About Frontiers

Frontiers is more than just an open access publisher of scholarly articles: it is a pioneering approach to the world of academia, radically improving the way scholarly research is managed. The grand vision of Frontiers is a world where all people have an equal opportunity to seek, share and generate knowledge. Frontiers provides immediate and permanent online open access to all its publications, but this alone is not enough to realize our grand goals.

Frontiers journal series

The Frontiers journal series is a multi-tier and interdisciplinary set of open-access, online journals, promising a paradigm shift from the current review, selection and dissemination processes in academic publishing. All Frontiers journals are driven by researchers for researchers; therefore, they constitute a service to the scholarly community. At the same time, the *Frontiers journal series* operates on a revolutionary invention, the tiered publishing system, initially addressing specific communities of scholars, and gradually climbing up to broader public understanding, thus serving the interests of the lay society, too.

Dedication to quality

Each Frontiers article is a landmark of the highest quality, thanks to genuinely collaborative interactions between authors and review editors, who include some of the world's best academicians. Research must be certified by peers before entering a stream of knowledge that may eventually reach the public - and shape society; therefore, Frontiers only applies the most rigorous and unbiased reviews. Frontiers revolutionizes research publishing by freely delivering the most outstanding research, evaluated with no bias from both the academic and social point of view. By applying the most advanced information technologies, Frontiers is catapulting scholarly publishing into a new generation.

What are Frontiers Research Topics?

Frontiers Research Topics are very popular trademarks of the *Frontiers journals series*: they are collections of at least ten articles, all centered on a particular subject. With their unique mix of varied contributions from Original Research to Review Articles, Frontiers Research Topics unify the most influential researchers, the latest key findings and historical advances in a hot research area.

Find out more on how to host your own Frontiers Research Topic or contribute to one as an author by contacting the Frontiers editorial office: frontiersin.org/about/contact

Big data analytics for smart healthcare applications, 2nd edition

Topic editors

Celestine Iwendi — School of Creative Technologies University of Bolton, United Kingdom

Thippa Reddy Gadekallu — Department of Electrical and Computer Engineering, Lebanese American University, Lebanon

Ali Kashif Bashir — Manchester Metropolitan University, United Kingdom

Citation

Iwendi, C., Gadekallu, T. R., Bashir, A. K., eds. (2025). *Big data analytics for smart healthcare applications, 2nd edition*. Lausanne: Frontiers Media SA. doi: 10.3389/978-2-8325-7275-7

Publisher's note: This is a 2nd edition due to an article retraction.

Table of contents

14 Performance Evaluation of Regression Models for the Prediction of the COVID-19 Reproduction Rate
Jayakumar Kaliappan, Kathiravan Srinivasan, Saeed Mian Qaisar, Karpagam Sundararajan, Chuan-Yu Chang and Suganthan C

26 Blockchain-Secured Recommender System for Special Need Patients Using Deep Learning
Eric Appiah Mantey, Conghua Zhou, Joseph Henry Anajemba, Izuchukwu M. Okpalaoguchi and Onyeachonam Dominic-Mario Chiadika

38 Recurrent Neural Network and Reinforcement Learning Model for COVID-19 Prediction
R. Lakshmana Kumar, Firoz Khan, Sadia Din, Shahab S. Band, Amir Mosavi and Ebuka Ibeke

50 A Predictive and Preventive Model for Onset of Alzheimer's Disease
Udit Singhania, Balakrushna Tripathy, Mohammad Kamrul Hasan, Noble C. Anumbe, Dabiah Alboaneen, Fatima Rayan Awad Ahmed, Thowiba E. Ahmed and Manasik M. Mohamed Nour

62 Fischer Linear Discrimination and Quadratic Discrimination Analysis–Based Data Mining Technique for Internet of Things Framework for Healthcare
Mohammad Kamrul Hasan, Taher M. Ghazal, Ali Alkhalifah, Khairul Azmi Abu Bakar, Alireza Omidvar, Nazmus S. Nafi and Johnson I. Agbinya

80 A Machine Learning Model for Accurate Prediction of Sepsis in ICU Patients
Dong Wang, Jinbo Li, Yali Sun, Xianfei Ding, Xiaojuan Zhang, Shaohua Liu, Bing Han, Haixu Wang, Xiaoguang Duan and Tongwen Sun

88 Smart Cardiac Framework for an Early Detection of Cardiac Arrest Condition and Risk
Apeksha Shah, Swati Ahirrao, Sharnil Pandya, Ketan Kotecha and Suresh Rathod

106 Deep Learning-based Sentiment Analysis and Topic Modeling on Tourism During Covid-19 Pandemic
Ram Krishn Mishra, Siddhaling Urolagin, J. Angel Arul Jothi, Ashwin Sanjay Neogi and Nishad Nawaz

120 Forecasting Dengue Hotspots Associated With Variation in Meteorological Parameters Using Regression and Time Series Models
Seema Patil and Sharnil Pandya

136 COVIDSAVIOR: A Novel Sensor-Fusion and Deep Learning Based Framework for Virus Outbreaks
Sharnil Pandya, Anirban Sur and Nitin Solke

149 A Comprehensive Review on the Optical Micro-Electromechanical Sensors for the Biomedical Application
Anup M. Upadhyaya, Mohammad Kamrul Hasan, S. Abdel-Khalek, Rosilah Hassan, Maneesh C. Srivastava, Preeta Sharan, Shayla Islam, Asma Mohammed Elbashir Saad and Nguyen Vo

177 NextGen Public Health Surveillance and the Internet of Things (IoT)
Kirti Sundar Sahu, Shannon E. Majowicz, Joel A. Dubin and Plinio Pelegrini Morita

186 Trustworthy Intrusion Detection in E-Healthcare Systems
Faiza Akram, Dongsheng Liu, Peibiao Zhao, Natalia Kryvinska, Sidra Abbas and Muhammad Rizwan

196 Neural Network Based Mental Depression Identification and Sentiments Classification Technique From Speech Signals: A COVID-19 Focused Pandemic Study
Syed Thouheed Ahmed, Dollar Konjengbam Singh, Syed Muzamil Basha, Emad Abouel Nasr, Ali K. Kamrani and Mohamed K. Aboudaif

205 Ontology-Enabled Emotional Sentiment Analysis on COVID-19 Pandemic-Related Twitter Streams
Senthil Kumar Narayanasamy, Kathiravan Srinivasan, Saeed Mian Qaisar and Chuan-Yu Chang

220 Machine Learning Applications for the Prediction of Bone Cement Leakage in Percutaneous Vertebroplasty
Wenle Li, Jiaming Wang, Wencai Liu, Chan Xu, Wanying Li, Kai Zhang, Shibin Su, Rong Li, Zhaohui Hu, Qiang Liu, Ruogu Lu and Chengliang Yin

228 An Explainable Intelligence Driven Query Prioritization Using Balanced Decision Tree Approach for Multi-Level Psychological Disorders Assessment
Sushruta Mishra, Hrudaya Kumar Tripathy, Hiren Kumar Thakkar, Deepak Garg, Ketan Kotecha and Sharnil Pandya

254 Development and Internal Validation of a Nomogram to Predict Mortality During the ICU Stay of Thoracic Fracture Patients Without Neurological Compromise: An Analysis of the MIMIC-III Clinical Database
Haosheng Wang, Yangyang Ou, Tingting Fan, Jianwu Zhao, Mingyang Kang, Rongpeng Dong and Yang Qu

265 Hybrid Deep Neural Network for Handling Data Imbalance in Precursor MicroRNA
Elakkiya R., Deepak Kumar Jain, Ketan Kotecha, Sharnil Pandya, Sai Siddhartha Reddy, Rajalakshmi E., Vijayakumar Varadarajan, Aniket Mahanti and Subramaniyaswamy V

277 Machine Learning Assisted Cervical Cancer Detection
Mavra Mehmood, Muhammad Rizwan, Michal Gregus ml and Sidra Abbas

291 Detecting COVID-19-Related Fake News Using Feature Extraction
Suleman Khan, Saqib Hakak, N. Deepa, B. Prabadevi, Kapal Dev and Silvia Trelova

300 Analysis of Tracheobronchial Diverticula Based on Semantic Segmentation of CT Images *via* the Dual-Channel Attention Network
Maoyi Zhang, Changqing Ding and Shuli Guo

313 The Construction and Development of a Clinical Prediction Model to Assess Lymph Node Metastases in Osteosarcoma
Wenle Li, Shengtao Dong, Bing Wang, Haosheng Wang, Chan Xu, Kai Zhang, Wanying Li, Zhaohui Hu, Xiaoping Li, Qiang Liu, Rilige Wu and Chengliang Yin

323 A Web-Based Prediction Model for Overall Survival of Elderly Patients With Malignant Bone Tumors: A Population-Based Study
Jie Tang, JinKui Wang and Xiudan Pan

335 Global Trends and Hotspots in Research on Rehabilitation Robots: A Bibliometric Analysis From 2010 to 2020
Xiali Xue, Xinwei Yang, Zhongyi Deng, Huan Tu, Dezhi Kong, Ning Li and Fan Xu

352 A Hybrid Framework for Intrusion Detection in Healthcare Systems Using Deep Learning
M. Akshay Kumaar, Duraimurugan Samiayya, P. M. Durai Raj Vincent, Kathiravan Srinivasan, Chuan-Yu Chang and Harish Ganesh

370 An Artificial Intelligence Approach Toward Food Spoilage Detection and Analysis
Ekta Sonwani, Urvashi Bansal, Roobaea Alroobaea, Abdullah M. Baqasah and Mustapha Hedabou

383 A Web-Based Prediction Model for Cancer-Specific Survival of Elderly Patients With Hypopharyngeal Squamous Cell Carcinomas: A Population-Based Study
JinKui Wang, XiaoZhu Liu, Jie Tang, Qingquan Zhang and Yuanyang Zhao

394 COVID-19 Related Sentiment Analysis Using State-of-the-Art Machine Learning and Deep Learning Techniques
Zunera Jalil, Ahmed Abbasi, Abdul Rehman Javed, Muhammad Badruddin Khan, Mozaherul Hoque Abul Hasanat, Khalid Mahmood Malik and Abdul Khader Jilani Saudagar

408 A Recommendation System Based on AI for Storing Block Data in the Electronic Health Repository
Vinodhini Mani, C. Kavitha, Shahab S. Band, Amir Mosavi, Paul Hollins and Selvashankar Palanisamy

420 An Empirical Model to Predict the Diabetic Positive Using Stacked Ensemble Approach
Sivashankari R., Sudha M., Mohammad Kamrul Hasan, Rashid A. Saeed, Suliman A. Alsuhibany and Sayed Abdel-Khalek

433 An Artificial Intelligence Approach for Expurgating Edible and Non-Edible Items
Dilip Kumar, Urvashi Bansal, Roobaea S. Alroobaea, Abdullah M. Baqasah and Mustapha Hedabou

446 Development and Validation of a Nomogram to Predict Distant Metastasis in Elderly Patients With Renal Cell Carcinoma
Jinkui Wang, Chenghao Zhanghuang, Xiaojun Tan, Tao Mi, Jiayan Liu, Liming Jin, Mujie Li, Zhaoxia Zhang and Dawei He

458 A Nomogram for Predicting Cancer-Specific Survival of Osteosarcoma and Ewing's Sarcoma in Children: A SEER Database Analysis
Jinkui Wang, Chenghao Zhanghuang, Xiaojun Tan, Tao Mi, Jiayan Liu, Liming Jin, Mujie Li, Zhaoxia Zhang and Dawei He

470 Evaluation of Neuro Images for the Diagnosis of Alzheimer's Disease Using Deep Learning Neural Network
Ahila A, Poongodi M, Mounir Hamdi, Sami Bourouis, Kulhanek Rastislav and Faizaan Mohmed

480 Energy Expenditure Estimation of Tabata by Combining Acceleration and Heart Rate
Yiping Yan and Qingguo Chen

493 A Novel Extra Tree Ensemble Optimized DL Framework (ETEODL) for Early Detection of Diabetes
Monika Arya, Hanumat Sastry G, Anand Motwani, Sunil Kumar and Atef Zaguia

506 Development and Validation of a Competitive Risk Model in Elderly Patients With Chromophobe Cell Renal Carcinoma: A Population-Based Study
Jinkui Wang, Chenghao Zhanghuang, Xiaojun Tan, Tao Mi, Jiayan Liu, Liming Jin, Mujie Li, Zhaoxia Zhang and Dawei He

516 Development and Validation of a Nomogram to Predict Cancer-Specific Survival for Middle-Aged Patients With Early-Stage Hepatocellular Carcinoma
Chong Wen, Jie Tang and Hao Luo

526 Early-Stage Alzheimer's Disease Prediction Using Machine Learning Models
C. Kavitha, Vinodhini Mani, S. R. Srividhya, Osamah Ibrahim Khalaf and Carlos Andrés Tavera Romero

539 A Multi-Agent Formalism Based on Contextual Defeasible Logic for Healthcare Systems
Salwa Muhammad Akhtar, Makia Nazir, Kiran Saleem, Rana Zeeshan Ahmad, Abdul Rehman Javed, Shahab S. Band and Amir Mosavi

553 COVID-19 Identification System Using Transfer Learning Technique With Mobile-NetV2 and Chest X-Ray Images
Mahmoud Ragab, Samah Alshehri, Gamil Abdel Azim, Hibah M. Aldawsari, Adeeb Noor, Jaber Alyami and S. Abdel-khalek

568 Evaluation of the Predictors for Unfavorable Clinical Outcomes of Degenerative Lumbar Spondylolisthesis After Lumbar Interbody Fusion Using Machine Learning
Shengtao Dong, Yinghui Zhu, Hua Yang, Ningyu Tang, Guangyi Huang, Jie Li and Kang Tian

579 Improving Alzheimer's Disease Detection for Speech Based on Feature Purification Network
Ning Liu, Zhenming Yuan and Qingfeng Tang

588 A Web-Based Prediction Model for Cancer-Specific Survival of Elderly Patients With Clear Cell Renal Cell Carcinoma: A Population-Based Study
Chenghao Zhanghuang, Jinkui Wang, Zhaoxia Zhang, Liming Jin, Xiaojun Tan, Tao Mi, Jiayan Liu, Mujie Li and Dawei He

599 Cognitive Impairment of Patient With Neurological Cerebrovascular Disease Using the Artificial Intelligence Technology Guided by MRI
Lifang Zhang, Yanran Li, Lin Bian, Qingrong Luo, Xiaoxi Zhang and Bing Zhao

613 A Decision Support System for Diagnosing Diabetes Using Deep Neural Network
Osama Rabie, Daniyal Alghazzawi, Junaid Asghar, Furqan Khan Saddozai and Muhammad Zubair Asghar

626 Retinal Vessel Extraction *via* Assisted Multi-Channel Feature Map and U-Net
Surbhi Bhatia, Shadab Alam, Mohammed Shuaib, Mohammed Hameed Alhameed, Fathe Jeribi and Razan Ibrahim Alsuwailem

639 Classification of Non-Functional Requirements From IoT Oriented Healthcare Requirement Document
Iqra Khurshid, Salma Imtiaz, Wadii Boulila, Zahid Khan, Almas Abbasi, Abdul Rehman Javed and Zunera Jalil

653 Analysis of Factors Affecting Cranial Nerve Function of Patients With Vascular Mild Cognitive Impairment Through Functional Magnetic Resonance Imaging Under Artificial Intelligence Environment
Lifang Zhang, Yanran Li, Lin Bian, Qingrong Luo, Xiaoxi Zhang and Bing Zhao

662 A Study of Family Process Factors of Social Anxiety on the Internet Based on Big Data—Take Guangxi University Students as an Example
Dexu Bi

669 The Text Mining Technique Applied to the Analysis of Health Interventions to Combat Congenital Syphilis in Brazil: The Case of the "Syphilis No!" Project
Marcella A. da Rocha, Marquiony M. dos Santos, Raphael S. Fontes, Andréa S. P. de Melo, Aliete Cunha-Oliveira, Angélica E. Miranda, Carlos A. P. de Oliveira, Hugo Gonçalo Oliveira, Cristine M. G. Gusmão, Thaísa G. F. M. S. Lima, Rafael Pinto, Daniele M. S. Barros and Ricardo A. de M. Valentim

688 An Augmented Artificial Intelligence Approach for Chronic Diseases Prediction
Junaid Rashid, Saba Batool, Jungeun Kim, Muhammad Wasif Nisar, Amir Hussain, Sapna Juneja and Riti Kushwaha

708 A Classification Algorithm-Based Hybrid Diabetes Prediction Model
Michael Onyema Edeh, Osamah Ibrahim Khalaf, Carlos Andrés Tavera, Sofiane Tayeb, Samir Ghouali, Ghaida Muttashar Abdulsahib, Nneka Ernestina Richard-Nnabu and AbdRahmane Louni

715 Identification of a Four-Gene Metabolic Signature to Evaluate the Prognosis of Colon Adenocarcinoma Patients
Yang Zheng, Rilige Wu, Ximo Wang and Chengliang Yin

728 Deep Data Analysis-Based Agricultural Products Management for Smart Public Healthcare
Wenjing Yan, Zesheng Zhang, Qingchuan Zhang, Ganggang Zhang, Qiaozhi Hua and Qiao Li

737 Medical Image Segmentation Algorithm for Three-Dimensional Multimodal Using Deep Reinforcement Learning and Big Data Analytics
Weiwei Gao, Xiaofeng Li, Yanwei Wang and Yingjie Cai

746 Decision Support System for Predicting Survivability of Hepatitis Patients
Fahad R. Albogamy, Junaid Asghar, Fazli Subhan, Muhammad Zubair Asghar, Mabrook S. Al-Rakhami, Aurangzeb Khan, Haidawati Mohamad Nasir, Mohd Khairil Rahmat, Muhammad Mansoor Alam, Adidah Lajis and Mazliham Mohd Su'ud

761 Multichannel DenseNet Architecture for Classification of Mammographic Breast Density for Breast Cancer Detection
Shivaji D. Pawar, Kamal K. Sharma, Suhas G. Sapate, Geetanjali Y. Yadav, Roobaea Alroobaea, Sabah M. Alzahrani and Mustapha Hedabou

774 Artificial Intelligence-Based Ensemble Learning Model for Prediction of Hepatitis C Disease
Michael Onyema Edeh, Surjeet Dalal, Imed Ben Dhaou, Charles Chuka Agubosim, Chukwudum Collins Umoke, Nneka Ernestina Richard-Nnabu and Neeraj Dahiya

787 Testing the Stochastic Convergence of Ecological Indicators in BRICS in the Perspective of Public Health
Jinshun Wu

809 Application of Smart Healthcare in Comparative Analysis of Effect of Early External Fixator and Plate Internal Fixation Treatment on Postoperative Complications and Lower Limb Function Recovery of Patients With Unstable Pelvic Fracture
Hongwei Zhang, Fang Sun and Yao Li

817 Analyzing the Effect of People Utilizing Mobile Technology to Make Banking Services More Accessible
Jiale Zhu and Manyi Wang

826 The Mediating Role of New Media Engagement in This Digital Age
Zhang Yujie, Megat Al Imran Yasin, Syed Agil Bin Shekh Alsagoff and Ang Lay Hoon

835 Financial Budgets of Technology-Based SMEs From the Perspective of Sustainability and Big Data
Guobiao Zhang and Tao Wang

844 Integrated Blockchain-Deep Learning Approach for Analyzing the Electronic Health Records Recommender System
Eric Appiah Mantey, Conghua Zhou, S. R. Srividhya, Sanjiv Kumar Jain and B. Sundaravadivazhagan

854 Effect of Network-Based Positive Psychological Nursing Model Combined With Elemene Injection on Negative Emotions, Immune Function and Quality of Life in Lung Cancer Patients Undergoing Chemotherapy in the Era of Big Data
Shilu Yang, Lijuan Zheng, Yan Sun and Zhuoyun Li

861 Research on Diagnosis and Management of Postgraduates Mental Health Status Based on BP Neural Network
Jiangning Xie

869 Social Intervention and Governance of Youth School Bullying—Based on Computer Medical Data Analysis
Jiahui Zhao

881 The Relationship Between Adjustment and Mental Health of Chinese Freshmen: The Mediating Effect of Security and the Moderating Effect of Gender
Liu Cao

887 Deep Conviction Systems for Biomedical Applications Using Intuiting Procedures With Cross Point Approach
Hariprasath Manoharan, Shitharth Selvarajan, Ayman Yafoz, Hassan A. Alterazi, Mueen Uddin, Chin-Ling Chen and Chih-Ming Wu

901 A Visualized Dynamic Prediction Model for Overall Survival in Elderly Patients With Pancreatic Cancer for Smart Medical Services
Jiang Zhong, XingShu Liao, Shuang Peng, Junyi Cao, Yue Liu, Chunyang Liu, Ju Qiu, Xiaoyan Guan, Yang Zhang, Xiaozhu Liu and Shengxian Peng

914 Analysis of the Impacts on the Psychological Changes of Chinese Returning College Students After the Outbreak of the 2019 Coronavirus Disease
Yingying Xue, Kwak Han Pyong, Sae Sook Oh, Yingying Tao and Taofeng Liu

923 Application Research of Public Art in the Design of Old People's Rehabilitation Space Based on Virtual Information Interaction Platform From the Perspective of Developing Economies
Shaoqing Zhang

932 A Prognostic Model for Colon Adenocarcinoma Patients Based on Ten Amino Acid Metabolism Related Genes
Yangzi Ren, Shangwen He, Siyang Feng and Wei Yang

945 A Prediction Model for Peak Expiratory Flow Derived From Venous Blood Biomarkers and Clinical Factors in Amyotrophic Lateral Sclerosis
Xianghua He, Jiaming Feng, Xue Cong, Hongyan Huang, Quanzhen Zhao, Qiuyan Shen, Fang Xu and Yanming Xu

954 A Retrospective Study of Climate Change Affecting Dengue: Evidences, Challenges and Future Directions
Surbhi Bhatia, Dhruvisha Bansal, Seema Patil, Sharnil Pandya, Qazi Mudassar Ilyas and Sajida Imran

970 Convolutional Neural Network Based Real Time Arabic Speech Recognition to Arabic Braille for Hearing and Visually Impaired
Surbhi Bhatia, Ajantha Devi, Razan Ibrahim Alsuwailem and Arwa Mashat

980 Hybrid HCNN-KNN Model Enhances Age Estimation Accuracy in Orthopantomography
Fatemeh Sharifonnasabi, Noor Zaman Jhanjhi, Jacob John, Peyman Obeidy, Shahab S. Band, Hamid Alinejad-Rokny and Mohammed Baz

994 Analysis of the Impact of Supply Chain Relationship Strategy on Corporate Cash Dividend Policy Based on Chinese Data
Xingquan Yang and Lingyan Sun

1007 A Study on the Effect of the Pre-Go-Live Training in Anxiety and Depression of Medical Staff Based on the Data of Wuhan Fangcang Shelter Hospital During COVID-19 in the Era of Big Data
Qiang Feng, Huizhi Zhou, Lu Wang and Chuanyuan Kang

1013 The Effect of Big Data-Based Digital Payments on Household Healthcare Expenditure
Chengming Li, Daming Li, Si He, Shiqi Sun, Yuan Tian and Zeyu Wang

1025 Research on Infant Health Diagnosis and Intelligence Development Based on Machine Learning and Health Information Statistics
Siyu Wang, Min Li and Soo Boon Ng

1036 Analysis on the Cognitive Impact of Social Mobile Games on Left-Behind Children in the Era of Big Data
Mengyu Li, Jinglei Li, Megat Al Imran Yasin, Mohd Nizam Osman, Norliana Binti Hashim, Lay Hoon Ang and Yitian Xue

1046 Digital Analysis of Smart Registration Methods for Magnetic Resonance Images in Public Healthcare
Tao Chen, Mengxue Yuan, Jiajie Tang and Long Lu

1057 A Neural Network and Optimization Based Lung Cancer Detection System in CT Images
Chapala Venkatesh, Kadiyala Ramana, Siva Yamini Lakkisetty, Shahab S. Band, Shweta Agarwal and Amir Mosavi

1066 Effects of Osimertinib Combined With Pulmonary Rehabilitation and Health Care Training on Pulmonary Function, Complications, and Quality of Life in Patients After Radical Resection of Lung Cancer
Haijiang Xu, Ruixia Guo and Yantao Yang

