the curve; DCA, decision curve analysis; MSE, mean squared error; ROC, receiver operating characteristic curve; SEER, The Surveillance, Epidemiology, and End Results.

Methods

Clinical information and selection criteria

SEER*STAT (version 8.3.5) software was used to extract data including patient demographic characteristics, clinicopathological treatment, and patient treatment (surgery, radiotherapy, and chemotherapy) information.

SEER data inclusion criteria were as follows: (1) primary malignant tumor of osteosarcoma with International Classification of Diseases of Oncology ICD-O codes 9180, 9181, 9182, 9183, 9184, 9185, 9186, 9187, 9192, 9193, 9194, and 9200; (2) SEER database after 2010 incorporated relevant metastatic site information and included patients diagnosed between 2010 and 2016; (3) osteosarcoma was the first and only primary malignancy; (4) complete clinical information, including age at diagnosis, sex, race, primary site, tumor size, tumor stage and grade, metastatic site, surgery, and whether radiotherapy and chemotherapy were administered; (5) diagnosis was from surviving patients and did not include cadavers; (6) complete follow-up information was available; and (7) known cause of death and survival time after diagnosis.

The multicenter data were obtained from four medical institutions in China: the Second Affiliated Hospital of Jilin University, the Second Affiliated Hospital of Dalian Medical University, Liuzhou People's Hospital, and Xianyang Central Hospital. The follow-up period was more than 3 years. Three investigators were responsible for data acquisition at each institution during the survey period. Tumor size and stage were provided by the surgeon, and pathological grading was diagnosed by a senior pathologist at each hospital, or in case of uncertainty, confirmed by a pathologist at the Second Affiliated Hospital of Jilin University. Data were extracted by two of the three investigators, and data check was performed by the third

one. All data were checked for consistency and date was sorted using Microsoft Excel (Microsoft Excel, 2013, Redmond, USA).

Exclusion criteria were as follows: (1) incomplete clinicopathological and survival information; (2) unknown tumor size, stage, and race; and (3) vacant data.

Calibration of prediction model parameters and data baseline

Considering the characteristics of the SEER database and the multicenter study, we tried to unify the data standard. Three categories of race in SEER data were white, black, and other without specific subdivisions, while the race of real multicenter data from China was classified to "other". Treatment modality included surgery, chemotherapy, and radiotherapy, but the SEER database did not record treatment details; thus, it could only be classified as No (treatment) or Yes (treatment). Some patients were coded "999" on tumor size in the SEER database, which meant that their tumor size could not be assessed. To minimize data bias, we used x-tile to find the cutoff value of the data that can assess the tumor size, converting the tumor size from a continuous variable to a categorical variable.

Baseline tables were drawn for the modeling and validation group data, independent samples *t*-tests were used for continuous variables, and chi-square tests were used for categorical variables. Heat maps were plotted to show the frequencies and correlations between the parameters.

Selection of the prediction model

Three methods were used to screen variables in this study: (1) univariate Cox with $p < 0.05$ as a cutoff for screening variables and forest plot; (2) full subset regression to adjust for R^2 maxima to determine the best combination of variables; and (3) the LASSO regression and cross-validation to determine the combination of variables by the λ value while the mean squared error (MSE) was minimal.

The variables of the three methods were screened by using stepwise backward regression to achieve the minimum value of Akaike's Information Criterion (AIC). The models constructed by the three methods were compared by receiver operating characteristic (ROC) curves, and that with the largest area under the curve (AUC) was selected as the final model.

Survival analysis

In the prognostic analysis, Kaplan–Meier was used to estimate survival curves for each variable, and a log-rank test was used to determine the significant difference. Multivariate Cox regression analysis was used, and forest plots were drawn.

Development and visualization of prediction models

A nomogram was constructed using the parameters screened from the multivariate Cox results. For application convenience, a user-friendly web calculator was provided. Meanwhile, we built the decision tree.

Model validation and clinical application assessment

The actual and predicted probabilities were compared using calibration curves for the training and validation sets to evaluate the model consistency. The ROC of the validation set was plotted, and AUC was calculated to evaluate the prediction accuracy of the prediction model. Decision curve analysis (DCA) was used to evaluate the clinical application value.

Statistical analysis

Cutoff values were obtained by x-title software. Statistical methods and plotting, including *t*-test, chi-square test, LASSO, full subset regression, heat map, Kaplan–Meier, forest plot, nomogram, ROC curve, calibration plot, and DCA curve, were performed by R version 4.0.5. $p < 0.05$ was considered statistical significance.

Results

Continuous variables transformed into categorical variables

In Figure 1, the x-tile software calculated the optimal division of tumor size into the following groups: less than or equal to 95 mm, 95–127 mm, and more than 127 mm. Therefore, the continuous variable in tumor size was transformed into categorical variables in the three groups of ≤95, 95–127, and >127. Other patients coded "999" on tumor size were allocated to "Unable to evaluate".

Baseline data about SEER and multicenter data

Based on the SEER database, information was collected on all patients with osteosarcoma between 2010 and 2016, and according to inclusion and exclusion criteria, 1,144 patients were finally included, while a total of 112 patients were included in the Chinese multicenter data. Flowchart of data collection and analysis was shown in Figure S1.

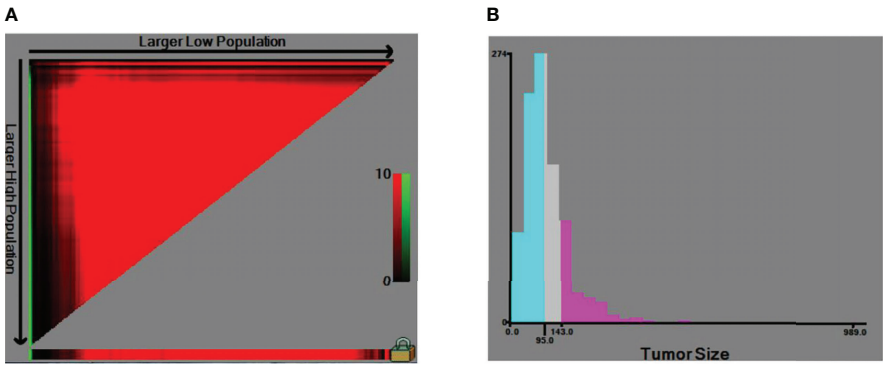

FIGURE 1
The cut-off of tumor size. **(A)** The x-tile software calculated the optimal division of tumor size. **(B)** Categorical variables.

Table 1 showed the demographic, clinicopathological, and treatment data characteristics of the SEER database versus the Chinese multicenter. Among the statistically significant differences between the two cohorts were race and chemotherapy. In the SEER data, Caucasians predominated, followed by blacks and other ethnicities. The multicenter data had a only Chinese population and a higher proportion of chemotherapy for osteosarcoma in China. No significant differences existed regarding other characteristics between the two groups (Table 1).

The heat map in Figure 2A showed the correlation between each parameter, and that in Figure 2B showed the frequency in each parameter. In Figure 2A, we could find moderate correlations for tumor size with T and stage group, race with category, and bone metastasis versus lung metastasis. In Figure 2B, the frequencies of each parameter were shown, and

the data distribution could be observed visually from the colors (Figure 2).

Univariate Cox regression

According to the results of the univariate Cox regression, the forest plot was drawn (Figure 3). According to the results of the univariate Cox regression forest plot, 14 variables ($p < 0.5$) were screened by univariate Cox regression, namely, age, primary site, grade, laterality, stage group, T stage, N stage, M stage, surgery, radiation, chemotherapy, bone metastases, lung metastases, and tumor size.

Full subset regression

The full subset regression was performed using the R packages' (leaps) regsubsets function to find the best combination according to the optimal subset regression model evaluation criteria, through adjusting the Marlowe's CP value to minimum, R^2 value to maximum, and Bayesian information criterion to minimum. The combination of variables was determined with the adjustment R^2 as criterion. Optimal full subset regression selected eight variables (age, grade, laterality, stage group, M stage, surgery, chemotherapy, and tumor size) (Figure 4).

LASSO regression and cross-validation

LASSO introduced the variable λ to find the most appropriate model. As λ increased, the regression coefficient β of each variable decreased, and some became zero, indicating that the variable contributed little to the model and could be eliminated. λ value determined which variables optimized the model, and the best λ value could be found using cross-validation (Figure 5A).

Figure 5B showed the Partial-likelihood deviance curve with Log(λ). The value (λ.min and λ.1se) was used to choose the good performance model in a minimum number of independent variables. Four combinations of variables (age, M, surgery, and lung metastases) were chosen *via* the LASSO regression.

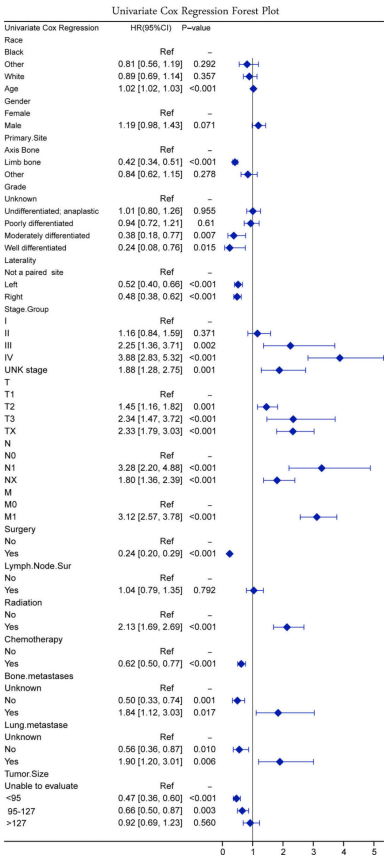

FIGURE 3
Forest plot on univariate Cox regression.

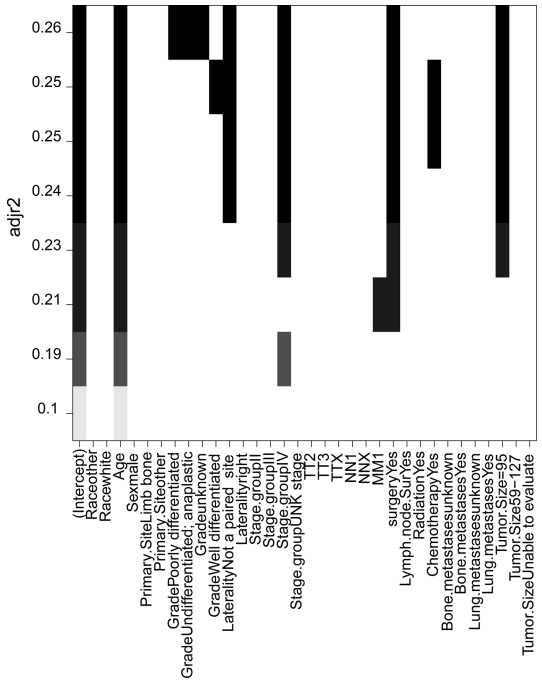

FIGURE 4
The combination of variables were determined with the adjustment R^2 as criterion in the full subset regression.

Multivariate Cox regression to determine the final model variables

A total of 14 variables were screened by univariate Cox regression. Based on adjusted R^2 maxima, eight variables (age, grade, laterality, stage group, stage M, surgery, chemotherapy, and tumor size) were screened by optimal subset regression (OSR). LASSO regression and cross-validation using a tuning factor (λ.1se) built an excellent model with a minimum number of four independent variables (age, M stage, surgery, and lung metastases).

The combinations of variables screened by each of the three methods were analyzed in a multivariate Cox model, and the final models of the three methods were determined using stepwise backward regression with minimum AIC values. After stepwise backward regression, eight variables were included in the univariate Cox (age, grade, laterality, M, surgery, bone metastases, lung metastases, and tumor size). Six variables were included in the optimal subset regression (age, grade, laterality, M stage, surgery, and tumor size). Four variables were included in LASSO regression (age, M stage, surgery, and lung metastases).

The AIC of the three models were 5,552.849 in univariate Cox, 5,570.204 in OSR and 5,611.193 in LASSO regression. ROC curves in three models were drawn at 1-year, 3-year, and 5-year survival. The models were evaluated by AUC values (Figure 6). The model constructed by univariate Cox was optimal with the largest AUC and the smallest AIC.

Survival analysis

The multivariate Cox forest plot showed that eight univariate Cox parameters were independent risk factors ($p < 0.05$, Figure 7).

Kaplan–Meier survival curves revealed that there was no significant difference in patient survival between the SEER data and the real Chinese multicenter data ($p > 0.05$, Figure 8A). Kaplan–Meier survival curves about all patients are presented in Figure 8B. Bone metastases were at higher risk than no bone metastases ($p < 0.05$, Figure 8C). Well-differentiated grade patients held longer survival ($p > 0.05$, Figure 8D). Kaplan–Meier survival curves almost overlapped in left and right laterality, showing no difference ($p > 0.05$, Figure 8E). Lung metastases were at higher risk than no bone metastases ($p < 0.05$, Figure 8F). M1 showed a lower survival rate than M0 ($p < 0.05$, Figure 8G). Patients with surgery showed higher survival rate than no surgery ($p < 0.05$, Figure 8H). The larger the tumor size of patients was, the shorter was their survival ($p < 0.05$, Figure 8I). The consistent results were proved in the validation cohort (Figure S2).

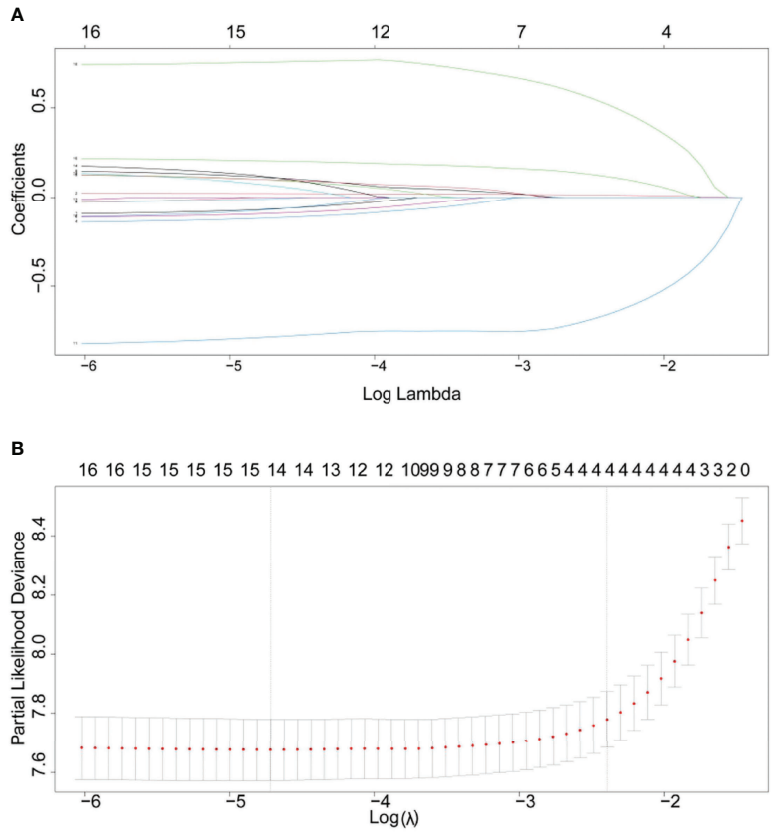

FIGURE 5
(A) LASSO coefficient profile. **(B)** Cross-validation for tuning parameter selection in the LASSO model.

Prediction model development

A nomogram is a method that allows quantification and visualization of Cox regression (16). The nomogram is evaluated by two methods: (1) Each variable is listed, and each sub-variable is quantified into a specific score. The cumulative scores of all variables are matched to the outcome scale to obtain predicted probabilities. (2) Web calculators or dynamic line graphs are developed to input specific variables and calculate the probability of an event. In this study, we constructed the nomogram using multivariate Cox variables (Figure 9A). Moreover, an online web calculator (https://dr-lee.shinyapps.io/osteosarcoma//) was designed to facilitate the user. A decision tree model was also provided as a supplement for the prediction model (Figure 9B).

Calibration chart and external receiver operating characteristic curve

The calibration chart was an assessment of how close the estimated risk of the line plot was to the actual risk. SEER data were applied for internal validation, and multicenter data were applied for external validation. The internal validation results (Figures 10A–C) and external validation results (Figures 10D–F) showed that the predicting outcomes were consistent with the actual outcome and the prediction model was well preformed in 1, 3, and 5 years. The ROC curves of the model were plotted in multicenter data. It proved the excellent predictive ability in 1, 3, and 5 years (AUC > 0.8, respectively) in Figure S3.

Risk score visualization and decision curve analysis

The risk score plots were used to visualize Cox survival risk models. Figure 11 could illustrate the risk factors heat map, the scatter plot of patients' status, survival time, and high/low risk group, in the training and validation groups, respectively.

As in Figure 12, in both the training and validation groups, there was no significant benefit for 1-year patients. In 3 years

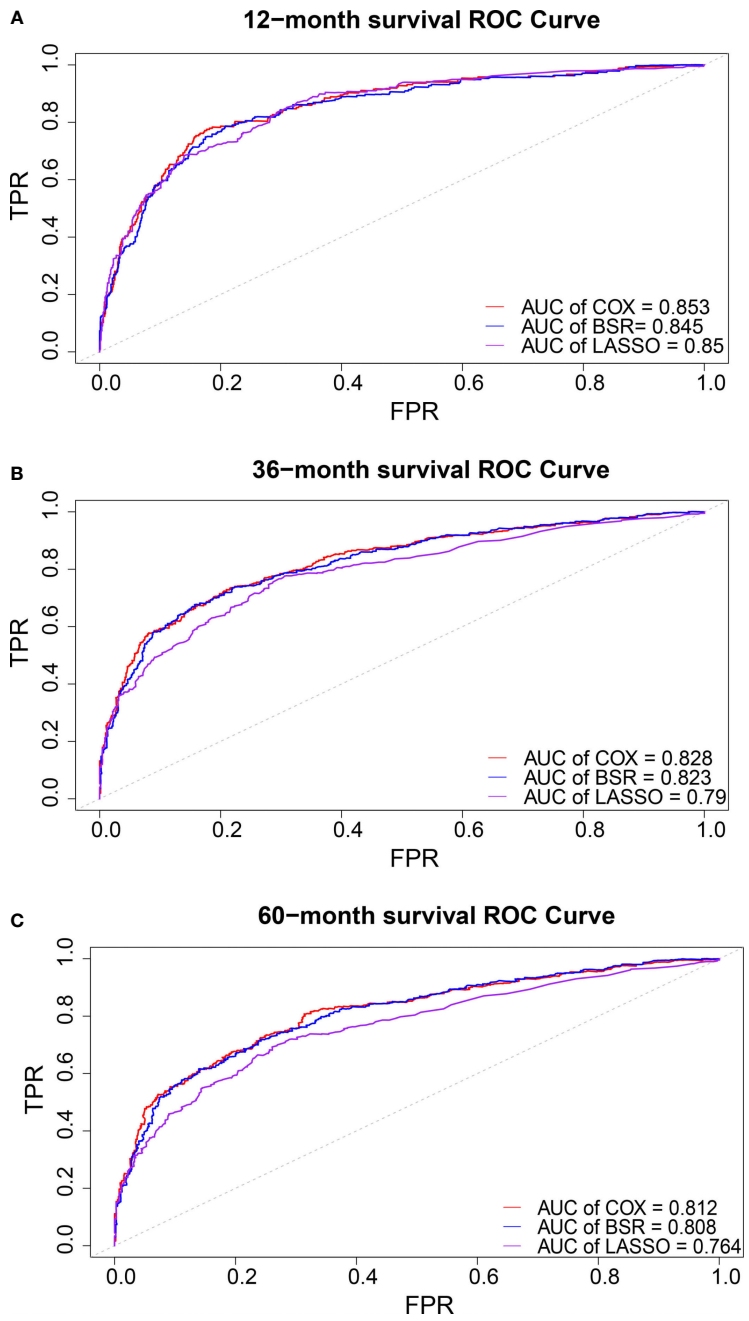

FIGURE 6
ROC cure in 1-**(A)**, 3-**(B)**, and 5- **(C)** years overall survival.

and 5 years, it was clear that the dashed line received a higher net benefit than the 1 year in both. Considering that osteosarcoma patients do not have a high mortality rate within 1 year of diagnosis, the prediction model developed in this study proved to have excellent clinical utility.

Discussion

Since the mid-1980s, with the standardization of treatment and the use of adjuvant chemotherapy, the 5-year survival rate for patients with osteosarcoma has arrived to approximately 65%

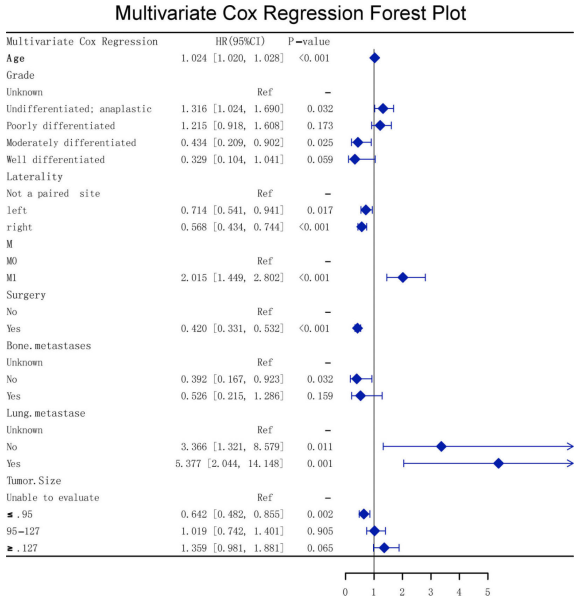

FIGURE 7
Multivariate Cox forest plot.

(17). No statistically significant differences were found between osteosarcoma patients from the United States and China, except in the ethnic distribution and the proportion of chemotherapy use (**Table 1**). All races were categorized as white, black, and other in SEER data, with other including Chinese. However, race was excluded as a predictor in three models (univariate Cox, full subset regression, and LASSO). In clinical practice, chemotherapy became a routine treatment option for metastases, especially concomitant lymphatic or vascular micrometastases (18). The proportion of chemotherapy in China was 87.5%, higher than that of the SEER database (**Table 1**). This might be related to the clinicians' preference and financial cause. Chemotherapy was a protective factor for patients with osteosarcoma in the univariate Cox results (**Figure 3**). However, the overall survival time from the multicenter data was not significantly different from the SEER database (**Figure 8A**). Proper indications for chemotherapy needed future research. This study had limitations since a retrospective study had bias in multicenter data collection, resulting in a higher proportion of chemotherapy.

In 2020, approximately 3,600 new cases with bone tumors and approximately 1,720 patients would die from the malignancy in the United States (19). Osteosarcoma with metastases clinically detected at initial presentation were approximately 20% of all osteosarcoma patients (17, 20). Approximately 30% of patients developed lung metastases within 1 year after diagnosis (21). Early detection of metastases could improve prognosis. Lung metastases had a strong correlation with bone metastases (M stage) and lymphatic metastases (N stage) (**Figure 2**). Bone metastases had a strong correlation with N. The mechanism of lymphatic metastasis from osteosarcoma has not been clear (22). Some studies found that osteosarcoma metastases disrupted the cortex, and the metastatic route might be through the lymphatic vessels of the synovial membrane and bursa (23). The incidence of lymphatic metastasis in patients with osteosarcoma did not exceed 5% in both SEER data and multicenter data, while lymphatic metastasis was a risk factor for patients with osteosarcoma in the univariate Cox results (**Figure 3**). Thus, we suggested that oncologists could not ignore the examination on lymph nodes. A nomogram has been constructed to predict distal metastases from osteosarcoma, which can be used as a method to screen for people at high risk of developing metastases (12). The first peak of mobility occurred at the age of 10–14 years, coinciding with pubertal growth (24, 25). Older patients may be less tolerant to treatment, and had a poorer prognosis. Osteosarcoma in an axial location showed poorer survival, and it was more difficult to completely resect focus due to location. Similarly, the larger tumor volume had poorer prognosis due to difficulty in complete resection, which was similar to previous studies (26).

AJCC (8) and Enneking (9) staging systems can only vaguely assess the clinical risk of osteosarcoma based on initial clinical features to help make treatment decision.

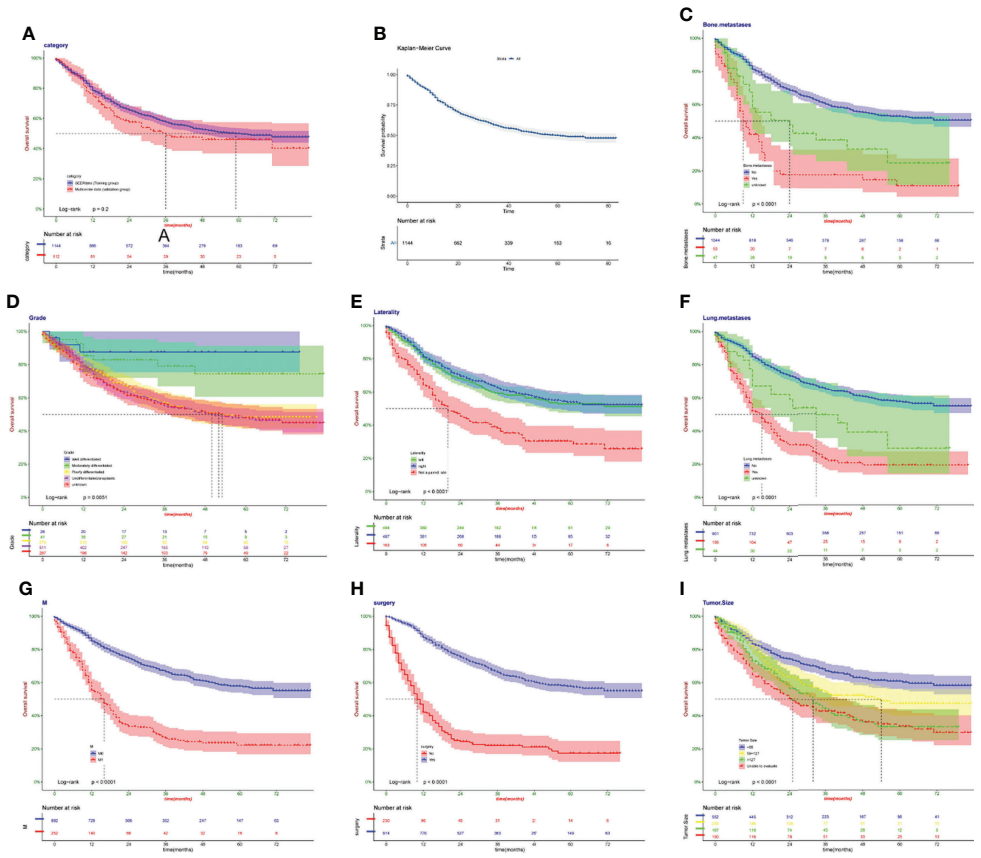

FIGURE 8

Clinical prediction models are widely used today as tools for predicting the occurrence of specific events and estimating medical prognosis, especially in clinical oncology. Clinical prediction models generate probabilities of individual clinical events by integrating different predictor and decision variables, and their visualization and quantification advantages are also of great practical value in clinical practice (27). Most prediction models are developed based on logistic regression and Cox regression models. However, the full model equation remains difficult. In our study, three models (univariate Cox, full subset regression, and LASSO) were performed in the SEER database. Univariate Cox model and eight predicting factors (age, grade, laterality, stage M, surgery, bone metastases, lung metastases, and tumor size) were selected based on the minimum AIC and maximum AUC value. The model was further externally validated and evaluated for its clinical utility with data from four medical centers in China. ROC curves revealed good predictive ability (AUC > 0.8 in both internal and external validation, **Figure 6**).

A nomogram and web calculators were applied and visualized. Decision trees were provided as prediction model aids. A major advantage of the web calculator is that, compared to a rating scale or approximations calculated by the nomogram, the full model equation can be embedded in a backend web page, is more accurate in its calculation, and is more convenient to use. Web calculators can provide user-friendly graphical interfaces for complex mathematical models reducing the learning cost for users in today's world of smartphones and mobile networks. The nomogram is an effective quantitative method to assess risk and benefit and is widely used in clinical decision-making in a variety of diseases (28). In previous studies, several nomograms have been developed and validated to predict specific survival and overall survival in chondrosarcoma (29, 30).