1074 Meta-Heuristic Algorithm-Tuned Neural Network for Breast Cancer Diagnosis Using Ultrasound Images
Ahila A, Poongodi M, Sami Bourouis, Shahab S. Band, Amir Mosavi, Shweta Agrawal and Mounir Hamdi

1088 SperoPredictor: An Integrated Machine Learning and Molecular Docking-Based Drug Repurposing Framework With Use Case of COVID-19
Faheem Ahmed, Jae Wook Lee, Anupama Samantasinghar, Young Su Kim, Kyung Hwan Kim, In Suk Kang, Fida Hussain Memon, Jong Hwan Lim and Kyung Hyun Choi

1105 Perception Exploration on Robustness Syndromes With Pre-processing Entities Using Machine Learning Algorithm
Pravin R. Kshirsagar, Hariprasath Manoharan, Shitharth Selvarajan, Hassan A. Alterazi, Dilbag Singh and Heung-No Lee

1119 Suggestions on Relieving Physical Anxiety of Medical Workers and Improving Physical and Mental Health Under the COVID-19 Epidemic—A Case Study of Meizhou City
Zhi-Cheng Lu, Chien-Hsing Tseng, Hsiao-Hsien Lin, Yuan-Shing Perng and Yi-Han Tseng

1134 Utility of Scoring System for Screening and Early Warning of Cervical Cancer Based on Big Data Analysis
Dan Hou, Binjie Yang, Yangdan Li and Ming Sun

1141 VCNet: Hybrid Deep Learning Model for Detection and Classification of Lung Carcinoma Using Chest Radiographs
Ritu Tandon, Shweta Agrawal, Arthur Chang and Shahab S. Band

1154 XGBoost-Based Feature Learning Method for Mining COVID-19 Novel Diagnostic Markers
Xianbin Song, Jiangang Zhu, Xiaoli Tan, Wenlong Yu, Qianqian Wang, Dongfeng Shen and Wenyu Chen

1160 A Survey on Machine Learning and Internet of Medical Things-Based Approaches for Handling COVID-19: Meta-Analysis
Shahab S. Band, Sina Ardabili, Atefeh Yarahmadi, Bahareh Pahlevanzadeh, Adiqa Kausar Kiani, Amin Beheshti, Hamid Alinejad-Rokny, Iman Dehzangi, Arthur Chang, Amir Mosavi and Massoud Moslehpour

1182 Mechanism of Negative Emotions of the Elderly in Normalization Period of COVID-19: A Mediated Mediation Model
Kai Xu

1190 Performance Evaluation of the Deep Learning Based Convolutional Neural Network Approach for the Recognition of Chest X-Ray Images
Sandhya Sharma, Sheifali Gupta, Deepali Gupta, Junaid Rashid, Sapna Juneja, Jungeun Kim and Mahmoud M. Elarabawy

1199 A Study on the Correlation Between Age-Related Macular Degeneration and Alzheimer's Disease Based on the Application of Artificial Neural Network
Meng Zhang, Xuewu Gong, Wenhui Ma, Libo Wen, Yuejing Wang and Hongbo Yao

1211 Breast Cancer Detection and Classification Empowered With Transfer Learning
Sahar Arooj, Atta-ur-Rahman, Muhammad Zubair, Muhammad Farhan Khan, Khalid Alissa, Muhammad Adnan Khan and Amir Mosavi

1229 Using Machine Learning Methods to Predict Bone Metastases in Breast Infiltrating Ductal Carcinoma Patients
Wen-Cai Liu, Ming-Xuan Li, Shi-Nan Wu, Wei-Lai Tong, An-An Li, Bo-Lin Sun, Zhi-Li Liu and Jia-Ming Liu

1242 A Web-Based Prediction Model for Cancer-Specific Survival of Elderly Patients Undergoing Surgery With Prostate Cancer: A Population-Based Study
Zhaoxia Zhang, Chenghao Zhanghuang, Jinkui Wang, Tao Mi, Jiayan Liu, Xiaomao Tian, Liming Jin and Dawei He

1253 Intelligent automatic sleep staging model based on CNN and LSTM
Lan Zhuang, Minhui Dai, Yi Zhou and Lingyu Sun

1269 Interpretable clinical visualization model for prediction of prognosis in osteosarcoma: a large cohort data study
Wenle Li, Genyang Jin, Huitao Wu, Rilige Wu, Chan Xu, Bing Wang, Qiang Liu, Zhaohui Hu, Haosheng Wang, Shengtao Dong, Zhi-Ri Tang, Haiwen Peng, Wei Zhao and Chengliang Yin

1284 Big data-driven intelligent governance of college students' physical health: System and strategy
Chenliang Deng, Qiaoyan Yu, Ganglin Luo, Zhangzhi Zhao and Yuchao Li

1296 An efficient modular framework for automatic LIONC classification of MedIMG using unified medical language
Surbhi Bhatia, Mohammed Alojail, Sudhakar Sengan and Pankaj Dadheech

1317 Influence of seamless nursing model of humanistic care on nursing quality and blood infection risk of neurosurgical ICU patients and its correlation with APACHE II score
Fuhua Liu and Xiaoting Wang

1325 Retinal Vessel Segmentation Based on B-COSFIRE Filters in Fundus Images
Wenjing Li, Yalong Xiao, Hangyu Hu, Chengzhang Zhu, Han Wang, Zixi Liu and Arun Kumar Sangaiah

1339 A home fitness satisfaction model for Chinese residents during the COVID-19 pandemic based on SEM analysis
Dexu Chen and Bin Zhang

Kaliappan J, Srinivasan K, Mian Qaisar S, Sundararajan K, Chang C-Y and C S (2021) Performance Evaluation of Regression Models for the Prediction of the COVID-19 Reproduction Rate. Front. Public Health 9:729795. doi: 10.3389/fpubh.2021.729795

This paper aims to evaluate the performance of multiple non-linear regression techniques, such as support-vector regression (SVR), k-nearest neighbor (KNN), Random Forest Regressor, Gradient Boosting, and XGBOOST for COVID-19 reproduction rate prediction and to study the impact of feature selection algorithms and hyperparameter tuning on prediction. Sixteen features (for example, Total_cases_per_million and Total_deaths_per_million) related to significant factors, such as testing, death, positivity rate, active cases, stringency index, and population density are considered for the COVID-19 reproduction rate prediction. These 16 features are ranked using Random Forest, Gradient Boosting, and XGBOOST feature selection algorithms. Seven features are selected from the 16 features according to the ranks assigned by most of the above mentioned feature-selection algorithms. Predictions by historical statistical models are based solely on the predicted feature and the assumption that future instances resemble past occurrences. However, techniques, such as Random Forest, XGBOOST, Gradient Boosting, KNN, and SVR considered the influence of other significant features for predicting the result. The performance of reproduction rate prediction is measured by mean absolute error (MAE), mean squared error (MSE), root mean squared error (RMSE), R-Squared, relative absolute error (RAE), and root relative squared error (RRSE) metrics. The performances of algorithms with and without feature selection are similar, but a remarkable difference is seen with hyperparameter tuning. The results suggest that the reproduction rate is highly dependent on many features, and the prediction should not be based solely upon past values. In the case without hyperparameter tuning, the minimum value of RAE is 0.117315935 with feature selection and 0.0968989 without feature selection, respectively. The KNN attains a low MAE value of 0.0008 and performs well without feature selection and with hyperparameter tuning. The results show that predictions performed using all features and hyperparameter tuning is more accurate than predictions performed using selected features.

Keywords: COVID-19, feature selection, machine learning, prediction error, reproduction rate prediction, regression

INTRODUCTION

The world has witnessed several deadly diseases at different times. In the year 2020, the world suffered a serious pandemic that took away many lives (1). The coronavirus disease (COVID-19) is a disease that started as an epidemic and evolved into a pandemic. The disease was first discovered in late December 2019 in Wuhan, China (2). The virus responsible for causing the disease is the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), which is highly contagious and causes severe respiratory issues. The virus rapidly spread across the world and affected 223 countries, infected more than 9.3×10^7 people, and took over 2×10^6 human lives, according to the WHO report in January 2021 (3). As a result, scientists and epidemiologists worldwide are investigating the virus to reduce its impact on human lives.

The coronavirus is named after the word, "coronation" since the spikes on the surface of the virus resemble a crown. This virus was believed to be an animal virus in 2002. The SARS-CoV is mostly found in bats and transmitted to other animals, such as cats. The first human-infected coronavirus case was reported in 2003 in Guangdong province in the south of China (4).

Knowledge of the immune system of our body is required to understand the mechanisms of the COVID-19 or any other viral infections. Viruses are microorganisms that make our body cells their hosts for replication and multiplication. The immune system of our body is activated by the entry of the virus and identifies the virus as an alien body for destruction. After attacking and killing the viruses, the immune system "remembers" the virus and launches the same protective measures when the virus enters again. Viruses are capable of fast evolutions. They evolve to new shapes or mechanisms to survive in the changing environment.

Viral infections often affect people with weak immune systems. The elderly, children, and people with medical conditions are prone to the attack of novel viruses. The virus can be deadly and threatening to the senior population, especially the elderly with chronic medical conditions.

The SARS-CoV-2 is transmitted *via* respiratory droplets expelled by sneezing, coughing, or talking. The virus can also be contracted by touching a contaminated surface. One significant property of the SARS-CoV-2 is its capacity to survive on various surfaces for up to 9 days at room temperature, which facilitates its rapid transmission (5). Acute Respiratory Disease Syndrome is caused predominantly by this virus and often leads to multiple organ dysfunctions, resulting in physiological deterioration and even death of the infected persons (6).

This study is intended to predict the rate of reproduction of the deadly SARS-CoV-2. The reproduction rate (R_o) is an important parameter to predict the spread of a disease in a pandemic situation. The R_o value indicates the transmissibility of a virus through the average number of new infections caused by an infectious person in a naïve population. The value of $R_o < 1$ indicates that the infection would die out. On the other hand, if the value is >1, the spread of the disease would increase. For example, a reproduction rate of 18 indicates that a single infected individual can potentially infect 18 more individuals. The reproduction rate is needed to determine whether the disease is under control or turning into an epidemic.

There are many standard methods to predict the reproduction rate. The XGBoost is an optimal Gradient Boosting algorithm with tree pruning, parallel processing, missing value handling, and by the efficient use of hardware resources and regularization to avoid overfitting and bias. The XGBoost has faster computational times (7) in all types of environments. The XGBoost is an improvement on the Gradient Boosting algorithm. Training models with an XGBoost iterative boosting approach remove errors at preceding boosting trees in the following iterations (8). Support vector regression (SVR) was based on the Vapnik–Chervonenkis (VC) theory. It is used when the output is a continuous numerical variable. Support vectors are data points closest to the hyperplanes. The hyperplanes represent the decision boundaries. The Radial Basis Function is a commonly used kernel function. The use of a kernel function is to transform the data into a higher-dimensional space. The SVR and convolutional neural network (CNN) have been used to detect groundwater location, and comparative results showed that the SVR outperforms the CNN (9). In k-nearest neighbor (KNN), the outcome of the variable is determined by taking an average of the observations found in the same neighborhood. The KNN algorithm assigns a weight, "W" to the KNN and a weight of 0 to the others.

The performance of the machine learning algorithms depends on the hyperparameter values. The values for the hyperparameters can be assigned in three ways:

1) Based on default values given in the software packages.
2) Manually configured by the user.
3) Assigned by algorithms, such as the simple grid search, random search, Bayesian optimization, ANOVA approach, and bio-inspired optimization algorithms.

The process of identifying the most relevant features is referred to as "feature selection." The three main advantages of feature selection are:

- Simplifying the interpretation of the model.
- Reducing the variance of the model to avoid overfitting.
- Reducing the computational cost (and time) for model training.

Motivation

Artificial intelligence (AI) has been successful in many fields and facilitates our daily life in various ways (10–17). The reproduction rate prediction is crucial in successfully establishing public healthcare in the battle against COVID-19. The prediction of the reproduction rate is performed by using not just the past values but also by using the closely related factors. This work also investigates the impact of feature selection and hyperparameter tuning on the performance of non-linear machine learning techniques.

Research Gap and Contribution

The reproduction rate is related to many factors, such as the average number of contacts a person has, number of days a

person is infected, from the day of exposure to the disease, the number of active cases, values of stringency index, testing capacity and positivity, and so on. As a result, the reproduction rate, time curve, and future values cannot be satisfactorily estimated by the probability distribution functions alone (18).

Time series prediction models, such as the autoregressive integrated moving average (ARIMA), Gray Model, and Markov Chain models do not consider multiple factors in reproduction rate prediction. Autoregressive models assume that future values resemble the past. Mechanistic models based on the susceptible, exposed, infected, and recovered (SEIR) states framework or modified version of the framework use the time series data to hold the currently confirmed cases, removed cases (including recovered and deceased cases), and time-varying transmission rates. However, some factors are still not included, and there is no weighting for the factors (19).

So there arises a need to study the various factors acting on the reproduction rate and to prioritize it. Hence identifying the importance of various features (for example, Total_cases_per_million, Total_deaths_per_million) under factors like active cases, stringency index, testing capacity, and positivity are done using feature selection algorithms. Multiple regression uses several explanatory variables to predict the single response variable. The performance of the non-linear machine learning techniques, such as Random Forest, XGBOOST, Gradient Boosting, KNN, and SVR are used in reproduction rate prediction. The performance of these approaches for predicting the COVID-19 reproduction rate was measured using the evaluation metrics like mean absolute error (MAE), mean squared error (MSE), **r**oot mean squared **e**rror (RMSE), R-Squared, relative absolute **e**rror (RAE), and root relative squared error (RRSE). The influence of feature selection and hyperparameter tuning operation on their performance is also studied.

Structure of the Paper

Section Introduction of the paper introduces the reproduction rate, feature selection, machine learning techniques and hyperparameters, and the motivation of this study. Section Related Works discusses the related works, as well as the identified research gap and the contributions. Section Materials and Methods describes the methods used in this work, including feature selection, hyperparameter tuning, and prediction and performance measurement. Section Results and Discussion discusses the experimental results. Finally, section Conclusion and Future Work provides the conclusion and future work.

RELATED WORKS

Zivkovic et al. (20) proposed a hybridized machine learning, adaptive neuro-fuzzy inference system with enhanced beetle antennae search (BAS) swarm intelligence metaheuristics. The results showed that the system is a good prediction model in time series forecasting. The defects in the BAS algorithm were rectified using the Cauchy exploration strategy BAS (CESBAS) using the Cauchy mutation and three additional control parameters. The selection of optimum values for the adaptive network-based fuzzy inference system (ANFIS) parameters became an NP-hard optimization problem. The ANFIS parameters values were determined using the CESBAS metaheuristics algorithm. The performance metrics, such as RMSE, MAE, MAPE, RMRE, and R-Squared, were used to evaluate the outcomes on influenza datasets.

The research goal in Mojjada et al. (21) was to forecast the number of new COVID-19 cases, mortalities, and recoveries using various machine learning regression models, such as the lowest absolute and selective shrinking operator (LASSO), vector supports, such as short message service (SMS), and exponential smoking (ES) models. While the linear regression and LASSO models were more effective in estimating and verifying the death rate, the ES model provided the overall best results.

Farooq and Bazaz (22) used an artificial neural network (ANN) to forecast the COVID-19 based on an online incremental learning technique using an adaptive and non-intrusive analytical model. The COVID-19 data was updated every day, so online incremental learning was the best option for forecasting since there is no need to retrain or rebuild the model from scratch.

Milind et al. (23) discovered many factors behind the spread of the coronavirus, such as the relationship between the weather and the spread of COVID-19, growth rate, and mitigation. Support vector regression (SVR) was used to predict the transmission rate, epidemic end, and the spread of the coronavirus across regions, and to analyze the growth rates and the types of mitigation across countries. The Pearson coefficient was used in the correlation between the coronavirus and weather correlation coefficient. Weather factors, such as the wind speed, temperature, and humidity of Milan city in Italy and New York City in the United States were considered. The SVR is a non-parametric technique since it only depends on the kernel function, implying that there is no need to change the explanatory variables in constructing a non-linear model. The study also compared the performances of SVR, linear regression, and polynomial regression.

Chicco and Jurman (24) predicted the survival of patients who had heart failure based on the ejection fraction and serum creatinine level. A database of 299 patients collected in 2015 was used. Feature selection was performed, and the factors were ranked. The ejection fraction and serum creatinine levels were found to be highly relevant among the 13 selected features. As a result, the prediction model was built and executed based on these two factors.

Mortazavi et al. (25) investigated the capability of machine learning techniques when applied to a high dimensional and non-linear relationship. They predicted the readmission of patients hospitalized for heart failure. The prediction was performed with various machine learning techniques, such as Random Forest, Gradient Boosting, and Random Forest combined hierarchically with support vector machines (SVMs) or logistic regression (LR) and Poisson regression. The obtained results were tested against traditional LR methods. The model was evaluated using the receiver operating characteristics (ROC) curve (C statistic), the positive predictive value (PPV), sensitivity, specificity, and

f-score. The ROC was found to be a good measure for model discrimination.

Balli (26) analyzed the COVID-19 data from Germany, the United States, and other parts of the world. Methods including the SVM, linear regression, multilayer perceptron, and Random Forest methods were used to model the COVID-19 data. The performances of the methods were compared using the RMSE, absolute percentage error (APE), and mean absolute percentage error (MAPE). Among the tested methods, the SVM outperformed all other methods in the COVID-19 data modeling and was successfully used to diagnose the behavior of cumulative COVID-19 data over time.

A system to handle the data with non-linear relationships and non-normal distribution was proposed by Kuo and Fu (27). A total of 52 input variables relating to confirmed cases, environment variables, country-dependent variables, community mobility variables, and time series variables were used in the study (27). The impact of population mobility had caused an increase in the number of infections over the weekend. This work served as a basis for researchers analyzing geographical characteristics, seasonality, as well as models, such as long short-term memory (LSTM), ARIMA, convolutional neural network (CNN), and so on.

The COVID Patient Detection System (CPDS) used by Shaban et al. (28) was designed using a Hybrid Feature Selection Method (HFSM) consisting of two stages, a fast selection stage (FS^2) and an accurate selection stage (AS^2). The FS^2 used several filter methods, and the filtered features served as the initial population of the genetic algorithm, which was used as a wrapper method. An enhanced K-nearest neighbor (EKNN) classifier was used to solve the trapping problem. The most significant features from the chest CT images of patients were selected. The HFSM allowed the EKNN classifier to obtain rapid predictions with high accuracy. The proposed feature selection algorithm was compared with four recent feature selection techniques, and the proposed CPDS had achieved an accuracy of 96%.

Sujatha et al. (29) utilized the linear regression, multi-layer perceptron (MLP), and vector autoregression (VAR) models to foresee the spread of the COVID-19 using the COVID-19 Kaggle data. The correlations between the features of the dataset are crucial in finding the dependencies. The VAR model is a more suitable analysis model for multivariate time series. It is an m-equation, m- variable model where an individual variable is based on its current and past values. The MLP methods provide better predictions than the linear regression and VAR models.

Yang et al. (30) predicted the number of new confirmed cases using SEIR and AI methods. The authors used the probability of transmission, incubation rate, and the probability of recovery or death as factors in the predictions. New case predictions made by the AI method are more accurate than the SEIR predictions.

The Gradient Boosting Feature Selection (GBFS) algorithm learns the ensemble of regression trees to identify the non-linear relationship between features with ease. The classification error rates for the GBFS and Random Forest methods are the lowest, whereas the L1-regularized logistic regression (L1-LR) and Hilbert–Schmidt independence criterion (HSIC) Lasso methods have higher error rates (31).

The XGBOOST algorithm was applied to calculate the business risk by Wang (32). Several feature selection methods were used to find the redundant features. Two hyper-parameter

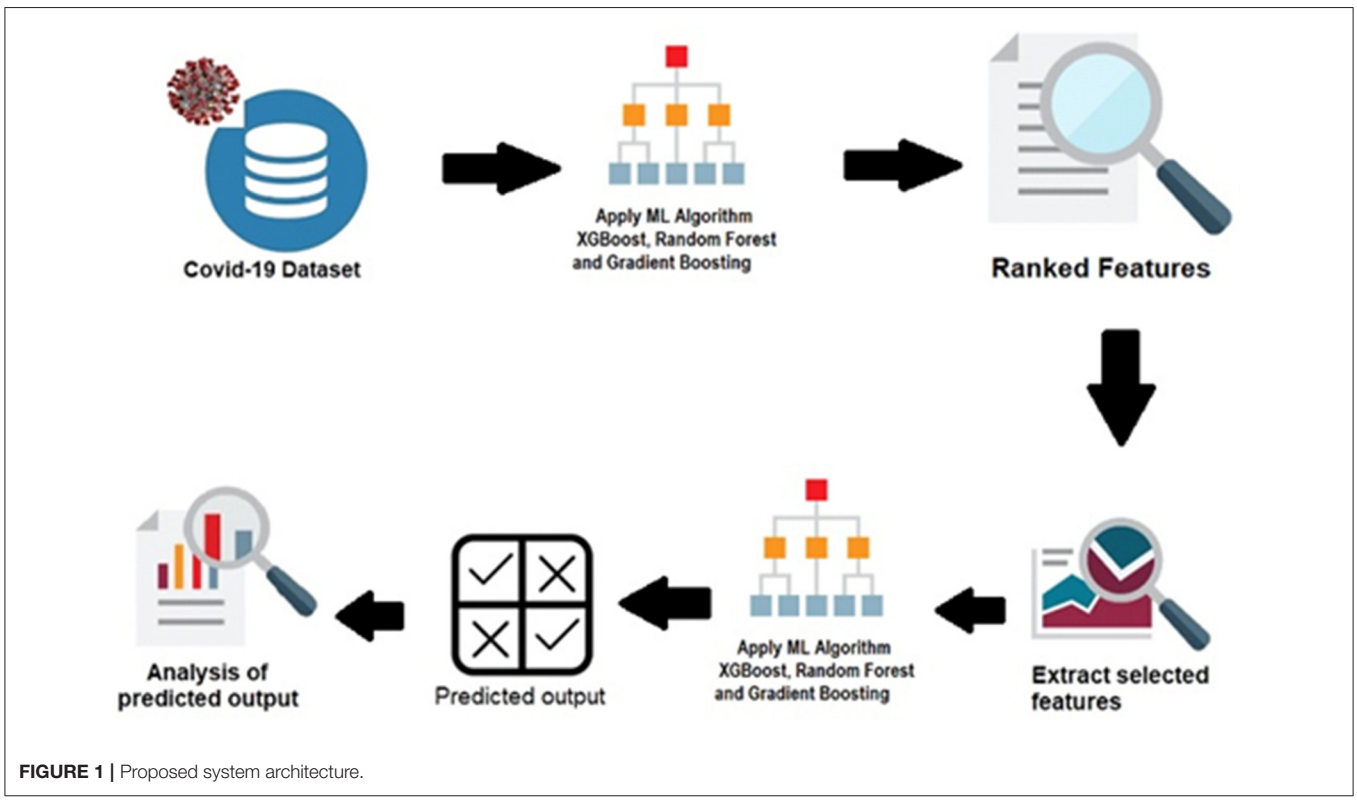

FIGURE 1 | Proposed system architecture.

optimization approaches were applied: random search (RS) and Bayesian tree-structured Parzen Estimator (TPE). The XGBOOST with hyper-parameter optimization performed well for business risk modeling.

Chintalapudi et al. (33) used the predicted reproduction rate to forecast the daily and the cumulative COVID-19 cases for the next 30 days in Marche, Italy. The probability-based prediction was performed with the maximum likelihood function. In the implementation, a simple linear regression method was used to fit the exponential growth of infected incidences over time, and the linear regression was applied over the incidence data. This study showed that the outbreak size and daily incidence are primarily dependent on the daily reproductive number.

Locatelli et al. (34) estimated the COVID-19 reproduction rate of Western Europe with the average from 15 countries. The authors used the generation interval, defined as the time needed for an infected person to infect another person and for reproduction rate estimation. The works by Zhang et al. (35) and by Srinivasu et al. (36), Panigrahi et al. (37, 38), Tamang (39), Chowdhary et al. (40), and Gaur et al. (41) demonstrated the efficacy of machine learning algorithms in various fields.

TABLE 1 | Feature Importance Scores obtained using Random Forest Regression, XGBoost, and Gradient Boosting.

Features	Feature	Random forest regression feature importance	XGBOOST feature importance	Gradient boosting feature importance
Feature: 0	Total_cases	0.10044	0.92185	0.03024
Feature: 1	New_cases	0.02539	0.00055	0.00058
Feature: 2	Total_deaths	0.08816	0.00011	0.10000
Feature: 3	New_deaths	0.01286	0.00209	0.00000

Feature: 14	Stringency_index	0.01744	0.00020	0.05846
Feature: 15	Population_density	0.00000	0.00000	0.00000

MATERIALS AND METHODS

The spread of the COVID-19 depends on many factors. New factors influencing the spread of the disease are still being discovered, and the identification of predominant factors is crucial. The prediction of COVID-19 spread is highly related to the feature-reproduction rate. Data science can be applied to track the crucial features used for the prediction from any number of features. Traditional statistical approaches, such as the chi-square and Pearson correlation coefficient provide the importance of the features in relation to the other features. Feature selection reduces the overfitting and underfitting problems, computational cost, and time. The reproduction rate prediction is important since it is associated with the status of the COVID-19. Feature-ranking is performed using Random Forest regression, Gradient Boosting, and XGBoost. Seven factors are considered in this study: the total number of cases, number of new cases, total number of deaths, total number of cases per million, total number of deaths per million, total number of tests conducted per thousand, and the positive rate. The proposed system architecture is represented in **Figure 1**.

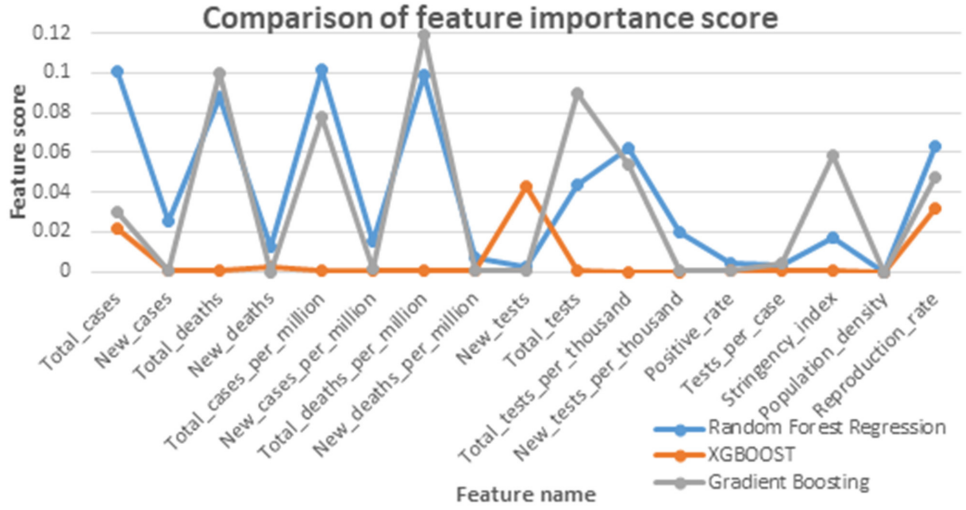

FIGURE 2 | Comparison graph of feature score given by feature selection algorithms.

Reproduction Rate

Newly occurring diseases can be detrimental for humans and other animals, whether the diseases are caused by a new pathogen or a modified form of an existing pathogen (19). In this work, the simple compartmental disease models and matrix methods are used to calculate the reproduction rate, R0.

Feature Selection

Embedded filter-based feature selection methods, such as Random Forest, Gradient Boosting, and XGBoost, which take into account the regression process, are used in this work. The Random Forest approach is an embedded feature selection method in which hundreds of decision trees are constructed by extracting random observation values of random features. The training determines features that reduce impurity. The principle of Gradient Boosting, and XGBoost methods are used to boost the weak learners. Gradient Boosting strives to minimize the error between the predicted and the actual values. The XGBoost is an extreme Gradient Boosting algorithm. The XGBoost is the regularized form of Gradient Boosting (42). The XGBoost is fast with L1, L2 regularization and parallel computing. It delivers high performance since it works on the second partial derivatives of the loss function. The main highlight of the Random Forest algorithm lies in its ability to prevent overfitting and increase accuracy. The advantage of gradient boosting is its ability to tune many hyperparameters and loss functions.

Parameter Settings

The experiments use multiple non-linear regression tree algorithms and the result is implemented in Python. For experiments without hyperparameter tuning, the default values in the SciKit library are used. For Random Forest regression, the parameter values are initialized as follows: n_estimators = 100, n_jobs = −1, oob_score = True, bootstrap = True, and random_state = 42. For XGBoost, the XGB Regressor method is used to fit the test data, and n_estimatorsis set to 100. The Gradient Boosting feature importance is calculated by setting the value of n_estimators to 500, max_depth to 4, min_samples_split to 5, learning_rate to 0.01, and loss as ls. For the KNN algorithm, the lower error rate is achieved when the K value equals 7. For the SVR, the radial basis function kernel is used with degree = 3 and gamma = scale. For experiments with hyperparameter tuning, grid search and randomized approaches are used. A grid search exhaustively tests all possible combinations of the specified hyperparameter values for an estimator. In a randomized search, the model selects the combinations randomly. Both approaches are very effective ways of tuning the parameters to increase the generalizability of the model. The GridSearchCV method of sklearn tunes the hyperparameters of the SVR, KNN, XGBoost, and Gradient Boosting approaches. The randomized search CV function is used for the hyperparameter tuning of Random Forest Regressor.

Dataset

The dataset was taken from the website "https://github.com/owid/covid-19-data/tree/master/public/data" (43). A total of 16 fields were used for the study of reproduction rate. They are Total_cases, New_cases, Total_deaths, New_deaths, Total_cases_per_million, New_cases_per_million, Total_deaths_per_million, New_deaths_per_million, New_tests, Total_tests, Total_tests_per_thousand, New_tests_per_thousand, Positive_rate, Tests_per_case, Stringency_index, Population_density. Records from April 1, 2020, to November 30, 2020, are used as training data (244 records/day). Records from December 1, 2020, to March 10, 2021, are used as testing data (100 records/day).

Performance Metrics

Numerous machine learning (ML)-based predictive modeling techniques are used in the COVID-19 predictions. Therefore, there is a need to measure the performance of each model and its prediction accuracy. The metrics used to assess the effectiveness

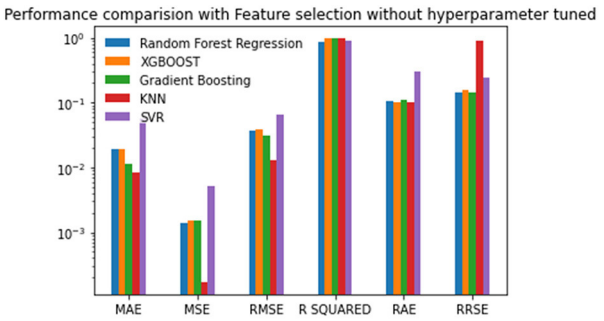

FIGURE 4 | Performance comparison graph of regression techniques with feature selection algorithm and without hyperparameter tuning.

of the model in predicting the outcome are very important since they influence the conclusion. The performance metrics to identify the error rate between the predicted and observed values are as follows:

- Root mean square error (RMSE)
- Mean absolute error (MAE)
- Determination coefficient (R^2)
- Relative absolute error (RAE)
- Root relative squared error (RRSE)

Mean Absolute Error

The mean absolute error measures the sum of the absolute differences between the predicted output and the actual output. One cannot identify whether it is under predicting or over predicting since all variations have equal weight.

Equation 1 provides the formula to calculate the MAE.

$$MAE = \frac{1}{N}\sum_{i=1}^{N}|SWL_{FOR,i} - SWL_{OBS,i}|, \tag{1}$$

where $SWL_{FOR,i}$ represents the forecast output, $SWL_{OBS,i}$ represents the actual output, N represents the total number of data points, and I represents a single data entry from the data points.

Root Mean Squared Error

The RMSE measures the square root of the average squared deviation between the forecast and the actual output, as given in Equation 2. It is used when the error is highly non-linear. The RMSE indicates the amount of errors in the predicted data on average and is a good measure of the prediction accuracy.

$$RMSE = \sqrt{\sum_{i=1}^{N}\frac{(SWL_{FOR,i} - SWL_{OBS,i})^2}{N}} \tag{2}$$

Determination Coefficient

The R^2 metric shows the percentage variation in y explained by x-variables, where x and y signify a set of data. It finds the likelihood of the occurrence of a future event' in the predicted outcome, as given in Equation 3.

$$R^2 = \left(\frac{n(\sum xy) - (\sum x)(\sum y)}{\sqrt{[n\sum x^2 - (\sum x)^2][n\sum y^2 - (\sum y)^2]}}\right)^2 \tag{3}$$

Relative Absolute Error

Relative Absolute Error (RAE) metric gives the ratio of residual or mean error to the forecast error of a naive model. Equation 4, returns a value less than 1, when the proposed model performs better than the naïve model. In Equation 4, "P" stands for the predicted value and "A" for the actual value.

$$RAE = \frac{\left[\sum_{i=1}^{n}(P_i - A_i)^2\right]^{\frac{1}{2}}}{\left[\sum_{i=1}^{n}A_i^2\right]^{\frac{1}{2}}} \tag{4}$$

Root Relative Squared Error

The Root Relative Squared Error (RRSE) is given as the square root of the relative squared error (RSE). The RSE metric compares the actual forecast error to the forecast error of a naive model. It can be used in models whose errors are measured in different units. As given in Equation 5 and 6, the total squared error is divided by the total squared error of the simple predictor. The simple predictor is just the average of the actual values. The predicted output is "P" and "T" is the target value. Further, the value "i" represents the model and j represents the record.

RRSE is given as the square root of the relative squared error, which provides the error in the dimensions of the quantity being predicted, as given in Equation (7). RSE_i represents the relative squared error for the model "i".

$$RSE_i = \frac{\sum_{j=1}^{n} (P_{ij} - T_j)^2}{\sum_{j=1}^{n} (T_j - \overline{T})^2} \quad (5)$$

$$\overline{T} = \frac{1}{n} \sum_{j=1}^{n} T_j \quad (6)$$

$$RRSE = \sqrt{RSE_i} \quad (7)$$

RESULTS AND DISCUSSION

Results

All experiments were performed using Python's Sci-Kit Library on a Jupyter notebook. The feature importance scores obtained by Random Forest regression, XGBoost, and Gradient Boosting are given in **Table 1** and plotted in **Figure 2**.

Out of the 16 features, the top seven features affecting the reproduction rate are identified from the obtained feature importance scores. The seven features are Total_cases, New_cases, Total_deaths, Total_cases_per_million, Total_deaths_per_million, Total_tests, Total_tests_per_thousand, and Positive_rate.

Experiments were conducted for the reproduction rate prediction using Random Forest, XGBoost, Gradient Boosting, support-vector regression (SVR), and k-nearest neighbor (KNN) regression methods. In addition, the experiments were intended to investigate the impacts of feature selection and hyperparameter tuning. Four experiments were conducted with and without feature selection or hyperparameter tuning. Experiment 1 was conducted using the five regression techniques without feature selection and without parameter tuning. Experiment 2 was conducted with feature selection and without parameter tuning. Experiment 3 was conducted without feature selection and with hyperparameter tuning, and finally, Experiment 4 was conducted with feature selection and with parameter tuning. The reproduction rate prediction was measured using the mean absolute error (MAE), mean squared error (MSE), root mean squared error (RMSE), R-Squared, relative absolute error (RAE), and root relative squared error (RRSE). The best, the second-best and the worst results for the particular metrics and experiments are discussed in detail below. The best results obtained for the metrics are given in bold in the **Tables 2**, **3**, **5**, **6**.

The first experiment used all features in the reproduction rate prediction, and each of the regression techniques used the default values for the hyperparameter. The resulting performance metric values are given in **Table 2**. The Gradient Boosting method performs well with the lowest MSE, RMSE, RAE, and RRSE values and the second-best score for MAE. Random Forest is the next best algorithm with the best R-Squared value and the second-best scores for MSE, RMSE, and RAE. The XGBoost has an average performance. The SVR has the worst scores in all of the performance metrics. The lowest MAE of 0.0189412 was obtained by XGBoost followed by Gradient Boosting with the second-best MAE of 0.02226608. The SVR has the highest MAE of 0.0712651. The minimum MSE, RMSE, RAE, and RRSE values of 0.00135535, 0.036815107, 0.1173159354, and 0.1472868, respectively, are achieved by Gradient Boosting. Random Forest

MAE	0.021551531	0.020971233	0.021192539	**0.008626385**	0.064263084
MSE	0.001430578	0.001684012	0.001578488	**0.000225718**	0.005462202
RMSE	0.037822976	0.041036714	0.039730185	**0.015023919**	0.073906711
R-Squared	0.977102535	0.973046128	0.974735124	0.996387212	**0.912573368**
RAE	0.113551075	0.110493591	0.111659615	**0.045450843**	0.338590443
RRSE	0.151319084	0.164176344	0.158949287	**0.060106472**	0.295679949

achieves the maximum R-squared value of 0.97923. The obtained metric values are plotted in **Figure 3**.

The seven selected features were used in the second experiment, and the prediction process was performed without hyperparameter tuning. There is a reduction in the MAE, MSE, and RMSE values of about 0.01 using Random Forest regression. There is a marginal reduction in the MAE, MSE, and RMSE values using XGBoost and Gradient Boosting for feature selection. The lowest MAE value of 0.018391, RAE value of 0.096898, and the best R-squared value of 0.9796126 is achieved by XGBoost. Random Forest gives the lowest MSE of 0.00139, RMSE of 0.037380, and RRSE of 0.159998. Out of all the algorithms, the SVR produces the highest error rate. The results are given in **Table 3** and plotted in **Figure 4**. The Random Forest regression and XGBoost techniques performed better than the other techniques. The performance of SVR is the worst among the algorithms compared for reproduction rate prediction. In the experiment with feature selection and without hyperparameter tuning, the Random Forest approach has achieved the top performance with three best scores and two second-best scores. The XGBoost has the best scores for the MAE, R-squared, and RAE, and the second-best score for RRSE.

Experiment 3 was conducted without feature selection and with hyperparameter tuning. The tuned hyperparameter values are listed in **Table 4**. The results are good after hyperparameter tuning is performed with the grid search or random search. The results are analyzed based on the best, the second-best, and the last scores. The performance of KNN tops all of the other algorithms when the experiment is performed without feature selection and with hyperparameter tuning. Random Forest is the next best algorithm with the second-best scores for the MSE, RMSE, R-Squared and RRSE. The values are given in **Table 5** and plotted in **Figure 5**.

Experiment 4 was conducted with feature selection and with parameter tuning. In this experiment, the Random Forest approach has the best scores for the MSE, RMSE, R-Squared, and RRSE. The XGBOOST has the best scores for the MAE and RAE. Nevertheless, Gradient Boosting has the second-best scores in the MSE, RMSE, R-Squared, and RRSE. The KNN has two second-best scores. Again, the SVR has the worst scores for all of the performance metrics. The values are given in **Table 6** and plotted in **Figure 6**.

The computation times for the different types of prediction are computed and listed in **Table 7**. The Random Forest algorithm uses a random search technique for hyperparameter tuning, which requires more time. All of the other algorithms use the grid search technique. The KNN and SVR are able to perform hyperparameter tuning rapidly. XGBOOST and Gradient Boosting regression have moderate running times of around 100 s.

The predicted and actual reproduction rates for Random Forest, KNN, SVR, XGBoost, and Gradient Boosting are, respectively, plotted in **Figures 7–11**. The graphs show that the predicted values are very close to the actual values.

DISCUSSION

The major contributions of this paper are the study of features affecting the COVID-19 reproduction rate, as well as the investigation into the effects of feature selection and hyperparameter tuning on the prediction accuracy. Furthermore, prediction accuracy comparisons of the state-of-the-art regression techniques for COVID-19 reproduction rate have also been performed.

The selected features suggest that the total numbers of death and testing also influence the reproduction rate. Instead of depending only on the past value of the predictor variable as cited by Milind et al. (23), our work finds the crucial features affecting the predictor variable. Different regression techniques are used in the prediction and they are used to determine the

final reproduction rate. The effectiveness of feature selection in prediction has also been proven. Random forest has achieved the best performance in the accuracy comparison of the state-of-the-art techniques, as has already been proven by Chicco and Jurman (24). In the results obtained by the four experiments, the overall best values of MAE, MSE, RMSE, RAE, RRSE, and R-Squared were all obtained by the KNN approach. Therefore, KNN has obtained the best performance on average, followed by Random Forest and XGBOOST.

CONCLUSION AND FUTURE WORK

Predicting the reproduction rate is crucial, especially when a country has to take preventative measures to protect its citizens from a pandemic. Autoregressive models rely on and work with previous values to forecast future values. Non-linear machine learning regression algorithms have consistently produced the best prediction results in various applications, including the stock exchange, banking, and weather forecasting. Among the many factors involved in the spread of the COVID-19, the prominent factors are identified using Random Forest, Gradient Boosting, and XGBOOST in this work. Random Forest returned the highest importance score for Total_cases_per_million as 0.10196. For XGBOOST, the maximum score was 0.92185 for Total_case, and for Gradient Boosting, the top value of Total_deaths_per_million is 0.1183. Out of 16 features selected for investigation, seven features, namely, Total_cases, New_cases, Total_deaths, Total_cases_per_million, Total_deaths_per_million, Total_tests, Total_tests_per_thousand, and Positive_rate, are found to be prominent in reproduction rate prediction. Furthermore, this work investigated the reproduction rate prediction with non-linear machine learning regression techniques. The experiments were performed using Random Forest, Gradient Boosting, XGBOOST, KNN, and SVR, with and without feature selection and hyperparameter tuning. The results showed a decrease in the prediction error rate with hyperparameter tuning and with all of the features. Overall, the KNN algorithm had obtained the best performance. The study shows that Random Forest obtained the best performance with hyperparameter tuning and selected features. Individual regression techniques are applied in this study. However, the ensemble of regression techniques can be applied to obtain better performances. The regression algorithms obtained improved results with hyperparameter tuning and Gridsearch or Randomsearch methods. There is no remarkable difference in the prediction accuracy of algorithms with and without feature selection algorithms, so there is a need to find out the optimal features related to the reproduction rate.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author/s.

AUTHOR CONTRIBUTIONS

C-YC and KSr: conceptualization. C-YC: resources, project administration, and funding acquisition. JK and KSu: methodology and software. KSr, SM, and C-YC: validation. Mantey EA, Zhou C, Anajemba JH, Okpalaoguchi IM and Chiadika OD-M (2021) Blockchain-Secured Recommender System for Special Need Patients Using Deep Learning. Front. Public Health 9:737269. doi: 10.3389/fpubh.2021.737269

Recommender systems offer several advantages to hospital data management units and patients with special needs. These systems are more dependent on the extreme subtle hospital-patient data. Thus, disregarding the confidentiality of patients with special needs is not an option. In recent times, several proposed techniques failed to cryptographically guarantee the data privacy of the patients with special needs in the diet recommender systems (RSs) deployment. In order to tackle this pitfall, this paper incorporates a blockchain privacy system (BPS) into deep learning for a diet recommendation system for patients with special needs. Our proposed technique allows patients to get notifications about recommended treatments and medications based on their personalized data without revealing their confidential information. Additionally, the paper implemented machine and deep learning algorithms such as RNN, Logistic Regression, MLP, etc., on an Internet of Medical Things (IoMT) dataset acquired *via* the internet and hospitals that comprises the data of 50 patients with 13 features of various diseases and 1,000 products. The product section has a set of eight features. The IoMT data features were analyzed with BPS and further encoded prior to the application of deep and machine learning-based frameworks. The performance of the different machine and deep learning methods were carried out and the results verify that the long short-term memory (LSTM) technique is more effective than other schemes regarding prediction accuracy, precision, F1-measures, and recall in a secured blockchain privacy system. Results showed that 97.74% accuracy utilizing the LSTM deep learning model was attained. The precision of 98%, recall, and F1-measure of 99% each for the allowed class was also attained. For the disallowed class, the scores were 89, 73, and 80% for precision, recall, and F1-measure, respectively. The performance of our proposed BPS is subdivided into two categories: the secured communication channel of the recommendation system and an enhanced deep learning approach using health base medical dataset that spontaneously identifies what food a patient with special needs should have based on their disease and certain features including gender, weight, age, etc. The proposed system is outstanding as none of the earlier revised works of literature described a recommender system of this kind.

Keywords: blockchain privacy system, deep learning, machine learning, IOMT, artificial intelligence

INTRODUCTION

The idea of a secured recommendation system has been proposed in recent times due to the nature of diseases and dietary effects suffered by patients with unique conditions that inhibit their ability to receive routine diet recommendation care. This system which is incorporated with a blockchain privacy mechanism is advantageous to both the hospital data management unit and the patients with special needs in terms of privacy violation protection, scandals, and longevity of the patients. In (1), the authors gave a comprehensive explanation, including their history and basic concepts of networks and how they could be applied in the field of pharmaceutical sciences as an option instead of just traditional methodology. The authors of (2) discussed the various ways Artificial Neural Networks (ANNs) can be applied to resolve challenges in the pharmaceutical field. Similarly, in (3), the authors discussed how ANNs can be used in diverse ways in medicine such as in the delivery of drugs, classification of cancer, research in pharmaceutics and others. The authors of (4) proposed an algorithm to solve the issue of classification, analysis, and summarization of document analytics. Experimental results showed the efficiency of the algorithm regarding its precision and implementation time. In (5), the authors proposed a solution based on deep learning for medical datasets which identifies what kind of food a patient should be fed based on factors like the nature of diseases, gender, age, and weight, among others. Their framework made use of machine learning and deep learning algorithms. Experimental results showed its efficiency and accuracy.

The motivation of this study is to enhance, secure, and analyze the performance of an expansive nutritional theory into the Internet of Medical Things (IoMT) using a blockchain privacy system and deep learning algorithms.

The contributions of this study are stated below:

- To propose and incorporate a reliable blockchain privacy system (BPS) for a secured diet recommendation system for patients with special needs.
- To investigate and perform analysis of machine learning, deep learning system previously used on IoMT such as Naive Bayes and logistic regression, recurrent neural network (RNN), gated recurrent unit (GRU), and long short-term memory (LSTM).
- To design an all-inclusive diet recommendation model which can be applied for patient special needs products and disease specifications.
- To analyze the behavior of our Enhanced Artificial Intelligence (AI) and deep learning mechanisms and how it is administered.
- The result showcased the Enhanced Machine Learning and deep learning for patients with special needs and for treating varied patient diseases with varied recommender evidence that is secured using a blockchain privacy system.

Structure

The remaining part of the study laid out on this paper is organized as follows. Several literature are revised and detailed in the related works section. Introduced in section System Model are the methods and materials of the system, including its execution utilizing AI. Summarized in section Experiments and Results are the findings of the conducted experiment in this study. Finally, the conclusions of the study are discussed in section Conclusion and Future Work.

RELATED WORKS

Blockchain is one of the most recent subjects currently understudied and has been recently incorporated into several societal, industrial and academic scenarios (6). One of the areas that have extensively incorporated the BPS is the hospital and patient recommender systems. The authors in (7) proposed research for customizing a service for the recommendation of diet for its customers which prevents and manages heart diseases in the area of healthcare. It provides this service by putting into consideration factors like family history of illnesses, preferences of food, vital signs, etc., of the customers with the issue of heart diseases. This service can aid customers to change their living habits to healthier ones. The study conducted by the authors of (8) proposed a framework for nourishment recommendation where input is retrieved from children and analyzed, which results in output that provides for a better and healthier diet plan. Its goal is to provide kids from the age of eight to their early teens with a healthier eating lifestyle which varies according to their age, gender, and other related factors. The study of the authors in (9) suggested a platform that smartly plans the meals of users according to their health conditions. This platform makes use of machine learning algorithms to function. The authors of (10) studied the impact of various factors which influence the adoption and use of a user of online health facilities, specifically in Ukraine and China. The authors in (11) proposed a framework that recommends healthy diet plans to patients that have hypertension. It utilizes machine learning algorithms and considers factors such as allergies, food preferences, age, and blood pressure, among others. The study conducted by the authors of (12) discussed how blockchain technology in conjunction with the Internet of Things (IoT) could be used to monitor the supply chain efficiently. The \ study of the authors in (13) proposed a system that recommends healthier diets specifically for American Indians with diabetes, by studying the profile of the user with clinical regulations and guidelines. The system makes customized recommendations based on various factors for the AI patient. The authors of (14) used a neural network deep learning method to explain how big data analytics could be utilized in the execution of an efficient system for health recommendation, and demonstrates how the industry of healthcare could evolve from a customary system to a more customized one in the online health environment.