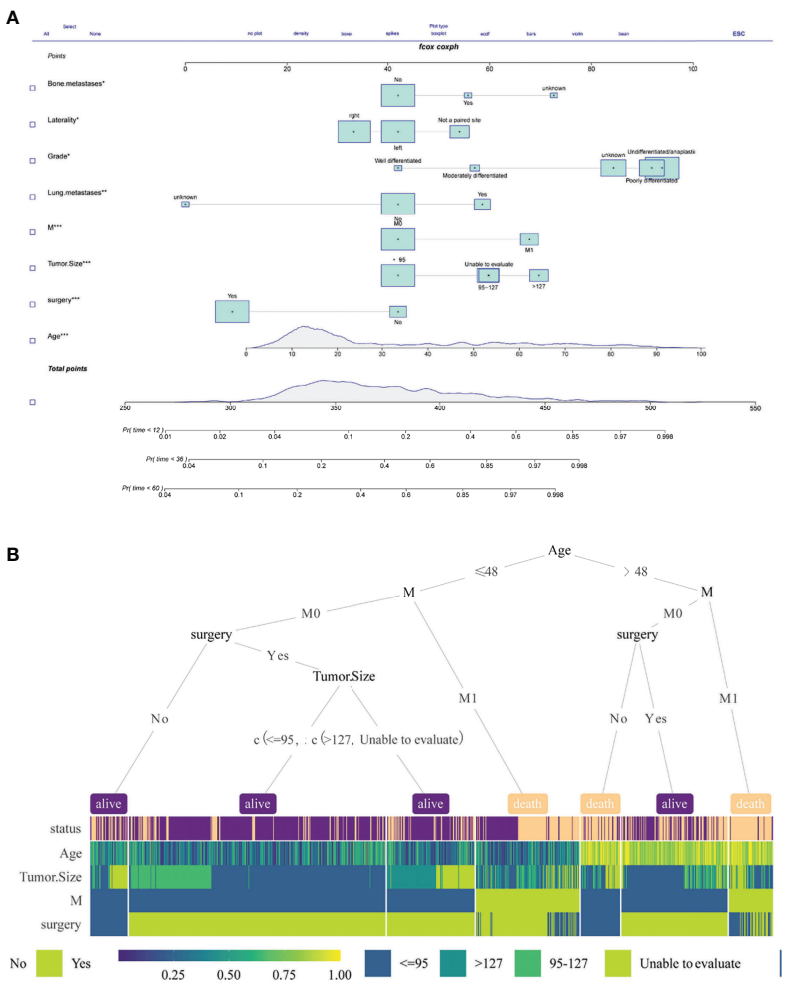

FIGURE 9
(A) A nomogram was constructed using multivariate Cox variables. **(B)** The decision tree of multivariate Cox variables.

In this study, a clinical prediction model to predict the overall survival of patients with osteosarcoma was developed to provide an objective reference for clinicians when making medical decisions. In clinical practice, lacking large-scale prognosis statistics for osteosarcoma patients in China, we chose the SEER database to develop the prediction model, and collected patient data from four medical centers in China to verify the feasibility of the model. In terms of clinical utility, the risk factor plots showed good stratification in both cohorts, effectively differentiating between high- and low-risk patient populations (**Figure 10**). The DCA displayed that both cohorts had better patient benefit from medical interventions in 3 years and 5 years. The 1-year model did not have a great net benefit, which may be related to the low mortality within 1 year (31).

Despite our efforts to refine the clinical prediction model, some limitations remained. (1) Training data (SEER database) to develop the prediction model were from North American patients, while the multicenter external data of China were tested for the model's predictive power. (2) The model was based on retrospective data and inevitably had inherent biases. (3) Previous studies showed that metastasis of osteosarcoma was associated with genes, metastatic mechanisms, proteins, and RNAs (32, 33). Since the SEER database did not contain relevant information, there was still room to improve the predictive power of the model.

Conclusions

In this study, based on the SEER database and data of osteosarcoma patients from 4 different regional medical centers in China, the model with the highest predictive ability was selected by three methods of screening model predictors, and the model was visualized for predicting the overall survival of osteosarcoma patients using three methods: nomogram, web calculator, and decision tree. The model was shown to have very good predictive power and consistency by both calibration plots and ROC curves. DCA demonstrated that the predictive model could provide greater benefit to patients. External validation results show that it still has predictive power and clinical use outside of North America.

Data availability statement

The data analyzed in this study is subject to the following licenses/restrictions: SEER database within the article is public data set. The clinical information data of China's multicenter, analyzed during the current study are not publicly available for patient privacy purposes, but are available from the corresponding author upon reasonable request. Requests to access these datasets should be directed to CY, chengliangyin@163.com.

Ethics Statement

This study was exempted from Institutional Review Board approval, in view of the SEER's use of unidentifiable patient information. Due to the strict register-based nature of thestudy, informed consent was waived. The study of multicenter data was approved by the ethics review committee of the Second Affiliated Hospital of Jilin University, the Second Affiliated Hospital of Dalian Medical University,Liuzhou People's Hospital, and Xianyang Central Hospital(No. 20210021).

Big data-driven intelligent governance of college students' physical health: System and strategy

Chenliang Deng[1]*, Qiaoyan Yu[2], Ganglin Luo[3], Zhangzhi Zhao[1] and Yuchao Li[1]

[1]Sports Department, University of Electronic Science and Technology of China, Chengdu, China, [2]School of Gymnastics, Chengdu Sport University, Chengdu, China, [3]Department of Military Education and Training, Police Academy of the Armed Police, Chengdu, China

With the development of information technology, the application of a new generation of information technologies, such as big data, Internet Plus, and artificial intelligence, in the sports field is an emerging, novel trend. This paper examined the relevant research results and literature on physical education, computer science, pedagogy, management, and other disciplines, then used a self-made questionnaire to investigate the physical health status of Chinese college students. The big data were subsequently analyzed, which provided a scientific basis for the construction of an intelligent governance system for college students' physical health. Intelligent devices may be used to obtain big data resources, master the physical sports development and psychological status of college students, and push personalized sports prescriptions to solve the problems existing in college students' physical health. Research shows that there are four reasons for the continuous decline in Chinese college students' physical health levels. These are students' lack of positive exercise consciousness and healthy sports values (85.43%), a weak family sports concept and lack of physical exercise habits (62.76%), poor implementation of school sports policies (55.35%), and people's distorted sports value orientation (42.27%). Through the connecting effect of data, we can bring together the positive role of the government, school, society, family, and students so as to create an interlinked impact to promote students' physical health. The problems of insufficient platform utilization, lack of teaching resources, lagging research, and insufficient combination with big data in the intelligent governance of physical health of Chinese college students can be solved by building an intelligent governance system of physical health. Such a system would be composed of school infrastructure, data resources and technology processing, and intelligent service applications. Among these, school infrastructure refers to the material foundation and technical support. The material foundation includes perceptions, storage, computing, networks, and other equipment, and the technical support includes cloud computing, mobile Internet, the Internet of Things, artificial intelligence, and deep learning. Data resources refer to smart data, such as stadium data, physical health management data, and students' sports behavior data, which are mined

from data resources such as students' physical development, physical health, and sports through big data technology and intelligent wearable devices. Intelligent managers provide efficient, intelligent, accurate, and personalized intelligent sports services for college students through data resource value mining, venue space-time optimization, health knowledge discovery, sports prescription pushes, etc. Finally, we put forward the development strategy for further deepening and improving the big data-driven intelligent governance system for college students' physical health. The intelligent governance system of physical health driven by big data and its development strategy can not only accurately guide and improve the physical health level of college students but also realize integrated teaching inside and outside physical education classes.

information technology, big data, information physical education, physical health of college students, intelligent governance of physical health

Introduction

Physical health is the basic right and the first wealth of college students and, more importantly, the basic premise of their healthy study, work, and life in the future. Therefore, how to improve the physical health level of college students is a very meaningful and valuable work pursued by the country, school, society, family, and students.

During the past 70 years, since the founding of the People's Republic of China, the party and the state have remained concerned and attached great importance to the health of students. To encourage and promote students to actively participate in physical exercise and enhance students' physical fitness, the relevant competent departments developed a series of systems in different periods, such as the "Labor Hygiene System" (1954), "National Physical Exercise Standards" (1975), "Student Physical Education Qualification Standard" (1990–1991), and "Sports Examination Methods for Junior High School Graduates" (1997). In 2002, the "Standards for Students' Physical Health" was piloted in schools across the country and has been implemented for more than 10 years. In 2014, the Ministry of Education issued a new "Standards for Students' Physical Health," which required that "all schools carry out physical health tests covering students of all grades every school year and stipulates that students whose physical health test score is <50 points will be treated as lacking completion or having incomplete study and unqualified schools will be rejected in the evaluation." In 2016, the Opinions on Strengthening School Physical Education and Promoting the All-round Development of Students' Physical and Mental Health contended that "we should carry out strategic, forward-looking, and applied project research aimed at improving students' physical health, teaching quality, after-school training, and sports cultural level through multiple channels so as to improve the overall level of school physical education work." In 2018, President Xi Jinping stressed at the National Education Conference that "health comes first in education, and physical education classes should be provided to help students enjoy fun, enhance their physical fitness, improve their personality, and temper their willpower." In 2020, the Opinions on Comprehensively Strengthening and Improving School Physical Education in the New Era clearly pointed out that "under the guidance of Xi Jinping Thought on Socialism with Chinese Characteristics for a New Era, by fully implementing the party's education policy, adhering to the socialist direction of school running, and taking moral education as the fundamental and socialist core values as the guidance, we aim to serve the all-round development of students and enhance their comprehensive quality, adhere to the education concept of health first, and promote the coordinated development of cultural learning and physical exercise for young people." In the same year, the "Notice on Deepening the Integration of Sports and Education to Promote the Healthy Development of Teenagers," which was jointly issued by the General Administration of Sport of China and the Ministry of Education, also suggested to "establish the education concept of health first, then open full physical education for all students, to help students enjoy fun in physical exercise, enhance their physical fitness, improve their personality, temper their will, realize the civilization of their spirit, and savage their body." In 2021, the "Opinions on Comprehensively Strengthening and Improving School Health and Health Education in the New Era" suggested to "implement the fundamental task of moral education, adhere to the education concept of health first, and comprehensively improve students' health literacy into a high-quality education system as an important goal and evaluation standard of school education. We will deepen the reform of health education in schools; promote students' physical and mental health, develop a healthy lifestyle; and

train them to be socialist builders and successors who are well-developed morally, intellectually, physically, aesthetically, and laboriously." The implementation of a series of national policy documents and systems has pointed out the direction for the development of physical education in schools, and it is of great significance to further strengthen the physical education of young students, enhance their physique, and vigorously promote quality-oriented education.

At present, domestic experts and scholars' research on big data sports is still in the initial stage of exploration, and some research results have been accumulated. The research directly related to this paper mainly includes four aspects, one of which is research on big data in sports. Since 2013, big data in sports has become a hot topic widely discussed. In 2015, the five trillion sports industry's goal was to attract Internet giants to break into big data of physical layout, but the research on theory and practice is limited and only a small number of researchers' findings have focused on big data in sports, new ecosystems, forward-looking analysis, sports communication, etc. The second aspect is the research on the sports industry against the background of big data. Representative research in this field includes work by Tong et al. (1), Dong et al. (2), Yu (3), Xie et al. (4), and other documents and materials. This research has mainly focused on the development of the sports industry in the era of big data, including opportunities and challenges, paths, and financial risk prevention and control as well as facility operation, operation for sporting events, sports marketing, sports industry integration, and so on. The third aspect is the research on physical education in the era of big data. Currently, there are only a few studies, mainly those of Zhang and Sun (5). The research results mainly discuss the application of big data in school physical education, the reform of physical education teaching methods, the change of physical education learning methods, and the precision teaching mode of physical education from the aspects of appeals, trends, and action. Fourth is the study of intelligent sports. Representative research results in this aspect are concentrated in the areas of intelligent sports classrooms (6), intelligent sports stadiums (7), intelligent sports services (8), and intelligent governance of public sports services (9). Experts and scholars have conducted their research from the perspectives of the Internet, big data, the mobile Internet, cloud platforms, and artificial intelligence. Overall, the related research results for this research laid the foundation and provide a theoretical reference. However, available big data technology research to improve the physical health of university students is limited; the qualitative-quantitative combination of sports science and medicine is lacking; the combination of computer science, management, sociology, and related influencing factors of college students' physical health in comprehensive research is unexplored; and there is no research on college students' physical health service system driven by big data.

With the in-depth development of information technology, big data has brought new development opportunities to all walks of life, and school physical education is also currently facing many opportunities and challenges. The integrated development of school physical education and information technology has become a core task and urgent demand to solve the existing problems of school physical education in China. At present, the development of school sports informatization in China is poor, lacking both talents and technology, which does not match the current national strategic environment. Given the current research and development situation, how to integrate college students' physical health and college sports resources with computer technology, physical health services, and other elements remains challenging. Equally daunting is how to build a big data-driven college students' physical health service system for management coordination, decision support, intelligent governance, and the construction and development of college students' intelligent sports venues. Therefore, based on the challenges of college students' physical health under the current big data environment and the relevant research status of intelligent governance, this study starts from the key integration of advanced information technology, such as big data, and the development of student's physical health. It carries out innovative research in theory, technology, application, evaluation, and other aspects, and improves the level of college students' physical health through data accuracy technology to build an intelligent governance system for college students' physical health based on big data.

Methods

Based on the theoretical and practical knowledge of school physical education, computer science, pedagogy, management, and other disciplines, this paper studied the research results and available literature on college students' physical health at home and abroad and used existing theoretical and practical results to support and build the theoretical framework and methodology of this paper.

By using self-compiled questionnaires to investigate the physical condition of college students and through big data analysis and sorting, this study provides a scientific basis for building an accurate system for the improvement of college students' physical health. To collect and assess students' physique, health, and influencing factors, the head of the department in charge of local sports and sports science, management, and computer science or a scholar of related fields visited the relevant domestic school to conduct a full investigation.

The influencing factors of this study are determined by a factor analysis method. Based on the contents obtained from the literature discussion and interviews with experts and scholars, questionnaires were designed according to the preliminarily constructed influencing factors of college students' physical health; three rounds of expert surveys were undertaken to

establish the influencing factors. In the study of students' physique health service systems, determination by wisdom is one of the most widely used methods in social science research employing the Delphi method. Through literature review, interviews of experts, and based on the content according to the preliminary build of the students' physique health service system, designed the questionnaire, performed three rounds of expert investigation, and established the system.

We grasped students' physical sports development, and psychological conditions by using emerging information technology that pushed personalized teaching and sports prescriptions, and addressed the existing problems of college students' physical health by using big data technology. We summarized and studied while providing timely feedback and revision of the plan, and performed the experiment laid out in this study.

Results

Analysis of reasons for the decline in Chinese college students' physical health

In recent years, the physical health level of Chinese college students has continued to decrease due to the effect of subjective and objective factors of the government, schools, society, families, and students.

Subjective factors of declining physical health of college students

According to the survey results, at present, 85.43% of students in Chinese universities lack active sports consciousness and correct values. In other words, they do not know why they want to exercise. As Mao Zedong said in the vernacular translation of the Study of Sport: to deal with a matter is reflected in behavior; we must first start to be interested in or like it. In particular, we must first have a specific understanding of the matter and why such wisdom is necessary and must clearly understand the specifics and why, which is the embodiment of self-consciousness. Many college students do not know the benefits of sports for themselves, either very well or not at all. In short, the stimulation of sports potential is inadequate, so there is no emotion to mobilize sports interest. Those students who can study tirelessly and assiduously think that the relationship between sports and learning is not close, and their survival is not based on sports. Some even think that sports will delay their cultural learning and other activities. Therefore, sports self-consciousness is resulting in worrying physical health. This portion of the reason for non-participation should be blamed on students' inability to deeply understand the benefits of sports. However, teachers do not know how to enlighten students or how to work hard ideologically, which also accounts for half of the responsibility. On the other hand, students lack correct sports values. They are embarrassed to exercise and consider people who can exercise stupid. This is the big reason why people do not like sports. Gentle and slow people look very good and are also respected by society. What does a person who suddenly opens their arms and feet, stretches their limbs, and bends their body look like? Shouldn't this be considered particularly strange? So, there are people who know that the body must move and want to take action but don't take action. There are also people who can exercise together but can't exercise alone, and then there are those who can exercise in their own home but can't exercise in places with many people (10). In short, the subjective reason for the decline of college students' physical health is that they are self-conscious and shy, do not form the habit of physical exercise, and do not establish a correct concept of physical education.

Objective factors of declining physical health of college students

One objective factor at play is the concept of family sports and exercise habits, which accounts for 62.76%. Family is the main place where students grow up and live and also the important base of students' enlightenment and education (11). In a sense, the concept of family sports, sports atmosphere, and sports habits will directly affect the enthusiasm of students in participating in physical exercise. Specifically, if the family has good sports traditions and a physical exercise atmosphere and parents generally like to participate in sports fitness activities, students will naturally fall in love with sports fitness activities in college. These individuals tend to experience the passion and fun of sports in a family atmosphere. On the other hand, if the family does not have the atmosphere and tradition of sports activities, their participation in sports activities will inevitably be less. In effect, the concept of "preconception gives priority to" decides the outcome. Compared to school education, family education is more likely to stimulate students' enthusiasm and participation. Family intimacy, tacit understanding, and other factors determine the important position of family education in cultivating students' good physical exercise habits (12). According to a 2019 survey report, 64.8% of Chinese parents said physical health is always the top priority, while 75.9% of parents of kindergarteners and >50% of parents in other learning stages support physical education. In addition, 73.6% of parents believe a lack of exercise is the main reason for college students' poor physical fitness. However, although the importance of physical development is recognized, in the actual home environment, the lack of momentum is very serious. A family's poor sports atmosphere and lax education are common phenomena. On the one hand, parents exercise an average of 2.5 h a week, and >60% exercise with their children no more than once a week. On the other hand, 66.8% of parents have adopted a relaxed educational approach to cultivate their children's sports habits,

focusing on their children's interests rather than discipline. Only 1/3 of parents adopt a strict physical exercise regimen. The decrease in exercise time and frequency is directly reflected in the physical condition of students, resulting in the continuous decline of students' physical health levels. Parents rate their children's physical health as passing, not good. Parents of high school students awarded the lowest scores for their children's physical health.

Second, the school sports policy implementation deviation accounts for 55.35%. According to the survey results, most colleges and universities have problems with the implementation of school sports policies, be it in its scale, insufficient depth, insufficient strength, or false implementation methods. In fact, most schools have not really implemented relevant sports policies, which has led to a sharp decline in the physique of Chinese teenagers to a certain extent. Additionally, the school does not pay enough attention to the cultivation of core literacy regarding physical fitness. The study of cultural courses occupies a large portion of the college students' spare time and increases with the advancement in grade, resulting in the lack of exercise time among college students. Nearly 67.6% of college students exercise no more than twice a week. The above problems are caused by the issues in school sports policies, their weak implementation, and the lack of an effective supervisory mechanism. Therefore, we should improve and optimize the level of policy formulation, enhance capacity for policy implementation, identify and support policy implementation objectives, provide resources and the environment for policy implementation, and have a monitoring and oversight system for policy implementation (13).

Finally, the influence of distorted sports value orientation of social groups accounts for 42.27%. In China, although people know they should be active in sports and believe that promoting sports can make a country strong, they tend to pay more attention to cultural education than physical education. Such ideas and actions lead most people to hover between welcoming and rejecting sports. So, most people do not really like sports. Second, most of today's educators are not good at sports. They don't know much about sports and may have only heard of the word "sports," so when they come to teach sports, they start from a dishonest point of view, and they can't or won't do anything about it, so they weaken students' curiosity about sports. In addition, most people who teach physical education have shallow knowledge. They only know a few sporting events, and they may not be proficient in them. They lack in-depth knowledge and only their mechanical movements are seen by others every day. Therefore, many think that sportspersons are uneducated. Indeed, only focusing on the "body" of sports without also focusing on "education" or only paying attention to the form but not the substance will not do for a long time, and the fact of today's school sports is the same.

Current situation of intelligent management of physical health of Chinese college students

At present, information technology closely links the world promoting the process of sports informatization and development of sports worldwide (14). The intelligent management of physical health has become an important way to improve the physical health level of college students and an important means to promote the intelligent services of college students' physical health. However, there are still many problems in the intelligent governance of college students' physical health, such as insufficient platform utilization, lack of resources, lagging research, and a low governance level.

Insufficient use of intelligent governance platforms for college students' physical health

According to our survey, although some Chinese universities have established an information platform for student physical health monitoring systems, the platform is only a decoration and has not been really used. Both the Ministry of Education and the General Administration of Sports have information technology centers, which are mainly responsible for monitoring and have been specifically set up to relay the macro-management and scientific decision-making efforts of ministries and commissions. Despite the establishment of sunshine sports and national fitness platforms, due to its outdated model lagging in products and services, their benefits are poor. How to reasonably combine school sports with informatization, build an intelligent governance platform for physical health in colleges and universities, and make full use of this platform to guide students' scientific sports and healthy life is an urgent problem that needs to be solved.

Lack of intelligent physical health service teaching resources for college students

For a long time, physical education teaching in colleges and universities has had a single structure, outdated content, traditional methods, and insufficient interactions. Teachers are the absolute owners of knowledge, and students can only learn from teachers in class. Therefore, the lack of communication and sharing in teaching makes it difficult to carry out educational and teaching activities creatively. The construction of physical health intelligent governance systems driven by big data has had great influence and significance. On the one hand, information-based physical education teaching resources can break through the traditional narrow teaching methods, letting the life experiences of teachers and students enter the physical education teaching process and rendering the classroom truly active. On the other hand, it can also change the status of learners in the physical education curriculum from passive cognitive audience

members to knowledge-builders so as to transfer students' learning interests and play a positive role. At the same time, it can also broaden teachers' educational horizons, alter teachers' teaching concepts, and obtain the possibility of interaction and resource-sharing with various sports teaching resources, especially teaching material resources. The possibility of mutual cross-transformation of sports teaching resources inside and outside the school will also be increased, and an integrated sports teaching method inside and outside the curriculum will really be realized. Although many enterprises, colleges and universities, and individual teachers have carried out corresponding sports teaching resource construction projects by using big data, and networks, most have employed single sports material resource databases. At the same time, due to the various selection and use environments of sports materials, they sometimes have no way to start within their own schools or individual teachers in the selection process, and even need to be modified again; therefore, teachers must spend significant amounts of time and spiritual resources to do this kind of thing well. Sometimes, it goes against the original design and even impacts the improvement of school physical education teaching quality, which has no obvious effect on the improvement of college students' physical health. Colleges and universities should make full use of information technology, integrate physical education teaching resources, integrate network physical education courses, build high-quality and rich physical education teaching resources, and attain diversified physical education teaching processes and space. They must enable teachers to obtain physical education teaching resources they want in a limited time frame and encourage students to adopt exercise habits through an effective autonomous learning mode so as to finally achieve the purpose of improving their health (15).

The research on intelligent physical health services for college students lags behind

At present, there is still a lack of sports informatics specialty knowledge in China. The research on physical health and intelligent governance is mostly interdisciplinary research, while at the application level, it focuses on sports products on the market, mainly forming a new ecological environment of the Internet industry in the form of a platform, including mobile terminal applications such as sports fitness and running programs. Because China's sports intelligent governance started late and lacks relevant disciplines, there are those who understand sports but do not understand informatization, and those who understand informatization do not understand sports. Moreover, these mobile terminal products and information technology research fields are not well-integrated, and the technical content of products is generally not high. They mainly make profits through content and capital movement. Based on the Internet of Things, artificial intelligence competition training, physical education, physical health monitoring, and other research fields, there is still a large space to fill at present.

The level of intelligent governance of college students' physical health is low

According to the survey results, college students' physical health management services still lack the support of big data, mainly in three aspects. First, the college sports intelligent governance system is not enough. Only the venues in China's college sports intelligent governance at present have the "Internet of Things," while construction at the infrastructure level remains focused on local support of facilities for activity service processes. To realize big data-driven college sports intelligent governance in China, we must establish a systematic and overall intelligent governance system based on intelligent technology and infrastructure. In addition, Chinese universities pay more attention to static information, while real-time and dynamic stream data information has not been widely used, and this data information is often necessary to support the school's intelligent movement behaviors. Second, the current results of big data analysis of college students' physical health have not been systematically organized and managed. In its current form, the existence of large quantities of college students' physical health information data increases the difficulty of obtaining big data analysis information from relevant institutions, which seriously interferes with the reasonable screening, identification, and mining of information data. Third, the current college students' physical health service system structure has been unable to meet the requirements of big data-driven intelligent development. At present, the collection, management, storage, and big data analysis of college students' physical health information and the school decision-making system have been unable to support decision-making through big data technology and cannot realize intelligent school physical education and intelligent physical health services.

Construction of big data-driven intelligent governance system for college students' physical health

From the perspective of being big data-driven, this paper explores the development of a college students' physical health intelligent governance system. According to information ecological chain theory and guided by college students' physical health, a big data-driven college students' physical health intelligent governance system has been formed that can integrate infrastructure, health data resources, and business applications with students; explore the value of data intelligence in college students' physical health data resources by using big data analysis technology; provide learners with efficient, intelligent, accurate, and humanized intelligent sports consulting services;

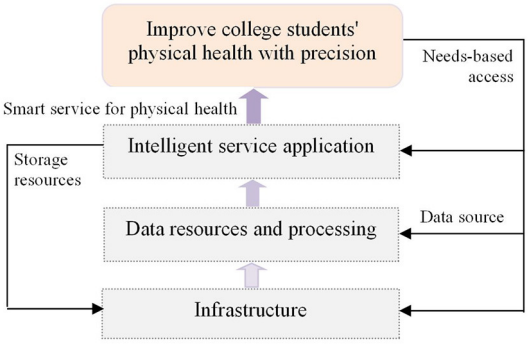

FIGURE 1
Data-driven intelligent governance system architecture of college students' physical health.

and realize integrated physical education inside and outside the classroom. Intelligent wearable devices are used to achieve physical fitness testing, sports monitoring, disease and health management, and dynamic adjustment of physical education teaching content. In combination with the physical health management system, a home-school linkage mechanism is established to master students' physical sports development, and psychological conditions with the use of emerging information technology. Personalized teaching and exercise regimens are pushed to truly achieve individualized teaching and accurate guidance and improvement of college students' physical health.

The data-driven intelligent governance system for college students' physical health includes three levels: school infrastructure, data resources and processing technology, and intelligent service application (see Figure 1). Among these, school infrastructure refers to the material foundation and technical support. The material foundation includes sensing, storage, computing, networks, and other equipment, and the technical support includes cloud computing, mobile Internet, the Internet of Things, artificial intelligence, and deep learning. Data resources are those available through big data technology and intelligent wearable devices about students' physical development, physical health, and movements at sports venues data mining. Data resources include physical health management data and student behavior data such as wisdom and are made available by machine learning, artificial neural networks, data visualization, and social network analysis means and methods for data processing to provide managers with intelligence data services. Smart administrators provide efficient, intelligent, accurate, and personalized smart sports services to college students through data-driven procurement (exercise information, good exercise methods), venue space-time optimization (field exercise experience), health knowledge discovery (knowledge transfer), and sports prescription alerts (16). This system can not only accurately guide and improve the physical health level of college students but also bring about the integration of teaching in and out of class.

Infrastructure: The supporting environment for the intelligent governance system of college students' physical health

The collection, storage, processing, organization, analysis, and application of big data depend on the support of a stable infrastructure framework. The infrastructure provides a guaranteed platform for college students' physical health and intelligent life for big data-driven research. Its main structure is composed of hardware equipment and information technology (see Figure 2). College students' physical health intelligent service facilities cover radiofrequency identification technology, monitors, sensors, smartphones or sports bracelets, and other sensing devices as well as various information technology facilities, including memory, computing equipment, network equipment, and so on. The complete layout of a big data analysis sensor identification system has the functions of in-depth understanding, detection, and capture of sports information data, operation status of stadiums and gymnasiums, and students' needs. It is a physique and fitness big data analysis system that can comprehensively perceive, intelligently screen, and upload in real-time. At the same time, hardware equipment with high performance, high bandwidth, and a large cache is an important material premise for the analysis, storage, analysis, and application of college students' physical health big data. It should offer a solid hardware foundation for solving new challenges, such as the diversification of data sensing ports, the scale of big data analysis resource centers, and the distribution of college students' physical health intelligent services. To realize big data analysis-driven college students' physical health and intelligent services, we must also combine new technologies, such as cloud computing technology, mobile Internet, the Internet of Things, artificial intelligence, and deep learning, which is also the key basis of big data analysis of Chinese college students' physical health. We can complete big data statistical analysis, visual data analysis, semantic analysis, and predictive data analysis and find the implied knowledge relationship and other basic functions in a large number of data analyses.

Data resources and processing technology: Data mining for intelligent governance system of college students' physical health

The data resources and management stage is responsible for the organization, management, and data analysis and mining of college students' physical health big data analysis, which is mainly composed of college students' physical health big data resources and big data processing technology (see Figure 3). College students' health big data is a mass of data formed during the process of students' daily physical exercise

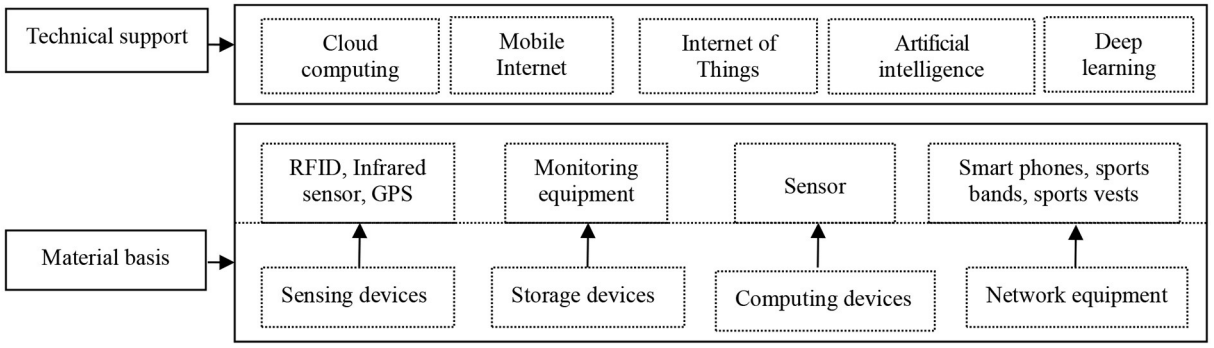

FIGURE 2
Infrastructure architecture.