The authors in (15) examined the ways for calculating and measuring the similarities of users in health websites. The recommendation of similar users to customers aids in the support search, whether emotional or not in a more efficient way. The study conducted by the authors of (16) presented an overview of the literature that examines how machine learning algorithms are used in recommender systems and also pinpoints

opportunities for research in the software engineering field. It concluded that the algorithms are used because they are not complex. The study of the authors in (17) proposed a method for recognizing parameters that influence processes and suggests a framework for machines by executing a device that can collect a large amount of data and integrate them into the Cloud for more studies. The authors of (18) identified various ways big data analytics could be utilized and gave its benefits regarding IT framework in strategic areas. They also suggested tactics for organizations concerned with healthcare to adopt big data analytics. The authors in (19) proposed a recommendation of threads to health communities' online users by making use of diverse healthcare information network mining. The study conducted by the authors of (20) proposed a scheme to improve the efficacy of recommender systems and preserve privacy, as long as the data collected are examined efficiently. The study of the author in (21) provided an exhaustive review of all research regarding and related to recommender systems that are based on deep learning technology. The authors of (22) proposed a model that is based on fog deep learning that acquires data from people and forecasts their fitness statistics and abnormalities making use of a model that is based on a neural network that is capable of handling diverse and large amounts of data.

The authors in (23) proposed a recommender system that delivers accommodative nutrition information to extend and improve the lives of people with diet-related illnesses, as well as healthy people. The system recommends nutrition according to the health profile of the user. The study conducted by the authors of (24) proposed an architecture that collects and collates data from different primary indicators of performance in healthcare communities, as well as predicts possible values of these principal performance indicators. The study of the authors in (25) proposed a system that utilizes customized features concerning nutrition that aids users in the change of their attitude toward healthier food choices and diets. The authors of (26) conducted a review to determine if dieted and nutritional products are issues often left out in shortages research. The authors in (27) proposed a framework for the recommendation of everyday meals while also managing preference-inclusive and nutritional information. The study conducted by the authors of (28) proposed a recommender system making use of analysis of food clustering for patients with diabetes. The study of the authors in (29) reviewed numerous existing works of literature and discovered lacunas in the existing systems of diet management. The authors of (30) in their study concentrated on developing a recommender system that integrates Artificial Intelligence methods and creates a base of knowledge following the appropriate and lawful guidelines and regulations concerning diabetes. The recommended menu is according to the preferences and conditions of the patients.

The authors in (31) presented a recommender system that is based on the pathology report of the user. This system utilizes the ant colony algorithm to create a menu and suggests appropriate food in line with the values of the pathology report of the user. The study conducted by the authors of (32–34) discussed error sources regarding nutrition, as well as possible solutions to tackle those challenges for future systems. They also discussed the incorporation of nutritional propositions into information systems. The study of the authors in (35) proposed a management system to aid in the preparation of a proper and healthy diet for children. The authors of (36) studied the shifts in obesity and its various kinds from the richer to the less fortunate across an era of economic growth in a developing country (Malaysia). They concluded that as the country develops, the risk of obesity among the less fortunate should be expected. The authors in (37) proposed a customized recommender system fashioned to meet the nutritional restrictions, preferences, and expectations of the user. The conducted by the authors of (38) recommended a diet plan to patients with jaundice using a hierarchy process that considers vital nutrients to determine the best choice for meals for all times of the day. The study of the authors in (39) discussed the uses and benefits of deep learning methods and ANNs in the advancement of the medical field in areas such as electroencephalography and the collation of physiological data. On the other hand, the authors in (40) presented a review of recommendation methods for people and groups to eat healthier foods. They also studied the existing recommender systems and challenges regarding research of recommendation technology. The study of the authors in (41) presented a Privacy-Preserving and Secure Framework (PPSF) for IoT-driven smart cities. The proposed PPSF is subject to two key schemes: a two-level privacy mechanism and an intrusion detection mechanism. Finally, the potentials of blockchain-enabled edge-of-Things (BEoT) by Prabadevi et al. in (42) was designed to provide security and services which comprises trust management, attack detection, data privacy preservation and access authentication.

SYSTEM MODEL

The methodology used in this study is explained in the following discussions. The objective of this study is for the recommendation of diet to various patients with special needs with a BPS utilizing machine and deep learning classifiers for the health-based medical dataset which will spontaneously identify what kind of food a patient with special needs should have, based on their disease and other factors such as weight, gender, and age, among others. For this reason, we have incorporated a BPS utilizing various deep and machine learning classifiers. A random forest classifier was utilized to know what feature has a greater effect on the dataset.

Dataset

The dataset utilized in this study comprises about a thousand products and 50 patients collated using IoT and cloud methods. The products experimented on various disease patients. The dataset possesses over 13 features and has stored in it almost 17,000 records. The features of the products are listed in **Table 1**, the features of the patient are listed in **Table 2**, while **Table 3** is the Training accuracy of models after BPS.

Data Preservation and Protection

The proposed BPS can be used by patients to store and preserve their personal data which are applicable to recommender systems. Example of such data includes diagnosed

TABLE 1 | Number of features in the product.

LSTM	96.5
Naïve Bayes	92.81
Logistic Regression	92.79

illness, treatment status, demographic attributes, prescribed medications, and response performance, among others. The BPS stores and fully encrypts this set of data, such that, accessing them without permission is almost impossible. Other related data, such as health history, diets of the patients, and more, which illustrates the actual treatment performance that is vital for the recommender systems are classically gathered by the hospital database system (HDS). These user-sensitive data are transmitted and stored in the BPS instead of the database of the hospitals, as illustrated in **Figure 1**, in order to enhance privacy by preventing attacks of the eavesdroppers, hacker attacks, and other intruding vulnerabilities. On the other hand, the BPS grants adequate permission to the patients to access these data in a very secured and trusted format. In case of a recommendation, prescription, check-ups, or emergencies, the BPS also sends a prompt notification to the registered smart device of the patient. This ensures adequate transparency about the data collection events of the hospitals for the patients (users).

Cooperative Filtering

One of the major advantages of the BPS over other existing privacy technology is its ability to perform efficient data computations while keeping all input data confidential. As illustrated in **Figure 2**, the hospital is notified each time the patient (user) attempts to obtain a recommendation for their confidential medical details. Because the hospital runs a multi-user system with several of its patients, their individual data are employed as input variables for the cooperative filtering algorithm of the recommender systems to sort and locate the best recommendations for each enquiring patient. Meanwhile, the hospital database manager can only view basic information of the patient as the rest of the sensitive data and computations are performed at the BPS. In conclusion, the patient gets a notification alert and receives secure permission to access the subsequent recommendations.

Data Processing

Data Normalization

Functions of data cleaning are carried out to get rid of noise and regularize the features after choosing a dataset. The aim of regularization is for the dataset to be scaled into a single range. This is done because the dataset has varied scale values. They can be one-digit, two-digit, or three-digit values so every value is brought into one scale so that the machine learning models perform more effectively. For this reason, we carried out min-max normalization. In this study, min-max scaling normalizes values within the scope of [0, 1] and is illustrated in Equation (1) below.

$$N_i = \frac{c_i - min(c_i)}{max(c_i) - min(c_i)} \tag{1}$$

where $y = (C_1, C_2 ... C_n)$ are the number of features. C_i is the feature to be normalized and N_i stands for the features that have been formalized. As a result of doing this, all the features now have identical weights, and they are all in a single scope.

Data Encoding

While this research was carried out, values that were duplicated and inconsistent were eliminated from the dataset before data encoding was performed. Subsequently, the nominal features are transformed into arithmetic values. The objective of this is to ensure that the backend functions of the machine learning models are performed using arithmetic values prior to their implementation. In this study, non-arithmetic data was transformed to arithmetic data prior to the performance of data encoding. Machine learning (ML) algorithms backend computations were also carried out on arithmetic values before data was passed to the suggested model.

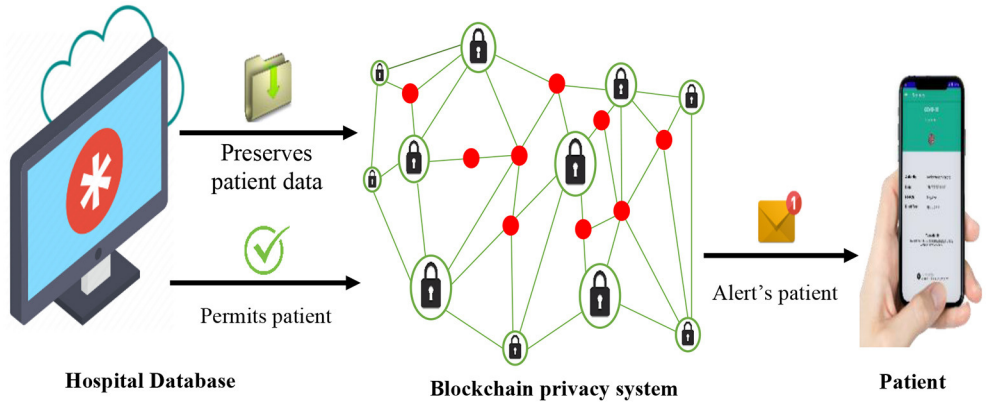

FIGURE 1 | BPS-based data storage and patient alert preservation system.

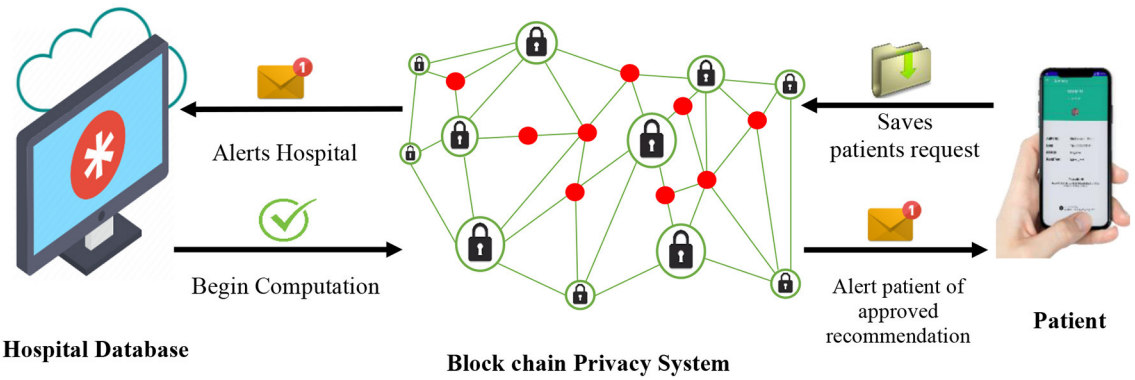

FIGURE 2 | BPS-based data storage, hospital management and preservation system.

Optimal Feature Visualization

A Product calorie has an important percentage of 48% in the dataset. Product fat has a significance percentage of 12%. Product protein and carbohydrates have significance percentages of 8%. Product sodium has an important percentage of 6%. The user number has an important percentage of 5%. Furthermore, product fiber, user fat, and protein have significance percentages of 2% each. Age, user weight and calories, disease, product barcode, and user carbohydrate have important percentages of 1% each in the dataset. Random Forest is a combination of decision trees. For the prediction to be correct, it integrates all the decision trees and gives more precise results. It is used not just for regression and classification, but also in the application of the best features in the dataset. Its best attribute is that regression and classification can be performed using it. When classifying Random Forest, the majority vote was utilized in the prediction of the target. However, for the evaluation of regression, Random Forest takes the average value of all the decision trees and predicts it as a threshold as stipulated for each node. Subsequently, there is a performance of splitting based on that threshold. The threshold is stipulated by computing gain-index and entropy. Their various equations are shown below.

$$Entropy: K(b_1, b_2, ...b_s) = \sum_{i=1}^{s} (b_1 \, log(\frac{1}{b_1}) \quad (2)$$

where b_1, b_2...b_s stands for the probabilities of the class labels.

$$Gain(R, S) = K(R) \sum_{i=1}^{S} x \, (R_1) \, K(R_1) \quad (3)$$

Deep Learning Classifiers

Multilayer Perception

There exist various kinds of neural networks created and developed previously. All the existing ANNs may be distinguished by their processing unit (PE) transfer functions. Their techniques of learning and by the link equations. Processing unit is a basic constituent of ANN. It collects numerous signals that are weighted from other existing processing units. The framework of forwarding ANN is like this. The first layer has its input units. There are hidden layers in the middle. Finally, the last layer comprises output units. The function of the input unit is the provision of data from

outside sources. Next, the data that is collected is transported to concealed layers where it is amplified with weights. Finally, it is passed to the output layer to initiate the final signals. The classification capacity of ANN is based completely on concealed layers. These concealed layers are linked by the synapses with the neighbor's layers. If there are *p* input data points (b_1, b_2... b_p), we call it *p* number of features in the data. In the ANN framework, all the features are amplified with weights (e_1, e_2...e_p) and then added as is stated in Equation (4) below.

$$E.B = e_1b_1 + e_2b_2 + ... + e_pb_p = \sum_{1=1}^{p} e_ib_i \quad (4)$$

where *"p"* represents the total amount of features present in the dataset given as input B to the input layer. While *"e"* stands for the weights of all the features amplified with its weight. It is referred to as the dot product too. The addition of the bias function is done next in the dot product function. It will lead to Equation (5) stated below.

$$a = \sum_{1=1}^{p} e_ib_i + bias \quad (5)$$

In Equation (5), *a* denotes the activation function f (a). In this manner, we will obtain the output for the first neuron and the first hidden layer. This procedure will be repeated until the last weight and the last input is seen.

Recurrent Neural Network

Recurrent Neural Network is a kind of ANN where node-to-node links create a graph administered along with a corporeal order which makes provision for the display of dynamic behavior. It is a type of new ANN that has memory cycles that are directed.

Long Short-Term Memory

This is a framework that carries out a memory augmentation for the RNN. In this study, 3 layers of LSTM with a batch size of 32, as well as the sigmoid function is used to activate it. The Adam function is utilized for optimization. Binary cross-entropy is used to compute function loss.

Gated Recurrent Units

The principle of the GRU is more current than the LSTM. Basically, it functions more effectively. It is quicker in the training of models as opposed to the LSTM. The model can be modified and manipulated easily. However, LSTM performs better than the GRU if a longer memory is needed. Eventually, the comparison of performance depends on the kind of dataset being used. The frameworks LSTM and GRU are somewhat similar, but there are some important differences stated below:

- The GRU comprises two gates, but the LSTM has three.
- Gated recurrent units do not have internal memory that is opposed to the detectable hidden form. The output gate which is embedded in LSTMs is also not present in the GRUs.
- There is no application of second non-linearity when calculating GRU output as opposed to the LSTMs.

Machine Learning Classifiers

Logistic Regression

This is a popular classification algorithm utilized in machine learning. Basically, a bipartite result is acquired with it. Its purpose is to find a link connecting the possibility of a particular outcome and its features. A logit (odds) function is utilized in this algorithm. In Equation (6), the algorithm is described as seen below:

$$\log\left(\frac{r(b)}{1-r(b)}\right) = \beta_o + J_{1b} \quad (6)$$

In the equation above, the logit function is $\log\left(\frac{r(b)}{1-r(b)}\right)$ and the odd function is $\left(\frac{\mathbf{r(b)}}{\mathbf{1-r(b)}}\right)$. The odds show the probability proportion of insertion of the feature to the likelihood of failure or lack of features. Output is normally done in this algorithm subsequent to the mapping of inputs to log-odds in a straight blend. Now, the contrary of the function stated above would be;

$$R(B) = \frac{1^{\beta_o + \beta_{1b}}}{1 + 1^{\beta_o + \beta_{1b}}} \quad (7)$$

Equation (7) is referred to as a sigmoid function which is a mathematical function that has an "S"—shaped curve characteristic, which converts the values between the range 0 and 1. As long as the probability value is initiated within the range of $0 < R < 1$, then we chose the variables in the logarithm in a manner to expand the likelihood of scrutinizing sample values.

Naive Bayes

This is a collation of algorithms that have a joint where all the pairs of the features are unconstrained. Two hypotheses are considered in the algorithm which are as follows:

1. All the functions are separate.
2. The texts need to be translated into arithmetic values in the instance of features in text format. Bayes' Theorem is shown in Equation (8) below:

$$R\frac{G}{H} = \frac{R\left(\frac{G}{H}\right)R(G)}{R(H)} \quad (8)$$

where G and H events, R (G) is the prior probability $R\left(\frac{G}{H}\right) = H's$ posterior probability. Now, Bayes' theorem can be implemented by Equation (9) as seen below:

$$R\frac{v}{B} = \frac{R\left(\frac{B}{v}\right)R(v)}{R(B)} \quad (9)$$

where B represents the dependent feature vector and v is the class variable, B is of size n so, B = (B_1, B_2, B_3 ..., Bn). For evidence to be split into unconstrained categories for events G and H: R (G, H) =R (G) R (H). The results then become:

$$R\left(\frac{v}{B_1 \ldots n}\right) = \frac{R\left(\frac{B_1}{v}\right)R\left(\frac{b_2}{v}\right)\ldots\ldots R(\frac{b_n}{v})}{R(B_1)R(B_2)\ldots\ldots R(B_n)} \quad (10)$$

It can be expressed as Equation (11) below:

$$R\left(\frac{v}{b_1 \ldots n}\right) = \frac{R(v)\Pi_{i=1}^{n} R\left(\frac{B_i}{v}\right)}{R(B_1)R(B_2)\ldots\ldots R(B_n)} \quad (11)$$

Because the denominator is continuous for input, so in Equation (12) below:

$$R\left(\frac{v}{b_1 \ldots n}\right) = \infty R(v)\Pi_{i=1}^{n} R\left(\frac{B_i}{v}\right) \quad (12)$$

For a classifier model to be produced, the input probabilities for v must be determined and the output with the highest probability has to be taken. Hence, in Equation (13) below:

$$v = argmax R(v)\Pi_{i=1}^{n} R\left(\frac{B_i}{v}\right) \quad (13)$$

Finally, what is left for calculation is $R\left(\frac{b_i}{v}\right)$ which is the initial probability and R (v) which represents the contrast of the logit function.

Evaluation Metrics

Various metrics are utilized in the evaluation of the performance of our suggested model. These are stated below:

$$Accuracy = \frac{A_z + A_n}{A_z + C_z + C_n + A_n} \quad (14)$$

The objective of precision is to examine the True Positive (AZ) units in connection to False Positive (CZ) units.

$$Precision = \frac{A_z}{A_z + C_z} \quad (15)$$

The objective of recall is to examine True Positive (AZ) units in connection to False Negative (CN) units that are not classified. The arithmetic arrangement of recall is stated in Equation (16) below:

$$Recall = \frac{A_z}{A_z + C_n} \quad (16)$$

Sometimes, assessment of performance may not be very efficient with recall and accuracy. For example, if a mining algorithm has high precision but low recall, then another algorithm is needed. Then comes the question of which algorithm is more effective. This challenge is solved utilizing F1-measure that gives a mean recall and precision. F1-measure can be calculated as follows:

$$Measure = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (17)$$

Software Analysis

A Colab software installed on a Core-i7 computer system is employed in performing the Deep Learning experiments. The system is fully equipped with 16GB RAM, 4 CPUs, a 1.7 GHz processor, and about 20GB obtained from Google Colab laboratory. The overall dataset was partitioned into three segments which includes training segment, cross-validation segment, and testing segments. Constituting 80% of the dataset was utilized in the research as the training set, 20% was used as the testing set, while *K*-Fold Cross-validation was employed and is applicable to both the training and testing sets.

TABLE 4 | Performance of training score accuracy for selected classifiers.

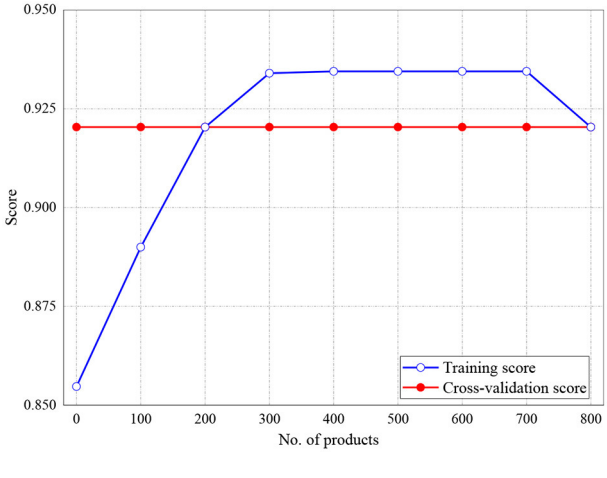

FIGURE 4 | Result for Training and Cross-Validation Scores of Logistic Regression classifier.

The study employed both machine and deep learning classifiers in this research and their training accuracies are presented in **Table 4**. Using a 32-batch sized 3-layer LSTM with sigmoid activation function, it is established that the LSTM classifier ranked maximum with 95.45% training accuracy, while MLP ranked as the least at 86.5%. The training accuracies for the rest classifiers which are GRU, RNN, Logistic regression [LR], and Naive Bayes were at 94.6, 92.3, 88.5, and 87.2% training accuracies, respectively.

EXPERIMENTS AND RESULTS

The training and validation scores of Naive Bayes, LR, and MLP classifiers are presented in **Figures 2**, **4**, **5**, respectively. For all the figures, the training scores are denoted with a blue line/curve while the red curve represents the scores of cross-validations. For Naive Bayes in **Figure 3**, it is observed that the training and cross-validation scores merged at 87.2%. The cross-validation score of the logistic regression in **Figure 4** remained stable and linear while the training score increases up to 93.8%, stabilizes, and further decreases. The validation and training scores of the MLP classifier is illustrated in **Figure 5**. The experiment shows that both the training and validation scores of the MLP classifier training scores increase at some point and ultimately decreased.

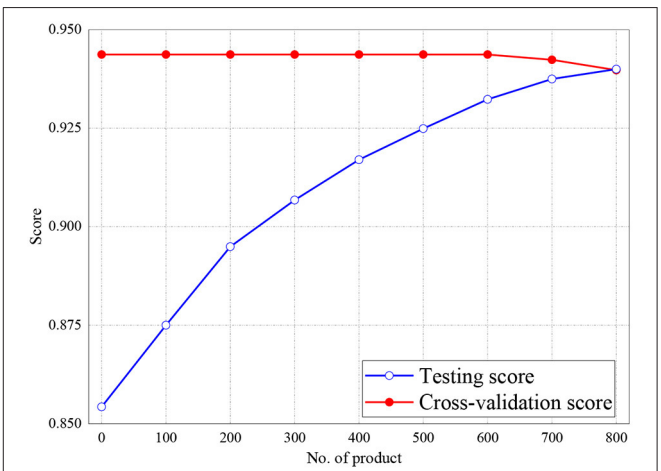

FIGURE 7 | Result for Testing and Cross-Validation of Logistic Regression.

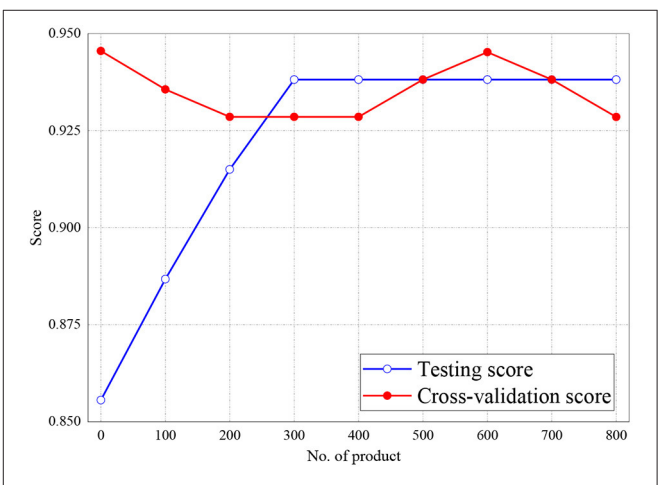

FIGURE 8 | Result of Testing and Cross-Validation for MLP classifier.

The test accuracies of the MLP classifiers are presented in **Table 5**. The result shows that the LSTM classifier realized a maximum of 99.5% test accuracy, while the MLP classifier achieved the least score of 90.3% test accuracy. The rest classifiers which are GRU, Naive Bayes, RNN, and LR all attain 98.8, 95.6, 95.5, and 90.8% testing accuracies, respectively.

Figures 6, **7** represent the testing accuracies and cross-validation scores of both Naive Bayes and LR models, respectively, it is observed that the testing accuracies and validation scores for both models merged at 94 and 94.28%, respectively. Similarly, **Figure 8** shows that the validation and testing scores for MLP merged at 93.81 and 92.85%, respectively.

The study further investigated the accuracies and loss performance of training scores against the testing scores for all the models. The results of these investigations are presented in **Figures 9–11**. The red curves denote the training scores, while the blue curves denote the testing scores for both the accuracy and loss performances. **Figure 9A** represents the performance accuracy of the training and testing scores for the GRU classifier. It is observed that the performance started from 87.5% and remained stable until after about 45 epochs. It further witnessed instabilities till it achieved an apex of 93% at 96.6 epoch. Similarly, the blue curve which represents the testing score started and remains stable at 85.5%, witnessed several instabilities but attained its apex of 90.2% at 100 epochs.

On the other hand, the loss performance of the training and testing scores for the GRU classifier is represented in **Figure 9B**. The figure indicates that the loss performance of the training

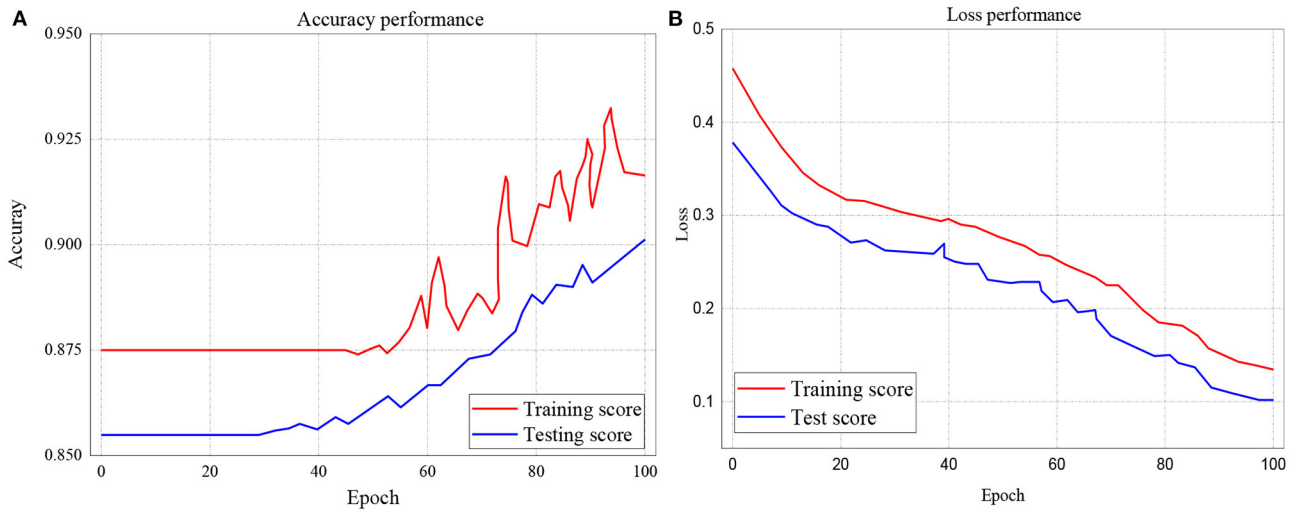

FIGURE 9 | (A,B) Performance accuracy and loss of Training and Testing Scores for GRU classifier.

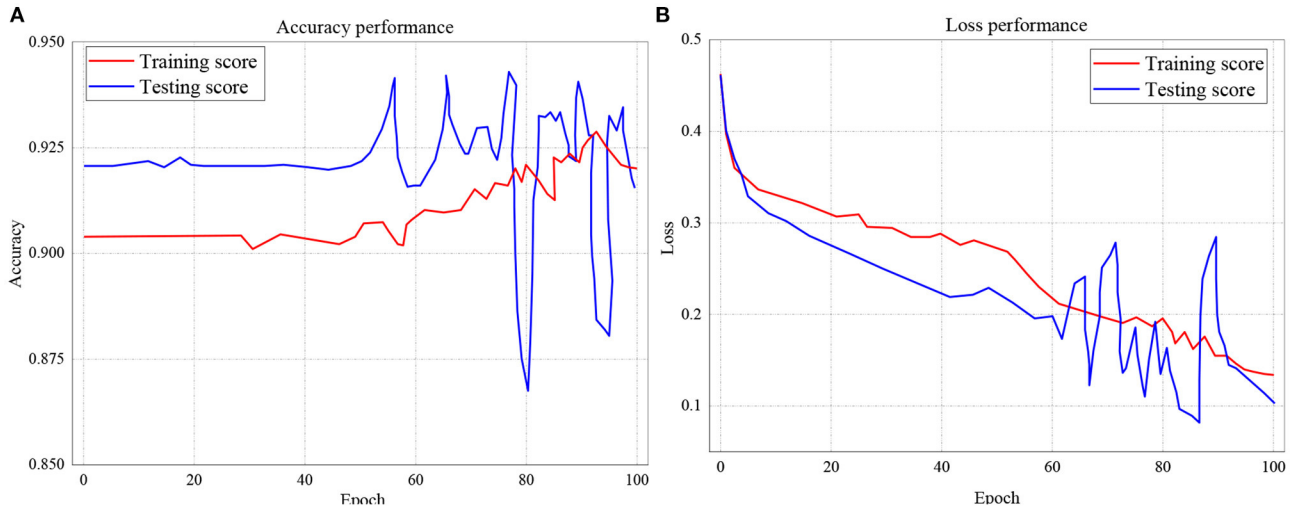

FIGURE 10 | (A,B) Performance accuracy and loss of Training and Testing Scores for LSTM.

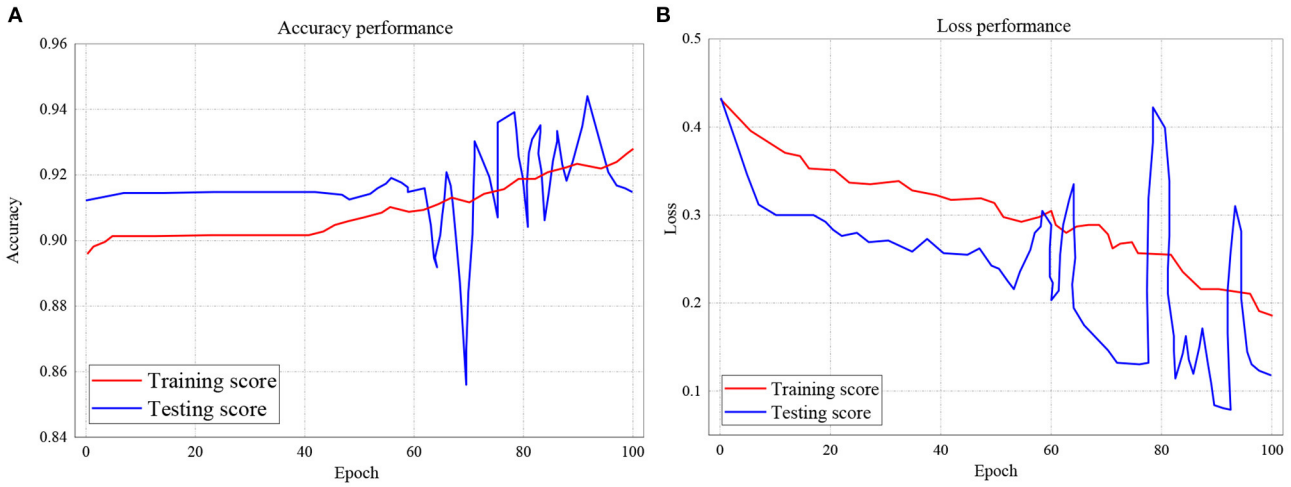

FIGURE 11 | (A,B) Performance accuracy and loss of Training and Testing Scores for RNN.

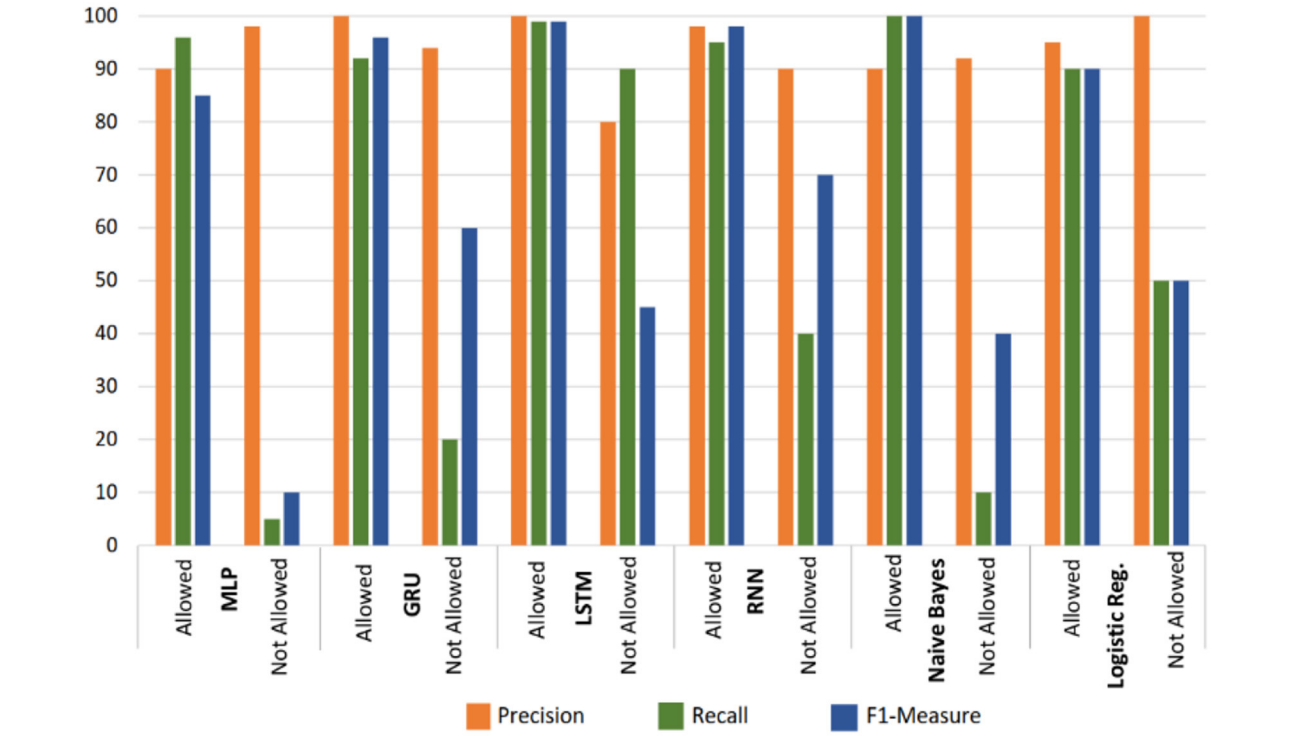

FIGURE 12 | Result of the Classification for Deep and Machine Learning classifiers.

score began from 0.45 and decreased to 0.14. In the same way, testing loss performance commenced from 0.38 down to 0.102.

The training and testing scores accuracy for LSTM is presented in **Figure 10A**, while the loss performance for the same model is illustrated in **Figure 10B**. Considering **Figure 10A**, the experiment shows that for accuracy, the training score started from 92.1%, with the least performance of 86.8% and peak performance of 94.3%. Likewise, for testing score accuracy, the performance began from 90.4% to a peak of 92.8% with the least performance of 90.1%. On the other hand, the training and testing loss performance of the LSTM classifier is illustrated in **Figure 10B**. The performance indicates that the training loss score commenced from 0.46 and declines to 0.14 after 100 epochs. The testing loss performance shows that the

reading also started from 0.46 but decreased down to 0.1 after 100 epochs.

In **Figure 11A**, the testing and training scores accuracy for the RNN model is presented, while the loss performance for the same model is illustrated in **Figure 11B**. With respect to **Figure 11A**, the experiment shows that for accuracy, the training score started from 89.5% and also records as the least performance with a peak performance of 92.9% after 100 epochs. Also, for testing score accuracy, the performance began from 91.3% to a peak of 91.5% with the least performance of 85.8%. On the other hand, the training and testing loss performance of the RNN classifier is illustrated in **Figure 11B**. The performance indicates that the training loss score commenced from 0.435 and declines to 0.185 after 100 epochs. The testing loss performance shows that the reading also started from 0.435 but decreased down to 0.12 after 100 epochs.

The classification further recorded the deep learning and machine learning classifiers which are presented in **Figure 12**. The result indicates that the LSTM classifier outperforms the rest of the tested classifiers with reference to recall, F1-measure, and precision. The experiment is divided into allowed and not allowed classes. The performance of the LSTM classifier for the allowed class is measured at 99, 100, and 99% for recall, precision and F1-measure accordingly. Meanwhile, the disallowed class performance of the LSTM classifier measure at 90, 80, and 45%, for recall, precision, and F1-measure, respectively. The rest of the experimented models performs well in terms of the allowed class. However, they did not perform well with the disallowed class.

CONCLUSION AND FUTURE WORK

The analysis of collected automated medical data has been established to have the potential in providing adequate recommendations for the improvement and management of patients with special needs in the hospitals through different algorithm developments and knowledge discovery. However, several medical facilities and special care patients are yet to grasp the usage and intent of secured recommender systems. One of the reasons for not embracing the systems is due to fear of data Privacy Breach. This research proposes a secure deep learning-based recommender system that estimates and issues basic treatment and diet recommendations to patients with special needs without revealing their sensitive health details. The system automatically issues exact recommendations to ailing patients based on their basic demography, diet, health history and other related data. The deep learning classifiers considered in this research include LSTM, MLP, GRU, RNN, Naive Bayes, and LR. The results of the performed experiments show that LSTM and GRU outperform every other classifier with reference to their recall, precision, and *F*-1 measures for both the allowed and not allowed classes. The performance of the LSTM classifier for the allowed class is measured at 100, 99, and 99% for precision, F1-measure, and recall, respectively. Meanwhile, the disallowed class performance of the LSTM classifier measures 90, 80, and 45% for recall, precision, and F1-measure, respectively. In the future, we shall incorporate the concept of multidimensionality in the secured diet recommender systems, where patients with special needs will maintain privacy after the whole process.

Detection and prediction of the novel Coronavirus present new challenges for the medical research community due to its widespread across the globe. Methods driven by Artificial Intelligence can help predict specific parameters, hazards, and outcomes of such a pandemic. Recently, deep learning-based approaches have proven a novel opportunity to determine various difficulties in prediction. In this work, two learning algorithms, namely deep learning and reinforcement learning, were developed to forecast COVID-19. This article constructs a model using Recurrent Neural Networks (RNN), particularly the Modified Long Short-Term Memory (MLSTM) model, to forecast the count of newly affected individuals, losses, and cures in the following few days. This study also suggests deep learning reinforcement to optimize COVID-19's predictive outcome based on symptoms. Real-world data was utilized to analyze the success of the suggested system. The findings show that the established approach promises prognosticating outcomes concerning the current COVID-19 pandemic and outperformed the Long Short-Term Memory (LSTM) model and the Machine Learning model, Logistic Regresion (LR) in terms of error rate.

Keywords: COVID-19, deep learning, LSTM, RNN, prediction reinforcement learning

INTRODUCTION

With the spread of the unfamiliar Coronavirus (COVID-19), which was first discovered in Wuhan city in China in 2019, societies worldwide continue to face very distressing times. On March 11, 2020, the World Health Organization (WHO) flagged the COVID-19 as a pandemic, exceeding 118,000 cases in over 110 countries. The epidemic has quickly spread through many countries, including Italy, Spain, France, the United States, and India, wreaking havoc on healthcare systems (1). Modeling and predicting the expanse of verified and recovered COVID-19 cases accurately is critical for understanding and helping decision-makers to slow down or arrest its progression. Since the COVID-19 pandemic has shifted into a global pandemic, there is a necessity for real-time epidemiological data examinations to provide the population with a strong course of action to combat the infection. Following the novel COVID-19, the world has been restlessly battling its cause (2). As of August 27, 2020, there were 24,631,906 confirmed cases worldwide, of which

TABLE 1 | Top 5 affected countries COVID-19 data.

Country	Cases	Deaths	Recovered	Fatality (%)
USA	28,765,423	511,133	18,973,190	1.8
India	11,005,850	156,418	10,699,410	1.4
Brazil	10,168,174	246,560	9,095,483	2.4
Russia	4,164,726	83,293	3,713,445	2.0
UK	4,115,509	120,580	2,494,218	2.96

TABLE 2 | Top 5 affected countries COVID-19 data.

Name	COVID-19	MERS	SARS
Year	2019	2012	2003
Confirmed	110,927,514	2,494	8,096
Deaths	2,454,587	858	774
Fatality %	2.21	34.1	9.6
Countries	220	27	26

17,089,939 recovered, and 841,310 ended in death (3). **Table 1** shows the topmost countries affected. The COVID-19 relate itself to the species as that of SARS-CoV and MERS-CoV.

Table 2 shows the comparison, where the symptoms initially appear as a common cold then progress to those of respiratory diseases that cause breathing problems, tiredness, fever, and dry cough. Once a large-scale break out of a contagious disease occurs and a significant public health emergency ensues, researchers use outbreak models to evaluate and forecast the disease's development pattern and determine direct measures to prevent and restraint based on the effects of the analysis.

The most frequently used conventional pandemic schemes are susceptible—infected—recovered (SIR), and susceptible—exposed—infected—recovered (SEIR) models (4), where "S," "E," "I," and "R" signify every number of susceptive persons, the magnitude of individuals during the incubation phase, the magnitude of contagious persons and the number of individuals improved, respectively. These models are trained to forecast multiple diseases, such as Ebola and SARS, due to their robust predictive abilities of the linked indications. With the emergence and spread of COVID-19, the significant research challenge is arresting the growth patterns of the spread of this disease which has been observed in several science fields throughout the globe. Thereby, different approaches (5) to modeling, estimating, and forecasting are implemented to understand and control this pandemic. Traditional disease models measure the rate of infection based on the complex variation in the number of contaminations and then determine the disease's spread and evolution pattern. Yet, those approaches assume that all individuals with Coronavirus hold an equal chance of infection, and hence, their predictive results can only suggest general patterns and are restricted.

Artificial Intelligence (AI) is lately being applied toward stimulating biomedical study and toward numerous fields such as image identification, object categorization, image segmentation, and deep learning approaches (6). For example, individuals affected with COVID-19 will possibly have pneumonia since the infection reaches the lungs. Many deep learning investigations identify the condition using X-ray images of the chest (7). Three different deep learning models (8) have been employed in the past to distribute X-ray images of pneumonia, and those are the fine-tuned model, the non-fine-tuned and the scratch-trained model. On the other hand, most prediction models use X-ray and CT images (9) based on the deep learning method, which requires more time to extract the features and train the model.

Famous classical mathematical differential equations and population prediction models have limitations on predicting the population in the time-series and significant estimation errors. Analytical methodologies, for instance, Auto Regressive Moving Average (ARIMA), Moving average (MA), and Auto-Regressive (AR) methods, are primarily formulated on the premises. Still, they have difficulties in predicting live circulation rates. A vast variety of demographic and computative models (10) were developed for modeling COVID-19's rampant transmission dynamics. However, in multiple situations, these approaches don't adhere to the provided information, and the accuracy of the forecast is usually low. Therefore, this work investigates the modified LSTM approach to forecasting the likely COVID-19 cases and deaths. It also describes deep reinforcement learning for optimizing the prediction results based on symptoms. Experiments using real data and various metrics reveal the improved performance of the work. The specific contributions of this paper include:

- Deep and reinforcement learning to predict COVID-19,
- LSTM model modified with new activation function for efficient prediction,
- Deep reinforcement learning applied to optimize results based on COVID-19 symptoms

The remainder of the paper is ordered as follows. Section related work reviews the related work. Preliminary information regarding the used approaches and the problem statement is given in section methodological preliminaries, while section optimized prediction of covid-19 describes the proposed method. The experiential details, evaluation criteria, and performance comparison are given in section optimized prediction of covid-19, along with an analysis of the conclusions attained. Lastly, section results and discussions gives some concluding observations.

RELATED WORK

COVID-19 Prediction and Forecasting

Various prediction techniques that are regularly used to tackle forecasting problems include Machine Learning (ML) models (4), which can be employed toward determining the number of potential COVID-19 infected patients. Rustam et al. (4) used four simple statistical models: Linear Regression, Least Absolute Shrinkage and Selection Operator, Support Vector Machine, and Exponential Smoothing to forecast threatening COVID-19 factors. Petropoulos and Makridakis (11) presented an analytical procedure to forecast the continuation of COVID-19. The work presents a timeline of a live forecasting activity with

significant possible planning and decision-making consequences and offers realistic forecasts for confirmed COVID-19 cases. Malavika et al. (12) adopted a logistic growth curve model for short-term prediction of COVID-19, and SIR models was employed in identifying the highest possible live individuals and peak seasons. In addition, the Time Disrupted Regression model is used to estimate the influence of lockdown and other important proposals.

Pal et al. (13), combined medical data with the trend and local weather data to forecast each country's level of risk. Specifically, a shallow LSTM neural network is employed in solving difficulties in limited datasets, and a country's risk level (high, medium, and recovery) is categorized using the Fuzzy rule. Hu et al. (14) used Coronavirus-specific dataset to fine-tune the pre-trained multi-task deep model. The re-trained prototype was then utilized to decide possible commercial medications upon targeted proteins of SARS-CoV-2. Finally, Salgotra et al. (9) developed Genetic programming (GP) prediction models for confirmed individuals and death cases across three of the most affected states, namely Maharashtra, Gujarat, Delhi, and India. The predictive models are expressed utilizing the specific formula, and predictive powerless variables were studied.

Velásquez and Lara (1) analyzed historical and expected COVID-19 death infections based upon the Reduced-Space Gaussian Process Regression correlated with disordered Dynamical Systems. COVID-19 forecasted with Gaussian models mean-field models can be meaningfully applied to obtain a quantitative summary of virus spread with contamination, death, and recovery rates. Jia et al. (10) adopted Logistic, Bertalanffy, and Gompertz models to prove the validity of the current statistical models by fitting and analyzing the SARS epidemic patterns. The findings were then used to fit and evaluate the COVID-19 scenarios. The forecasted outcomes of the three different mathematical models varied for different parameters and in different regions. Kavadi et al., (15) proposed partial derivative regression and a non-linear machine learning system toward the global pandemic verification of COVID-19. Dehesh et al., (16) considered the best predictive models for regularly reported individuals in nations with a huge magnitude of verified cases and then made predictions based on those models to better prepare healthcare systems. For predicting the pattern of reported events, the Auto-Regressive Integrated Moving Average model was used. Ngabo et al. (17) proposed an artificial intelligence (AI) algorithm that predicts the survival rate of COVID-19 patients based on their immune system, exercise rate, and age quantiles.

Deep Learning for COVID-19

Arora et al. (18) used deep learning-based models to forecast the number of recorded positive cases of novel Coronavirus (COVID-19) for 32 Indian states and union territories. Recurrent Neural Network (RNN)-based LSTM variants, such as Deep LSTM, Convolutional LSTM and Bi-directional LSTM, were applied to the Indian dataset to forecast the number of positive cases. Huang et al. (19) suggest that Convolutional Neural Network (CNN) can accurately estimate and determine the number of verified cases. The emphasis was on various towns with the most reported cases in China, and a COVID-19 prognostication model was suggested based upon the CNN system of Deep Neural Network (DNN). Three deep learning models (20), namely DNN, LSTM, and CNN, were stacked in learning models for the ensemble to achieve the most reliable results. The meta-learners used these forecasted values of these models as inputs to produce the final prediction of outbreaks. Ramchandani et al. (21) proposed a deep learning model to forecast the range of increase in COVID-19 and offer an unusual approach for determining equidimensional multivariate time scale illustrations and multivariate spatial time scale results.