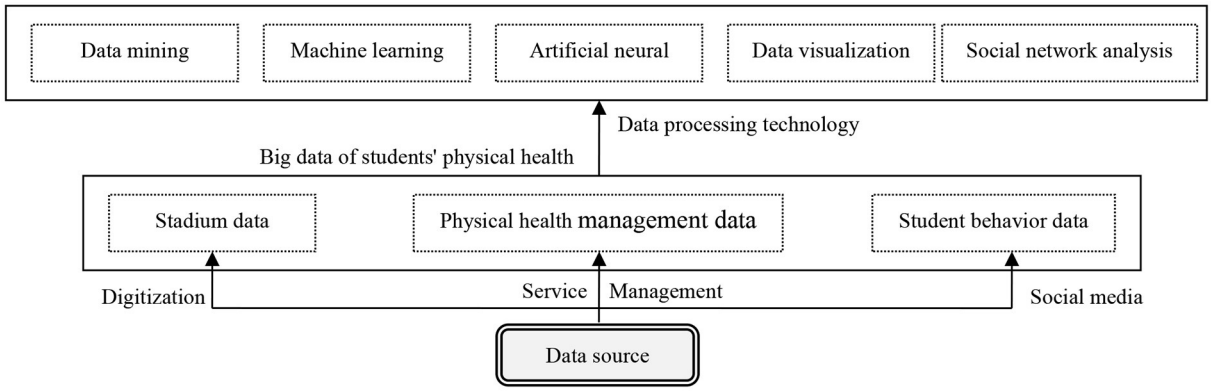

FIGURE 3
Data resources and processing architecture.

life and health management services. Generally, according to different data-formation methods, it is roughly divided into the following three types. The first is stadium database data, including venue reservation, sports knowledge base, online learning data, etc. The second is management and service data analysis. The data analysis generated during college students' daily sports includes resource construction status information records and radiofrequency identification system data analysis, access control information, monitoring information, and other Internet of Things end-user data analyses. In addition, it also involves business data analyses such as management consultation information records, training and guidance service information records, service quality evaluation feedback, and so on. The third is students' sports behavior data—that is, the behavior data left by students on the social platform, including evaluations, text, photos, videos, and so on. However, the volume of college students' physical health data is so huge, massive, and heterogeneous that new computing algorithms and protocols, more computing power, and new strategies are needed to properly and effectively combine and integrate data (17). The systematic construction of intelligent service capability is also inseparable from the support of relevant science and technology. The big data analysis of college students' physical health includes the data analysis of complex categories, such as text, pictures, sound, and videos, which requires the processing and exploration of international leading data mining technology. For example, text mining, natural language processing technology, and cognitive graphics are used to analyze text data; graphics recognition, speech recognition, video data analysis, and other means are used to analyze text, sound, and video big data; and data mining, social Internet, in-depth learning data analysis, and other means are used to analyze social media data (18, 19). To sum up, college students' physical health problems should be effectively managed and controlled through the flexible use of big data analysis, visual research, information mining, machine learning, artificial neural network, social Internet, and other analysis technologies so as to achieve the goal of maximizing the value of college students' physical health big data.

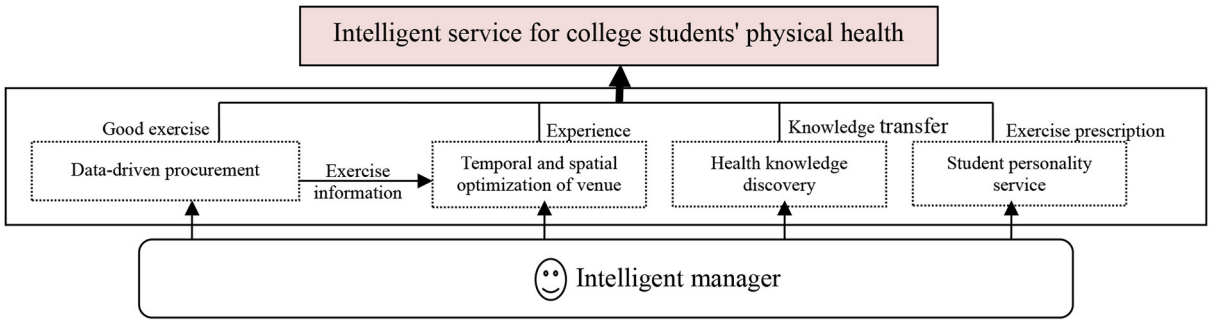

FIGURE 4
Service application architecture.

Intelligent service application: Value-shaping of intelligent governance system of college students' physical health

The intelligent service application stage is the top-level interactive port of the whole system, which directly interfaces with students and is composed of three elements: intelligent managers, students, and intelligent governance (see Figure 4). First, university intelligent managers use big data analysis methods, such as machine learning, data mining, image visualization, and artificial intelligence technology, to discover and process knowledge of college students' physical health big data and to impart professional knowledge to students. Second, college students will use the physical health intelligent management system to carry out higher-level physical exercise activities, and the formed data information will continue to enrich data resources to promote the vigorous development of college students' physical health management. In the ecological chain of intelligent governance of college students' physical health, intelligent administrators shoulder the mission of information decomposers and information disseminators, while students hold roles as both consumers and producers of information. They cooperate and coordinate with each other to jointly construct an important human resource element that is indispensable in the intelligent governance of college students' physical health. In addition, intelligent managers also mainly provide students with intelligent management of physical health of four types, including big data-driven procurement, venue space optimization, fitness knowledge discovery, and personalized services. Data-driven procurement services provide direct data resources for venue space optimization and health knowledge discovery. Health knowledge discovery and personalized services focus on the mining of physical health data and student sports behavior activity data, respectively, combining the in-depth exploration of professional knowledge and skills with the customized recommendation of professional knowledge and skills and continuing to promote the innovation of governance models, such as more accurate college students' physical health services and reference consultations, under the environment of big data and the Internet.

Big data-driven intelligent governance strategy for college students' physical health

With the comprehensive development of physical health intelligent big data services, the wide application of the Internet of Things and artificial intelligence technology, the collaborative integration of multi-source heterogeneous information, and the gradual formation of intelligent sports atmosphere, a new service strategy has been put forward for the development of physical health intelligent service systems driven by big data. This paper applies the new generation of information technology, such as big data, the Internet of Things, and intelligent equipment, to improve the physical health of college students and suggests governance strategies, such as building an intelligent governance ecosystem of school sports, establishing a support system of school stadiums and gymnasiums, and building an integrated intelligent governance model of physical health.

Top-level design: Build an intelligent governance ecosystem of school physical education

The main application purpose of intelligent technology is to help establish a physical health intelligent environment that can mobilize people's creativity by coordinating the interaction between science and technology, resources, and people. While stimulating the physical health intelligent service ability driven by students' needs, it can attract potential students and promote the intelligent development and innovation of school physical education. A physical

health intelligent management system can integrate students' physical health status into the construction of the campus sports network, resulting in a complex and integrated health ecosystem. In addition, the physical health intelligent service integrates big data analysis in the fields of physical education teaching, sports training, sports skills, after-school exercise, sports activities, academic research, and fitness management It integrates and links various sports environments, forms a network platform supporting health data analysis and decision-making, and helps the development and innovation of school sports. It also promotes the innovation of the campus sports network, and through this attracts more students to participate in the ranks of sharing sports and sports innovation. It encourages users to activate intelligent sports activities and intelligent sports services in a wider region and makes the physical health intelligent governance system truly become a network platform connecting cross-domain research, development, innovation, and various sports knowledge-intensive applications to obtain sustainable growth of new intelligent data in the campus sports network.

Interconnection of all things: Constructing the supporting system of school stadiums and gymnasiums with intelligent perception

The Internet of Things is a network of communication between people and objects and between objects, which is a perception technology for intelligent stadiums and gymnasiums. By applying high and new technologies like big data technology, Internet of Things technology, and artificial intelligence to the design and construction of campus stadiums and gymnasiums, the services of campus stadiums and gymnasiums will become more automatic and intelligent. By taking advantage of the advanced technology and equipment advantages of intelligent sensing systems and cognitive equipment, virtual reality, and intelligent robots in the Internet of Things, we can further enhance personalized, convenient, and efficient physical health services so as to make campus stadiums truly automated. For example, in terms of intelligent sensing systems, campus stadiums and gymnasiums can promote the convenience of venue resources and space management through the effective use of Internet of Things sensors. First, the use of a radiofrequency identification system, sports software, indoor navigation robots, and other advanced technical means can facilitate site reservation and management so that students can easily access site materials. Second, connections and communication among people, machines, and mobile networks can be realized through machine-to-machine technology. The module that can monitor the operation parameters of a distribution network can be installed in the power equipment of stadiums and gymnasiums to realize the real-time monitoring, control, management, and maintenance of distribution systems. Third, face recognition, infrared sensors, cameras, and other technical means help to understand students' sports behavior; infer students' needs through students' sports behavior data; and provide data support for students' personalized sports suggestions and services. In addition, through augmented reality, virtual reality, and other technical means, students can also have virtual and intelligent space service experiences of virtual and real integration (20).

Action practice: Build an integrated intelligent governance model of physical health

Through the Internet, mobile Internet, big data, artificial intelligence, and other new-generation information technologies and knowledge, we can carry out intelligent physical education and training, after-school physical exercise, physical health monitoring, and evaluation, and campus sports events. We can form an integrated physical health intelligent governance model that can accurately guide, manage, supervise, and improve the physical health of college students. Intelligent physical education is mainly embodied in information-based physical education teaching design, mobile education, and ubiquitous learning. Through big data, we can build physical education courses and online, offline, and hybrid physical education courses; independently design and develop school-based physical education curriculum resource databases, design learning methods, teaching evaluations, and other modules. It can help realize resource appreciation through the screening, evaluation, reorganization, and integration of curriculum experiences, which can meet students' online physical education learning at any time. Through big data technology, we can also carry out the integrated application of mobile teaching platforms, smart terminal teaching, and university sports services. It can be used to develop mobile teaching tools of wearable devices and university sports public service products based on big data analysis to carry out in-depth teaching research, technical innovation, system incubation, detection and evaluation, application demonstration, and other physical health intelligent services. In terms of students' intelligent after-school physical exercise and physical health monitoring and evaluation, we can use big data, the Internet, and other analysis technologies to comprehensively and dynamically manage students' physical and mental health, mastery of sports skills, and extracurricular physical exercise. The administrator transmits the sports load, physical condition, motion trajectory, and other data collected as front-end data to teachers and students through sensor devices such as smartphones, sports bracelets, and sports vests while simultaneous background calculations of the server and the global positioning system are ongoing. Teachers and systems

set the amount of exercise and monitor the situation of extracurricular exercise according to the specific situation and measurement data, then formulate exercise schedules and provide accurate guidance to students so as to reduce sports injury, realize scientific exercise and learning, and accurately serve and manage students' physical health., The new generation of information technology may be used to build the school competition platform, and an information system integrating competition qualification examinations, registration data, competition arrangements, scoring systems, and score information. Competition data analysis can be established within the platform. With this approach, both teachers and students can view the competition results in real-time; the competition situation can be recorded, analyzed, and managed. This approach allows managers, teachers, and students to master students' sports level and physical health in real-time, and data support for dynamic adjustment of physical health intelligent governance strategies can be provided. The college and students can be urged to meet relevant indicators to form an effective intelligent and dynamic integrated physical health governance system.

Conclusions

This study, based on the realistic background of big data, the Internet, mobile Internet, and artificial intelligence, sought an angle to explore the precise path and methods for improving the physical health of university students, which is a relatively new research field. The research method of traditional improvements to physical health and their innovation is of great significance to promote college students' physical health levels. The intelligent governance system of physical health driven by big data can quickly and comprehensively understand the dynamic state of the physical health of college students, while at the whole-time monitoring sports, disease health management, and dynamic adjustment of physical exercise content. Combined with a physical health management system to establish the linkage mechanism, the government, school, society, and family can use emerging information technology to master students' sports, physical development, and psychological situation; personalize push exercise prescriptions; realize students' aptitude, and precisely promote the physical health of college students to solve the problem of Chinese college students' declining physical health (21). For example, relying on cloud platforms such as the Lejian Sports app, the WeChat public platform, QQ, and online live broadcasts, the University of Electronic Science and Technology built an integrated interactive intelligent physical health management system that combines online plus offline and in-class plus after-class data. Club teaching or online teaching and practice requirements are mainly implemented for students in class, and offline guidance and cloud interactive practice are implemented for students after class. Analysis of the sports data platform revealed that, since the construction of intelligent governance systems for physical health, the daily number of extracurricular sports has increased greatly, the qualified rate of physical health has improved year by year, and the physical quality level has also improved significantly.

It is suggested that schools at all levels should make full use of modern information science and technology in the future, monitor the physical health of college students, monitor their physical activities, set up a physical activity guidance and service platform, guide students to exercise scientifically, and strive to improve the physical health level of students. How to make full use of big data, artificial intelligence, intelligent equipment, and the Internet of Things as part of a new generation of information technology to improve students' physique health as well as to create intelligent physical health service models for precise improvements in students physical health patterns remain future research directions to be explored.

Data availability statement

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

Ethics statement

Ethical review and approval was not required for the study on human participants in accordance with the local legislation and institutional requirements. The patients/participants provided their written informed consent to participate in this study.

Author contributions

CD and QY studied the current situation of college students' physical health and its informatization governance problems, the construction of governance system, and intelligent governance strategies. GL, ZZ, and YL participated in the exchange and discussion. CD drafted and revised the paper. All authors contributed to the article and approved the submitted version.

Funding

This research was supported by the Basic Scientific Research Operating Expenses Project of the Central

University of China (Grant No. ZYGX2019J143), the Educational Research Project of Sichuan Province (Grant No. SCJG20A169), the Ideological and Political Demonstration Course Construction Project of UESTC (Grant No. 2021KCSZ0196), and the Relay Action Plan for Young Teachers in Philosophy and Social Sciences of UESTC in 2021.

Handwritten prescriptions and radiological reports: doctors use handwritten prescriptions and radiological reports to give drugs to patients who have illnesses, injuries, or other problems. Clinical text data, like physician prescription visuals and radiology reports, should be labelled with specific information such as disease type, features, and anatomical location for more effective use. The semantic annotation of vast collections of biological and biomedical texts, like scientific papers, medical reports, and general practitioner observations, has lately been examined by doctors and scientists. By identifying and disambiguating references to biomedical concepts in texts, medical semantics annotators could generate such annotations automatically. For Medical Images (MedIMG), we provide a methodology for learning an effective holistic representation (handwritten word pictures as well as radiology reports). Deep Learning (DL) methods have recently gained much interest for their capacity to achieve expert-level accuracy in automated MedIMG analysis. We discovered that tasks requiring significant responsive fields are ideal for downscaled input images that are qualitatively verified by examining functional, responsive areas and class activating maps for training models. This article focuses on the following contributions: (a) Information Extraction from Narrative MedImages, (b) Automatic categorisation on image resolution with an impact on MedIMG, and (c) Hybrid Model to Predictions of Named Entity Recognition utilising RNN + LSTM + GRM that perform admirably in every trainee for every input purpose. At the same time, supplying understandable scale weight implies that such multi-scale structures are also crucial for extracting information from high-resolution MedIMG. A portion of the reports (30%) are manually evaluated by trained physicians, while the rest were automatically categorised using deep supervised training models based on attention mechanisms and supplied with test reports. MetaMapLite proved recall and precision, but also an F1-score equivalent for primary biomedicine text search techniques and medical text examination on many databases of MedIMG. In addition to implementing as well as getting the requirements for

MedIMG, the article explores the quality of medical data by using DL techniques for reaching large-scale labelled clinical data and also the significance of their real-time efforts in the biomedical study that have played an instrumental role in its extramural diffusion and global appeal.

KEYWORDS

MedIMG, deep learning, LIONC, accuracy, natural language processing

Introduction

The digitization of documents has created plenty of new opportunities for liberalising data collections for NLP pipelines like machine translation as well as web search engines. Automatically creating captions for a certain image is problematic, while the foundation of understanding the scene is partly due to computer vision's exceptional achievement. Books, manuscripts, letters, bills, catalogues, and other digital documents (MedIMG) are machine-printed, handwritten, or radiology images (1). Learning effective representations of document images that are rich in preserving both lexical as well as semantic information is the only way to gain access to content-level in such a vast numerical corpus. In this paper, we focus on encoding the word MedIMG in a featuring space that conserves its verbal data, and we limit our stability by only using the number of declarations. The restricted availability of large-scale labelled datasets within the medical realm justifies their construction, as they play a vital role in developing medicine using Machine Learning (ML) techniques (2). Clinical text data like physician notes as well as radiology reports must be annotated using labels that include specific information, namely the kind, features, and anatomical area of disease, for more effective use. However, since text contains highly specialised language, ambiguous terms, and narrative sentences, labelling text is challenging and must be done manually by health experts. Some of the things that make it hard for clinical text to be used in considerable medical research and mostly with DL approaches is that it does not have annotations (3).

This study can be presented as a completely innovative descriptor of word pictures that may be utilised to construct MedIMG-based applications (X-rays, handwritten and printed documents, radiology images) (4). To obtain the UMLS concept, annotations/captions use picture data, which will subsequently be compared to the images' original text captions. The images utilised are clinically relevant radiological images, and the captions were written by medical professionals. Moreover, DL approaches are used to extract medical knowledge using clinical documents. We believe that the classification of scanned documents into words is provided to us either through underlying data or through an external word suggestion approach, which may be chaotic. In this paper, a word-level description is presented as a model. It has to do with extracting information from medical records that include radiographs. In addition, MetaMapLite pays attention to real-time processor speed and then begins with a restricted range of essential functionalities like the longest-term match as well as negation detection. MetaMapLite is presented in this work, and its execution equals that of the existing Prologue operation of MetaMap is assessed (5). We examine whether employing high-resolution MedIMG rather than downscaled and low-resolution MedIMG can lead to improved clinical work performance. We anticipate that increasing the size of an image would improve MedIMG segmentation's work performance (6). Throughout all input resolutions, the experimental results show how to stack groups across determinations beat each discrete learner. We additionally give easily understandable Ensemble Model (EM) scale weights, implying that multi-scale features are required for automated detection of a higher level of MedIMG. Extensive research is being conducted in the field of handwritten character recognition. Handwritten character recognition has been developed by many users. A few systems have been examined: Using fuzzy logic, a character recognition system was created (7). They have designed a system that is compatible with VLSI technology. Their system for recognising characters can't be changed or messed up. They have incorporated hammering NN into their system. It has been found that NN can be used to recognise handwritten characters in a novel way. A Kohonen Self-Organising Map (SOM), an unsupervised NN, has been utilised.

The following contributions are focused on this paper:

- Information Extraction from Narrative Clinical Texts: An automatically generated mapping system connects basic phrases as well as codes collected throughout several clinical terminology and programming systems for Systematised Terminology of Medicine-Clinical Terminology concepts to standardise multi-site heterogeneous Electronic Healthcare Record (HER).
- Automatic Classification for MedIMG with Image Resolution: Next, an innovative large-scale dataset of X-rays is used to accurately assess its chances of attaining increased clinical work performance using high-resolution visuals rather than downscaled low-resolution MedIMG.

MedIMG, as well as findings of multi-label annotations, are being developed.

- Hybrid Model to Predictions of Named Entity Recognition (NER)by RNN + LSTM + GRM: Our goal is to present an innovative UMLS-based RNN+LSTM+GRM for NER tool and compare its outcome to state-of-the-art, broadly utilised, accessible public medical NER tools.

Apart from trying to implement and obtain results for clinical testing and MedIMG, this article refers to the study of health data, the innovation of using DL methods for obtaining large-scale labelled MedIMG datasets (8), as well as the relevance of its applications in the medical research that has played a role towards its extramural diffusion and global reach. This paper summarises the journey in such a way that the reader is guided through multiple disciplines, from engineering to medicine, all the way up to the ethical implications of implementing Artificial Intelligence (AI) in treatment.

Literature review

The health care industry must have commonly recognised and advertised the partial use of EHR systems throughout the previous decade. The Health Information Technology to Economic and Clinical Health (HITECH) Act of 2009 (9) motivated medical hospitals and clinics to implement EHR systems. Though HER systems are planned for operational purposes, they were later used to process data. All of the information recorded by the EHR system could now be analysed. The enormous data acquired by progress notes, combined with the rapid adaptation of EHR systems, has resulted in a significant research area of predictive medical analytics, which employs narrative progress notes. For many years, conventional Machine Learning (ML) models were used to perform predictive analysis, mainly in the medical domain. Because of the operational excellence of DL methods in recent times, many have been widely used in biomedical disease prediction. For example, using EHR data, researchers created a Long Short-Term Memory (LSTM) network model for predicting heart failure. A Deep Convolutional Neural Network (CNN) is used to predict diabetes. In addition, a CNN methodology to detect colorectal cancer, which uses diagnoses as well as medication of patients in the HER, was developed (9). Using real-world Pashto/Urdu text, another research was performed, and this text can be rotated in any direction, not just in a straight line. The results were analysed using various ML techniques, including Scale Invariant Feature Transformation (SIFT), LSTM, and Hidden Markov Model (HMM) to detect rotated text. In this study, the LSTM got 98.9% accuracy, while HMM-based techniques got 89.9% accuracy and SIFT got 94.3% accuracy.

Multiple successful efforts were made in the earlier days, focusing on various factors like data modality (radiology and handwritten images), nature of depiction (firmed/adjustable length), and also by categorising of entrenching structure. It is divided the debate of associated studies are: (a) traditional techniques developed by means of flexible length depiction plans, (b) static length depiction attained by means of a bag of words structure, and (c) different classifier models with learned representation implemented on a maximum of hand-crafted features as well as in DL networks (10).

A data analysis Language Model (LM's) goal is to approximate the probabilistic model on classifications of distinct entities or tokens. This work includes a variety of Natural Language Processing tasks (NLP), and the majority of NLP tasks necessitate the use of NLP models. An NLP model shown in such a task describes the possibility distribution function of word sequences and stemmed word-token sequences (11). This approach's efficacy was tested using a variety of datasets, including three well-known Handwritten Text Recognition (HTR) datasets, as well as three cutting-edge Optical Models for text recognition and eight different spellcheck correction techniques, including both traditional statistics and current approaches utilising NN in NLP. They made a model for spelling correction that was tested statistically with HTR system metrics. In the tests, the average sentence correction rate was 54% higher than with the most advanced decoding method. An LM, on the other hand, can define probability distribution function on sequences for some other type of token, like bytes/characters. So, this is the issue of LM character-level, which models language to be distribution functions on sequences to characters rather than words- for example (12), without a clear and specific notion of sentence-level boundaries. It has been demonstrated that for learning to forecast the next character based on earlier characters, such models also can understand inner depictions, which obtain syntactic and semantic properties and then produce accurate grammar transcripts with words, subclauses, quotations, and sentences.

Word Embeddings (WE) (13), recognised as word vectors and distributed representations, are complex depictions of words in a low-dimensional actual vector space that overcome the dimensionality blow of n-grams. Neural Word Embeddings are those WE studied by a Neural Network (NN). In terms of computer visualisation, these embeddings are analogous to image embeddings acquired as images in CNN models' hidden layers.

Convolutional neural network has been used to process the data with a grid-like structure and spatial patterns. CNNs have been effectively applied to various forms of data wherever they can be presented as discrete units grouped in periodic intervals together in a grid-like variety of dimensions. The local spatial features of images are determined by CNN and reported to generate relatively high features. The first CNN layer generates feature maps that include spatial features that were extracted locally. This shows how high-level features and local spatial features are made. Despite the fact that they were initially

developed for picture data, it is presented as a 2-D set of pixels. Data of Time-series, which is presented like the 1-D grid with examples collected during periodic intervals, then text, which can be thought of like a 1-D grid of ordered tokens, are two examples (13).

Recurrent Neural Networks (RNN) are developed to evaluate sequential data by recursively sharing the same weights across successive time steps "t." At each time step, a member of an input sequence is therefore fed into the network. RNNs can be designed in various ways based on recurrent connexions within their units. LSTM (14) is a sort of gated RNN which uses self-loops to create routes with long gradient flows and has been found to learn long-term dependency easier than vanilla RNN designs. Gated RNNs provide temporal pathways with a derivative that does not explode or vanish, similar to leaky units. These pathways include connexion weights that can vary for every time step, enabling knowledge to be accumulated or forgotten by erasing the previous state.

A Multi-Label Text Classification (MLTC) (15) task is one that involves extracting many medical categories from radiological data. MLTC is indeed an NLP task that allows you to apply one or even more labels per document. This differs significantly from the typical binary but rather multi-class classification issues that have been extensively researched inside this machine learning literature (16). Binary classifier treats classes as separate target variables, which is naturally inefficient for MLTC because label dependencies cannot be exploited. A mutually exclusive assumption concerning classes is used by multi-class classifiers. According to this concept, each document should have one class, which is not valid in multi-label setups. This section's related works are primarily concerned with MLTC (16). A novel method for recognising handwritten characters has been advanced using NN. They used an unsupervised NN called the Kohonen Self-Organising Map (SOM). They developed a system that can be used for character recognition as well as the recognition of other Indic languages. If the handwritten characters are not effectively segmented, the system occasionally provides false results. One of the authors can use the handwriting of a human to verify their authenticity. In their system, the author has implemented an FFNN with multiple layers. One sophisticated hypothesis in this paper is that the handwritten alphabet's height and width are unique to the writer's individual hand size and handwriting. It has been demonstrated that a patient's handwriting can be used to identify them. Hyper-parameters and model parameters can differ significantly, as demonstrated by (7). Some hyper-parameters, such as the number of epochs, hidden units, hidden layers, Learning Rate (LR), kernel size, and activation function, must be set before training begins. It is stated that if the hyper-parameters are selected improperly, CNN performance may suffer. Some CNN models have 27, 57, 78, and 150 hyper-parameters, respectively, for AlexNet, VGG-16, GoogleNet, and ResNet-52. In the field of handwriting recognition, implementing researchers play a big role in making sure that CNN parameters are set up well so that recognition performance can be improved.

We present an automated picture denoising method based on quasi-periodic denoising. The Fourier transformation is used to detect the image's high amplitude noisy spectrum. The proposed model for noise filtration has a threshold value of 30. The threshold value is updated in response to user input. Thresholding, as well as filtration-based models, are used to minimise the noisy components (17). Finally, an adaptable restoration filter is used to obtain the noise profile's exact outline. A method for denoising images using a quicker and more flexible CNN is provided. This study takes into account various levels of noise that use a non-uniform noise level map to eliminate the spatial noise. For applying local low-priority matrix recovery with global spatial-spectral variation, a hyperspectral image denoising algorithm is suggested. A unified mixed Gaussian noise plus sparse noise removal model is recommended in this research article. To separate the filtered image regions from sparse noise, the hyperspectral images are first segmented into overlapping local patches, and thus the matrix recovery scheme is used. This work rebuilds the image with global acceptance (18). As a result of this, a machine is trained to correctly identify Pashto handwritten characters that have never been seen before. With the help of this dataset (7), we trained and tested three FFNN models (Model 1 with a 1-ReLU layer, Model 2 with 2-ReLU layers, and Model 3 with 3-ReLU layers) using the backpropagation algorithm. Sample images of user-defined handwritten text were used to test the proposed overall system performance. This preprocesses images to prepare them for CNN training (19). The input document is then segmented by line, word, and character. Multiple experiments yielded results deserving of high recognition. At one point in the character segmentation method, they were able to get up to 86% accuracy.

The labelled datasets of the most frequent named entity recognition tasks are used widely and are publicly available. CoNLL-03, a shared study from the Conference on Computational NLP Learning in 2003, the MUC-7 dataset (20), and also the Onto Notes corpus consists of around ten named entity types as well as seven various entity forms like TIME and DATE, which are the three most common corpora used to train such extractors. The jobs are typically modelled using BIO upgraded labels–separate labels for the beginning, inside, and outside tokens of an entity.

Mathematical model

Generation of MedIMG caption

Encoder of convolutional features

Our model provides a caption X that is encrypted as a series of 1-n encrypted words from a single input image Eq. (1).

$$X = \{X_1, ...X_C\}, X_i \equiv R^n \quad (1)$$

WHERE the size of the syntax by K and the length of the tagline by C.

To retrieve a sequence of a feature vector that refers to an annotation vector (21), we employ a CNN. The extractor generates Y (vectors); each one is the d-dimensional description of image segmentation, Eq. (2)

$$Y = \{Y_1, ...Y_L\}, Y_i \equiv R^d \tag{2}$$

In contrast to prior work, which used a fully connected layer, we extract the features from such a lower convolutional layer to derive a correspondence between feature vectors and sections of the 2-D image. By weighting a subclass of whole feature vectors, the interpreter can preferentially focus on some areas of a picture.

Decoder of LSTM

We apply an LSTM network to construct captions by producing one word at a time based on the context vector, the initial Hidden State (HS) (22), and earlier generated comments, Eq. (3)

$$\begin{aligned} a_t &= (P_i Q_{t-1} + R_t T_{t-1} + S_i s_t + b_i) \\ b_t &= (P_i Q_{t-1} + R_t T_{t-1} + S_i s_t + b_f) \\ c_t &= f_t c_{t-1} + i_t + \tanh(P_c Q_{t-1} + R_c S_{t-1}) \\ d_t &= (P_i Q_{t-1} + R_{t-1} + b_i) \\ e_t &= O_t + \tanh(c_t) \end{aligned} \tag{3}$$

The input, output, forget, HS, and memory of the LSTM are represented by at, bt, ct, dt, and et, respectively. P●, Q●, R●, and S● are weight matrices as well as biases that have been learned. An embedding matrix is PϵQ mxn. Let "P" and "Q" stand for LSTM and embedding dimensions as the logistical sigmoid initiation.