Yoo et al. (22) examined the usefulness of applying a deep learning-based decision-tree classifier to distinguish COVID-19 from CXR images. This classifier consists of three binary decision trees, each trained by a deep learning model based on the PyTorch system with a neural convolution network. The primary decision tree divides the CXR images as either regular or anomalous. The second tree recognizes the irregular images bearing symptoms of tuberculosis. The final tree identifies the signs of COVID-19. Ozturk et al. (23) introduced a different approach for automated COVID-19 detection employing raw X-ray images of the chest. The developed system offers honest diagnostics for binary (COVID-19 vs. No-Findings) and multi-class (COVID-19 vs. Pneumonia vs. No-Findings) classification. Panwar et al., (24) proposed a deep learning neural network-based approach nCOVnet, which employs an alternative rapid screening system to identify COVID-19 by analyzing patients' X-rays to check for visual markers present in COVID-19 patients' chest radiography images.

Hu et al. (25) proposed the weakly controlled deep learning strategy for recognizing and distinguishing COVID-19 contagion from computed tomography (CT) images. This approach reduces the manual labeling requirements for CT images, reliably diagnose infection, and distinguish COVID- 19 from non-COVID-19 cases. Deep learning-based research about CT in the chest has proven to be reliable and effective for determining COVID-19. Mohammed et al. (26) proposed ResNext+, which offers an end-to-end semi-supervised strategy to COVID-19 discovery, including data labels at volume level only, and can provide a slice level prediction. A deep, long-term bidirectional memory network with a mixed density network (DBM) model was established by Pathak et al. (27), namely the Memetic Adaptive Differential Evolution (MADE) algorithm which can fine-tune the hyperparameters for the DBM model.

Deep Reinforcement Learning

Reinforcement Learning (RL) is a machine-learning model, where agents learn efficient techniques from trial-and-error encounters with their surroundings that produce the single most massive, long-term reward. The Q-learning algorithm (28) is the most descriptive of the RL algorithms. Q-learning can learn an acceptable method without an environmental operating prototype by modifying an action-value algorithm called the Q function. When the state-action space is large and complex, deep neural networks can approximate the Q-equation, and the corresponding algorithm is called Deep Reinforcement Learning

(DRL) (29). This has promising application for rational decision-making in diverse fields, such as energy management, robotics, agriculture, healthcare, etc. This model successfully resolved a wide range of complicated decision-making assignments which were earlier outside the machine's limits.

Wang et al. (30) offered an adaptive design that relies on graph embedding in the training process during state representation and reinforcement learning. Depending on a couple of real-life datasets, the findings show that the scheme can beneficially decrease the infection's epidemiological replication rate. This approach can aid in the initial exposure of COVID-19, whereby RL may represent an effective method to combat the spread of an outbreak. Dell'Aversana (23) combines multi-layer Artificial Neural Networks with Reinforcement Learning architecture to allow software-defined factors to acquire environmentally optimized functioning. Iwendi et al., (31) utilized COVID-19 patients' geographical and demographic data to predict the severity of cases, recovery, and death. In (32) a semantic privacy framework that uses sensitive and semantically related terms to sanitize healthcare documents was proposed, and (33) uses deep learning to detect and sanitize social media comments. In (34), the authors discussed the concepts of an incentive approach for COVID-19 planning using Blockchain Technology. Deep learning and medical image processing for Coronavirus (COVID-19) pandemic were analyzed by the authors in (35) and the results are nicely presented.

METHODOLOGICAL PRELIMINARIES

This section describes the COVID-19 prediction problem and gives information about the technical background of DL and RL used within this work.

Problem Formulation

Time scale forecasting aims to utilize the input sequences witnessed earlier to forecast a fixed-length series of expected time scale values. In machine learning, a part of the input time-series sequence, i.e., delayed values, is replaced to assist the input functions. The number of leading time levels is recognized as the width/size of the frame. Provided with a single variable time-series:

$$TS\,(t) = \{s_1, s_2, s_3, \ldots, s_t\} \tag{1}$$

the intention is to forecast the future k values of the sequence, $\hat{y} = \hat{y}_1, \hat{y}_2, \hat{y}_3, \ldots, \hat{y}_k \cong \left(s_{t+1}, s_{t+2}, s_{t+3}, \ldots, s_{t+k}\right)$ utilizing the values of former conclusions.

Long Short-Term Memory Network

RNN is one of the deep learning techniques which automatically selects appropriate characteristics from the practice specimens and later supplies activation from the previous time step as information for the current time step and network's self-connections. RNN is proper for data processing and has outstanding potential in time-series forecast by saving extensive historical data in its inner state. Still, it has the limitation of disappearing and gradient-exploding difficulties, which leads to an extended practice period or practice that does not work. In 1997, Hochreiter and Schmidhuber (36) devised a long short-term memory structure to determine long-term dependence on the multiplicative passages that coordinate information and memory cells movement in the recurrent hidden layer.

Figure 1 exhibits an LSTM memory cell's primary arrangement with two distinct components: (C_t) and the short-term state component (h_t).

The structure of LSTM consists of the following gates: input, forget, control, and output gate. The input gate determines which information can be passed on to the cell and is defined as:

$$i_t = \sigma\, W_i \times h_{t-1} x_t + b_i \tag{2}$$

The information to be ignored from the previous memory input is determined by the forget gate and is defined as:

$$f_t = \sigma\, W_f \times h_{t-1} x_t + b_f \tag{3}$$

The cell update is controlled by the control gate, based on the following equations:

$$\tilde{C}_t = \tanh W_c \widetilde{\times} h_{t-1} X_t + b_f \tag{4}$$

$$C_t = F_t^* \tilde{C}_{t-1} + i_t^* \tilde{C}_t \tag{5}$$

The hidden layer (h_{t-1}) is updated by the output layer, which is also responsible for updating the output gate as is given by:

$$O_t = \sigma\, W_o \times h_{t-1} x_t + b_o \tag{6}$$

In the above equation, W and b represent the weight matrix and bias vector, respectively; tanh is used to scale the values in the range −1 to 1, and σ denotes a standard logistic sigmoid function. The variables *i, f, o,* and *c* are the input gate, forget gate, output gate, and cell activation vector.

Reinforcement Learning

Reinforcement learning (RL) is an artificial intelligence model with a progressive programming guide instructing algorithms to apply an award and penalty strategy. A Markov choice system is designated for the RL study process, which endorses the formalism of reinforcement learning difficulties. The RL algorithm is an agent that receives through communicating and associating with society. The agent will obtain incentives for the appropriate steps and penalties for the inaccurate performances. Without individual intervention, the agent learns by itself via improving his incentives and reducing his punishments. The intercommunication process between the agent and environment of RL is shown in **Figure 2**.

An agent available in a state (S) executes an action (A). The agent collects a reward R(S, A) for acting and shifts into a different state. A policy (π) means any mapping function of the states and actions that decide an agent's action in every state. The central goal in an agent's existence is to obtain an optimal

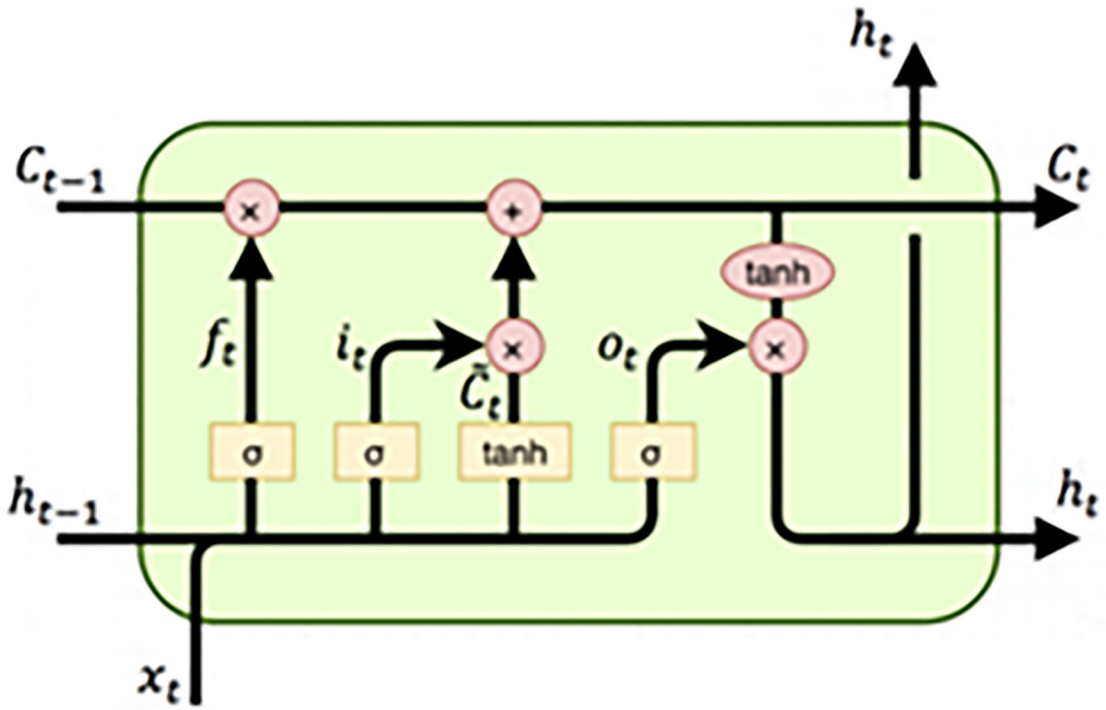

FIGURE 1 | The structure of the LSTM.

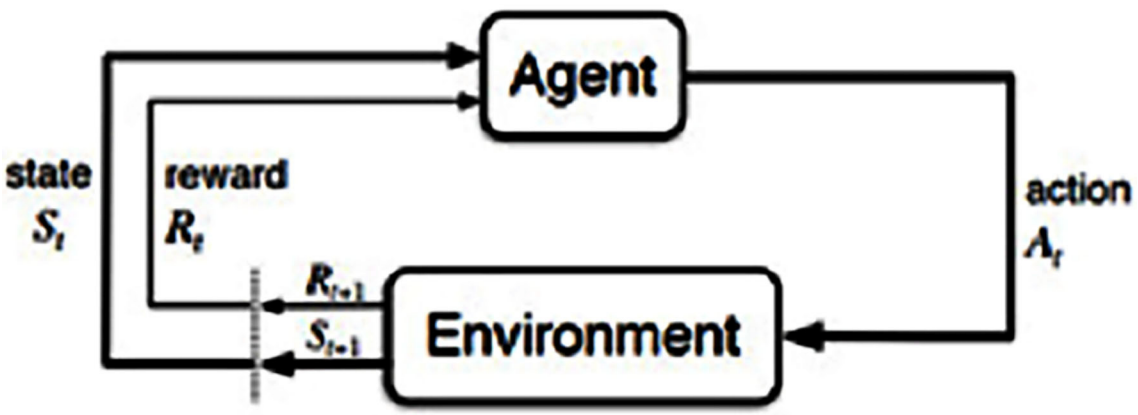

FIGURE 2 | Interaction process of reinforcement learning.

strategy π^* for which the overall reduced incentive is expanded. The optimal system π^* is defined in equation (7):

$$\pi^*(S) = argmax_{a\epsilon A}\gamma \sum_{s'\epsilon S} P_{sa}\left(s', a\right) V^*(s', a) \tag{7}$$

The best assessment function is obtained from the most dependable optimal plan; it is defined through some benefits an agent receives from all the other states. The aforementioned function with optimum power is expressed in equation (8):

$$V^*(s, a) = R(s, a) + max_{a\epsilon A}\gamma \sum_{s'\epsilon S} P_{sa}\left(s', a\right) V^*\left(s', a\right) \tag{8}$$

Thus, a reinforcement learning agent learns through experiences with the environment. Using complex programming functions, agents optimize their compensations through estimating individual fittest optimal strategy and power function for the bellman.

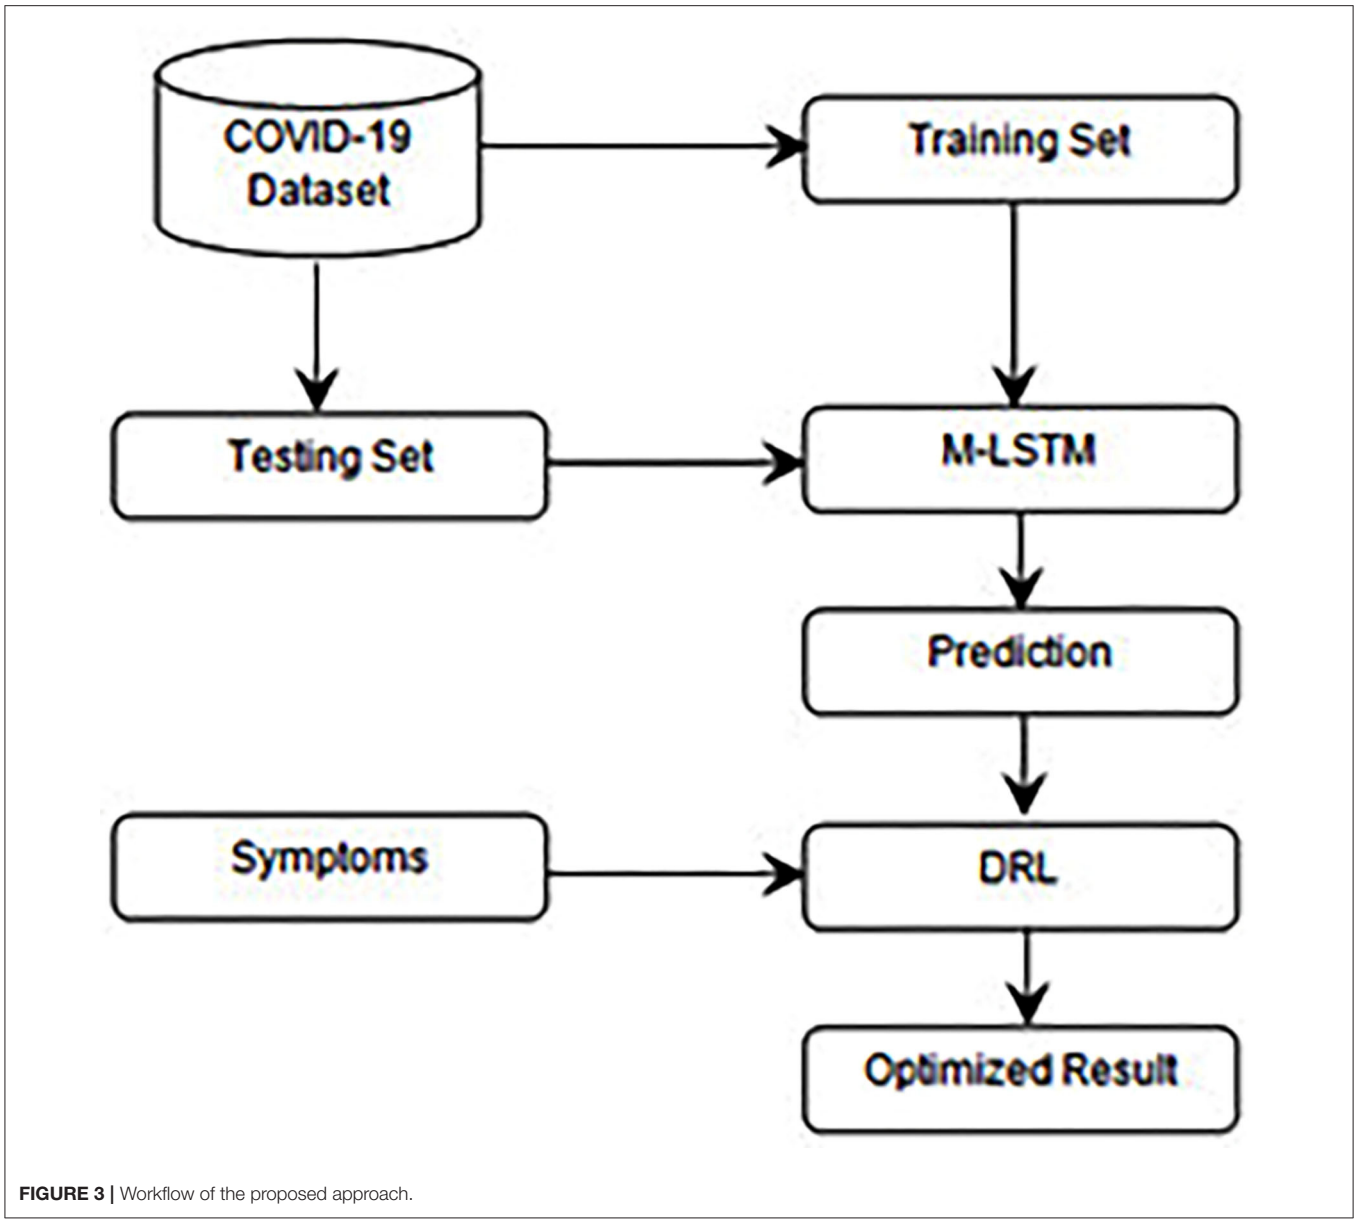

FIGURE 3 | Workflow of the proposed approach.

OPTIMIZED PREDICTION OF COVID-19

The presented research investigates predictions for the novel COVID-19 using the discussed reinforcement learning. COVID-19 has proved to be a serious threat to people of all ages all over the world. It has resulted in tens of thousands of deaths so far, with the mortality rate continuing to rise regularly. This research sought to assess future estimates of the death rate, the number of infected individuals reported every day and the number of healing cases in the following 15 days to add to the pandemic's tracking. The forecasting was done using a Deep Learning framework that was designed specifically for this study.

AI is a growing platform with many different intelligent applications, such as Machine Learning (ML) and Deep Learning (DL). ML indicates the capability to acquire and deduce significant patterns of these data; furthermore, ML-based algorithms and practices' accomplishment depends heavily on the individual functions. Meanwhile, by learning from simple representation, DL can solve complex systems. DL possesses a pair of critical features (14): (1) the capacity to acquire the correct phrases and (2) the ability to help the machine discover data by sequentially using several layers to understand more meaningful representations.

This paper proposes an optimized prognostication of COVID-19 employing deep reinforcement learning (DRL). Primarily, Modified-LSTM was utilized to forecast the figures of verified cases and death cases. Next, the forecasted outcomes were optimized by employing

TABLE 3 | Daily and weekly sample data for COVID-19.

Date	Confirmed	Deaths	Weekly confirmed	Weekly deaths
30–01–20	1	0	1	0
31–01–20	0	0	1	0
01–02–20	0	0	1	0
02–02–20	1	0	2	0
…	…	…	…	…
14–08–20	64,553	1,007	434,116	6,455
15–08–20	65,002	996	437,581	6,518
16–08–20	63,490	944	436,672	6,601

DRL based on the symptoms. **Figure 3** shows the proposed workflow.

LSTM is an RNN deformation structure, where the memory cell is added to the hidden layer to restrain the memory data of the timeline data. Data is transmitted through several controllable gates between different cells of the hidden layer, thus allowing control of the memory and ignoring the amount of the former and prevailing data. Two LSTM gates are designed to control the status of the memory cell. One is the forget gate, which shows how much "memory" can be preserved from the last moment of the cell; the second is the input gate, which specifies how much information about the current time can be kept to the cell status and regulates the fusion ratio of "old" data and "present" incentive. Lastly, LSTM's output gate is designed to control the extent of cell status information outputs. The structure of LSTM can be found in **Figure 1**.

Herein, two activation functions of LSTM are used: linear and non-linear. The traditional LSTM uses the non-linear tanh function. For best results, select the best activation function.

$$f(x_i) = \frac{\exp(x_i)}{\sum_j \exp(x_j)} \tag{9}$$

Deep learning stimulates the improvement in RL, whereby DL algorithms within RL describe the deep reinforcement learning (DRL) area. Deep learning allows RL to scale up the earlier unmanageable issues, i.e., settings by a high-dimensional state, areas for the interruption, and decision-making. Deep reinforcement training employs a deep neural network to approximate every reinforcement learning function, including value function, Q function, transformation system, and reward function. Q-Learning is an RL system that decides which action an agent should take, depending on an action-value role. This determines the significance of remaining in a particular state and completing a specific activity at that state depending on an action-value role.

It is one of the most meaningful progress in reinforcement learning by developing an algorithm to limit off-policy temporary deviation. Q-Learning measures a state-action value function for a target system that decides the highest value in picking the

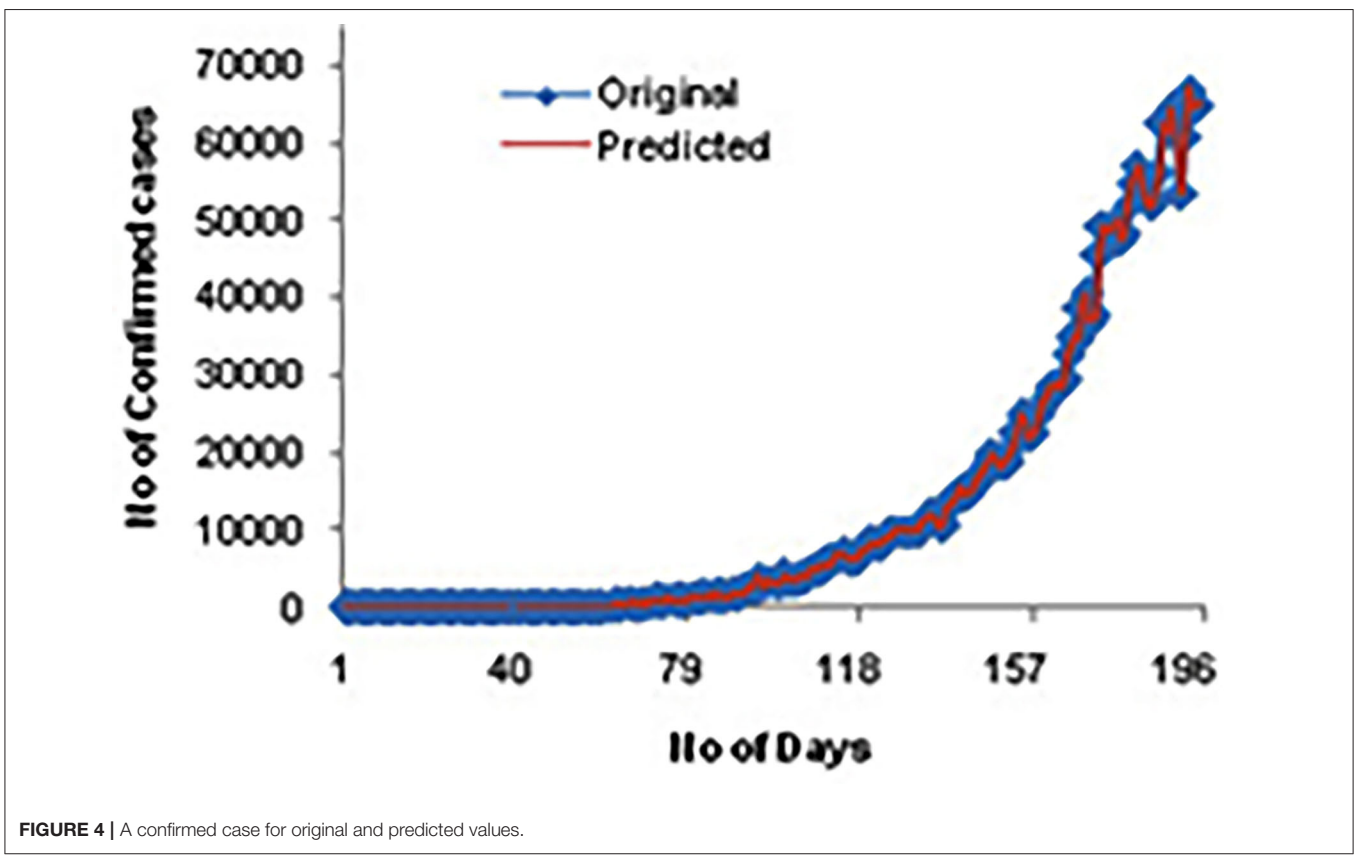

FIGURE 4 | A confirmed case for original and predicted values.

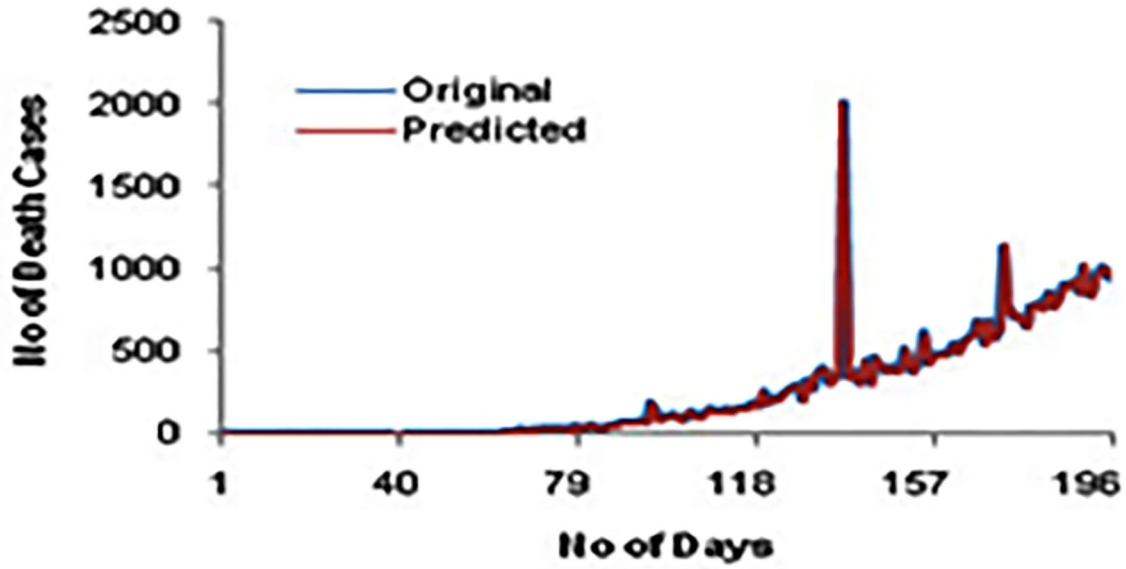

FIGURE 5 | Predicted values for death cases.

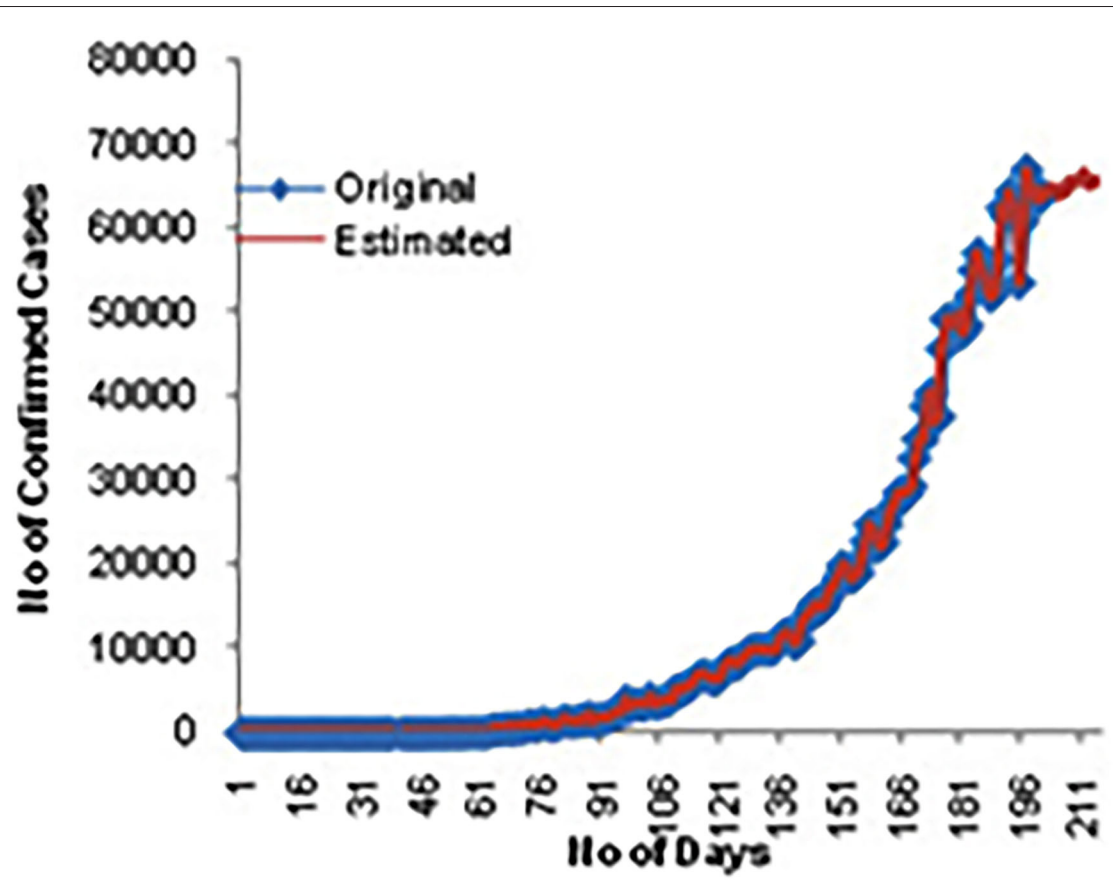

FIGURE 6 | Estimated confirmed cases for 15 days.

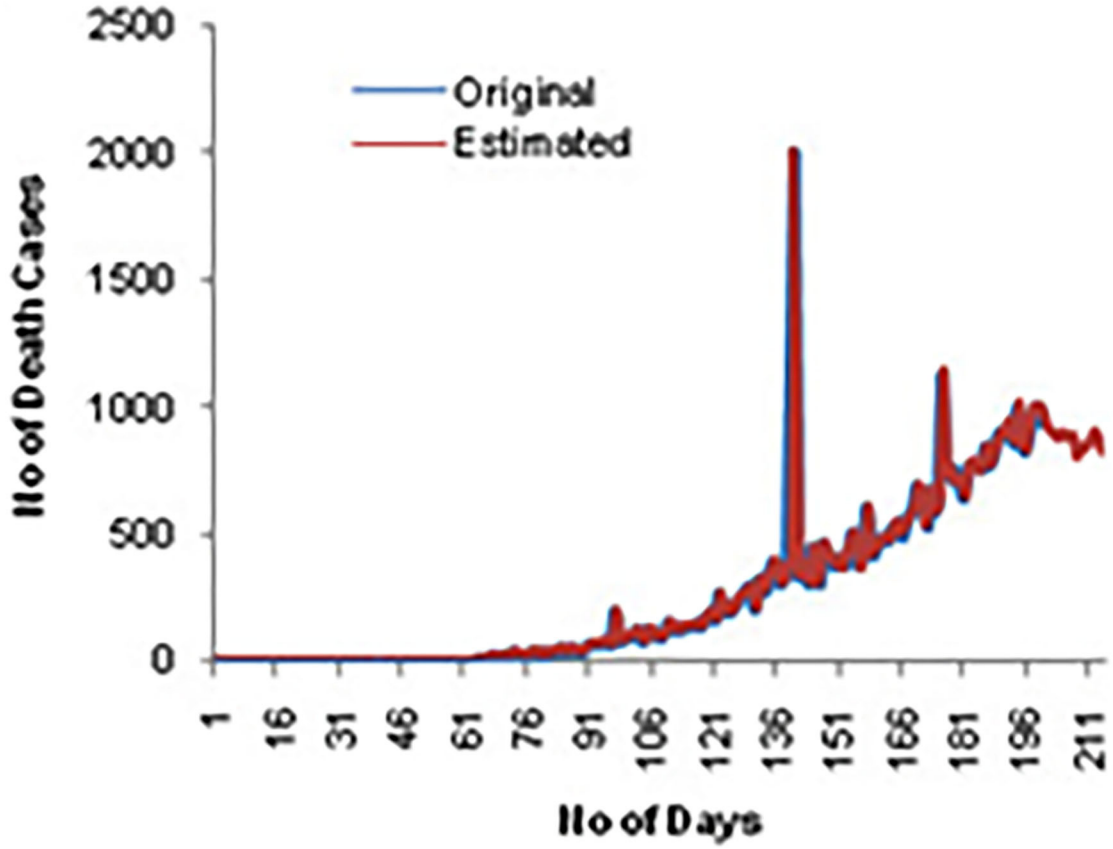

FIGURE 7 | Death case estimated for next 15 days.

action. Function Q accepts the information as a current state (S) and action (A) and returns an estimated reward for that action in that state. Thus, q functions provide the arbitrary fixed values in the beginning before investigating the situation.

In this work, the following symptoms were considered to predict COVID-19 cases: fever, tiredness, dry cough, difficulty breathing, sore throat, pains, nasal congestion, runny nose, and diarrhea. Groups of symptoms are considered states, and action is taken based on the states. Here, the action is taken based on the increments in the confirmed and death cases. A reward is received when the foresight of verified cases and death cases are accurate. The action-value function defined as:

$$q(s, a; \theta) \approx Q^{*}(s, a) \tag{10}$$

where q (s, a) represents the neural network approximation and θ is a reference variable representing the network's edge weights. The input to the neural network is a state, and the outputs for unconnected activities $Q=\{q(s,a,\theta)|a\epsilon A\}s$ are approximate q values.

The system is trained by depreciating forecast faults of $q(s, a; \theta)$. The DRL agent taking action at time t is $a_t = \arg\max_a q(s_t, a; \theta)$, where $q(s_t, a; \theta)$ for various activities are supplied through the outcomes of the network. For example, assume that the resulting compensation is r_{t+1} and the state move to s_{t+1}, then various actions are provided by the outputs of QNN. Consider that the resulting reward is r_{t+1} and the state moves to s_{t+1}, then $(s_t,a_t,r_{t+1},s_{t+1})$ establishes an "experience sample" that might be used to train the network. For training, the prediction error of network for the particular experience sample $(s_t,a_t,r_{t+1},s_{t+1})$ is defined as:

$$L_{s_t}, a_t, r_{t+1}, s_{t+1}(\theta) = (y_{r_{t+1}}, s_{t+1} - q(s_t, a_t; \theta))^2 \tag{11}$$

Where $\theta = weights$; and $\left(y_{r_{t+1}}, s_{t+1}\right) = targetoutput$, which is defined as:

$$\left(y_{r_{t+1}}, s_{t+1}\right) = r_{t+1} + \gamma \max_{a'} q(s_{t+1}, a'; \theta) \tag{12}$$

RESULTS AND DISCUSSIONS

This segment displays the trial setup and evaluation manner of the suggested prognostication design. Data of COVID-19 cases in India from Kaggle were employed with the Java framework to authenticate and examine the recommended standard.

The dataset utilized in the report comprises summary tables of regular time scales, including the number of reported cases and

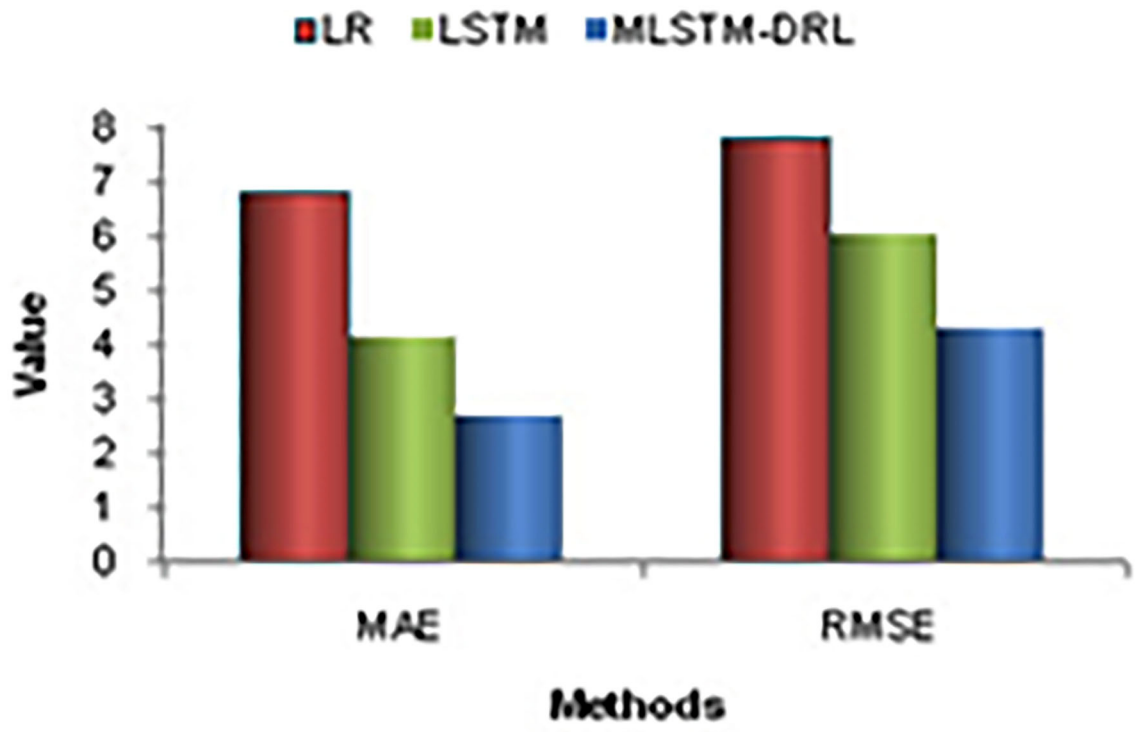

FIGURE 8 | Comparison of evaluation metrics.

deaths over the past number of days from which the pandemic began. Data from January 30, 2020 (when the first case of COVID-19 was registered in India) to August 16, 2020, were analyzed, with 75% data employed for practice and 25% for predictive and validation purposes. **Table 3** shows the sample data of confirmed and death cases daily and weekly.

Figure 4 shows the comparison of confirmed cases for the original and predicted values for 200 days. Here, we could see a high correlation between the actual and predicted cases.

Figure 5 shows the comparison of death cases for original and predicted values. It can be seen that the death rate slightly increased on specific days.

Figure 6 shows the estimated confirmed cases for the next 15 days. **Figure 7** displays the estimated death cases for the next 15 days.

The proposed algorithm can evaluate the performance of learning in terms of the following metrics: Mean Absolute Error (MAE), Mean Square Error (MSE), and Root Mean Square Error (RMSE). **Figure 8** shows the comparison of evaluation metrics. Based on the outcomes, the recommended MLSTM-DRL has a lowest error rate matched to other systems. We also see the ML model, Logistic Regression (LR) obtained the highest error rate. Deep learning methods are utilized to develop a system for future prediction of the COVID-19 affected cases. The study performs predictions on confirmed and death cases. It is a troubling circumstance for the world day by day as death and reported cases are rising. The number of individuals in various countries affected by the COVID-19 pandemic is not well-known. This analysis attempts to estimate the number of individuals who will be affected over the next 15 days in terms of freshly authenticated cases and deaths.

Individuals being affected by COVID-19 get increased daily, and the death rate has many ups and downs. The correlation between original and predicted data of confirmed and death cases are 0.999. The future prediction results can assist governments in planning lockdown or other medical decisions.

CONCLUSION

COVID-19 is an ongoing pandemic that significantly endangers the health of people worldwide in a short period. A DL-based prediction method for forecasting the risk of COVID-19 has been proposed in this work. The framework analyses the actual day-to-day data dataset and uses deep learning algorithms to make predictions for upcoming days. This study determines the best activation function for M-LSTM; specifically, a deep reinforcement learning algorithm to optimize the prediction results. The proposed approach was compared with widely used existing algorithms like LR and LSTM. The finding of this work proves that the DL method can efficiently predict future cases of COVID-19. Overall, it can be concluded that the model's predictions are at per with the status of the virus; this may help understand and curb the spread of the virus.

Therefore, this study's forecast may be of great help in taking timely actions and making decisions to tackle the COVID-19 crisis. In the future, we advise using a semi-supervised hybrid

design to identify COVID-19 and social media platforms to prevent further spread. It is also planned to publish the predicted results as a dashboard through Google Data Cloud.

Alzheimer's Disease (AD) is a neurodegenerative irreversible brain disorder that gradually wipes out the memory, thinking skills and eventually the ability to carry out day-to-day tasks. The amount of AD patients is rapidly increasing due to several lifestyle changes that affect biological functions. Detection of AD at its early stages helps in the treatment of patients. In this paper, a predictive and preventive model that uses biomarkers such as the amyloid-beta protein is proposed to detect, predict, and prevent AD onset. A Convolution Neural Network (CNN) based model is developed to predict AD at its early stages. The results obtained proved that the proposed model outperforms the traditional Machine Learning (ML) algorithms such as Logistic Regression, Support Vector Machine, Decision Tree Classifier, and K Nearest Neighbor algorithms.

Keywords: machine learning, Alzheimer's disease, prediction, prevention, convolutional neural networks, support vector machine

INTRODUCTION

Alzheimer's disease (AD) is 60–70% the cause of dementia (1, 2). It is a slowly progressing brain disorder. The individuals that express symptoms of AD have abnormal deposition of a protein called amyloid-beta in their brain. This amyloid-beta protein forms plaques in the brain and strands of protein tau twists around, causing tangles that ultimately kills the brain cells. The degeneration of brain cells causes loss of memory, thinking and reasoning skills (3).

A few investigations have demonstrated that trained radiologists can be outflanked by computer-helped-diagnosis utilizing Support Vector Machines (SVMs) in distinguishing patients with AD and different ailments (4). Convolutional Neural Networks (CNNs) are simply neural networks that use convolution in place of general matrix multiplication in at least one of their layers (5). These are special type of Deep Neural Networks (DNNs) (6). Several applications of DNN can be found in (7). Deep learning techniques are used abundantly used in healthcare (8). For example various uses of CNNs for Magnetic Resonance Imaging (MRI) segmentation are presented in (9). CNNs are used for several applications Different groups have tried utilizing CNNs (10, 11) to analyze and separate AD from healthy or no condition (NC), patients using MRI scans as an input, while others have utilized a special type of MRI scan technique—the functional magnetic resonance imaging (fMRI) time-series

information (12, 13). An investigation was performed by Thompson et al. (14) in this regard in a paper titled, "Applying Convolutional Neural Networks for pre-detection of AD from structural MRI data." In this study, the authors utilized SVMs and CNNs on sectioned areas of interest after post-processing utilizing edge-detection algorithms on grouped MRI scan. This study achieved a sensitivity of 96% and a specificity of 98% on a dataset of 1,615 MRI images. Segmented images with edge-detection were used to classify them according to the required to the required quality standards.

The level of amyloid protein in the brain varies from individual to individual. Researchers have found (15, 16) that the rate of death from Alzheimer's has increased by 50% in the recent years, from 16 deaths in 1,00,000 in 1999 to 25 deaths in 1,00,000 in 2014. Also, the number of people who have died of AD has increased two-fold, from 44,536 in 1999 to 93,541 in 2014. In 2015, there were about 29.8 million people worldwide affected by AD. The cause of AD is still not properly understood. About 70% of the cause is inferred to be genetic in nature (17). A methodology to track, predict and cure AD can be analyzed with the history of the illness, cognitive testing with medical imaging and blood tests. People affected by AD chiefly rely on others for assistance which often turns out to be a burden on the caretakers. This results in social, psychological, physical, and economic pressure (18). Hence, we propose a model that would accept Positron Emission Tomography (PET) brain scans as inputs, process and analyze them and finally predict whether the individual will have Alzheimer's within a given time window of two years. It is said that prevention is better than cure. Hence, early detection of the onset of AD is highly beneficial. The techniques that are currently available to detect AD rely on cognitive impairment testing which is not efficient in yielding accurate diagnosis. The cognitive tests mostly rely on results of questionnaires directed toward the subjects and do not consider medical developments within the subject's brain explicitly. Such tests will prove to be an assuring method to predict the level of onset of AD in a subject only if there exists a one-on-one correspondence between the results of the tests and the physical state of the brain (the concentration of proteins that regulate the onset of AD). Thus, a new technique or algorithm was proposed in (19) with the aim of reducing the high dimensional MRI vector space to 150 dimensions using Principal Component Analysis (PCA). To categorize the reduced dimensions to PCA for progression of AD, multi-class neurons were employed. In comparative studies as in (20), Percent Whole Brain Volume Change (PBVC) was measured from serial MRI scans and dementia with Lewy bodies. The conclusion was that the atrophy of AD was significantly greater than that of Dementia with Lewy bodies (DLB) for one year in various regions of the brain including periventricular areas. PBVC was not significantly different from DLB and it was concluded that AD showed faster rate of global growth than DLB. Certain research has also been done to determine alterations occurring in Parahippocampal Cigumul bundle (PhC) and Posterior Cingulum bundle (PoC) in patients suffering from Mild Cognitive Impairment (MCI) (21, 22). This was done through diffusion tensor imaging (23–28). An atlas-based Region-Of-Interest (ROI) was used to calculate the fractional anisotropy, mean diffusivity, axial diffusivity, and radial diffusivity. For the primary health centre (PhC), a significant decrease was observed in the FA value, whereas an increase was observed in the MD and RD values. It is forecasted that by 2050, the prevalence of AD will quadruple to 26.6 million cases, where approximately 43% of them will need a high level of care. If the diagnosis of AD can be improved upon and treated at an earlier and more manageable stage, where therapeutics and preventive care are more useful, then the numbers of future AD patients will likely decrease.

The aim of this paper is to bring forward a predictive model for early prediction of AD and thus, develop a preventive model based on it. This model would be helpful in identifying patients with AD and those at risk of developing it. Furthermore, we suggest a preventive course of action to be followed to limit the growth in AD. In this paper, we propose an integrated algorithm that identifies a patient with AD and predicts the onset of AD with a data-oriented approach. In the predictive model, we consider amyloid protein concentration in MRI scans as one of the biomarkers to predict the onset of AD within a window of 2 years. Initially, based on MRI scans and cross sectional and longitudinal MRI scan datasets, we classify subjects as AD or No Condition (NC). Following this, we analyze the datasets to compute the accuracy of onset of AD for the subjects. This is without considering the subjects classified as AD or NC by the first algorithm. We further use this to outline the preventive measures that should be taken to prevent (or delay) the onset or worsening of AD. The preventive measures are aimed at reducing the Critical Design Reviews (CDR) score and hence, reduce the severity of the onset of AD. The rest of the paper is organized as follows: In materials and methods, we broadly discuss the algorithm that we suggest with the data used, the model description and the performance of the algorithm. In results and analysis, we analyze the results of our algorithm and discuss the same. In result analysis, we provided a conclusion that briefly describes results and analysis and provides further improvement and upgrades that can be made in the proposed algorithm.

MATERIALS AND METHODS

In this section, we broadly discuss the architectural design of the algorithm, the types of data used and the methods of data acquisition. We also discuss the performance of the algorithm and the classification algorithms used.