Figure 1 shows an LSTM cell, along with bolded squares indicating projections of the learned weight vector. Every cell learns how to balance its input components while also studying how to control its memory supply. Also, it learns weights that delete the memory cell as well as weights that govern the emission of memory. The Context Vector (CV) is a dynamic depiction of a related component of such visual input to a given point in time (t). By defining a method, "ϕ," which calculates CV beginning Annotation Vectors (AV) ai, I = 1,..., loc corresponding to such features obtained at various picture settings. The mechanism generates a positive weight I for each location "loc" that can be taken as whichever is the probability of such location "loc," it remains the best place to develop and to generate the succeeding word (stochastic attention method) or else the virtual importance to bounce to location "loc" in merging the αi's (αi's blending mechanism) (23). Non-linear and linear data can be learned by NN. Where the neurons are thought to consist of multiple layers. An MLP is a directed graph of input nodes that connects the input and output layers. As a supervised learning technique, backpropagation is used to train the NN in this case. An attention model, for which we apply a multilayer perceptron conditioned here on preceding HSt−1, computes the weight αi of all vector annotation AI. The HS changes to be the output of RNN that progresses through their output sequence: "here" the next network search is determined by its previous series of words (Figure 1).

$$\begin{aligned} HS_t &= f_{ATTN}(ai, HS_{t-1}) \\ \alpha_t &= \frac{Exp(HS_t)}{\sum_{n-1}^{Loc} Exp(HS_i)} \end{aligned} \tag{4}$$

From Eq. (4), the CV (St) is calculated after the weights have been computed, while "ϕ" is stated as a function, which gives a specific vector based on a sequence of AV as well as its related weights. An average of such AV fed *via* two distinct MLPs (Intc, Inth) predict the LSTM's initial memory state as well as HS, Eqs (5), and (6)

$$S_t = \alpha[a_i], [\partial_i] \tag{5}$$

$$S_0 = F_{\text{int}}, a(\frac{1}{loc}\sum_{n}^{loc} a_i), h_0 = F_{\text{int}}, h(\frac{1}{loc}\sum_{n}^{lco} a_i) \tag{6}$$

An average of AV fed into two independent MLPs predicts the LSTM's baseline memory state and not the HS (Intc, Inth). For calculating the output word probability in this study, we are using a deep output layer. Cueing out from the image, the predefined word, as well as the Decoder State are all used as input (DSt), Eq. (7)

$$P(Y_t|a, Y_1^{t-1}) \equiv Exp(loc_0(E_{t-1} + L_t DS_t + L_t R_t) \tag{7}$$

Named entity recognition using LONIC

We designed a rule-based approach to automatically normalise a local testing name towards a Logical Observation Identifiers Names and Codes (LONIC) code of MedIMG utilising data from several medical systems. Following tokenization of the input lab testing names, specific items are recognised, and relevant LONIC codes get automatically mapped depending upon that coding rules (24). Figure 2 depicts an overall view of the MedIMG TestNorm system's module,

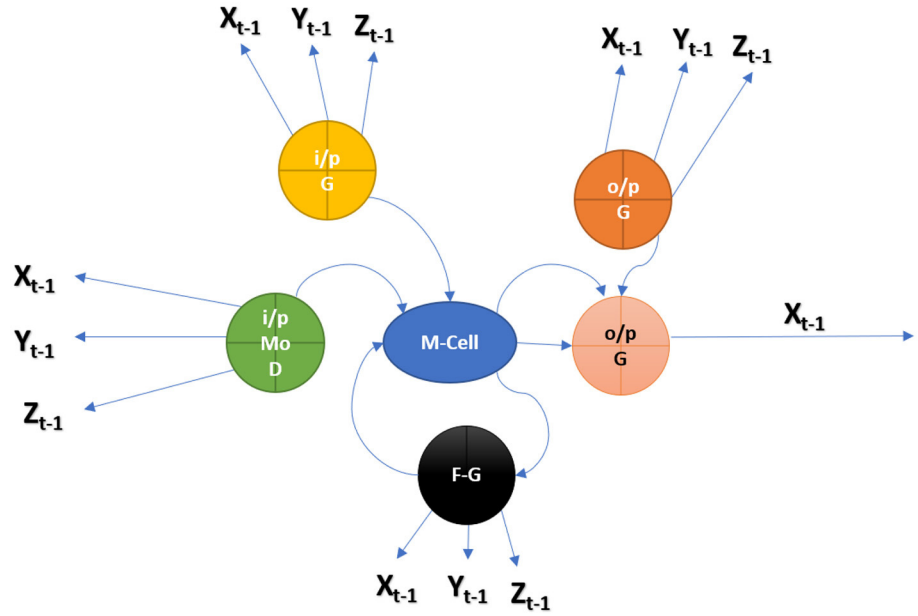

FIGURE 1
Cell format of LSTEM.

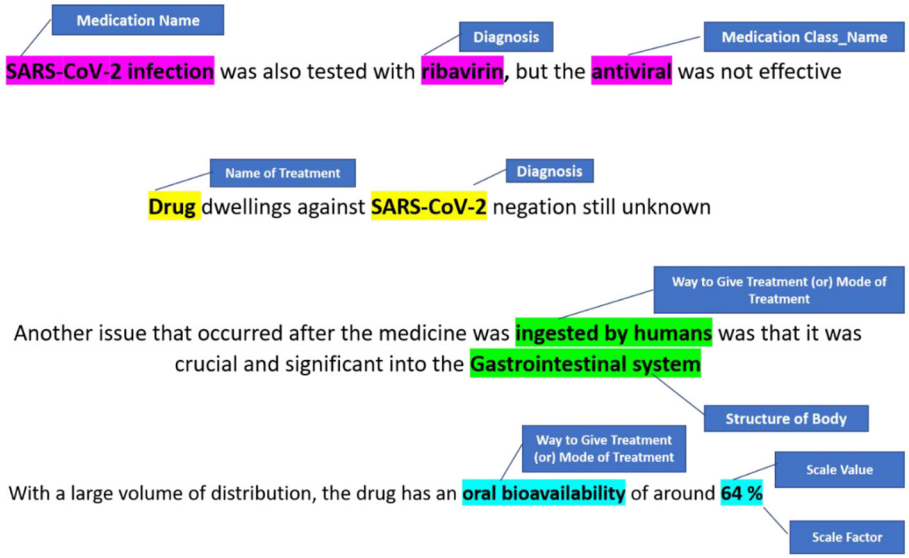

FIGURE 2
Example of NER for clinical symptom extraction.

which primarily includes NER as well as LONIC map-based modules, using inputs from lexicons/coding rules.

NER is a text processing technique that recognises words belonging to specific Named Entity categories (25). This is a crucial tool in NLP to extract information from documents. The network is trained to self-learn subject-related terminology with the aid of a dense architecture with DL models. All named entities inside the document are identified by NER. The NER annotator, in particular, uses multiple ML algorithms that can tag entities using standards for identifying numerical entities such as time/date formats. The goal of NER is to find the symptoms that

are associated with the sentences collected from EHR system (26).

Logical Observation Identifiers Names and Codes is a database with a vocabulary coding system designed to make detecting and presenting medical laboratory observations more uniform and global. Component, System, Method, Time, Property, and Scale are six fundamental axes used by LONIC to characterise each notion (27). Nine of these were included with our MED IMG entity classifications. Component, System, Method, and Quantitative/Qualitative define whether a test produces a quantitative/qualitative result, and Institution, that specifies a testing kit maker is our five root groups (28). The entity recognition process is divided into two phases: (a) a preliminary phase, which integrates dictionary lookup with regular pattern matching, then (b) a class of activities phase that translates unclear tags from preliminary step to final tags using a set of predetermined rules (Table 1).

Many data can be recorded and categorised with their appropriate category within the first stage, but some problematic words will have to be examined further. For instance, the letter "IA" could be mapped to either a "method" and is the abbreviation of "immunoassay" or a "system," which is the state of "Iowa." To select the relevant semantic classifications for such phrases, we built context-based criteria. Such investigation code must be now a LONIC code so that an identifier can be sent. A LONIC code (Figure 3) may be provided additionally towards a legible registered displaying name, which correlates for specific internal purposes to the degree permitted by the protocol. These characters can be classified with high accuracy because they have a range of data about the flow of the text being written. This makes it simpler to distinguish between different characters in the text. After the raw text has been preprocessed, a feature extraction step is performed to determine important details about each character, such as loops, quality of decision making, aspect ratios, etc. A proposed model is then used to analyse these features. Due to the manual step of extracting features and the fact that DL models can only do so much, their performance is not very good. In this section, we analysed the data to determine whether the researchers should revise certain sections of the paper. Tables listing handwritten names, layout, results obtained, and remarks are preferable because most empirical studies use the same algorithm with comparable performance datasets.

The use of LONIC across many application fields is becoming progressively acknowledged worldwide over the last 25 years (29). According to the Regenstrief Institute's LONIC webpage, there were about 85,000 clients of LONIC in over 176 countries, and LONIC is becoming the "lingua franca for medical data interchange."

Construction and structure of LONIC

Whatever the laboratory test, medical observation/clinical examination is clearly determined in Terms of six axes, as per the following LONIC concept (Figure 4): Component, Property, Time Aspect, System, Scale, and Method Type. The above six axes are given in the LONIC database by corresponding columns (30).

The technique of investigation in the sixth axis is limited in that it must be specified as required for precise determination to assess the examination under issue, and this differentiation is crucial in clinical practice. As a result, this column is frequently empty. All six axes add up to the unique, complete generic identity for the examination, as per the LONIC nomenclature guideline (31). Each form of investigation, measurement, or observance, which varies in any of these six axes, is assigned a unique LONIC code, as well as an individual entry inside the LONIC database. These LONIC codes are being posted sequentially to the access; unlike a categorisation, the codes need not indicate links within concepts. It is made up of a numeric multi-digit code of only a check digit at the end that is generated using the Mod10 method (32). The process is documented inside the LONIC User Manual primarily by Regenstrief Institute and the LONIC Board (33) (Figure 5).

Towards summation, all medical adherence/clinical assessment is represented with seven axes: the previous LONIC encryption as well as the recognised name, which consists of the six axes defined on top. Figure 5 shows the example of measurable urine sugar quantity using test strips.

The probable discrimination between purposes of the similar chemical, such as glucose, with dissimilar test materials like urine, cerebrospinal fluid, or serum, as well as through different procedures, scaled type, also attributes, occurs using the six axes (34). Only the property is clearly defined on the Property axis, not the allocated measuring unit and its representation. To accurately attain the specific LONIC code for such an evaluation issue, it is vital to recognise and describe all six axes. By taking a glucose amount, for example, that is shown by determining [Property = SCNC], a molar substance absorption would be distinct from determining a mass absorption [Property = MCNC]; collected results will obtain different LONIC codes in a similar example category. However, whether the LONIC code is represented in component g/L or mg/dl, and specific components are being stated at machine-readable procedure, it has no bearing on the code's uniqueness (35).

TABLE 1 Summary of database and LOIN code.

Database type	Meaning	Abbreviation	Full name
Characteristic	Measurement component/anion	Acnc	The surface of the hepatitis B virus
Area	The type of measurement; includes a conceptual model (dosage, composition, factor, subset, and exceptional)	P_t	Single point time
Monitoring	Identifies the testified measurement's time things, which are treated as a SPT	Ser/Pls	Plasma vs. serum
Method	It refers to a set of data/specimens being measured	Q_n	Qualitative research
Level	Qualitatively channeling's the monitoring value	IA	Biosensors based on metabolites
Procedure	It involves the procedure used to extract the standard size

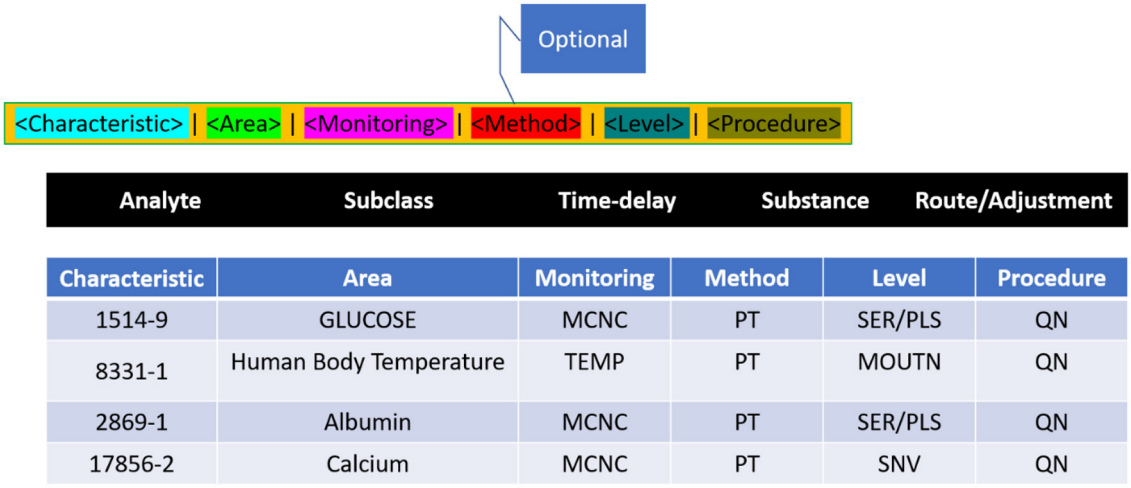
Mapping of LOIN codes and rules.

Proposed methodology

Investigation of clinical texts for information retrieval

An end-to-end "pipeline" for obtaining crucial clinical information from narrative texts is being designed. Negation detection is used to filter these features, and the residual features are mapped to SNOMED-CT terminology.

A feature extraction pipeline of clinical text is depicted in Figure 6. The TextRank algorithm (36) is used to implement the content summarising module. Primary clinical information such as problems, procedures, and tests are extracted using the CLiNER concept recognition algorithm. The features inside a negated context are subsequently filtered using an updated Negex algorithm. This part of the pipeline is a secure in-house online application that allows users to submit files that contain descriptive clinical notes and extract essential clinical features together with their contexts. From this, you can pursue one of two paths: (1) Use MetaMap to map the retrieved features towards the SNOMED-CT terminology systems and filter out unmapped features. Eliminate standard terms (e.g., "Human Body Structure," "Clinical investigations," "Biological agent") from the top two levels of the SNOMED-CT concept tree using the hierarchical system of SNOMED-CT and MetaMapLite; (2) use the terminology mapping tool



Characteristic	Area	Monitoring	Method	Level	Procedure
1514-9	GLUCOSE	MCNC	PT	SER/PLS	QN
8331-1	Human Body Temperature	TEMP	PT	MOUTN	QN
2869-1	Albumin	MCNC	PT	SER/PLS	QN

formulated to map those particular concepts to SNOMED-CT effectively. These standardised concepts can be aggregated in input features that can be directly fed into knowledge discovery ML algorithms. We illustrate the usage of EHR information extraction strategies for several patients in this section (37).

Automatic classification of MedIMG by image resolution

The IAM Handwriting Database is applied to arrange the handwriting, as previously stated. To begin, everyone must first register on the website and retrieve a folder of photos as well as XML files containing the text location in the image. In this study, N's do not require significant pre-processing of raw data (33). As a result, it will not make any changes or adjustments in these images but rather send the entire image and just patches of text to the NN.

Generating patches of data

Instead of transferring specific sentences or words, merely random patches containing text are allowed to train the NN that comprehends the writing style of doctors. Cropped photos with a random size of 113 × 113 can be used to generate patches from each sentence. Figure 7 below is a mosaic of eight of these patches.

A simple generating function is constructed using Python to traverse over each text, allowing for cropping as well as generating random patches for images. We can limit the number of patches caused for each image to 70% of the total generated patches.

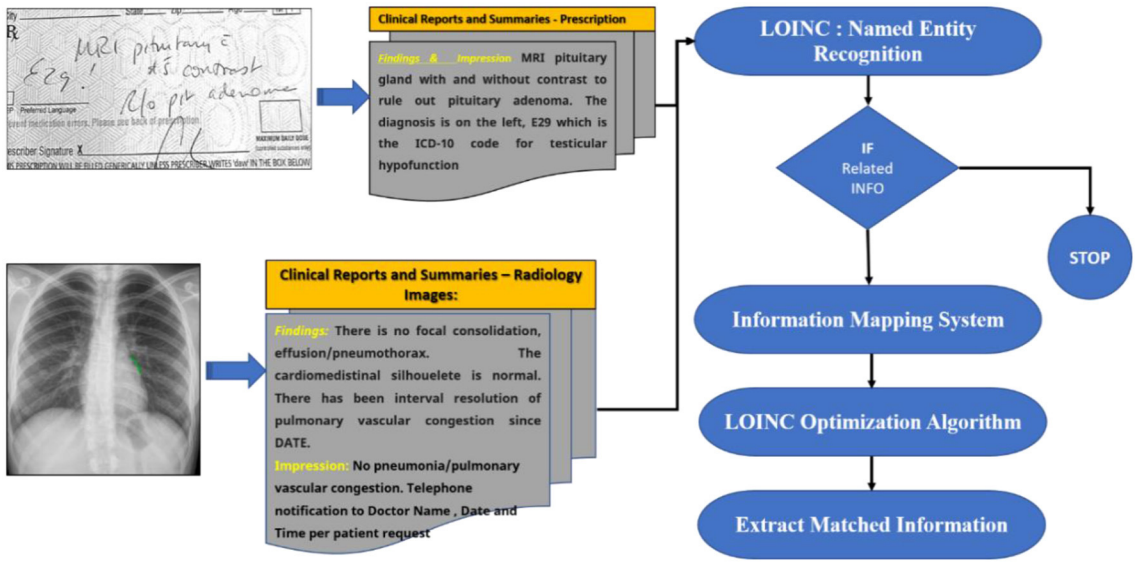

FIGURE 6
A proposed model for extracting patient treatment features from MedIMG.

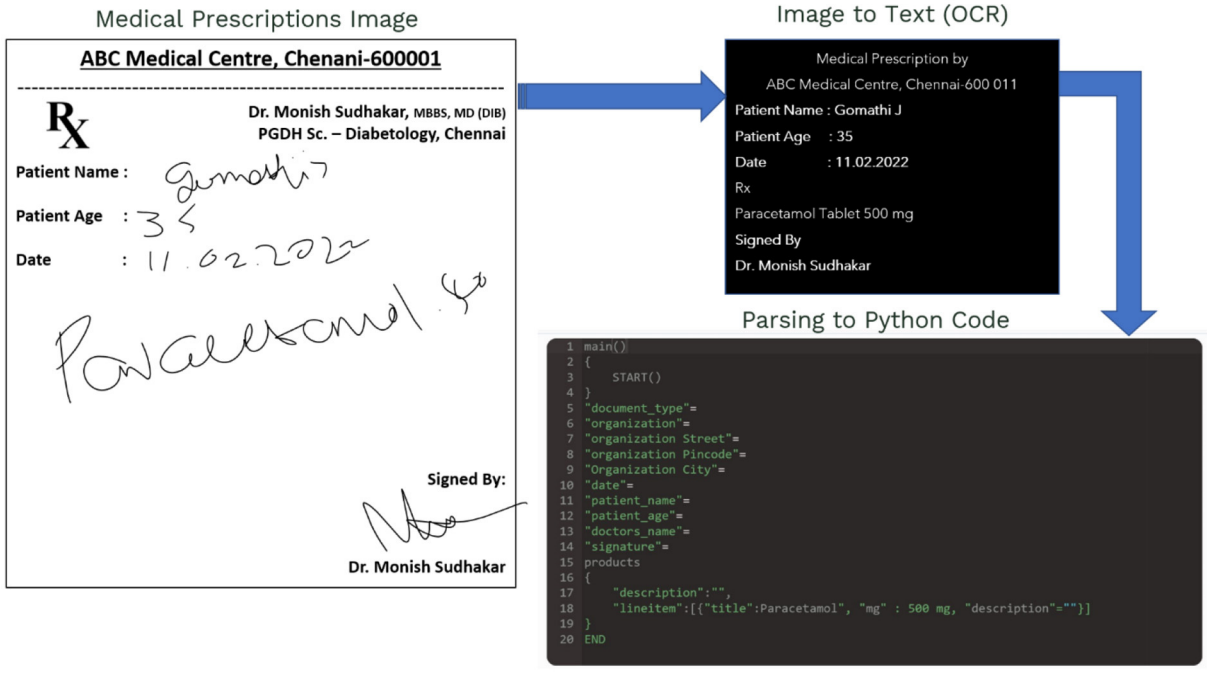

FIGURE 7
Cropping and generating random patches of MedIMG.

HWNet v2

HWNet v2 is a new version of the HWNet network. We restricted the number of convolutional layers in our basic HWNet architecture to five, which is equal to such suggested layers at AlexNet. Innovative structures, like VGGNet, GoogLeNet, as well as ResNets, have recently demonstrated deeper CNN networks enabling greater performance but more discriminative features. The following are some of the important

TABLE 2 Layer configuration of HWNet v2.

CNN	L-1	L-2	L-3	L-4	ROI	FCNN
3 × 3	[3 × 3,64] × 3	[3 × 3,128] × 4	[3 × 3,256] × 6	[3 × 3], 3	[6 × 12]	[2,048] × 2

architectural innovations used in such networks that result in more efficient training: (a) using lower-dimensional filters (3 × 3), thus taking fewer parameters with large size filters that also perform as an essential regularizer, (b) by using (1 × 1) filters that perform as dimensionality lessening unit to retain the no. of parameters in rheostat, (c) by using inception layer that presents multi-scale functioning to have several equivalent layers functioning with different scales, and (d) using remaining blocks for studying remaining function $F(x) := H(x) - x$. Here $H(x)$ is anticipated for underlying mapping. The remaining layer is usually applied with a crosscut linking in the absence of available parameters.ResNet34 network of four blocks, each containing several ResNet modules in our upgraded HWNet architecture, dubbed HWNet v2, is used. Rather than employing globally averaged pooling, we discovered completely connected layers towards the conclusion of the process to learn superior features from the penultimate layer. The HWNet v2 network configuration is summarised in Table 2. Every ResNet module has two convolutional layers in it.

DenseNet models

The 121-layer DenseNet model is chosen as the basic model in this investigation since it produced the best results in most of the previous experiments on CXR classification. This model was initially trained by scratch, but we were able to improve its performance by using pre-learned weights using ImageNet. Binary Cross-Entropy (BCE), a multi-label loss, is used to train the model. We use the ImageNet dataset's mean as well as a standard deviation to normalise all the images. We apply data enhancement techniques like random horizontal flipping as well as uniformly random rotation from -15° to 15°.

To various image sizes, the Adam optimizer is applied at multiple primary acquiring rates. To varied image dimensions, the learning rate is measured by the actual batch size, which is shown in Table 3. If a validation loss does not reduce across three epochs, the learning rate decay is doubled to 0.5. If such a validation deficit cannot increase after ten epochs, the test must be terminated. Rather than using the MIMIC-CXR-JPG dataset's official train validation-test split, five-fold cross-validation is applied to 20% of test data from a dataset. The residual 80% of the data is being split as 90–10 for training validation purposes.

TABLE 3 Classification of learning rate.

Size of input image	Rate of learning	Group size of input image
256 × 256	0.0051	512
512 × 512	0.00034	256
1,024 × 1,024	0.000181	180
2,048 × 2,048	0.0000918	75

Effective receptive field

An effective receptive field (ERF) comprises the centre pixels inside the receptive field that have the maximum effect on the results. The impact of distribution inside the receptive field becomes asymptotically Uniform, according to Luo et al., and also, the effectual receptive field is just a segment of a theoretic receptive field. Moreover, as the network is taught, an effective receptive field grows larger. For calculating the ERF, a trained model is uploaded, run in evaluating manner, enters the data, and then averages the square gradients to get the uncentered sample variance. We use the centre pixel and backpropagation to generate one gradient per image. When computing the ERF, we also add huge random translations to the data. The value for image Xi at pixel (P, Q) is referred to as Xi (P, Q), as well as channel 'n', and pixel (x, y) of a NN's final convolutional layer activation is referred to as Fn (X_i, x, y). An ERF is a scalar image whose value shows the contribution of every pixel X_i (P, Q) to such activation. The partial derivative is used to calculate the impact, Eq. (8)

$$\frac{\alpha F^{a}(X_i,\ x,\ y)}{\alpha X_i(P,\ Q)} \tag{8}$$

This derivative is determined not just by the NN's weights but also by the input image X_i. Back-propagation is used for quickly calculating the partial derivative, Eq. (9)

$$ERF(P,\ Q) = \frac{1}{p,\ q}\sum_{p-1}^{p}\sum_{q-1}^{q}\frac{\alpha F^{a}(X_i,\ x,\ y)}{\alpha X_i(P,\ Q)} \tag{9}$$

where "n" denotes the number of links inside the network's final convolutional layer, and (x, y) denotes the central point for every image X_i. Since backpropagation gradients are positive and negative, first square them and then find the average for avoiding

cancellation, but the authors of the original ERF study do not square the gradients while averaging.

For various scale input images, we calculated the ERF from trained models. The ERF of DenseNet121 introduced models with different resolution photos is shown in Figure 8. With increased picture resolution, the ERF reduces in size in relation to the source image. When using CNNs upon high-resolution images, it suggests that large receptive fields are required.

Stacked scale-CNN model

We used a stacked CNN model in which discrete image scale sizes (256 × 256, 512 × 512, 1,024 × 1,024, and 2,048 × 2,048) are used to train the four models to enhance efficiency while keeping the flexibility for using pre-trained models. We train a specialised CNN model for deriving weights to each scale using the concatenation label probabilities of validation data from all these four classifiers providing features for a specific label. The CNN approach is depicted in Figure 9.

The weight to finding (F) and scaling (S) is wfs in our model of multi-label stacked CNN that possesses a single parameter P∈ $\mathcal{R}14 \times 4$, which is a 2-D tensor. In order to prove that a given label amount is one for the acquired weights of such four scales, we apply a SoftMax parametrization, Eq. (10)

$$w_{fs} = \frac{Exp(V_{fs})}{\sum_i Exp(V_{fs})} \tag{10}$$

For each finding f, its parameterization satisfies $\sum s\ w_{fs} = 1$. By defining $v_{fs} = 0$, we make the weights w_{fs} constant. These weights will then be used for averaging the probability of each scale.

Predicted label (PL):

$$\mathbf{PL_f\,(x_i) = \sum_i w_{fs} P_{fs}\,(x_i)} \tag{11}$$

We perform a numerically consistent calculation of $\sum s\ w_{fs}\sigma(\mathrm{PL}_{fs}(x_i))$ for each finding (F) for an image input of x_i with $\mathrm{PL}_{fs}(x_i)$, in which $\sigma(z) = (1 + \mathrm{Exp}(-R))1$ is the sigmoid function. Although all labels are calculated simultaneously in our approach, each label "F" is processed separately under this proposed model.

This stacking EM is trained using the validation data's output log produced by four classifiers with the help of four scales. The model is trained across 100 epochs with a 0.1 learning rate that decays exponentially, guaranteeing the converging of weights. For acquiring the ensemble probabilities for each label, multiply the learned weights by this model using predictions generated from test data.

Lion optimization algorithm

The lion optimization algorithm (LOA) is a bio-inspired algorithm that imitates lions' basic personality. Lions are naturally socialised, which causes them to divide into rover and habitant lions. A grown male lion is usually removed from the pride, and now these lions have no role in the pride, thus making them rovers. The rover lion can attack the lions inside the pride at some point in order to join the group. As a result, the LOA looks for rover lions and evaluates their quality. Fitness evaluation is the name given to this type of quality assessment, and only the fittest lions/lionesses are allowed to join the pride. The lions with lower fitness levels are omitted from the evaluation process. This cycle is repeated till better solutions are found. A certain percentage of lions are designated as rovers, while the others are assigned to points of pride. The gender ratio, as well as the border limit for each pride of lions, have been established.

The main key points of LOA are:

- In order to join the pride, the rover lion attempts to defeat the resident lion at any given time.
- The pride's fittest lion is the only one that can survive, and the rest unfit lions are ignored.

The overall number of points of pride remains constant, and rover lions have a chance of finding a proper fulfilment with a probability of [0,1].

Taking such benefits into consideration, this work uses LOA to determine the ideal filter order to denoising the image. When a filter is applied to a picture, the image's fitness is evaluated. The Peak Signal of Noise Ratio (PSNR) value is used to calculate the fitness value of such a work. The second filter is applied to the image once more, and the fitness value is checked. This method is repeated until the image does not quite improve for three consecutive rounds, at which point it is regarded as the best response. The following is the algorithm for the suggested task.

(A) Proposed Lion Optimization Algorithm
Step 1. The input of Noise-filled picture
Step 2. Denoised output Images
Step 3. Begin
Step 4. Establish a starting population of lions and prides
Step 5. Do
Step 6. Assess rover lions' matching;
Step 7. If matching (New)> matching (Old)
Step 8. Replace matching (Old);
Step 9. While (close condition);
Step 10. End

The PSNR value of an image is used to calculate image fitness, which analyses the quality between source

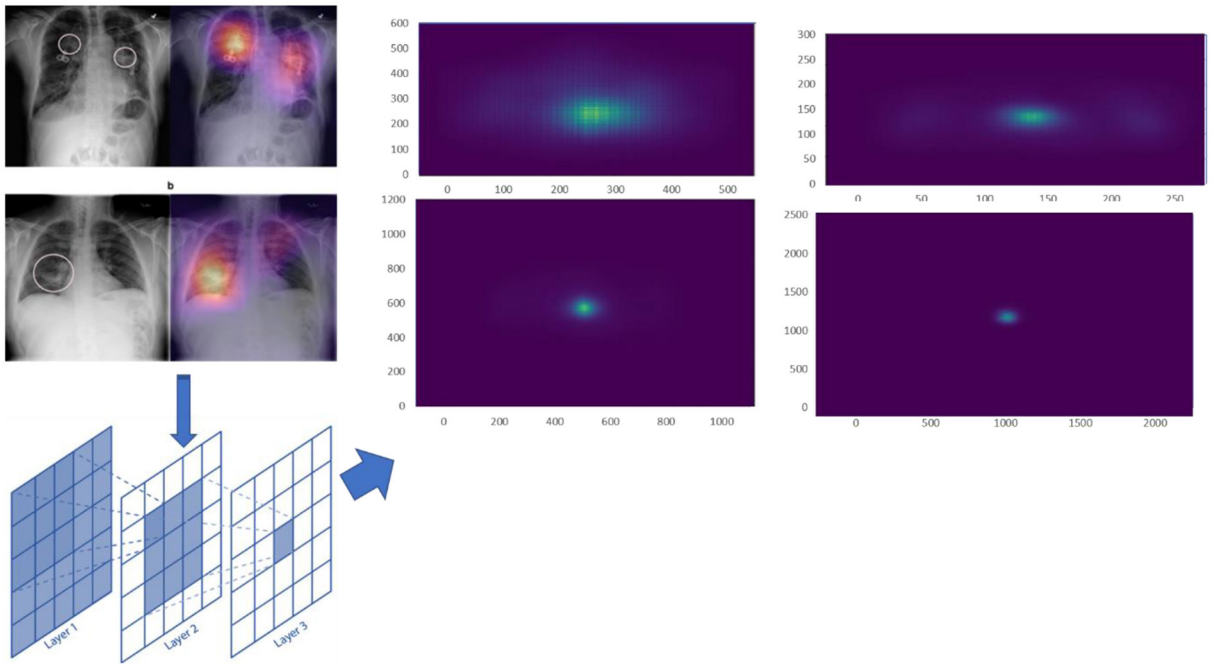

FIGURE 8
A trained Dense'et121's ERF.

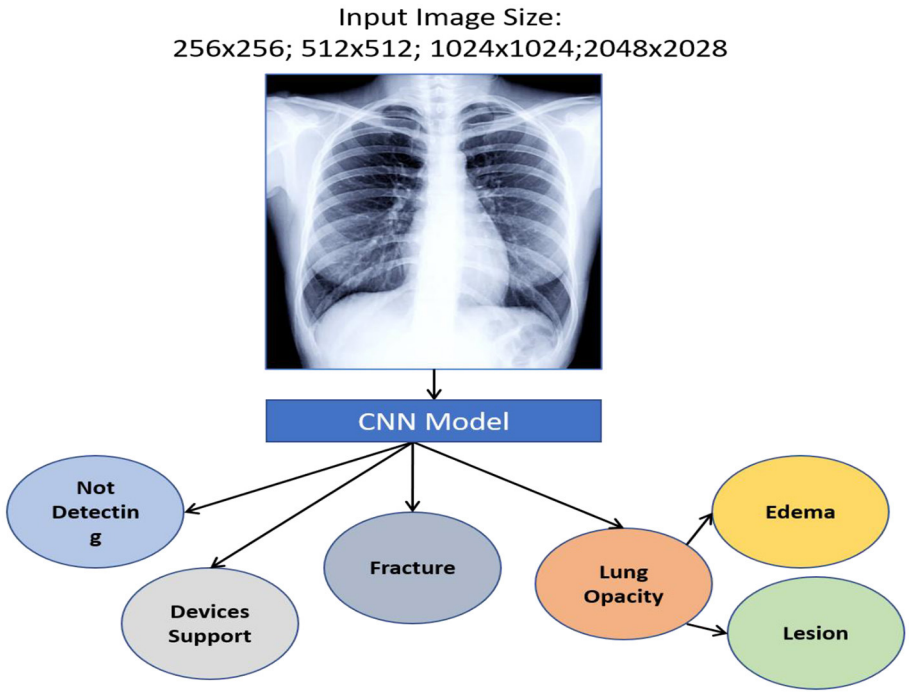

FIGURE 9
Workflow of CNN-based MedIMG.

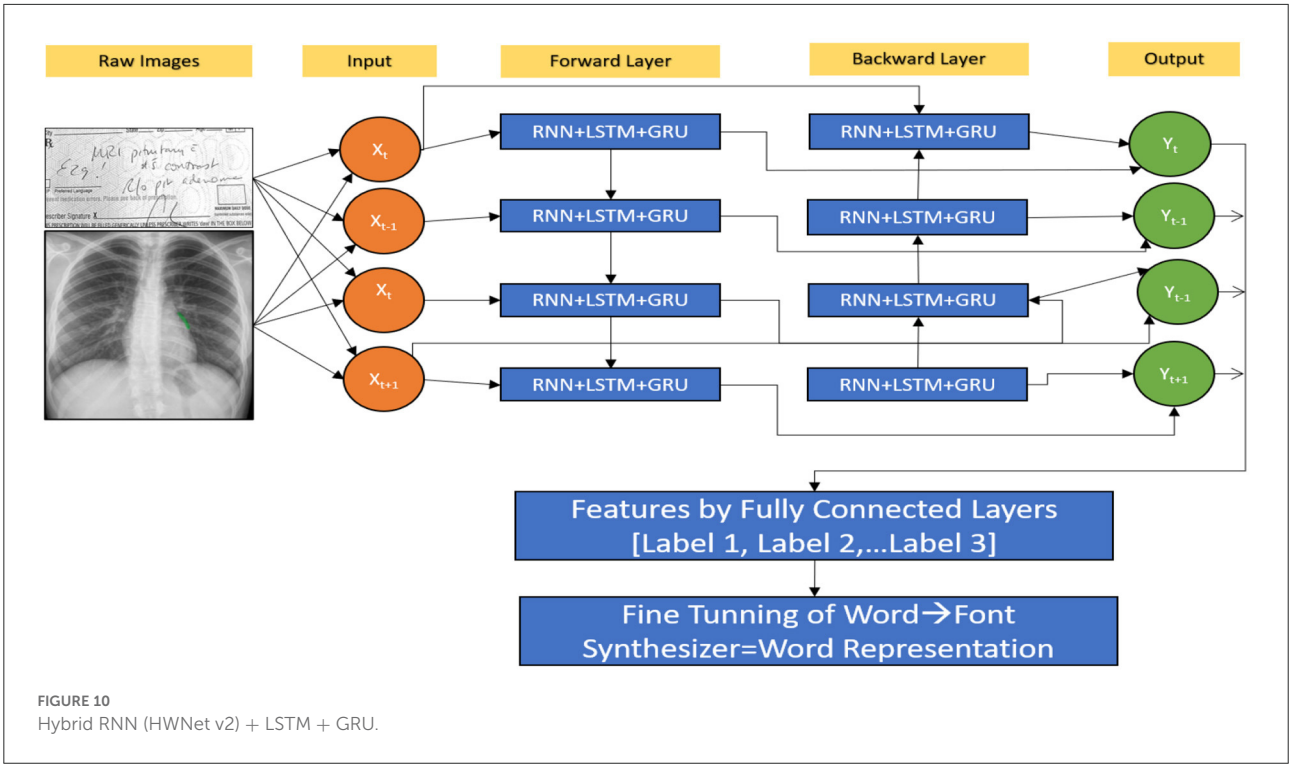

FIGURE 10
Hybrid RNN (HWNet v2) + LSTM + GRU.

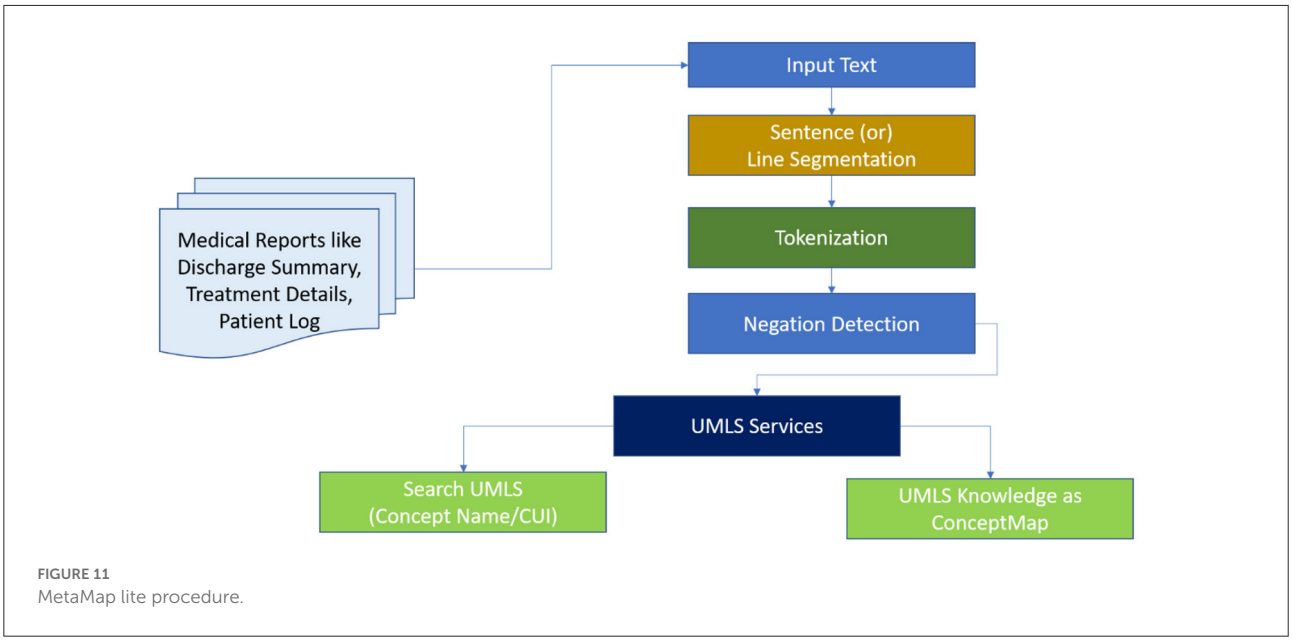

FIGURE 11
MetaMap lite procedure.

and denoised images. The following Eq. (11) is used to calculate this.

$$Suitable = 10 \times \log_{10} \frac{512 \times 512}{\frac{1}{hxw} \sum_{a-0}^{h-1} \sum_{b-0}^{w-1} [F(a,b) - G(a,b)]} DB \quad (12)$$

The height, as well as width of such images, are represented by h and w. The grey levels of the original MedIMG and denoised image at the (a, b) position are $F(a, b)$ and $G(a, b)$, respectively. The trial-and-error method is used to select all of the work's beginning settings. The PSNR value is used to calculate the

fitness, which allows the image quality to be evaluated and processed appropriately.

Proposed hybrid model to predictions of RNN (HWNet v2) + LSTM + GRM

The next character from MedIMG is predicted using an RNN. RNN's LSTM cell is used in this study. Each time LSTM processes a word, the following letter in the drug's name is determined by computing the probability of such possible values. The memory state of the network is initialised with a vector of '0's. So that it may be readily updated when each word has been scanned. The "x" in Figure 2 represents a feature, while the "o" represents a vector of size length probabilities. Because of their sequential structure, RNNs have gotten much attention for EHR predictive modelling. RNNs are Artificial Neural Networks that have recurrent connexions in the hidden layer. The HS of "ht" is updated successively based on activating the current input "xt" at a time "t," as well as the last HS of the layer ht−1. The Gated Recurrent Unit (GRU) and LSTM models are two popular RNN versions. The necessity for these variants arises because of the problems encountered while training traditional RNNs, where gradients would frequently vanish. Two major approaches have been investigated to address the vanishing gradient problem for extended sequences: (a) Develop an alternate training algorithm to the stochastic gradient, such as a clipped gradient. (b) Contain an internal cell state which controls the information flow *via* a series of gates in conventional RNN units. LSTMs and GRUs, unlike typical RNNs, have a recurrent internal loop at every unit and also with three and two gates to regulate information flow. Data have demonstrated that gated RNNs can identify long-term dependencies as well as avoid the problem of vanishing gradients.

A patient in an EHR is made up of a series of visits, and if each visit is represented as a numerical vector, those vectors can be fed into the RNN model in order to predict the desired outcome. In this study, we predominantly used the LSTM network to be the prediction model (Figure 10). The model recognises one visit for each time step of a patient "p" with "Tp" visits. From $t = 2$ to $t = \text{Tp}$, the new LSTM state is determined by the previous time step's state as well as the new input visit. The LSTM block spreads its state to subsequent dense layers at each time step. This indicates that the network has an input and output at each stage. Sequence-to-sequence prediction is the name given to this LSTM arrangement. We explored the multiple baseline prediction models, including several ML methods and LSTMs.

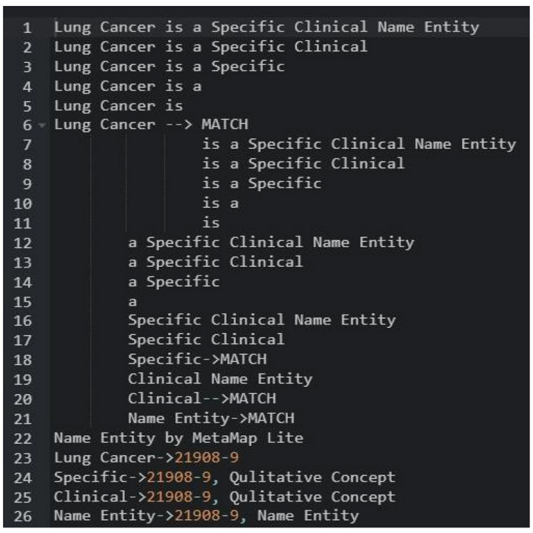

FIGURE 12
Test finding of UMLS-based NER.

NER-based open-source UMLS

MetaMapLite leverages ConText19/NegEx13 to negation detection. Consequently, the users who supply the longest concept appropriate to the semantic type of UMLS are provided. The processing pipeline is divided into seven steps, as shown in Figure 11 and detailed below.

Either the default OpenNLP sentence segmenter12 or its blank line segmenter is used for sentence/line segmentation. The basic MetaMapLite tokenization algorithm is used for tokenization. The part-of-speech tags that are optional are done by default OpenNLP part-of-speech tagger. The predefinition of the token window occurs for paralleling the sentence length using the OpenNLP segmenter; on using the blank line segmenter, a nonoverlapping window with 15 tokens occurs. There is no additional chunking. With minor modifications, term normalisation is based on MetaMapLite string normalisation. Before a dictionary lookup, the following procedures are performed on a term: (a) Parentheticals are removed, (b) syntactic inversion is performed, (c) lowercase is converted, and (d) possessives are stripped.

As shown in Figure 12, mapping is done to sentence/line-based chunks that are dynamically separated into sub-lists during processing. Each piece is normalised before being compared to a dictionary. Any dictionary match that is obliterated by a lengthier match gets discarded. MetaMapLite presently uses three dictionaries generated specifically for MetaMapLite for dictionary lookup: (1) CUI Concept, which maps CUIs to concept predefined names; (2) CUI Source Info, which holds the UMLS CUI, the UMLS string ID, a sequence ID, a source-derived string ID, a source abbreviation ID, and also a source term type ID; and (3) CUI St, that maps CUIs into semantic types. As an example of sentence-level NER, a token

list for the phrase "Papillary thyroid cancer is a unique clinical object" is initiated and filtered.

Experimental results

The accuracy of a model can be improved by training it using a vast amount of data. As previously stated, we train the model using all generated data. TensorFlow's training is divided into two categories: iteration and model during training. We apply the TensorFlow standard model limiting iteration to around 10,000 for this research work. The dataset of MIMIC-CXR-JPG that was used in this investigation is discussed. It is a big one, comprising 377,110 X-rays and 227,827 MedIMG studies. It was created at the investigation level, which is an accumulation of photographs connected with a specific report.

As a result, many chest X-rays with frontal or lateral views can be included in a single scan. The dataset contains a sum of 2,50,100 frontal-view pictures and 1,20,300 lateral-view MedIMG. DICOM images are transformed into JPEGs in this collection. JPEG photos are not only less in size, but they are also easier to understand. The photos were de-identified before being converted to JPEG. After extracting picture pixels from the DICOM input file, the image pixels are normalised to the range [0, 255]. It was examined to determine if pixels are inverted and, if needed, images are inverted to ensure the image's greatest pixel appears as white and the low pixel as black. The contrast of the images was then improved using Contrast Limited Adaptive Histogram Equalisation (CLAHE). Finally, the photos are converted to JPEG format with a 95.78% quality factor and an 8-bit bit depth.

Computational setup

The NVIDIA DGX-A100 system, which consists of High Bandwidth Memory integrated with eight NVIDIA A100 40 GB Graphics Processing Units (GPUs), was utilised for training the DL models (HBM2). A total of 320 GB GPU memory and the highest level of system power consumption of 6.5kW are contained in this system. The code for our techniques was written using the Pytorch framework and the torch vision package. Table 4 shows a single GPU's consumption of memory for each resolution in gigabytes (GB) during training. As the solution improves, so does the amount of memory used. It depicts the computing capabilities and power required to carry out the experiments. Four A100 GPUs were used for a resolution of 256 × 256 and 512 × 512; however, six A100 GPUs are used simultaneously for 1,024 × 1,024 and 2,048 × 2,048 resolutions to speed up the training. As the image size is doubled, the number of trainable parameters increases, while the number of photos per second drops throughout validation.

A fascinating result of transfer learning using synthetic data. By changing the rate of training data associated with earlier studies, we test the reduced demand for real data for training the HWNet v2 model. We use the IAM dataset as our testbed again, but we are using a different composition of real data to compare performance with a model that uses all of the training data. Full is represented by 1.0, whereas 0.0 denotes the usage of just synthetic data. It is worth noting that all of these test results are trained on the completely synthetic data set before being fine-tuned with different proportions. As noticed, the performance reduction with less real training data begins slowly and only lowers by 6% when just 10% of genuine data is used. Although this Table 5 shows a lower reliance on real data, a more in-depth investigation (beyond the scope of this project) is required to assess the difference in domain space among synthetic data and handwritten target styles.

TABLE 6 Analysis of word on MedIMG.

Model	Supervision	Dataset 1	Dataset 2	Dataset 3
Hybrid	YES	0.9618	0.97182	0.9827

It is interesting to note that performance in the interval of 32–1,024 dimensions suffers little or no degradation, and we even notice a slight performance boost for 128 dimensions. This shows that the initial HWNet network may capture non-linear data relationships, but the final representing space exclusively contains linear components. On MedIMG with 32 sizes, we achieve an mAP of 0.8942, which is still state-of-the-art when compared to other related approaches shown in Table 6. It is worth noting that the performance attained with only eight dimensions (0.5942) remains superior to several non-DL techniques.

We want to compare the benefits of supervised vs. unsupervised learning, as well as compare performance on such datasets having in-depth features. Table 6 shows the results, which compare HWNet v2 (TPP) to previous techniques. For the English dataset, we apply the pre-trained model by IIIT-HWS with no fine-tuning; however, for the Hindi as well as Telugu datasets, we fine-tune their respective training corpus. The results show that word spotting performance has significantly increased on all of these datasets and that for printed English, HWNet v2 could be used off-the-shelf for various document tasks. The improved results in multi-languages show that architecture could be applied to a wide range of languages with different scripts and language elements. The qualitative outcomes displayed in the last two rows of Figure 13 also demonstrate the level of degrading in the retrieved words, indicating the efficiency of the suggested characteristics (Table 6).

Compression of embedding representation

There is inspiration from our prior studies on integrating the representation into a two-dimensional space, where we discovered surprising similarities between neighbours even under great compression. We now use Principal Component Analysis (PCA), a well-known linear dimensionality reduction technique, to explicitly obtain a lower-dimensional representation of HWNet characteristics. We retrieve the top eigenvectors within representation space from the validation data and use them to project each of the test data. On MedImg datasets, Figure 13 presents the performance difference across variable compression levels ranging from 4 to 1,024. Note that the original HWNet features are 2,048 bytes in size.

The outcome of hybrid model (RNN (HWNet v2) + LSTM + GRM)

The Hybrid model has the maximum area under the curve (AUC) for all 14 labels, as shown in Table 7. For each label, an AUC is at least 0.4% greater when compared with the outstanding performance of the single-scale model inclusive of the 1.1% average AUC, which is greater than the model of 1,024 × 1,024. This gap suggests that specialisation happens across scales to any given label, with certain examples best suited to other scales, so that the ensemble can be used to increase accuracy. Table 7 shows that the AUC values acquired for individual models closely resemble the learnt weights. The 1,024 × 1,024 scale, which seems to be the best performing unique model (bold), has been assigned the maximum weight

10.3389/fpubh.2022.926229

TABLE 7 AUCs for 15 TRAINED MedIMG.

ID	Finding	256 × 256	512 × 512	1,024 × 1,024	2,048 × 2,048	Hybrid model
1	Aches, pain, fever	81.8 ± 0.7	82.7 ± 0.2	81.9 ± 0.4	80.9 ± 0.5	82.4 ± 0.51

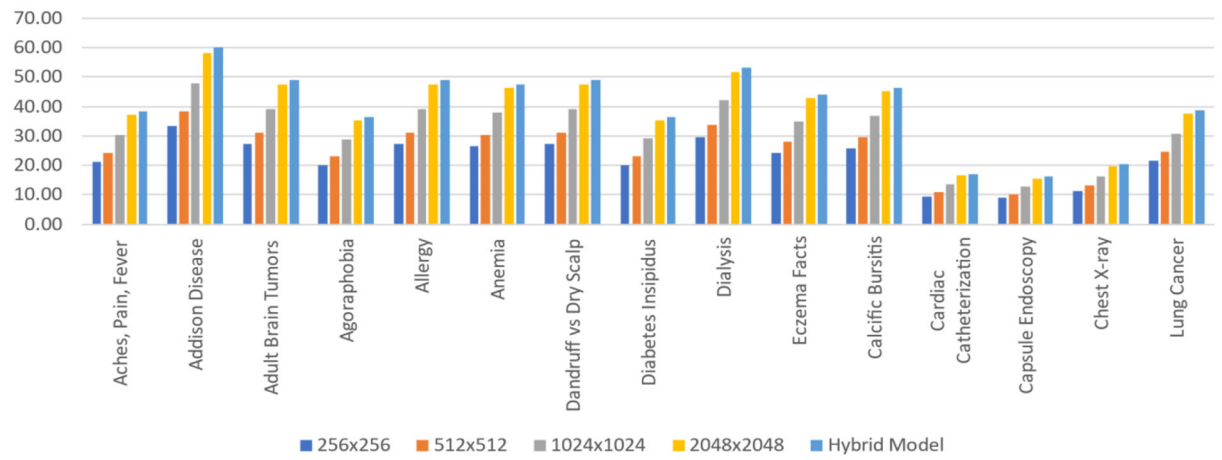

FIGURE 14
Average stacked scale CNN hybrid model.

(32.7%) in computing prediction for "Aches, Pain, Fever" with the Hybrid model. Ten of 15 tasks fall under this category.

This study evaluates model performance using the AUC metric. The area beneath the Receiver Operating Characteristic (ROC) curve (38) is measured by AUC (39). True Positives (TP) and True Negatives (TN) are improved by a model with a higher AUC (40). Table 3 shows the AUC scores for all 15 labels, including the average, for various scales. Because, throughout training, the application of five-fold cross-validation was prevalent. Those AUC scores are the AUC scores average from each of the five folds. Throughout the standard deviations calculated over the five-folds, the AUC scores are displayed. As per our hypothesis, the AUC score for all labels should grow as the input image size increases, i.e., all the bold values should be in 2,048 × 2,048. However, as the table shows, it is not a fact. Some labels meet up to our expectations, while others do not. The AUC score for "Cardiac Catheterization," for example, drops as image size increases. When compared to 256 × 256 resolution, a few labels performed well with 512x512 resolution, but their AUC scores drop when the resolution is raised to 1,024 × 1,024 resolution.

For each of the 15 tasks, Figure 14 represents the layered Hybrid Model's learnt weight distribution on four scales. When

calculating the predictions for the Hybrid Model, this bar chart displays that resolution is assigned more weights to a specific task. It is worth noting that such weights are given in percentages, and for each task, the weights from all five scales add up to 100%.

Implementation of MetaMap lite

Table 8 shows the F1scores, Recall, and Precision [42, 43] on every tool to every collection that we are capable of proceeding with it. Because negative detection isn't a natural MetaMapLite feature, and just comparing this one with MetaMapLite implementations of NegEx is to make sure of not losing any performance. We were unable to assess DNorm on two datasets due to difficulty in getting relevant offsets.

TABLE 8 Test report of feature extraction using MetaMapLite.

MetaMapLite	Model
3 m 31.89 s	Aches, pain, fever
2 m 21.17 s	Addison disease
1 m 34.17 s	Adult brain tumours
2 m 24.28 s	Agoraphobia
3 m 25.38 s	Allergy
2 m 17.38 s	Anaemia
3 m 34.48 s	Dandruff vs. dry scalp
2 m 13.41 s	Diabetes insipidus
4 m 21.38 s	Dialysis
3 m 24.78 s	Eczema facts
2 m 17.89 s	Calcific bursitis
4 m 23.67 s	Cardiac catheterization
2 m 19.89 s	Capsule endoscopy
4 m 18.79 s	Chest X-ray
3 m 23.78 s	Lung cancer

We made considerable effort to install, run, and collect mention-level offsets to third-party programmes. However, with the versions of DNorm available upon this i2b2 2010 and ShARe collections, it cannot obtain mention-level data. It is reasonably sure that the findings we obtained are comparable with those obtained by average end-users of versions of such tools present at the time we conducted our research investigations. On all collections, MetaMapLite received F1scores that were greater than any other tool. The absolute results achieved in our trials may vary from those reported previously, which could be due to differences in tool versions and settings used in our experiments. On request, we may provide all of our tool installations and test collections, which can be made accessible for evaluation scripts. MetaMapLite also takes various restrictions (Figure 15).

It only implements a small portion of the rich MetaMapLite options. MetaMapLite is analysed with the default MetaMap setting, and its performance is equivalent to out-of-the-boxMetaMapLite setups that haven't been tuned for a particular activity.

The processing speed of MetaMapLite is determined by the options selected: the quickest processing is accomplished without POS tagging by a negligible drop in the F-score.

MetaMapLite does not currently have any word-sense disambiguation modules, although it will offer all UMLS senses for a given term. Roughly, mappings that are usually incorrect might be put to a rejection output, similar to MetaMapLite; otherwise, a custom-made data file is handled as a substitute for the tools' regular lexicon records. Finally, the examination has a significant restriction in that it only examines disorders and denials.

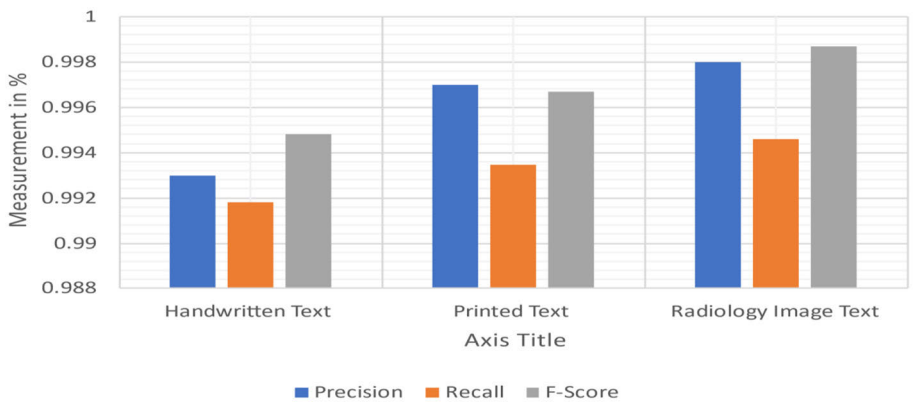

FIGURE 15
Measuring recall, precision, and F1-scores.

Conclusion

In this paper, Deep Learning is used to extract knowledge from a clever approach to distinguish the doctor's prescription photos and radiology images. The main outcomes are proof of ML methods' ability to discern which elements in short free-text clinical prescriptions are considered inclusion/exclusion criteria, as well as a huge radiology image dataset of images, metadata, radiological results, diagnoses, and anatomic locations. We provide a generic DCNN system for learning document image word image representation. The Hybrid DL Model's core architecture utilises synthetic data to rapidly pre-train multiple data expansion strategies to replicate a typical mechanism at document text formation. Some new visualisation approaches are used to provide other views into the fine-tuning process and to comprehend the differences learned at various levels. On challenging historical texts in both handwritten and radiology modalities, we successfully demonstrate the stability of learned representation in aspects of both performances as well as the dimensionality of the final word. The significance of feature and image resolution in CNN design enabling automated MedIMG categorisation is demonstrated in this study. MetaMapLite, a lightweight software application using MetaMap, is among very widely applied termed NER technique to identify Metathesaurus UMLS ideas as texts on bio-medicine, is described herein our research investigation.

Influence of seamless nursing model of humanistic care on nursing quality and blood infection risk of neurosurgical ICU patients and its correlation with APACHE II score

Fuhua Liu[1] and Xiaoting Wang[2]*

[1]Neurosurgery Department, Zhejiang Hospital, Hangzhou, China, [2]Intensive Care Unit Department, Zhejiang Hospital, Hangzhou, China

This research aims to explore the influence of seamless nursing mode of humanistic care on nursing quality and blood infection risk of ICU patients in neurosurgery, and the model of correlation with APACHE II score. 110 ICU patients are grouped into control set and study set, which are, respectively, given the previous routine nursing and the seamless management based on humanistic care to compare the two sets in the following aspects: nursing quality, blood infection rate, anxiety and depression extension before and after nursing, nursing satisfaction and APACHE II score, and to figure out the correlation between patient nursing quality score, and to compare blood infection and APACHE II score. Comparison and statistical analysis are used to disclose the influence and the correlation. The results show that there is not only a large negative correlation between nursing quality scores and APACHE II scores, but also a large negative correlation between the risk of blood infection and APACHE II score.

KEYWORDS

humanistic care, seamless nursing, neurosurgical ICU, nursing quality, blood infection, APACHE II score

Introduction

In the ICU treatment of neurosurgery, most patients are often confronted with the characteristics of disease severity and rapid variance in the disease so it is necessary to provide patients with timely and effective care to ensure their health and life. However, the number of ICU patients in neurosurgery and the heavy workload force nurses to undertake high psychological pressure, leading to a series of problems and errors in nursing, which, consequently, have side effects on the efficacy and prognosis (1). For neurosurgical ICU patients, most of them have gone through surgical treatment and may stay in the situation of severe physiological dysfunction and organ failure, not out of the danger period so they need further monitoring and treatment. However, surgery invasive operations such as trauma and tracheal intubation, which is required by the

diseases themselves, increase the infection risk to some extent and have a serious impact on the prognosis and recovery. It is important to make the prevention and control of nosocomial infection in the neurosurgical ICU. And there is a need to find a safe and reliable method. It is one of the key clinical processes at present (2, 3). With the medicine development and the advancement in medical technology, the nursing model has been continuously updated and developed. Humanistic care is a human-oriented nursing model, and its application in the process of ICU nursing management can help patients increase compliance (4) and establish confidence in overcoming the disease. The seamless management is one of new models in modern nursing. The concept is based on modernization, which can largely ensure the integrity and effectiveness of nursing services (5, 6). However, the application of humanistic care combined with seamless management in neurosurgical ICU patients is rarely seen in present clinical practice, and there is no strong and effective basis for evaluating its efficacy. The impact of the seamless care model on the care quality and blood infection risk in neurosurgical ICU patients will now be explained in the following. Humanistic care in the treatment of critically ill patients can make nursing staff fully respect the patient's personality and human rights and meet the reasonable needs of patients. This nursing model can not only provide the humanistic care required for overall nursing, but also support the improvement of the professional quality of nursing staff. Therefore, humanistic care is the new era for nursing staff.

In this paper, 110 neurosurgical ICU inpatients admitted to our hospital from September 2020 to January 2021 are selected for research, and they are grouped into control set and study set according to the sequence of admission, with 55 cases in each set. Among them, there are 26 patients diagnosed with underlying diseases and 29 patients without underlying diseases; there were 30 males and 25 females in the research set, with an age range of 39∼68, average age being 56.62 ± 4.75 for the male patients. In the routine set, there were 32 male cases, and 23 cases were female, the age range being 40–69 years old. The average age was 57.19 ± 4.86. There were 28 cases with underlying diseases, 27 cases without underlying diseases. For general clinical data such as disease, $P > 0.05$, there was no large difference between the sets. All patients signed the informed consent form, and this study was approved by the Medical Ethics Committee in our hospital.

This paper finds that the nursing quality scores of the study set, including theory, practice and comprehensiveness, were notoriously higher than those of the control set; the risk rate of blood infection during hospitalization in the study set was 5.45%, which was notoriously lower than that of the control set, 25.45%. After nursing, the SAS and SDS scores of the two sets decreased, and the research set was lower than the control set; after nursing, the APACHE II scores of the two sets were improved, and the improvement effect of the research set was notoriously better than that of the control set ($P < 0.05$); the seamless nursing model based on humanistic care can improve nurses' service attitude, improve doctor-patient relationship, provide patients with appropriate psychological care, correct patients' misunderstandings, create a positive attitude, eliminate negative emotions such as fear and anxiety, and make them treat the disease with optimism and increase the confidence in treatment. Additionally, this study also compared the nursing satisfaction of the two sets. The results found that the total nursing satisfaction of the research set was 89.09%, which was notoriously higher than that of the control set (63.64%) ($P < 0.05$). For neurological ICU patients, seamless nursing mode based on humanistic care can help improve the quality of care, reduce the risk of blood infection and APACHE II score, promote the recovery of patients, improve the prognosis of patients, and present clinical application potential.

The rest of this paper is organized as the follows: Section *Related work* discusses the related work, followed by the proposed methods in Section *Our proposed method*. Section *Experimental results and analysis* is the content of results in which the contrast between the main factors is conducted, and Section *Conclusion and the future work* concludes the paper with summary and future research directions.

Related work

In recent years, with the continuous improvement of people's living standards, people's demand for medical care is increasing too, especially for the quality of patient care in ICU, which is directly related to the health of patients. The intensive care unit is an important place to provide emergency care for critically ill patients so a comprehensive, systematic, scientifically and professional nursing is required to provide a safer guarantee for the lives of patients (7). Therefore, strengthening effective nursing measures in the treatment of ICU patients is very important for the treatment and recovery of ICU patients. Seamless nursing management is a method that mainly includes the detailed understanding and management of the patient's condition, and the development of a targeted nursing plan (8). The good nursing management system ensures the smooth nursing process, thereby effectively improving the quality of nursing, reducing the incidence of patient infection, and enabling ICU patients to receive high-quality and safe nursing services during the treatment process. Humanistic care nursing is based on the principle of "human-oriented", which can show more emotional respect and love for patients while carrying out routine nursing (9). The main reasons for the analysis are that after nutritional support based on the seamless nursing model based on humanistic care, the patient's immunity can be notoriously improved; the standardized application of antibiotics can effectively prevent superinfection and the formation of drug-resistant bacteria; strengthening environmental management and oral care can prevent respiratory infections; good disinfection of the urethra and catheter can effectively reduce the risk of infection and

avoid urinary tract infections by closely monitoring the situation of the surgical incision and puncture site, and changing the bandage in time, as well as helping the patients turn over regularly, to effectively prevent skin and soft tissue infections (10, 11). Romero-Garcia et al. (12) explored the application value of seamless management model for nosocomial infection in surgical ICU, and found that providing appropriate seamless management nursing intervention can notoriously reduce the possibility of nosocomial infection in patients, which is consistent with some results of this study. For most ICU doctors and nurses, most of the time is highly stressful. In this regard, hospitals should actively take appropriate measures to reduce the pressure on nursing staff and provide better services for patients (13). The seamless nursing model focuses on scientific management, creating a seamless nursing management team so that ICU patients can create a rigorous, continuous, and integrated seamless nursing process before admission, during treatment, and after treatment (14, 15).

The application of seamless nursing management strengthens nursing management, makes nursing measures practical, improves the awareness and motivation of nursing staff, and enhances the sense of responsibility of nursing staff. At the same time, nursing responsibility can notoriously improve the quality of nursing through perfect supervision (16). It is a new nursing model that is welcomed by patients and recognized by the society (17). The application of seamless management can effectively care for the psychology of patients and improve the bad mood of patients, enable nursing staff to communicate well with patients, improve patients' confidence in nursing staff, and reduce the occurrence of medical disputes, with employees' awareness of risk prevention greatly enhanced, preventing risk events before they occur, controlling every reference and detail in nursing work, and notoriously reducing the incidence of nursing risk events while providing patients with safe, high-quality, and comprehensive nursing services (18, 19).

Our proposed method

For the selection of patients, there are two standards including inclusion and exclusion.

The inclusion criteria include the following aspects: (1) All patients were neurosurgical ICU patients; (2) The selected patients were over 18 years old; (3) The patients had barrier-free consciousness and could communicate and communicate with doctors normally; (4) All patients signed informed consent notice.

The exclusion criteria include the following aspects: (1) Patients with poor treatment compliance and unable to determine the curative effect; (2) Patients with severe illness requiring emergency treatment; (3) Patients with severe complications; (4) Patients who have used contraindicated drugs; (5) Patients with missing data on cases and related impact examinations; (6) Patients' condition deteriorated suddenly during the research process; (7) Patients with other diseases affected the research results; (8) Patients who had unexpected circumstances during the research process, made it difficult to continue the research; (9) Serious disease during the research process affected other researchers.

Control set

The set of patients can use the previous routine nursing mode, and the details are as follows: (1) closely monitor and observe the patient's condition and vital signs, evaluate the patient's physical responses according to the patient's actual situation, and give appropriate medication or (2) during the nursing process, closely observe and record the changes in the patient's condition, and carry out routine management and monitoring; (3) if the patient's condition improves, appropriate measures should be taken, and instruct patients to carry out relevant rehabilitation exercises, and communicate with the patient's families to guide some precautions after surgery, and provide necessary health guidance or advice to reduce the incidence of postoperative complications.

Study set

Based on the nursing in the control set, the patients in the set were given seamless management under humanistic care. The specific operation methods are as follows:

Humanistic nursing: (1) Nursing staff need to do a good job in interviewing patients, know the patient's condition through effective communication and make the evaluation, and communicate with relevant doctors; according to the patient's operation method, condition and anesthesia method, different methods are adopted to manage patients; at the same time, formulate a set of personalized precautions for patients. Since ICU patients are relatively cumbersome and large-scale, both anesthesia and surgical procedures are more complicated. Therefore, nurses need to nurse patients carefully and cautiously. (2) Nursing staff need to adjust the temperature in the ward, preferably between 22 and 25°C, and the humidity is about 55% to ensure the comfort; do a good job in keeping the patient warm, observe the blood flow in the compressed part, and record the patient's vital signs in real time; (3)nursing staff should ensure that the drainage tube is fixed securely, the infusion channel unobstructed and the exposed parts covered; after the ward, the nursing staff make handover and communication with the nursing staff in the ward, including intraoperative responses and blood loss, etc., comfort the family members, and give them spiritual encouragement.

Seamless management: (1) Preparation stage is going to establish a seamless management team to cooperate in the entire

nursing process, with the deputy chief nurse or the chief nurse as the team leader responsible for management guidance and supervision. The team consists of 6 nurses. They are responsible for completing the basic nursing operations with due diligence. At the same time, they put forward corresponding suggestions according to the problems existing in the nursing process. The goal of the seamless management team is to reduce nosocomial infections. (2) Contents: ① nutritional support management: since ICU patients are relatively weak, their immunity is low, and their defense and resistance to foreign bacterial infection is weak so the first thing to do is to strengthen nutritional support for patients, which is also the most important thing to do as one of the basic nursing cares. Nursing staff provide nutritional support to patients in the following ways of parenteral support, on-site nutrition, etc., but it should be noted that in the process of nutrient solution deployment they should be prepared and used immediately. In theory, it should not exceed 24 h to avoid the deterioration of the nutrient solution and cause unnecessary impact on the patient, and the container for placing the nutrient solution should be dry and sterile; ② abdominal infection management: generally speaking, the occurrence of abdominal infection. It is usually due to self-infection so the drug susceptibility test results should be tested for the patient in time, and appropriate sensitive antibiotics should be selected for the patient, and antibiotics should be used correctly if the patient has related symptoms;③respiratory tract infection management: intraoral care: guide the patient to take half in the sitting position, use chlorhexidine solution to rinse the patient's mouth every day to ensure the cleanliness of the oral cavity; environmental management: it is necessary to purify the ambient air regularly, mainly using a turbocharger to ensure that the temperature in the ward is maintained at 23∼25°, the humidity is about 55% in order to ensure that the patient's airway will not be excessively dry; a humid heat exchanger can be used to properly humidify it; ventilator management: it is necessary to place the humidifier sterile liquid and thread. The tube should be replaced regularly, and the condensed water should be cleaned up in time to avoid reverse flow; ④ urinary tract infection management: after the patient is indwelled by the catheter, the vulva and urethral orifice should be disinfected with iodine with a concentration of 0.05%. The frequency is 3 times per day. After the patient defaces, the patient's perineum should also be cleaned, and the patient's urethral opening should be scrubbed at the same time in order to shorten the indwelling time of the patient's urinary catheter as much as possible to avoid complications related to the urinary catheter. ⑤ skin and soft tissue care: for ICU patients, there will be surgical incisions and puncture sites, and the skin at this site is relatively fragile so it needs to be disinfected daily, and at the same time, use a one-time sterile applicator and require frequent replacement, closely observe the skin around the puncture site of the patient; if there is redness, pain or fever, the tissue should be taken immediately for bacterial culture to ensure that the infection of the patient can be controlled in time. For long-term bedridden patients, nursing staff should instruct patients to turn over regularly to avoid local pressure and pressure ulcers.

Observation of indicators

Indicator observation includes the following steps:

(1) The nursing quality of the two sets was compared, and the nursing quality survey scale prepared by the hospital was used to evaluate the nursing quality. The Cronbach's alpha value of this scale is 0.787.

(2) The blood infection rate of the two sets of patients was compared, and the blood infection rate (%) = the number of blood infections / the total number of people × 100%.

(3) The anxiety and depression of the two sets of patients before and after nursing were compared. The self-rating anxiety scale (SAS) was used to determine the degree of anxiety. The scale has a total of 20 items, and the scoring standard for each item is 1–4 points. A score >50 indicates that the patient has an anxiety tendency, and the higher the score indicates a higher level of anxiety in the patient (20). The self-rating depression scale (SDS) is used to assess the degree of depression. The scale has 20 items, and the scoring standard for each item is 1 to 4 points. A score >53 points indicates that the patient is prone to depression, and the higher score indicates that the degree of depression is more severe (21).

(4) To compare the nursing satisfaction of the two sets of patients, the nursing satisfaction survey scale prepared by the hospital was used for evaluation, including 10 items such as work attitude, nursing effect, nursing technology, etc. Each item was

TABLE 1 Contrast of nursing quality between two sets ($\bar{x} \pm s$, points).

Set	Theoretical nursing quality	Quality of practice nursing	Integrated nursing quality
Control set ($n = 55$)	75.25 ± 5.39	72.52 ± 5.71	73.58 ± 5.26
Study set ($n = 55$)	95.33 ± 4.16	94.16 ± 5.27	94.89 ± 4.26
t	−21.827	−20.654	−23.349
P	<0.001	<0.001	<0.001

TABLE 2 Contrast of blood infection rates between the two sets of patients.

Set	Risk of blood infection (%)
Control set ($n = 55$)	14 (25.45)
Study set ($n = 55$)	3 (5.45)
$\chi 2$	8.419
P	0.004

scored as 0–10 points <95 points are satisfied, 60-<80 points are fair, and <60 points are unsatisfactory. Satisfaction = very satisfied rate + satisfaction rate. The Cronbach's alpha value of this scale is 0.763.

(5) To compare the difference in APACHE II score between the two sets, using the APACHE II scoring system (22), the vital signs, blood routine, liver and kidney function, electrolytes, blood gas analysis and Glasgow coma score within the first 24 h of ICU admission were collected (23). The total data APS (A), age adjustment (B), chronic health adjustment (C) inspection data were obtained, and all data were entered into the APACHE II scoring scale, and finally A + B + C was obtained to obtain the APACHE II score. The patients were divided into sets according to the APACHE II total score: severe set, with scores ≤15 points; critically ill set, between 16 and 35 points; extremely critically ill set, >35 points.

(6) The correlation between nursing quality score, blood infection and APACHE II score of patients was compared.

Statistical methods

In this study, all the data were organized, and a corresponding database was established for it. All databases were entered into SPSS 26.0 for data processing, and the measurement data was tested for normality, expressed as ($\bar{x} \pm s$), and between sets as t-test; the rate is expressed as %, and the test method is $\chi 2$; the correlation between nursing quality, blood infection risk and APACHE II score was analyzed by Pearson; when $P < 0.05$, the difference between the data was statistically large.

Experimental results and analysis

Contrast of nursing quality between the two sets

The scores of nursing quality in the study set, including theory, practices and comprehensiveness were notoriously higher than those in the control set (all $P < 0.05$), as shown in Table 1.

Contrast of blood infection rates between the two sets of patients

The risk rate of blood infection in the study set during hospitalization was 5.45%, which was notoriously lower than

Correlation between nursing quality score, blood infection risk and APACHE II score

Correlation analysis between scores of nursing quality and APACHE II score

There was a large negative correlation between various scores of nursing quality and APACHE II score ($P < 0.05$), as shown in Table 6 and Figure 2.

Correlation between blood infection risk and APACHE II score

There was a large negative correlation between the risk of blood infection and the APACHE II score ($P < 0.05$), as shown in Table 7.

Conclusion and the future work

For neurological ICU patients, the seamless nursing model of humanistic care can improve their nursing quality reduce the risk of blood infection and APACHE II score, promote patient recovery, and improve patient prognosis, which is worthy of clinical application. Although this paper has achieved certain results, it still has certain limitations. Since this study did not evaluate the prognosis of patients, it is impossible to determine the long-term effect and compliance of nursing care. Therefore, in future research, the scope of sample selection should be expanded and extend the follow-up stage and further evaluate the long-term effect of the seamless nursing model of humanistic care on neurosurgical ICU patients.

Retinal vessel extraction plays an important role in the diagnosis of several medical pathologies, such as diabetic retinopathy and glaucoma. In this article, we propose an efficient method based on a B-COSFIRE filter to tackle two challenging problems in fundus vessel segmentation: (i) difficulties in improving segmentation performance and time efficiency together and (ii) difficulties in distinguishing the thin vessel from the vessel-like noise. In the proposed method, first, we used contrast limited adaptive histogram equalization (CLAHE) for contrast enhancement, then excerpted region of interest (ROI) by thresholding the luminosity plane of the CIELab version of the original RGB image. We employed a set of B-COSFIRE filters to detect vessels and morphological filters to remove noise. Binary thresholding was used for vessel segmentation. Finally, a post-processing method based on connected domains was used to eliminate unconnected non-vessel pixels and to obtain the final vessel image. Based on the binary vessel map obtained, we attempt to evaluate the performance of the proposed algorithm on three publicly available databases (DRIVE, STARE, and CHASEDB1) of manually labeled images. The proposed method requires little processing time (around 12 s for each image) and results in the average accuracy, sensitivity, and specificity of 0.9604, 0.7339, and 0.9847 for the DRIVE database, and 0.9558, 0.8003, and 0.9705 for the STARE database, respectively. The results demonstrate that the proposed method has potential for use in computer-aided diagnosis.

INTRODUCTION

The color fundus image (**Figure 1A**) is a non-invasive tool generally used to diagnose various pathologies, including diabetic retinopathy, glaucoma, and age-related macular degeneration. Retinal vessels are the only part of the blood circulation system of humans that can be non-invasively observed directly (1, 2). Inspection of the attributes of the retinal vessel such as width, tortuosity, branching pattern, and angles can play significant roles in early disease diagnosis. Moreover, vessel segmentation is a key and indispensable processing step for further

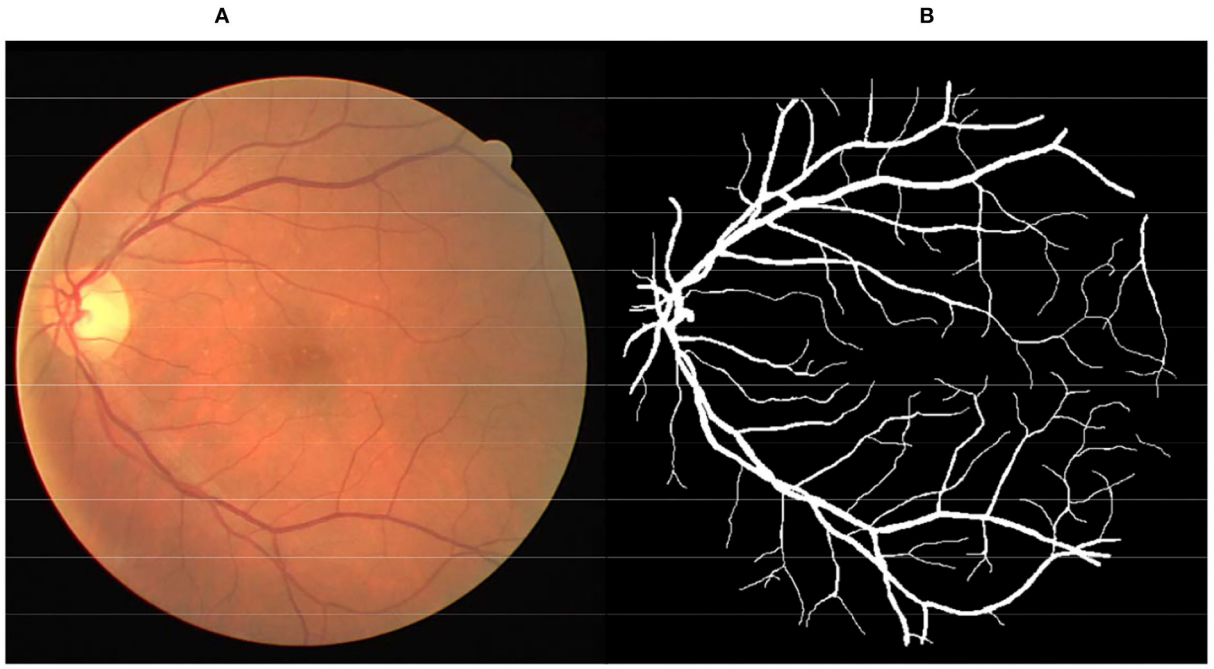

FIGURE 1 | (A) Color fundus image from DRIVE database. **(B)** Corresponding manual segmented image.

processing operations. This means that the accuracy of vessel segmentation greatly affects the diagnostic effect. But, it is a work of redundancy and boredom for professional ophthalmologists, as shown in **Figure 1B**. Consequently, to save medical resources and improve the effect of diagnosis, the effective vessel segmentation algorithm with high accuracy and less time consumption is remarkably necessary in computer-aided diagnosis.

A bar-selective COSFIRE filter (B-COSFIRE) is highly efficient for bar-shaped structure detection (3). Therefore, it is a novel and valid method for the automatic segmentation of blood vessels. It is based on the Combination of Receptive Field (CORF) computational model of a simple cell in visual cortex (4) and its implementation, called Combination of Shifted Filter Response (COSFIRE) (5). The COSFIRE filter is trainable, meaning it is not predefined in the implementation, but it is determined from a user-specified prototype pattern (3). COSFIRE has the versatility that can be configured to solve many image processing and pattern matching tasks.

In this article, we propose an efficient retinal vessel segmentation method based on the B-COSFIRE filter based on a previous work mentioned in Azzopardi et al. (3). The original method has good time complexity, but its performance is not as satisfactory as we expected. In the proposed method, we have made many attempts, such as employing denoise operation and post-processing operation. The proposed method has achieved a better performance result without losing the nature of good time complexity.

The rest of this article is organized as follows: In Related Works, we examine the existing blood vessel segmentation method and other applications of COSFIRE filters. In Proposed Methodology, we present our method explicitly. In Experimental Results and Analysis, we introduce the datasets used for experiments and reported the experimental results and the comparisons with existing methods. The discussion for future work and conclusion are presented in Findings and Conclusion, respectively.

RELATED WORKS

Due to the importance of vascular segmentation in computer-aided diagnosis, an efficient vessel segmentation algorithm has always been a research hot spot. Existing approaches for retinal blood vessel segmentation in fundus images can be divided into two groups: unsupervised methods, which include matched filtering, vessel tracking, model-based approaches, and morphological processing, and supervised methods, which use feature vectors to train a binary classification model (6–8). Whether the method is supervised or not depends only on whether manual marking information with a priori is used.

Supervised methods use pixel-wise feature vectors with labeled information, where manually segmented images are referred to as the gold standard, to train a classifier that can distinguish between vascular and non-vascular pixels. This kind of method mainly includes the following two steps: form pixel-wise feature vectors by feature extraction methods and learn

a classification model based on vessel and non-vessel training feature vectors (9). Soares et al. (10) reported a segmentation method based on a Bayesian classifier combined with multi-scale analysis for two-dimensional Gabor wavelet transform. Marin et al. (11) proposed a supervised method for retinal vessel segmentation, by applying a multi-layer neural network to classify pixels based on moment-invariant features. Fraz et al. (12) proposed a classification scheme that fuses boosted and bagged decision trees. Aslani et al. (13) presented a supervised method using the random forest classifier, which constructs a rich collection of a 17-dimensional feature vector including B-COSFIRE filter response and trains a random forest classifier to accomplish the segmentation of fundus images. Strisciuglio et al. (14) proposed a method of retinal vessel segmentation by transforming and re-scaling the features composed of the responses of the bank of selected B-COSFIRE filters to train a support vector machine classifier. Zhu et al. (15) presented a supervised ensemble method for segmenting the retinal vessels by extracting a 39-dimensional feature vector to train the extreme learning machine classifier.

Unsupervised methods mainly extract pathological features through linear operation filtering techniques with predefined kernels. Al-Diri et al. (16) proposed an unsupervised method based on the active contour model to achieve retinal vessel measurement and segmentation. Lam et al. (17) presented a multi-concavity modeling approach based on differentiable concavity measure, which can simultaneously process retinal images of two different health states. Azzopardi et al. (3) proposed a method of retinal vessel segmentation based on the COSFIRE approach, called B-COSFIRE filter, by constructing two kinds of the B-COSFIRE filter which are selective for vessel and vessel-ending, respectively. Khan et al. (18) presented an unsupervised method of vasculature segmentation, by applying pixel AND operation between the vessel location map and B-COSFIRE segmentation image. Bahadarkhan et al. (19) proposed a less computational unsupervised automated technique with promising results for the detection of retinal vasculature by using morphological Hessian-based approach and region-based Otsu thresholding. Khan et al. (20) used distinctive preprocessing steps, thresholding techniques, and post-processing steps to enhance and segment the retinal blood vessels. Khan et al. (21) proposed a framework with fast execution and competing outcomes using MISODATA and B-COSFIRE filters to produce better segmentation results.

Generally, supervised methods perform better than other kinds of methods in retinal vessel segmentation, but supervised methods consume a lot of time in the process of classifier training. On the other hand, the advantage of unsupervised learning is that it does not require artificial label information to train the classifier, which makes it more versatile and easier to implement (6, 22). To sum up, a robust method that can have good performance results and does not require much preparation time is necessary for computer-aided diagnosis.

Deep learning has always been a hot topic in the field of computer research. Deep learning can achieve high-quality performance but requires more training time than supervised learning (23, 24). The advantages and disadvantages of deep learning are obvious. Many scholars have attempted using methods of deep learning to segment vessels in retinal images. Melinsca et al. (25) proposed a method using deep neural network to segment retinal vessels. Khalaf et al. (26) proposed a method of retinal vessel segmentation based on convolutional neural networks for deep feature learning. Fu et al. (27) employed deep learning network and fully connected conditional random fields to accomplish retinal vessel segmentation. Deep learning can often achieve better performance than machine learning; however, deep learning requires much training time and better hardware equipment conditions. Yue et al. (28) introduced the multi-scale input layer and dense block to the conventional U-net so that the network can make use of richer spatial context information. Cheng et al. (29) added a dense block to the U-Net network to make each layer's input come from all the previous layer's output, thereby improving the segmentation accuracy of small blood vessels. In order to follow the discussion easily, we summarize the discussed studies in **Table 1**.

The COSFIRE method was proposed by Azzopardi et al. (5), based on the CORF computational model. Due to the fast and accurate nature of COSFIRE, it has received great attention in the field of image processing and pattern recognition. In addition to the application of retinal vascular segmentation as mentioned before, there are some applications based on the COSFIRE filter in other directions. Azzopardi et al. (33) employed descriptors of different shapes based on trainable COSFIRE filters to recognize handwritten digits, detect vascular bifurcations in segmented retinal images in Azzopardi et al. (34), and achieve gender recognition from face images in Azzopardi et al. (35). Gecer et al. (36) proposed a method that can recognize objects with the same shape but different colors, by configuring different COSFIRE filters in different color channels. Guo et al. (37, 38) further developed the COSFIRE method, by configuring the COSFIRE filter with the inhibition mechanism to recognize architectural and electrical symbols and to detect key points and recognize objects.

The aforementioned work has the following problems:

1) Related supervision methods (10–15) have high computational cost and high time cost in the process of model training. Supervised methods need to use a large number of pixel-level data labels for supervised computation, and it consumes much time to produce segmentation results. As shown in **Tables 6**, **7**, the overhead of the relevant supervised methods in the segmentation time is about 1 min.
2) When considering the combined effects of performance and time overhead, some unsupervised (16–21, 30) methods lack efficient application value. Some unsupervised methods have higher time overhead when obtaining higher segmentation performance. While another part of the unsupervised method achieves lower time overhead, the segmentation performance is also reduced. That is to say, these methods cannot guarantee lower time overhead and a better segmentation effect at the same time; in addition, these methods are not versatile and cannot achieve good results in multiple dataset tests.

3) The images that have been processed by binary thresholding are destroyed by noise. Distinguishing the thin vessel from the vessel-like noise is still a challenge (18, 20, 21).

In this article, an improved unsupervised method based on the B-COSFIRE filter is presented. Compared with traditional methods, the proposed method has stronger robustness. The proposed unsupervised method uses image contrast enhancement algorithms and morphological operations and uses the B-COSFIRE filter, which can effectively extract bar-like blood vessels in the fundus image. While improving the effect, it reduces the time overhead. At the same time, our method uses a post-processing algorithm based on connected domains, which can effectively distinguish small connected blood vessel

pixels from vessel-like noise. This proves once again that the proposed method has a great application capability in computer-aided diagnosis.

PROPOSED METHODOLOGY

Vessel segmentation is a basic step in image processing of the fundus image; thus, the process should be fast and efficient. The main idea is taking advantage of the high efficiency of the B-COSFIRE filter and employing other operations that do not need much consumption of time to obtain a better result. **Figure 2** represents a flowchart of our proposed method with main processing steps. **Algorithm 1** shows the implementation steps of our proposed system. The mission of the B-COSFIRE filter is to select all vessels from the fundus image, while the other operation is to enhance vascular features, denoise background noise, and reduce error classification.

Preprocessing

Before employing operations to segment vessels, we used the following operations to improve or enhance the characteristics of blood vessels:

a. Green channel extraction: The green band is extracted from RGB retinal images, and the FOV mask (field of view) image is obtained by thresholding the luminosity plane of the CIELab version of the original RGB image. Previous works by Niemeijer et al. (39), Mendonca et al. (40), Soares et al. (10), and Ricci et al. (41) have demonstrated that the green channel of RGB fundus images can best highlight the difference between blood vessels and background, whereas the red and blue channels show low contrast and are very noisy.
b. Mask produce: The FOV mask is an important tool for determining the ROI in the process of vessel segmentation. Although the DRIVE dataset provides the FOV mask, most other datasets do not. For the sake of versatility of the proposed method, we adopt this method to obtain FOV mask images by shifting the original RGB images to CIELab version and then thresholding the luminosity plane.
c. CLAHE: Next, the contrast-limited adaptive histogram equalization (CLAHE) algorithm is used to enhance images for expanding vessels characteristics. The CLAHE algorithm can effectively limit noise amplification in relatively uniform areas and improve local contrast, which is usually used as a preprocessing step in retinal image analysis research (42).

Segmentation Processing

The proposed segmentation method is based on the feature of the B-COSFIRE filter with the highest correlation to the bar/vessel shape. A B-COSFIRE filter was originally proposed in Azzopardi et al. (3). It takes the responses of a group of difference-of-Gaussians (DoG) filters at certain positions with respect to the center of its area of support as input. In the proposed method, the B-COSFIRE filter has been used for efficiently obtaining vessel-like structures. The B-COSFIRE filter is trainable and is configured to be selective for bar-like structures (3). The term trainable refers to the ability of determining these positions in an automatic configuration process by using a synthetic vessel or vessel-ending image.

The application of the B-COSFIRE filter consists of four main process: Convolution with DoG filters, blurring response, shifting the blurred responses, and estimating a point-wise weighted geometric mean. In the following, we will introduce these steps.

A center-on DoG function with a positive central region and a negative surround denoted by $DoG_\sigma\left(x,\ y\right)$ is given by (3):

$$DoG_\sigma(x,\ y)\overset{\text{def}}{=} \frac{1}{2\pi\sigma^2}\exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) - \frac{1}{2\pi(0.5\sigma)^2}\exp\left(-\frac{x^2+y^2}{2(0.5\sigma)^2}\right) \quad (1)$$

where σ is the standard deviation of the Gaussian function that determines the extent of the surround, 0.5σ is the standard deviation of the inner Gaussian function, and (x, y) represents a pixel location of an image I. The response of a the *DoG* filter $C_\sigma\left(x,\ y\right)$ with a kernel function $DOG_\sigma\left(x-x\prime\ ,\ y\ -y\prime\right)$ is computed by convolution, where $\left(x\prime\ ,\ y\prime\right)$ represents intensity distribution of image I:

$$C_\sigma(x,\ y)\overset{def}{=}|I*DoG_\sigma|^+ \quad (2)$$

where $|\ \cdot\ |^+$ half-wave rectification operation is to suppress (set to 0) the negative values.

In the proposed B-COSFIRE filter (3), every point i is described by a tuple of three parameters $DoG(\sigma_i,\ \rho_i,\ \phi_i)$, where σ_i represents the standard deviation of the *DoG* filter that provides the input, ρ_i and ϕ_i represent the polar coordinates of the B-COSFIRE filter, and a set of three tuples of a B-COSFRE filter is denoted by $S=\ (\sigma_i,\ \rho_i,\ \phi_i|i=\ 1,\ ..,\ n)$, where n stands for the number of considered *DoG* response.

The blurring operation of the *DoG* filter is shown as follows. It allows for some tolerance in the position of the specific points.

$$\sigma'=\sigma_0'+\alpha\rho_i \quad (3)$$

where σ_0' and α are constants.

Each blurred *DoG* response is shifted by a distance ρ_i in the direction opposite to ϕ_i, and they meet at the support center of the B-COSFIRE filter. The blurred and shifted response of a *DoG* filter for each tuple $(\sigma_i,\ \rho_i,\ \phi_i)$ is denoted by $S_{(\sigma_i\ ,\rho_i\ ,\phi_i)}\left(x,\ y\right)$ in set *S*. The *i_th* blurred and shifted *DoG* response is defined as follows:

$$S_{\sigma_i,\rho_i,\phi_i}(x,\ y)\ =\ max_{x',y'}\{C_{\sigma_i}(x-\Delta x_i-x',y-\Delta y_i - y')G_{\sigma_i}(x',\ y')\} \quad (4)$$

where $-3\sigma'\le x',\ y'\le 3\sigma'$.

Last, the output of the B-COSFIRE filter is defined as the weighted geometric mean of all the blurred and shifted DoG response:

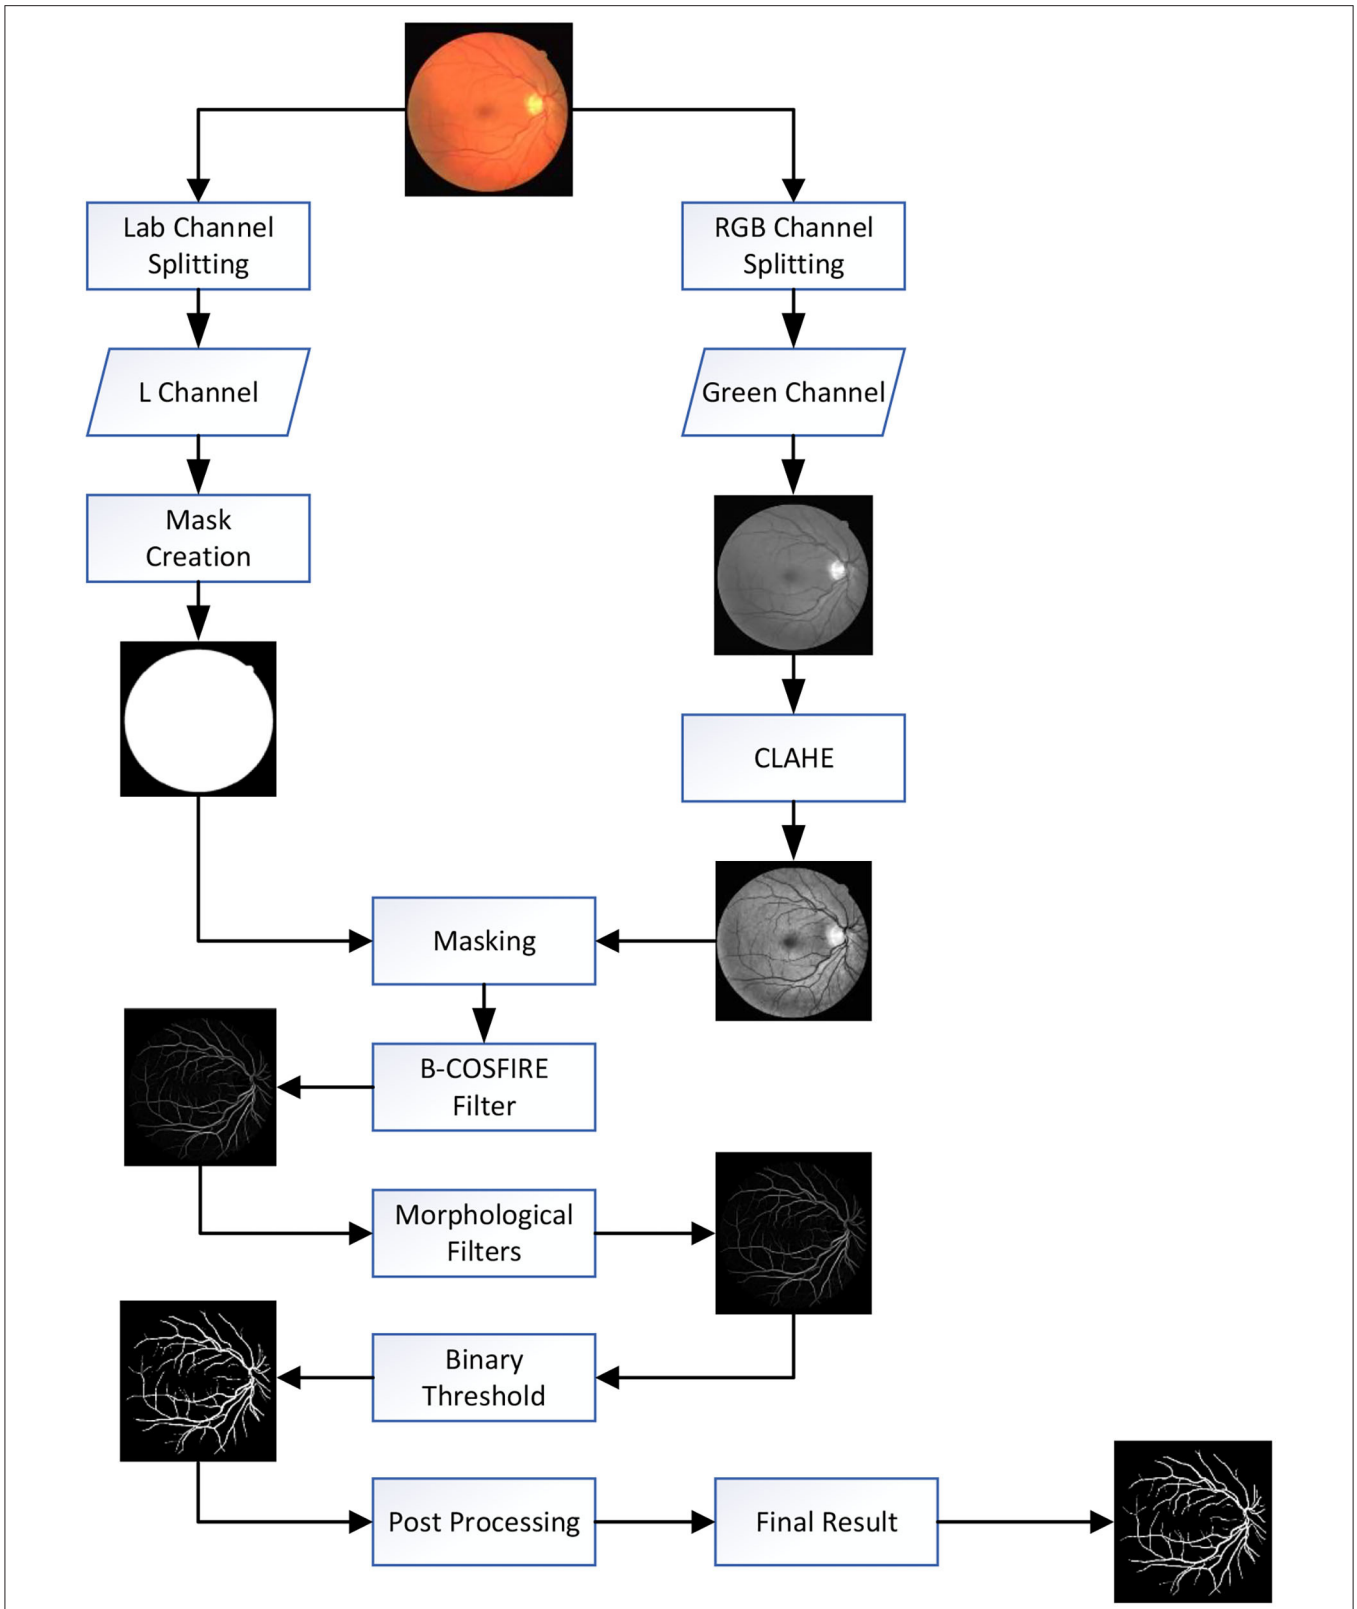

FIGURE 2 | Flowchart of proposed method: first, we using contrast limited adaptive histogram equalization (CLAHE) for contrast enhancement. Second, we threshold the luminance plane of the CIELab version of the original RGB image to produce a mask. Third, we apply the B-COSFIRE filter and morphological filter to detect blood vessels and remove noise. Fourth, the binary threshold was used for vessel segmentation. Finally, unconnected non-vessel pixels are eliminated by post-processing to obtain the final segmentation map.

Algorithm 1 | B-COSFIRE vessel segmentation algorithm.

Input: Original RGB retinal images
Output: Final segmented vessel maps
1 *Step*1:
2 Extract green band image G form Original RGB retinal images.
3 Extract CIELab version image L form Original RGB retinal images.
4 *Step*2
5 Using CLAHE algorithm to green band image G.
6 Thresholding the luminosity plane of L and produce the mask M.
7 *Step*3
8 Perform masking operation on G and M.
9 Produce the input I of the following vessel segmentation operation.
10 *Step*4
11 Applicate B-COSFIRE filter on I and produce I1.
12 *Step*5
13 Perform Morphological filters (top-hat) on I1 and produce I2.
14 *Step*6
15 Operating binary threshold on I2 and produce I3.
16 *Step*7
17 Post processing on I3.
18 Return: Final segmented vessel maps

$$r_S(x,y) \stackrel{def}{=} \left| \left(\prod_{i=1}^{|S|} \left(S_{\sigma_i,\rho_i,\phi_i}(x,y) \right)^{\omega_i} \right)^{\frac{1}{\sum_{i=1}^{|S|}\omega_i}} \right|_t \tag{5}$$

where $\omega_i = exp^{-\frac{\rho_i^2}{2\sigma^2}}$ and $|.|_t$ represent thresholding the response at a fraction $t(0 \leq t \leq 1)$. The equation is an AND-type function that a B-COSFIRE filter achieves as response when all *DoG* filter responses are >0.

Moreover, to achieve multi-orientation selectivity, the number of B-COSFIRE filters is configured by using prototype patterns in different orientations. A new set is created by manipulating the parameter ¦× of each tuple:

$$R_\psi(S) = (\sigma_i,\ \rho_i,\ \phi_i + \psi) | \forall(\sigma_i,\ \rho_i,\ \phi_i) \in S \tag{6}$$

A rotation-tolerant response is achieved by merging the response of B-COSFIRE filters with different orientation preferences and taking the maximum value at each location (x,y):

$$\hat{r}\, S(x,y) \stackrel{def}{=} \max_{\psi \in \Phi} r_{R_\psi(x,y)} \tag{7}$$

The aforementioned operation is an AND-type function that is achieved by the B-COSFIRE filter when all *DoG* filter responses are non-zero. In total, two kinds of the B-COSFIRE filter are configured (3): symmetric B-COSFIRE filter and asymmetric B-COSFIRE filter. One is selective for vessel, and the other is selective for vessel-ending. For more details, refer to Azzopardi et al. (3).

Morphological filters are used to denoise and to reduce the influence of ophthalmic disorders and to extract useful and meaningful information in small regions of images. Combining image subtraction with openings and closings result in top-hat and bottom-hat transformations (15). The role of the two kinds of transformation is the same, making non-uniform backgrounds uniform and enhancing the image contrast. The top-hat transform is used for light objects on a dark background, so it can make characteristics of vessels more apparent in the dark background. We used the top-hat transform to process the response image produced by the B-COSFIRE filter to enhance vessel structures and reduce noise. As a result, during the threshold segmentation operation, more vessel pixels will be correctly classified and noise pixels will decrease.

The top-hat transformation is defined as follows:

$$G = I - I \circ S \tag{8}$$

where I is a gray-scale image, S is a linear structuring element, and $\circ$ is opening operation. The top-hat transformation of I is defined as I minus the opening of I. Opening operation can effectively extract useful information of the background that is the same size of the structuring element so that employing top-hat transformation can relatively obtain uniform front-view information.

In this study, the structuring element is square. We experimentally found that the use of morphological top-hat transformation has less noise and better performance in vessel segmentation.

There are two ways to select threshold processing vessel response images. The first method is selecting a manual threshold for each dataset, as in Azzopardi et al. (3). This method does not need too much processing time, but the result is relatively bad. The second one is called adaptive thresholding, which automatically selects the threshold value for each image, instead of the whole dataset, as in Khan et al. (18). In proposed method, we choose the first method to select threshold standing in the point of quickly and effectively segmenting vessels. There are no significant differences between the results obtained by different methods, but the first method can save as much processing time as we expected.

Post-processing

The images that have been processed by binary thresholding are destroyed by noise. The present results of vessels segmented are far from satisfactory, that is, some vessel pixels are wrongly classified and disappear in the segmentation images. At the same time, many noise points are classified into vessels. So, we consider the post-processing measures to reduce this phenomenon to obtain a better segmentation result.

The adopted post-processing method is based on the connected domain to recover vessels. Specific steps are as follows:

*Step*1. Carry out thinning operation on binary image I_{re} and then the expansion operation with the template of 3 by 3, followed by morphology complement operation so that 0 surround by 1 in the eight neighborhoods is set to 0.

*Step*2. Repeat *Step* 1 to obtain a relatively complete vascular connected domain and the resulting image I_{fin}.
*Step*3. Obtain I_τ by taking the intersection of I_{re} and I_{fin}, then I_{fin} minus I_τ, and obtain connected regions I_{in} which can fill I_{re}.
*Step*4. In the model of the eight neighborhoods, in this study, each connected domain of I_{in} have been used to recover vessels that were denoised. The number of the connected domains before and after the recovering operation have been compared. If reduced, it implies that there are misclassified vascular bifurcations and crossovers in this noise region, and the vascular vessels should be recovered. On the contrary, if it increases, it shows that the noise region is real, and it should not be recovered.
*Step*5. Remove the connected domain that is less than 20 pixels to obtain a better optimized result.

The segmentation results usually consist of some small isolated regions caused by noise, and these regions are sometimes wrongly detected as vessels (18, 20). We used a post-processing method based on connected domains and removed less than or equal to 20 unconnected pixels considered as a non-vessel or a part of the background noise. So the unconnected non-vessel pixel was eliminated, and the thin connected vessel was preserved. After these steps, by identifying and recovering the vascular bifurcations and breakpoints, the continuity and the accuracy of vascular vessels segmentation results were improved. The post-processing operation gives a final resultant binary image.

EXPERIMENTAL RESULTS AND ANALYSIS

In our experiments, the proposed method was evaluated on the publicly available DRIVE database and STARE database. It is worth mentioning that the scarcity of artificial calibration image data is a major obstacle for medical image processing research and development. So, even if the number of images in each database is not big enough, the two databases still occupy a very important position in the field of blood vessel segmentation in fundus images. Since these databases contain ground truth maps manually segmented by different professionals, they have gained popularity in the field of retinal vessel segmentation. Experiments on those two databases also facilitate the comparison of the methods proposed in this article with other methods. Three different measures are used to evaluate the performance. Our experiments were tested with MATLAB in the environment of 2.5 Ghz Intel i5-3210 M CPU and 4 GB memory.

In order to verify the versatility and feasibility of the proposed method, we added a set of experiments, using our method to segment the fundus image in the publicly available CHASEDB1 databases. We used the same three metrics as the aforementioned experiment to evaluate performance. In addition, in order to use a more meaningful measure for the evaluation of the quality of pixel-wise segmentation and to compare with the recent literature to show the effectiveness of our proposed method, the Matthews correlation coefficient (MCC) is introduced (6, 34), the supplementary experiment was tested with MATLAB in the environment of a 2.5 Ghz Intel i5-10300H CPU and 16 GB memory.

Database

The DRIVE database consists of 40 color images taken by a Canon CR5 3CCD camera with a 45○ FOV which are divided into a training set and a test set, each containing 20 images. The size of each image is 768 × 584 pixels, with 8 bits per color channel, and the FOV is circular with 450 pixels in diameter. In the DRIVE database, there is a corresponding mask that delineates the FOV area and the binary vessel segmentation. The images in the test set have been segmented by two human observers, while the images in the training set have been segmented by one observer.

The STARE database consists of 20 color images, and half of the STARE database images contains signs of pathologies. A Topcon TRC-50 fundus camera at 35○ FOV was used to acquire the images. The size of each image is 700 × 605 pixels with 8 bits per color channel, and the FOV in the images is around 650 × 550 pixels. The images in the STARE database have been manually segmented by two different observers.

The CHASEDB1 database consists of 28 color images taken from the eyes of 14 school children. Usually, the first 20 images are used for training, and the remaining eight images are used for testing. The size of each image is 999 × 960 pixels, and the binary field-of-view (FOV) mask and segmentation ground truth are obtained by manual methods.

For the comparability of experimental data, the performance of the proposed method is measured on the test set of the DRIVE database and on the all images of the STARE database and CHASEDB1 database by comparing the automatically generated binary images with the ones that are segmented by the first observer as gold standard.

Evaluation Method

Each resulting binary image was compared with the corresponding gold standard by computing the four performance measurements: true positive (TP) is the number of pixels correctly classified as vessels, false positive (FP) is the number of pixels misclassified as vessels, true negative (TN) is the number of pixels correctly classified as backgrounds, and false negative (FN) is the number of pixels misclassified as backgrounds.

In order to evaluate the performance of our method and compare with state-of-the-art methods, we computed the measures known as accuracy (Acc), sensitivity (Se), and specificity (Sp) in **Table 2**.

The Acc of one image is a fraction of pixels representing the ratio of the total number of correctly classified pixels to the total number of pixels in the image FOV. Se is determined

TABLE 2 | Performance measures of vessel segmentation.

Performance measures	Description
Sensitivity(Se)	TP/(TP+FN)
Specificity(Sp)	TN/(TN+FP)
Accuracy(Acc)	(TP+TN)/(TP+FP+TN+FN)

TABLE 3 | Performance of proposed method (DRIVE).

	Time Consuming(s)	Se	Sp	Acc
Average	9.1852	0.7339	0.9847	0.9604
Maximum	10.1094	0.8455	0.9965	0.9696
Minimum	8.2813	0.5006	0.9737	0.9543

TABLE 4 | Performance of proposed method (STARE).

	Time consuming(s)	Se	Sp	Acc
Average	12.2773	0.8003	0.9705	0.9558
Maximum	15.5938	0.9250	0.9900	0.9764
Minimum	10.7118	0.6426	0.9313	0.9245

by dividing the number of pixels correctly classified as vessel pixels by the total vessel pixels in the manual segmentation; thus, Se denotes the ability of correctly identifying the vessel pixels. Sp is determined by dividing the number of pixels correctly classified as background pixels by the total background pixels in the manual segmentation; thus, Sp reflects the ability to detect non-vessel pixels.

In addition, we evaluated MCC indicators referring to Ricci et al. (41). The MCC (7, 21) is a more appropriate indicator of the accuracy of binary categorization in the case of unbalanced structures. The MCC counting transformation is defined as follows:

$$\mathrm{MCC} = \frac{(\mathrm{TP}/\mathrm{N} - \mathrm{S} \times \mathrm{P})}{\sqrt{\mathrm{P} \times \mathrm{S} \times (1 - \mathrm{S}) \times (1 - \mathrm{p})}} \tag{9}$$

where $\mathrm{N} = \mathrm{TN} + \mathrm{TP} + \mathrm{FN} + \mathrm{FP}$, $\mathrm{S} = (\mathrm{TP} + \mathrm{FN})/\mathrm{N}$ and $\mathrm{P} = (\mathrm{TP} + \mathrm{FP})/\mathrm{N}$.

Performance of the Proposed Method

Because the proposed method does not need to train a classifier, images in the training set of the DRIVE database have not been used. We tested on 20 fundus images from the test set of the DRIVE database. The total segmenting time is about 185 s, while each image takes about 9.19 s. The performance results of retinal vessel segmentation on the DRIVE database are shown in **Table 3**. The average *Acc*, *Se*, and *Sp* of proposed method are 0.9604, 0.7339, and 0.9847, respectively.

For the STARE database, we tested all 20 fundus images since the proposed method does not have to select images to train a classifier. The total segmenting time is about 242 s, while each image takes about 12.28 s. The performance results of retinal vessel segmentation on the STARE database are shown in **Table 4**. The average *Acc*, *Se*, and *Sp* of the proposed method are 0.9558, 0.8003, and 0.9705, respectively.

For the CHASEDB1 database, we tested all 28 fundus images for the same reason that the proposed method does not have to select images to train a classifier. The total segmenting time is about 251 s, while each image takes about 8.96 s. The average Acc, Se, and Sp of the proposed method are 0.9606, 0.6921, and 0.9842, respectively. We still introduced the Matthews correlation coefficient with a score of 0.5886. The performance results of retinal vessels segmentation on the CHASEDB1 database are shown in **Table 5**.

TABLE 5 | Performance of proposed method (CHASEDB1).

	Time consuming(s)	Se	Sp	Acc	MCC
Average	9.3600	0.5921	0.9842	0.9606	0.5886
Maximum	10.4271	0.7864	0.9959	0.9717	0.75710
Minimum	7.7188	0.4959	0.9313	0.9554	0.3970

The proposed method can generate the segmentation map corresponding to the fundus map in a short time, as shown in **Tables 3**–**5**. The processing time for segmenting DRIVE, STARE, and CHASEDB1 fundus map data using our method can reach 8.2318, 10.7188, and 7.7188s, respectively. This shows that the proposed method has real-time feasibility. In addition, our experiments were tested using MATLAB in different environments, and the test results are shown in **Tables 3**–**5**, which shows that our experiments are experimentally feasible.

Step-by-step representation of the proposed framework applied to images of DRIVE, STARE, and CHASEDB1 databases has been depicted in **Figures 3**–**5**, respectively. In the final segmentation result graph, looking closely at the segmentation of the vessel ends, it is obvious that the method used in this study has good effectiveness in distinguishing between vessel-like noise and thin vessels.

Comparative Experiment

We compared the proposed B-COSIRE filter approach with other state-of-the-art methods including supervised methods (the top six methods), unsupervised methods (in the middle), and five methods of deep learning (the last four methods) on DRIVE and STARE databases, respectively. The performance in the term of accuracy, sensitivity, and specificity is tabulated in **Tables 6**, **7**, respectively.

The proposed framework shows the almost highest results on the DRIVE images for supervised, unsupervised, and deep learning methods, with Acc = 0.9604, Se = 0.7339, and Sp = 0.9847. Our proposed technique also showed high efficiency in terms of sensitivity and specificity among all kinds of techniques on the STARE dataset. The accuracy Acc = 0.9558 also shows a great performance among the methods compared.

In the test experiments on DRIVE and STARE datasets, the proposed method consumed much lower time overhead than supervised methods and deep learning methods and also has advantages over some unsupervised methods. In the CHASEDB1 dataset supplementary experiment, we tested 28 fundus images; the total segmentation time was 251 seconds and the average time was 8.96 s, which shows that our time overhead is relatively low. Furthermore, in the experimental phase, our method does not need to use a large number of image annotations for training. This study used three lightweight public datasets but obtained relatively high test performance, as shown in **Tables 6**, **7**. It can

be seen that the proposed method has extremely low overhead on the dataset.

As illustrated before, the proposed unsupervised method is better than other unsupervised methods. The performance of the proposed method is almost the same as that of the supervised methods, although is slightly worse than that of the best performance of deep learning methods. It is important that the proposed method is very efficient, while supervised methods and deep learning methods both consume much time in the process of classifier training. It proves the favorable applicability

of the proposed method, which is fast and effective in the field of computer-aided diagnosis.

FINDINGS

In our work, we proposed a vessel segmentation method of fundus images. In the course of the experiment, we discovered some other issues that may be worth studying. First, in the image preprocessing process, the application of contrast enhancement algorithms to the image will not necessarily lead to better segmentation because some contrast enhancement algorithms will also enhance the background features (44), causing the segmented image to contain more noise. In supplementary experiment, we replaced the CLAHE algorithm in our proposed method with the GLM algorithm referring to Khan et al. (43) and found that the segmentation effect is comparable. We assume this is affected by the environment and data. This is also the direction of our next work. We look forward to making improvements in the method proposed by Khan et al. (43) to further optimize the segmentation method. Second, we found that there are white bars of noise in the blood vessels in part of the binarized images after segmentation. We were able to eliminate it through morphological operations, but the effect still has room for improvement. We believe that we can consider the method of multi-scale input fusion in future.

CONCLUSION

This article presents an improved unsupervised method for vascular segmentation on retinal color fundus images. The proposed method is based on the B-COSFIRE filter, through a series of operations including CLAHE, B-COSFIRE filters, morphological filters, and post-process to obtain final binary vessel images. The method is tested on the public databases, DRIVE, STARE, and CHASEDB1. The proposed method requires little processing time (around 9 s for each image in DRIVE and CHASEDB1, 12 s for each image in STARE) and results in the average accuracy, sensitivity, and specificity of 0.9604, 0.7339, and 0.9847 for DRIVE database; 0.9558, 0.8003, and 0.9705 for STARE database; and 0.6921, 0.9842, and 0.9606 for CHASEDB1 database, respectively. In general, the method used in this study has the following advantages: 1. low time overhead and low dataset overhead, 2. good versatility in the field of computer-aided diagnosis, and 3. a relatively high segmentation effect while maintaining a relatively low time overhead. Through the analysis of the experimental results, it is proved that the method proposed in this article is cutting-edge and effective in the field of retinal blood vessel segmentation. In conclusion, the proposed method can be employed for computer-aided diagnosis, disease screening, and any other circumstances that require fast delineation of blood vessels. It may help us prevent many related diseases, such as diabetes and glaucoma. The direction of our future investigation should be done by configuring specific COSFIRE filters of different shapes with other methods of image processing to solve lesion extraction in retinal fundus images.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://blogs.kingston.ac.uk/retinal/

A home fitness satisfaction model for Chinese residents during the COVID-19 pandemic based on SEM analysis

Dexu Chen[1] and Bin Zhang[2]*

[1]School of Physical Education, Shandong University, Jinan, China, [2]Zhejiang College of Construction, Hangzhou, China

In response to the COVID-19 epidemic, China proposes to take this epidemic as an opportunity to further cultivate residents' healthy living habits and meet their demand for healthy living. Based on relevant research reviews and theoretical analysis, the concept model of home fitness satisfaction for Chinese residents is constructed. The research hypothesis is tested by SEM, and the conceptual model is modified. Finally, the model of home fitness satisfaction for Chinese residents is obtained. The results show that during the epidemic period, Chinese residents' enthusiasm for home fitness remains unchanged, online services provide powerful social support, and the home fitness environment still has an enhanced space.

KEYWORDS

home fitness, satisfaction, healthcare, structural equation, COVID-19

Problem statement

The COVID-19 epidemic broke out all over the world, which imposed a near-total lockdown on citizens in China. In this war without smoke, staying at home played an important part. During the epidemic period, the General Office of the State General Administration of Sport issued the notice on vigorously promoting scientific home-based fitness methods, requiring local sports departments to actively promote scientific home-based fitness and promote people's health with the cooperation of local party committees and governments. Media platforms at all levels and of all kinds have launched home-based fitness programs, and home-based fitness has become a hot topic. The number of search results for "epidemic home-based fitness" and "epidemic home-based exercise" on Baidu was 18,300,000 and 43,900,000, respectively. On the one hand, the outbreak of the epidemic caused great mental trauma for people, forcing people to re-examine the importance of a healthy lifestyle, which helps people make greater progress between the residents of sports and healthy cognition. Meanwhile, the value function of sports fitness to improve people's physical fitness and promote physical and mental health is manifested again in this special period. On the other hand, affected by the epidemic, sports departments at all levels, schools, as well as sports and fitness institutions have launched online fitness courses and sports and fitness live broadcasts. Online fitness clocking and other services have attracted high attention. However, the flash-in-the-pan craze of home fitness is not what society needs. How to continue to promote home

fitness services, how to make more people more convenient to participate in in-home fitness, and how to make use of Internet technology to promote the reform of social sports services are the key points of our further study. Therefore, it is necessary to study home fitness from the perspective of residents' satisfaction to enhance the effect of home fitness, strengthen the weak links of home fitness, and promote the health of the people. Based on the investigation of residents' satisfaction with home fitness and its influencing factors during the epidemic period, this study builds a model of residents' satisfaction and analyzes the influencing factors of residents' home fitness during the epidemic period to improve the effect of home fitness and promote national fitness.

Infection with novel coronavirus pneumonia does not necessarily have a physical impact, as in a latent phase, but if it is in the onset phase, the condition is of varying severity, and the physical impact is different and cannot be generalized. (1) Latency. If the following infection with novel coronavirus pneumonia is found at a latent stage of the condition, usually without obvious symptoms, it may be detected at the time nucleic acid testing is performed, at which point there will be no apparent effect on the body. (2) Onset stage. Less severe: if the new coronavirus pneumonia develops after the onset, the condition is relatively mild and may present with fever, dry cough, and other symptoms, but also with generalized weakness, some people will have symptoms such as runny nose and sneezing, should actively visit the hospital for supportive care, make appropriate exercise to improve their physical fitness, the condition generally recovers slowly and does not cause many effects on their physical health; Severe disease: if the new coronavirus pneumonia continues to progress, is not treated promptly, causes more damage to the body, may present with symptoms such as dysgeusia, anosmia, or even dyspnea, and some may present with hypoxemia, sepsis, shock, or acute respiratory distress syndrome, as well as multiple organ failure.

Model construction and research hypothesis

The study of "satisfaction" is coined in the study of "customer satisfaction" in economic problems. It is generally believed in the academic area that customer satisfaction is the psychological reaction of customers after their needs are met, and it is the evaluation of customers of the product or the degree to which it meets their own needs (1). In the 1990's, the American Customer Satisfaction Model (ACSI) and the European Customer Satisfaction Model (ECSI) were widely adopted, and in the 21st century, the Chinese Customer Satisfaction Model (CCSI) was created (2). The satisfaction model can reveal the relationship between various factors affecting satisfaction, and a structural equation is often used to verify and adjust the satisfaction model (3). Structural equations provide a rigorous scientific procedure for quantitative research of abstract concepts and enable researchers to test research hypotheses through scientific statistical analysis. In this study, structural equations were used to verify and build a satisfaction model, and the residents' satisfaction with home fitness and its influencing factors were included in the same model, and the relationship among multiple factors was processed and analyzed at the same time. Compared with the simple descriptive analysis, the structural equation model can better explain the residents' satisfaction with home fitness and its influencing factors during the epidemic period.

Conceptual model construction

Through comparative analysis, the American customer satisfaction model and China customer satisfaction index (ACSI) model (CSCI) in the "customer perceived value (4), customer expectations, and quality awareness," are closer to the residents' home fitness satisfaction variables such as model building, so this study is based on ACSI and CSCI built during the outbreak of residents' fitness satisfaction model at home. In the model, the intention to exercise at home, the perception of social support, the perception of the environment of exercise at home, the residents' physical literacy, and the gain of exercise at home are the cause variables, while the residents' satisfaction with exercise at home is the target variable. Figure 1 is the conceptual model of residents' satisfaction with home fitness during the epidemic period.

The concept of home fitness intention comes from the survey of residents' sports awareness and draws on the concept of "customer expectation," which is the expectation of customers for the products or services that will happen. The intention of exercising at home during the epidemic period refers to the residents' expectation to participate in the exercise at home during the epidemic period, including the idea of exercising at home, the desire to exercise with others, the expectation to bring pleasure to the exercise at home, and the expectation to release pressure through the exercise at home (5). Previous studies have shown that residents' intention to exercise at home has a positive impact on satisfaction with exercise at home, perception of social support for sports, and perception of support for sports environment. This study assumes that residents' intention to exercise at home has a positive impact on their perception of social support and fitness environment at home, residents' physical literacy, and residents' satisfaction with sports (6).

The perception of social support refers to the quality perception in the customer satisfaction model, which refers to the subjective feelings of customers when they receive products or services. In this study, the perception of social support refers to the support that residents received from the government, schools, media, and other platforms on home fitness during the period of the epidemic, as well as the online or offline

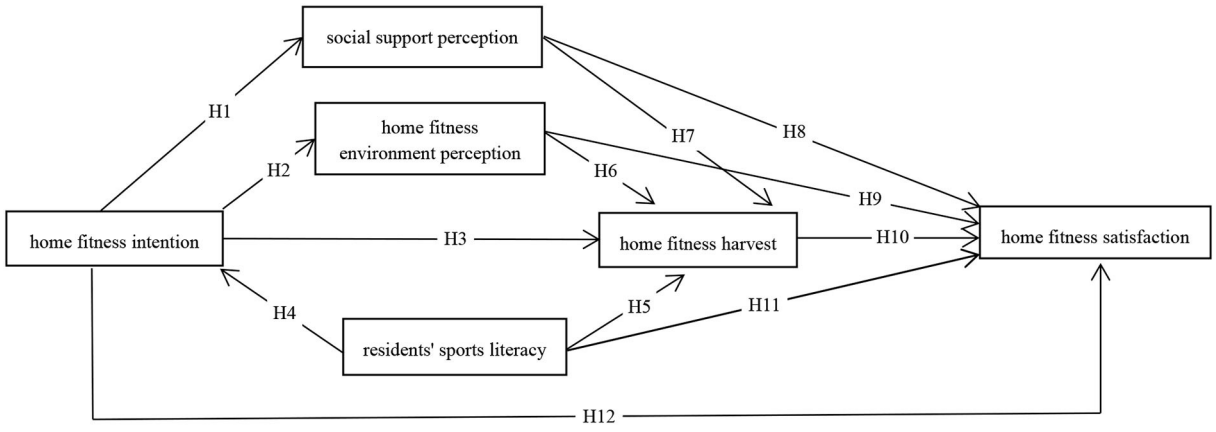

FIGURE 1
Conceptual model of residents' satisfaction with home fitness during the epidemic period.

home fitness guidance from others. This support can be either physical, such as mailing fitness books and equipment, or virtual, such as online guidance and a fitness clock. In this study, the perception of social support was mainly assessed by residents' evaluation of the above support methods and contents. In previous studies, researchers believe that quality perception directly affects customers' evaluation of products or services and is an important factor affecting customer satisfaction. Therefore, this study hypothesizes that the perception of social support has a positive impact on residents' sports harvest and satisfaction with sports (7).

The perception of a home fitness environment also comes from the concept of "quality perception." Home fitness environment perception refers to residents' evaluation of the size and comfort of the home fitness space, the type and quantity of equipment, and the home fitness atmosphere during their stay at home. The home-based fitness environment is the material guarantee for residents to participate in home-based fitness, which affects residents' home-based fitness to a great extent (8). This study hypothesizes that the perception of the home fitness environment plays a positive role in residents' home fitness harvest and satisfaction with home fitness.

Residents' physical literacy mainly refers to the acquired physical skills, physical knowledge, and physical behavior (9). To a certain extent, residents' physical literacy reflects their ability to participate in physical activities as well as their frequency of participation in physical activities. It is also an important indicator of whether residents can carry out independent scientific fitness tests. This study hypothesizes that residents' sports literacy has a positive effect on residents' sports harvest and satisfaction.

The home-based fitness harvest draws the concept of "customer value perception." Customer value perception refers to the overall evaluation of the product or service made by customers based on all their efforts and gains. The perception of home fitness gains refers to the evaluation of residents' physical and psychological feelings after home fitness practice. This feeling can be the physical relaxation of the exercise subject and psychological pleasure but can also be the emotional promotion between individuals participating in the exercise (10). The research believes that the gain of home fitness is an important factor in promoting residents' repeated participation in in-home fitness and that the gain of home fitness affects the satisfaction of home fitness to a large extent. The study hypothesizes that home-based fitness gains have a positive effect on home-based fitness satisfaction (11).

Residents' satisfaction with home fitness refers to residents' satisfaction with the "services" provided by society and their surroundings in the process of participating in in-home fitness. It is the psychological reaction of residents after they are satisfied with home fitness. Residents' satisfaction with home fitness is the target variable of this study. This study hypothesizes that residents' satisfaction with home fitness is affected by their intention to do home fitness, perception of social support, perception of the home fitness environment, residents' physical literacy, and gain from home fitness.

Research objectives and methodology

In this study, 1,052 residents in 30 provinces and cities were surveyed by a self-designed questionnaire, and the data were collected to verify the conceptual model. As the subjects involved in the questionnaire were somewhat affected by the outbreak, the questionnaire channels of this study could only communicate through online channels such as the Internet and telephone (subjects completed questionnaires at home).

TABLE 1 List of demographic characteristics of subjects ($n = 1,052$).

Variable	Frequency	Sample proportion (%)	Variable	Frequency	Sample proportion (%)
Gender			**Professional**		
Male	557	52.9	Cadres of state organs	95	9.0
Female	495	47.1	Employees of enterprises and public institutions	284	27.0
Age (years)			Professional and technical personnel	92	8.7
18–25	275	26.1	Production personnel in agriculture, forestry, and animal husbandry	126	12.0

Postgraduate or above	176	16.7	In the west	254	24.1

This study refers to the statistical table of the 2015 National Population Sample Survey published by the National Bureau of Statistics.

TABLE 2 Consistency analysis of each dimension.

The dimension	Cronbach's α coefficient
Home fitness intention	0.916
Perception of social support	0.904
Home fitness environment perception	0.903
Residents' physical literacy	0.925
Home fitness gains	0.929
Satisfaction with home fitness	0.936

Research objectives

In this study, a total of 1,194 questionnaires were sent out, and 1,052 were effective, with a rate of 88.1%, including 557 males, accounting for 52.7%, and 495 females, accounting for 47.1%. A total of 275 people aged 18–25 years accounted for 26.1%; 266 people aged 26–39 years accounted for 25.3%; 234 people aged 40–49 years accounted for 22.2%; 181 people aged 50–59 years accounted for 17.2%; 96 people aged 60 years and above accounted for 9.1%. A total of 412 people in the eastern part accounted for 39.2%, 386 people in the central part accounted for 36.7%, and 254 people in the western part accounted for 24.1%. There are 259 people with a high school education or less, accounting for 24.6%; 617 people with a college education, accounting for 58.7%; 176 people with a master's degree or above, accounting for 16.7%. In total, 95, or 9%, were cadres of state organs; 284, or 27%, were employees of enterprises and public institutions; 92, or 8.7%, were professional technicians; 126, or 12%, were production workers in agriculture, forestry, and animal husbandry; 74, or 7%, were self-employed; 297, or 28.2%, were students; and 84, or 8%, were others. Table 1 is the list of demographic characteristics of subjects ($n = 1,052$).

Research methodology

The compilation of the questionnaire in this study is based on two aspects: first, by referring to the Chinese citizens' sports awareness survey report (2018) and related literature on the home fitness satisfaction survey, and combining it with the reality of home fitness during the epidemic, the interview outline was formulated [summing up the dimensions of the questionnaire of residents' satisfaction with home fitness during the period of the epidemic (participation degree of home fitness, the content of home fitness, space of home fitness venue, time, and frequency of participation in-home fitness)] and the second is to draw on the American Customer Satisfaction Model (ASCI) and the Chinese Customer Satisfaction Model (CSCI), formulate the contents of the questionnaire through interviews and revisions, and finally, determine the causal variables of the model based on home

TABLE 3 Correlation coefficients of factors in the questionnaire of satisfaction with home fitness and between factors and the total score.

Satisfaction with home fitness	Participation	Content	Floor space	Time and frequency	Total score

fitness intention, social sports culture support perception, home fitness environment perception, home fitness gain, and residents' sports literacy.

Based on the above content, writing the questionnaire on residents' fitness degree of satisfaction and its influencing factors at home during the outbreak of the COVID-19 epidemic, then eight experts reviewed the content of the questionnaire, the first draft of the questionnaire is identified after three rounds of modification, and try on a small scale questionnaire, with the respondents' feedback to the questionnaire of subject setting, the expression made revisions, the rationality and scientificity of the questionnaire are guaranteed. The revised questionnaire is divided into three parts. The first part is the demographic survey of the respondents, including gender, age, occupation, education background, and region. The second part is the questionnaire to assess residents' satisfaction with home fitness during the epidemic period. It uses 5-point Likert scale and sets 16 questions from four aspects, namely, sports participation, content, space, and time-frequency of home fitness. The third part is the questionnaire on influencing factors of residents' satisfaction with home fitness during the epidemic period. The 5-point Likert scale was also used to set 20 questions from five aspects, namely, home fitness intention, perception of social sports culture support, perception of home fitness environment, home fitness gain, and residents' physical literacy. SPSS22.0 and AMOS 24.0 were used for data processing.

Research results and analysis

Conceptual model analysis

Questionnaire reliability analysis mainly tests the consistency of each dimension of the questionnaire, which is generally measured by Cronbach's α coefficient. The consistency analysis of each dimension of this study is shown in Table 2. The Cronbach's α coefficient of each dimension is above 0.903, indicating that the questionnaire has high reliability.

Correlation analysis was used to verify the structural validity of the questionnaire. The correlation coefficient between the factors of residents' satisfaction with home fitness and the total score ranged from 0.756 to 0.914, showing a high correlation, and the correlation coefficient between the factors ranged from 0.677 to 0.826, showing a moderate correlation, as shown in Table 3.

The correlation coefficient between the influencing factors of home fitness satisfaction and the total score ranged from 0.856 to 0.909, showing a high correlation, and the correlation coefficient between each factor ranged from 0.612 to 0.813, showing a moderate correlation, as shown in Table 4. It shows that all factors are correlated with each other and also have some independence, which can reflect the contents of the questionnaire to be investigated. Based on the above analysis results, it can be concluded that the questionnaire on residents' satisfaction with home fitness and its influencing factors during

TABLE 5 The confirmatory factor analysis of residents' satisfaction with the home fitness questionnaire during the epidemic period showed that the fitting degree met the requirements.

Indicators	Squared/df	GFI	RMSEA	RMR	CFI	NFI	NNFI
The judgment standard	<3	>0.9	<0.10	<0.05	>0.9	>0.9	>0.9
Value	2.544	0.959	0.090	0.046	0.928	0.916	0.815

TABLE 6 Fit degree of influencing factors of residents' satisfaction with home fitness during the epidemic period.

Indicators	Squared/df	GFI	RMSEA	RMR	CFI	NFI	NNFI
The judgment standard	<3	>0.9	<0.10	<0.05	>0.9	>0.9	>0.9
Value	3.043	0.917	0.040	0.024	0.905	0.935	0.840

the epidemic period has good structural validity. Table 5 shows the confirmatory factor analysis of residents' satisfaction with the home fitness questionnaire during the epidemic period, showing that the fitting degree met the requirements.

The study conducted correlation analysis on the questionnaire of influencing factors of residents' satisfaction with home fitness during the period of the epidemic, and the fitting degree met the requirements. Table 6 shows the fit degree of influencing factors of residents' satisfaction with home fitness during the epidemic period.

The questionnaire score of each subject, whether in the influence factors, home fitness intention and social support perception problem is higher, shows that the participation of residents at the home had a higher fitness intention at home, and on the outbreak during the social from all walks of life support for home fitness is more satisfied, and home fitness literacy, environmental awareness, and home fitness score are not very high; it shows that there are still a large number of residents who do not have the habit of home exercise and enough fitness knowledge. They are not very satisfied with the overall environment of home exercise, and the gain of home exercise is not very great. Table 7 shows the average value, standard deviation, and average score for each dimension.

As can be seen from the satisfaction questionnaire, residents' sports participation scores are high, content and site equipment scores are average, and time and frequency scores are the lowest. It shows that the vast majority of residents participate in-home fitness but are not very satisfied with the content of exercise, exercise facilities, and equipment, and fail to form regular home fitness behavior.

TABLE 7 The average value, standard deviation, and the average score of each dimension.

The dimension	The average	The standard deviation	The topic split
Home fitness intention	14.88	2.41	3.72
Perception of social support	14.56	2.52	3.64
Home fitness environment perception	12.44	2.56	3.11
Residents' physical literacy	12.72	2.68	3.18
Home fitness gains	12.28	2.41	3.07
Participation	15.12	2.87	3.78
Content	12.56	2.65	3.14
Space equipment	12.16	2.51	3.04
Time and frequency	11.60	2.11	2.90

Hypothesis test

After a reliability and validity test and confirmatory factor analysis, the hypothesized model of this study was verified. After running the software, it is found that the fitting degree of the model does not meet the standard, and the path analysis results show that the hypotheses of H6 and H12 are not valid. Further modifications to the model are needed. Table 8 shows the test of significance of path coefficient of structural variables of a conceptual model.

Model modification

It is assumed that the reason why H6 is not completely true may be that some residents live in a poor home fitness environment, so residents do not feel the obvious impact of the home fitness environment on the harvest of home fitness. But given the outbreak period, residents' activity limitations, difficulty in obtaining normal home health supplies and equipment being unable to create a good fitness environment at home, and parts of the home fitness behavior, such as rope skipping, setting-up exercise, and treadmill running, is

TABLE 8 Test of significance of path coefficient of structural variables of a conceptual model.

TABLE 9 Modified model variable fitting index.

indicators	Squared/df	GFI	RMSEA	RMR	CFI	NFI	NNFI
The judgment standard	<3	>0.9	<0.10	<0.05	>0.9	>0.9	>0.9
Value	2.11	0.906	0.037	0.024	0.923	0.915	0.941

potentially kind of a nuisance, with the risk of affecting the relationship of neighbors. These factors in the particular historical period are likely to lead to a poor fitness environment at home for residents. However, with the end of the epidemic, people's demand for home fitness will be released, and the purchase of sports equipment will be convenient. Thus, residents are more likely to create a relatively satisfactory home fitness environment. Although the verification results indicate that residents' home fitness environment has no significant impact on the gain of home fitness ($P = 0.047$), it still has a certain impact. So, hypothesis H6 was not deleted in the correction.

The initial verification results show that residents' intention of home fitness has a certain negative impact on their satisfaction with home fitness, that is, the stronger the intention is, the lower the satisfaction will be. However, according to the analysis of $P = 0.214$, there is no significant relationship between residents' intention of home fitness and their satisfaction with home fitness. For this reason, delete H12.

In the model modification index, it is found that there is a positive influence on residents' physical literacy and residents' perception of their home fitness environment and social support. To a certain extent, residents' physical literacy reflects the comprehensive level of sports skills, sports habits, and sports knowledge. Residents with higher sports literacy prefer to obtain their required home fitness skills from various channels, which would create a good home fitness environment, and people with higher sports literacy usually have purchased a certain amount of home fitness equipment. Therefore, this study believes that residents' physical literacy has a positive impact on residents' perception of the home fitness environment and social support. So, hypotheses H13

and H14 are added. Figure 2 shows the modified model of residents' satisfaction with home fitness. In summary, one hypothesis H12 is removed and two hypotheses H13 and H14 are added.

After revision and re-examination, the model fitting degree index meets the standard, which indicates that the model is valid and has the significance of practical analysis. Finally, the satisfaction model of residents' home fitness is shown in Figure 3 (Table 9).

Table 10 shows the path relationships of each factor. The results show that hypotheses H1, H2, H3, H4, H5, H6, H7, H8, H9, H10, H11, H13, and H14 are valid, but H6 is not supported. Since H6 has been explained, H12 is finally deleted and H13 and H14 are added.

Discussion

This study validated the satisfaction model of home fitness with structural equations and revealed the relationships among the intention of home fitness, perceived social support, perceived environment of home fitness, a gain of home fitness, residents' physical literacy, and satisfaction with home fitness. Findings (1) During the period of the epidemic at home, residents' enthusiasm for home fitness remained unchanged, online services provided strong social support, and the home fitness environment had a large room for improvement. Some residents failed to develop regular home fitness habits. During the outbreak, the sedentary lifestyle at home and the external pressure from the outbreak made the residents realize the importance of fitness and physical and mental health. Plenty of people are actively involved in home fitness, and at all levels of government, schools, media, sports departments, and service agencies have launched home fitness programs. In addition, pictures and text, video, and broadcast ways to promote fitness at home have been achieved successfully, but residents' home fitness environment still needs to be improved (12). Residents' participation degree in home fitness is high, but the time and frequency of participation are not satisfactory, which indicates that a large number of residents do not develop the habit of home fitness. (2) The perception of social support and home fitness environment have a positive impact on residents' home fitness harvest and satisfaction with home fitness. During the epidemic period, home fitness gained unprecedented social support. Professors and doctoral supervisors went online to popularize fitness knowledge, and physical education teachers became "18-line anchors," while handsome men and women from various sports service agencies opened online live-streaming fitness courses. People are creative and use everyday objects to create a fitness environment at home. For example, rice bags can be used instead of kettlebells, balloons can be used as air volleys, and tables can be used as table tennis tables (13). The more social support residents get, the better the home fitness environment will be; the more residents gain from home fitness, the higher their satisfaction with home fitness will be. (3) Residents' physical literacy directly affects residents' intention to exercise at home, perception of the environment of exercise at home, perception of social support, the harvest of exercise at home, and satisfaction with exercise at home (14). To a great extent, the level of physical literacy determines the size of a person's scientific fitness ability. The study found that physical literacy had a positive impact on the intention to exercise at home, the perception of social support, the perception of the environment of exercise at home, the harvest of exercise at home, and the satisfaction with exercise at home. The higher the sports quality, the more they can understand the benefits of physical fitness; the more people gain the benefits of physical fitness, the higher the loyalty to physical exercise will be; and good sports attainments can help to have a better channel to gain fitness knowledge, choose to science for their own home, and know how to make and use their living environment to create a satisfied and comfortable fitness environment at home with satisfaction.

According to the results of this study, during the outbreak of residents at home, the satisfaction degree of fitness is not high, especially the social support score with home fitness environment is not very outstanding. The major cause is that, on the one hand, physical sports consumption has been affected by the epidemic, which to a certain extent causes some residents to be unsatisfied with the exercise environment at home. However, after the end of the epidemic, physical sports consumption is expected to peak, especially home fitness equipment consumption. Persistence is the most important thing in sports and fitness. Although more people participated in the in-home exercise, the time and frequency of the exercise do not meet the expectations. First, the communication and guidance methods of home exercise content have been affected to some extent in the epidemic, and home exercise can only be promoted through offline channels such as the Internet and TV. Second, the content and form of home fitness are limited to a certain extent, which makes it difficult for some providers of home fitness content to find suitable shooting sites and filming equipment, and effectively organize filming personnel and logistics support personnel. Moreover, with the fierce outbreak of the epidemic, the time for shooting, organizing, and planning is relatively limited. Finally, such a large fitness activity at home is the first time to appear, so it takes time to get into the habit of home fitness. And scenes, space, during the outbreak of the above factors are affected by a certain, so residents fitness time and frequency are not high also understandable. It is believed that after the outbreak, with the recovery of the social order and continuous improvement of the high-quality fitness services, content at home and satisfaction with fitness at home will increase.

The emergence of the epidemic has forced departments at all levels, schools, sports enterprises, sports institutions, and others to think about solutions to home fitness. The importance

Modified model of residents' satisfaction with home fitness.

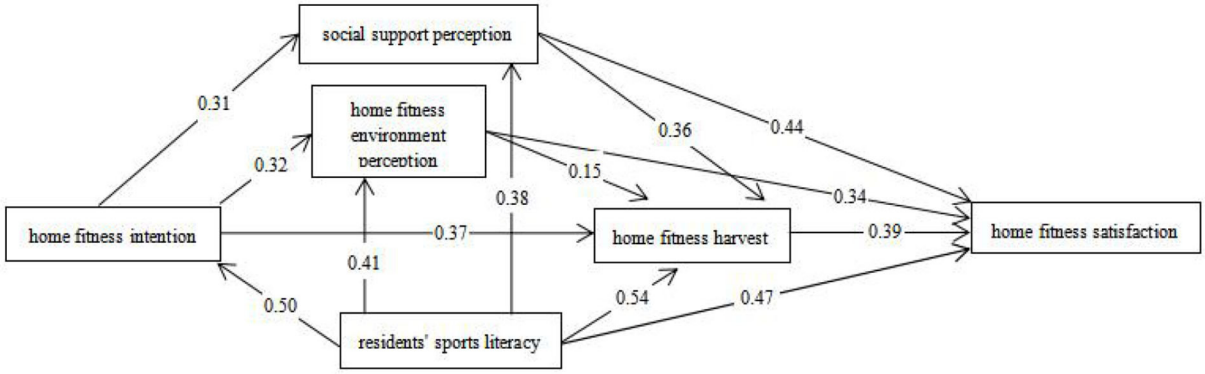

FIGURE 3
Satisfaction model of residents' home fitness.

of home fitness has received unprecedented attention from the whole society. Affected by various isolations and restrictions during the epidemic, the emerging intelligent fitness scenes and equipment have attracted much attention. In the future, home-based fitness will be characterized by diversification, intelligence, individualization, and entertainment. Internet, big data, 5G, and cloud technology will play an important role in the change. The outbreak of the COVID-19 epidemic is not only a heavy blow for the sports fitness service industry and equipment manufacturing industry but also an opportunity for reform. The outbreak will deeply affect people's lifestyles. Sports service departments should speed up the use of innovative technologies to build a new national fitness service platform and promote the upgrading and improvement of national fitness services.

Sports service departments should innovate their approaches to sports service, adopt the combination of online and offline approaches, and vigorously promote the establishment of digital and intelligent home fitness service mechanisms. Change the way of work; gradually change from offline to offline and online combination; gradually expand the path of sports and fitness services based on grassroots, community, family, and cooperation; deepen technological innovation; further, increase the guarantee of home fitness service funds; and build and constantly improve the home fitness service mechanism.

Conclusion

The sudden epidemic has caused great trauma to the mental health of people, especially those in the worst-hit areas and medical workers. In this period, sports have played a unique and irreplaceable role in regulating the psychological health of people. Electronic publications such as home fitness manuals have a calming and soothing effect. The square cabin hospital, transformed from the stadium, also played a significant role in the fight against the epidemic. After the end of the epidemic, residents' sports consumption will usher in a new upsurge, and

the upstream and downstream of the sports industry chain will absorb a large number of workers, which has played a positive role in social stability. At present, it is a critical period for China to realize sports power and build a healthier China. The outbreak makes people and the government realize the importance of physical fitness, which provides opportunities to discover and meet the needs of residents' sports fitness. The outbreak is also a good time to improve the public's sports attainments. Home exercise cannot rely only on the spontaneous behavior of the individual. Each department should better seize the opportunity to vigorously promote the national fitness and healthy life concept. At the same time, scientific knowledge of fitness should be publicized and actively encourage residents to form the habit of lifelong exercise, thus creating a fitness atmosphere as well as comprehensively improving the sports literacy of people.