Subjects and Data Acquisition

We have taken a data-oriented approach while developing the algorithm. This algorithm is developed consulting the existing algorithms. The data used for the algorithm was obtained from an Operational Applications of Special Intelligence Systems (29–32). It consists of cross-sectional MRI scan collection of 416 individuals within the age group of 18 to 96. About 100 of the individuals mentioned in the dataset were clinically diagnosed with mild or moderate AD. The data used here also comprises of longitudinal MRI scan collection of 373 individuals within the age group of 18 to 96. The dataset consisted of biomarkers

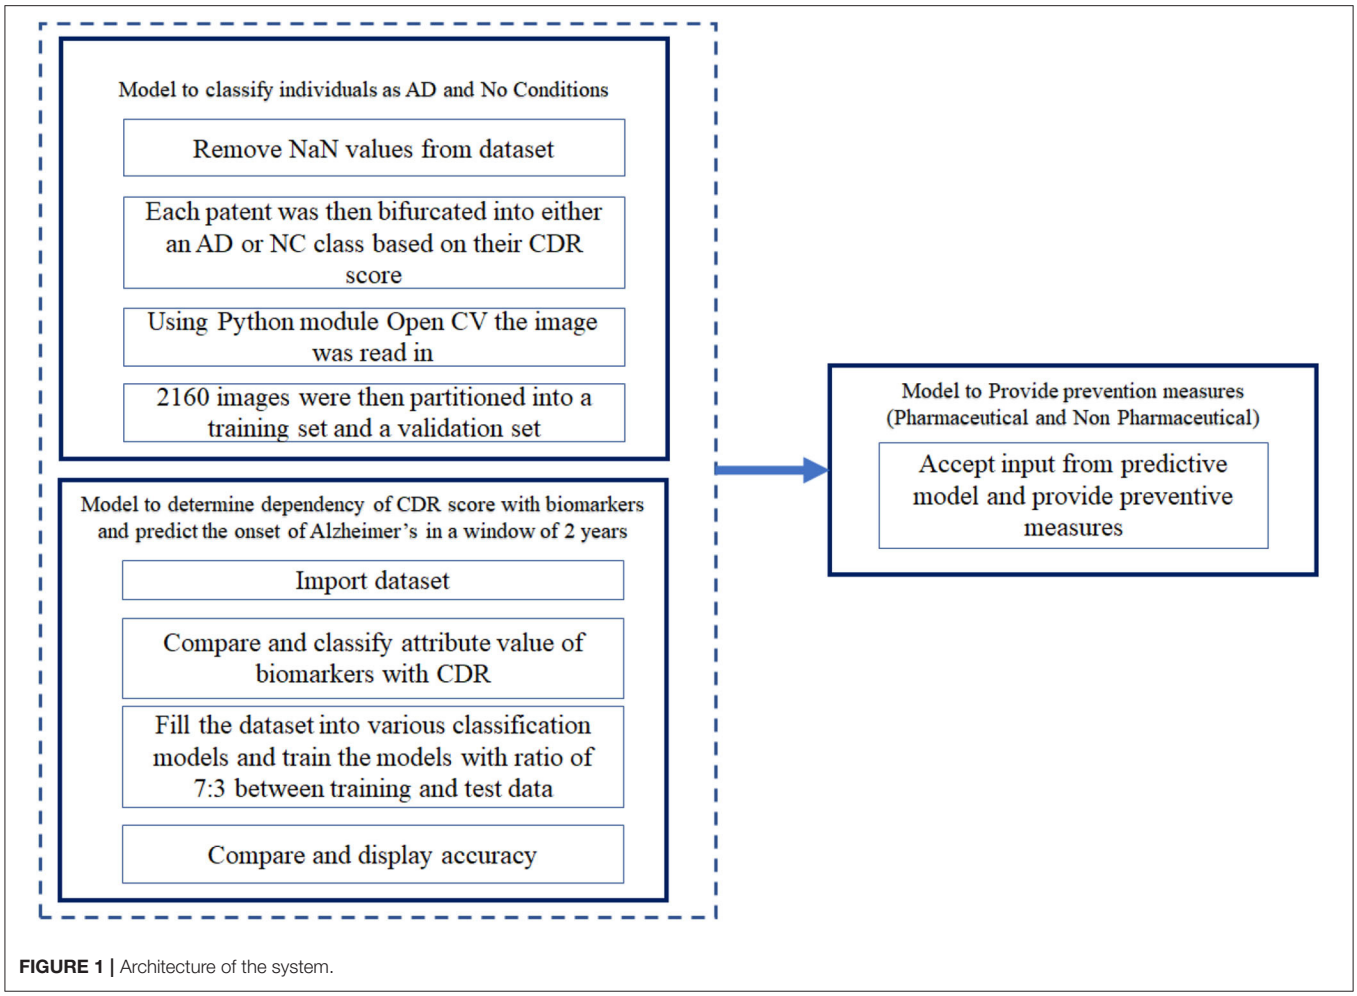

FIGURE 1 | Architecture of the system.

that have been scientifically proven to predict onset of AD. The primary attributes of the dataset were the Minimal Mental State Examination (MMSE) scores and the Clinical Dementia Rating (CDR) scores.

Model Description

The algorithm developed can be visualized as two modules, namely, the predictive model and the preventive model. The predictive model takes into consideration the dataset mentioned above and uses it to predict the possibility of onset of AD (**Figure 1**). The predictive model is divided into two sub models. The first model of the predictive algorithm takes into consideration the cross sectional dataset and the MRI scan images of the subjects mentioned in the cross sectional dataset and confirms whether a given subject is affected by AD currently. Initially, it removes null values from the dataset by dropping rows that have one such value. Due to unavailability of diverse range of Critical Design Reviews (CDR) scores, any individual having a CDR score equal to 0 was considered to be Non-Cognizable (NC) and the remaining CDR scores implied AD. Now, the removal of rows consisting of "NaN" values reduced the datasets to 216 data points and each of the individuals had 10 coronal slices of MRI scans.

Using the OpenCV algorithm available, the images were read as a numpy array. This was then normalized by dividing each intensity by 255, which is the maximum intensity. The k-means algorithm was run on the pixel space of each image. In the analysis phase, only two clusters were chosen for simplicity and maximum noise reduction. Each pixel was then assigned to the cluster it was in. The 2,160 image set obtained was divided into training set and validation set, such that a ratio of 7:3 was maintained between the training and validation set. The training set was then fed into the CNN, VGG16 in batches of 32. The model flattens the output and feeds it into two fully-connected or dense layers each containing 1,028 connecting units. Using a softmax activation function in the final layer, stochastic gradient descent as an optimizer, categorical cross entropy as a loss, the model was trained for 150 epochs. This algorithm classifies individuals with present traits of AD. In the second model of the predictive algorithm, the cross sectional and longitudinal datasets were fit into various classification models such as Decision Tree Classifier, Logistic Regression, TensorFlow, K nearest neighbour (KNN) (33–35), SVM etc. and compare the accuracy with which these classification algorithms predict the CDR scores when

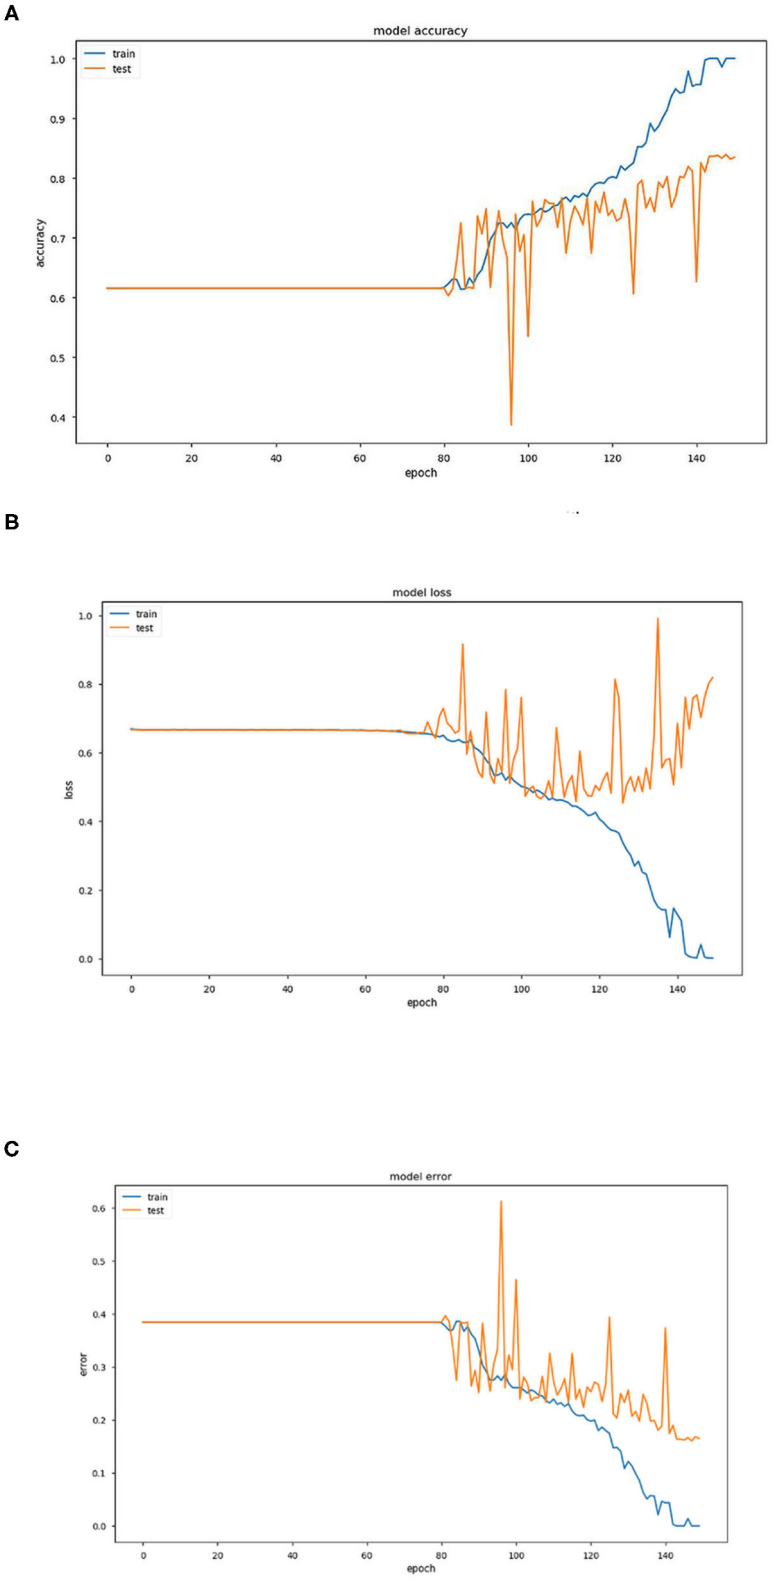

FIGURE 2 | (A) Graph representing variation of model accuracy with respect to epoch. **(B)** Graph representing variation of model loss with respect to epoch. **(C)** Graph representing variation of model error with respect to epoch.

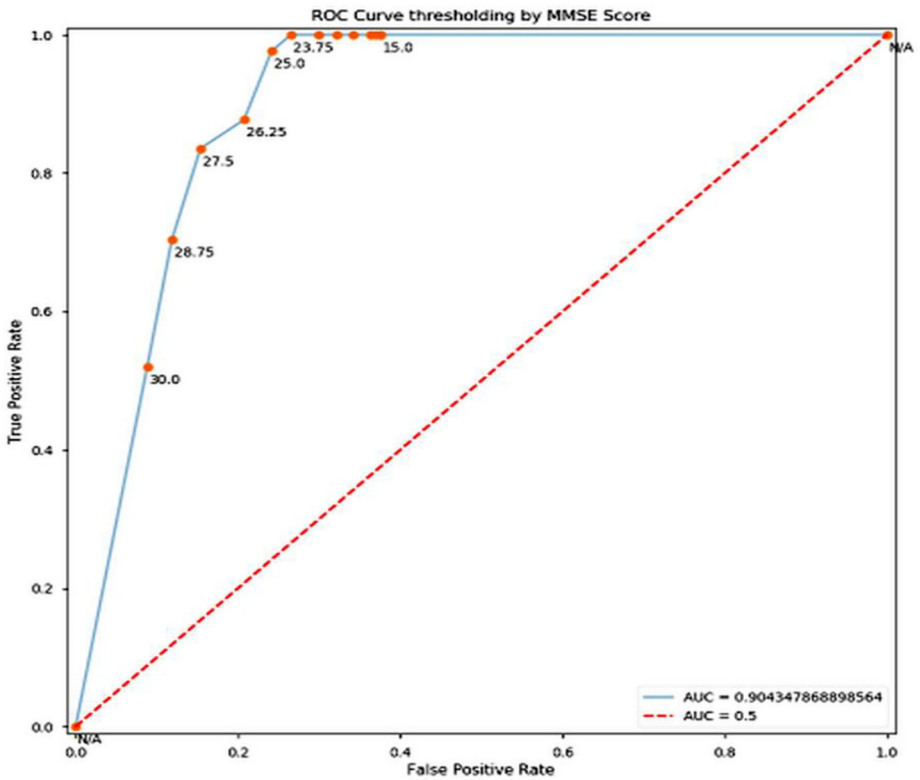

FIGURE 3 | ROC Curve.

provided the set of biomarkers and parameters available in the dataset. In the preventive model, we consider the most recent CDR score of the subject and accordingly provide the clinically approved preventive measure.

Performance Measurement and Classification

For a fixed set of Access Points (Aps), the probability of a user to be closer to any three out of the four APs is greater than that of being at equal distances from each of the APs. At every user location, the updated list of three APs based on maximum RSSI and minimum Program Visualization (PV) distances are utilized in the *k*-NN search to get the least localization error. Maximization of the RSSI objective function is computed as;

$$f(x) = B(0) + \sum_{i=1}^{n} \left(a_i * (x, x_i)\right) \quad (1)$$

Here, x represents the new input vector and a_i, x_i represents all the weights of the neural and the support vectors obtained from the training data respectively. *B (0)* is the bias input chosen. On the other hand, logistic regression is used for the binary classification and prediction using the parameters and biomarkers mentioned above to classify the subjects as AD or NC based on the MMSE and CDR scores available in the training data. The logistic function used to obtain the predicted value is given by:

$$f(x) = B(0) + \sum_{i=1}^{n} e^{(b_0 + b_i * x)} / (1 + e^{(b_0 + b_i * x)}) \quad (2)$$

Where b_0 represents the bias used in the network and b_i represents the vector values obtained from the training data. There were other classification algorithms used to predict the CDR scores. The architecture of the proposed system is depicted in **Figure 1**.

RESULTS AND ANALYSIS

In this section, we mention the results of the algorithm and discuss the same. The experimental evaluation approach has considered for the assessment of the proposed method. The algorithms were run on Intel(R) Core (TM) i5-7200U CPU with 2.50GHz. The experimental result is presented in **Figures 2**, **3**.

The above three **Figures 2A–C** provide estimations of the model accuracy, model loss and model error with respect to the increase in epoch during the training phase and testing phase. Before epoch reaches 80, all the three parameters of accuracy, loss and error remain constant and also coincide. The variations occur after this in the training phase and the accuracy increases continuously, the loss and error decrease as expected. In the

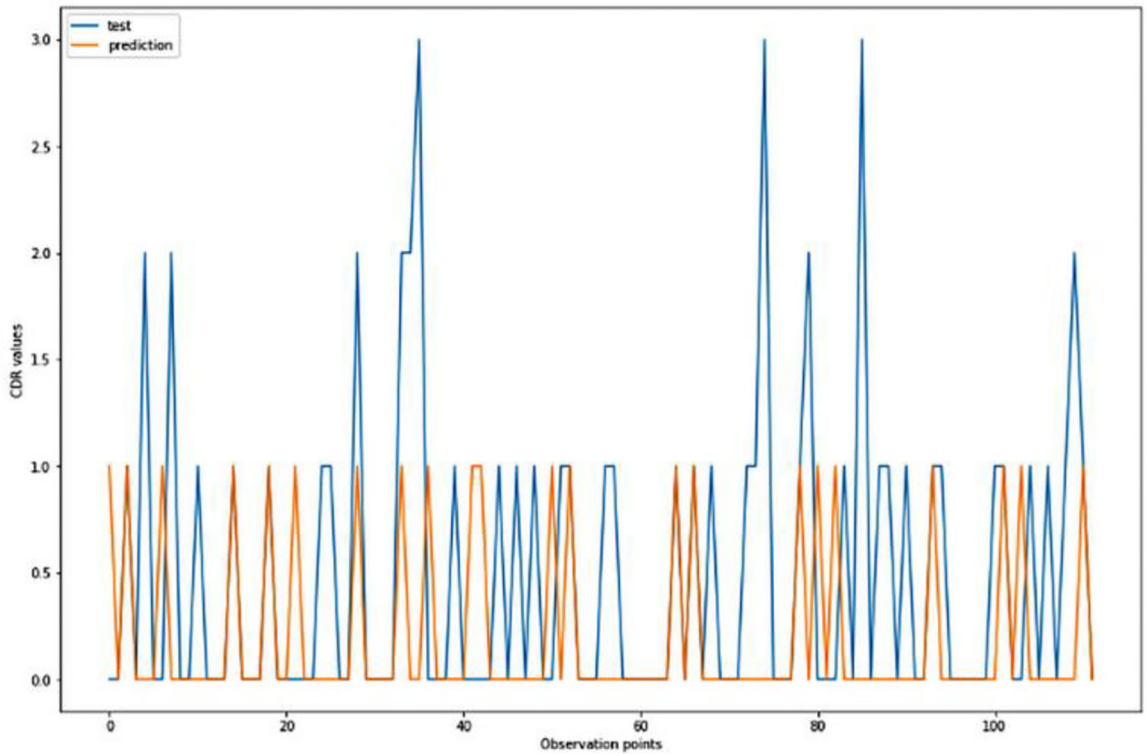

FIGURE 4 | Graphical representation of the comparison of test and predicted CDR values obtained using the logistic regression algorithm. (six parameters).

testing phase also, the same trend is observed but the extent becomes much restricted with large variations.

Training and test accuracy were measured at each epoch. The model stagnated and predicted that all brain scans were NC for the first 81 epochs. Then it moved out of its local minima and began increasing its accuracy. The training error ultimately became 0% at epoch 144, thus showing it had predicted all the brains correctly. This can be taken as an indication of overfitting on the training set. However, the lowest prediction error reached is 16.05%, by epoch 148. It can be argued that there could be a further decrease in the prediction error. But due to the model reaching 0% training error, it was stopped prematurely. As a consequence a part of the training dataset is typically set aside as the "test set" to check for overfitting.

Predictive Model

For the algorithm that predicts whether a person has AD or not, each epoch took around 1,890 s to train. The total number of epochs run was 150, which took about 4,725 min or around 79 h.

Training and test accuracy were measured at each epoch. The model stagnated and predicted that all brain scans were NC for the first 81 epochs. Then it moved out of its local minima and began increasing its accuracy. The training error ultimately became 0% at epoch 144, thus showing it had predicted all the brains correctly. This can be taken as an indication of overfitting on the training set. However, the lowest prediction error reached is 16.05%, by epoch 148. It can be argued that there could be a further decrease in the prediction error. But due to the model reaching 0% training error, it was stopped prematurely An ROC (Receiver Operating Characteristic) Curve was plotted by thresholding against a patient's Minimum Mean-Square Error (MMSE) scores, to evaluate the model (**Figure 3**). The ROC is a graphical plot that illustrates the diagnostic ability of a binary classifier system as its discrimination threshold is varied.

In conclusion, it can be stated that this model of pre-processing with k-means and training with VGG16 performed well (training accuracy = 100%, prediction accuracy = 83.95%, AUC = 0.904). It can perform better by increasing the number of clusters in the k-means step, combining edge-detection and segmentation steps, using better hardware and larger networks in terms of the number of layers and epochs run, and in general obtaining of more data. In terms of engineering the biological system of the brain in the context of AD, this model does well in interpreting the brain as a set of pixels and their intensities but easily disregards the numerous other variables that assemble a diagnosis, especially considering that MRI scans are already a large abstraction from the vastly complex human brain.

For the algorithm that predicts the onset (or worsening) of AD, the biomarkers and parameters were considered against the CDR score presented in **Figure 4**. The data was divided with a ratio of 7:3 and then fit into various classification models to predict the CDR scores. It is widely known that The CDR scores of 0 means "Normal," 0.5 means "Very Mild Dementia," 1 means "Mild Dementia," 2 means "Moderate Dementia" and 3 means

"Severe Dementia". Accordingly, the results in the **Figures 4–8** are interpreted for test and prediction. Further interpretations can be obtained from the table (36).

Figures 4–8 presented the CDR using the different parameters. Here, "sklearn" was used as a metric, whereas "TensorFlow" was used as a deep neural network classifier. There are two sets of results obtained—one by training the algorithm with the longitudinal and cross-sectional datasets, the other because of concatenating the datasets. The results obtained on training the neural network with the cross sectional and longitudinal datasets varied extensively for different models of classification. Here, results refer to the percentage of accuracy with which the model predicts onset of dementia or AD. The datasets were split into training data and test data using the CDR model with the training data: test data ration equal to 7:3. For the longitudinal dataset, the training data successfully predicted the onset of Alzheimer's with an accuracy of 83–88% for different classification models such as K Nearest Neighbors, SVM, TensorFlow, Standard Scalar and Logistic Regression, whereas the test data predicted the same result with an accuracy of 60–70%. The graphical representation of the correlation matrix proved that the dataset is random in nature and does not have any hidden pattern in it. On the other hand, when the datasets were classified using the CDR and MMSE scores and comparing them with the MRI scans, such that a ratio of 7:3 is maintained between the training data and test data set populations, the training data, and the test data both predicted the onset of AD with an accuracy of ∼85%.

Different scatter plots (**Figure 9**) are also plotted which represent the correlation matrix of individual parameters against the rest of the parameters in consideration. Different scatter plots (**Figure 9**) are also plotted which represent the correlation matrix of individual parameters against the rest of the parameters in consideration. Summarized results are presented in **Tables 1**, **2**.

Preventive Model

We further implemented a system which would display the preventive measures that should be taken by a patient (patient ID is provided as input) to prevent onset or control the severity of AD. The measures given for a particular patient were according to the present condition of the patient and keeping in mind that the condition will worsen (since AD is degenerative) over time if preventive measures are not taken. Any medication, if and wherever suggested were in accordance with the U.S. Food and Drug Administration (FDA). Also, medications were only suggested for the patients who are currently suffering from AD.

TABLE 1 | Accuracy obtained to predict AD in 2 years on the training and test sets.

Models	Accuracy			
	six Parameters (M/F, Age, EDUC, SES, eTIV, ASF)		11 Parameters (M/F, Age, EDUC, SES, eTIV, ASF, Group, Hand, MMSE, MR Delay, nWBV)	
	Training Set	Test Set	Training Set	Test Set

	six Parameters (M/F, Age, EDUC, SES, eTIV, ASF)	11 Parameters (M/F, Age, EDUC, SES, eTIV, ASF, Group, Hand, MMSE, MR Delay, nWBV)
Sklearn	70.54%	84.82%
TensorFlow	70.54%	84.82%

RESULT ANALYSIS

The predictive and preventive models were implemented successfully. The predictive model consists of two parts: to predict This model can further be improved upon by predicting the individuals who could develop AD or whose condition can worsen, instead of predicting for the whole dataset. Moreover, including genetic mappings, psychometric tests, mini mental state examination tests along with hand drawn images and shapes, etc. can make this whole system more comprehensive for the prediction of Alzheimer's disease. Systems with higher specifications can reduce the execution time. The algorithm can be further optimized and generalized using fuzzy logic concepts, such as fuzzy c-means instead of k-means algorithm which is essentially binary logic concept as implemented in this algorithm. Furthermore, hybrid models for clustering algorithms can also be used. One of the important prospects of this algorithm is to identify whether the preventive measures influence the subjects, either with mild, early stage or severe AD and to analyze the same based on MMSE and CDR scores over a period. Finally, the model can also be tested for scalability on big data (25, 30, 36–38). Whether a person has AD or not, using the T1 weighted coronal brain scan MRI, and to predict the severity of AD in the next 2 years, using the data from processed MRI images and through amyloid protein concentration. This achieved an accuracy of almost 85% and can be further improved as the number of executions is increased and data is added.

CONCLUSIONS

The preventive model was based on the present condition of the patient and the predictive model. The preventive measures for each patient can be obtained by giving the ID of the patient as an input. With the current treatments of AD only tackling the symptoms, research is needed to check the onset of AD along with a way to deal with the biological changes that are responsible for it. With more data on the patients of AD (or suspected) the algorithms can be improved upon. As is evident, more parameters improve the accuracy of the algorithm hence; research on more biomarkers that play a role in the progression of AD is required.

The internet of reality or augmented reality has been considered a breakthrough and an outstanding critical mutation with an emphasis on data mining leading to dismantling of some of its assumptions among several of its stakeholders. In this work, we study the pillars of these technologies connected to web usage as the Internet of things (IoT) system's healthcare infrastructure. We used several data mining techniques to evaluate the online advertisement data set, which can be categorized as high dimensional with 1,553 attributes, and the imbalanced data set, which automatically simulates an IoT discrimination problem. The proposed methodology applies Fischer linear discrimination analysis (FLDA) and quadratic discrimination analysis (QDA) within random projection (RP) filters to compare our runtime and accuracy with support vector machine (SVM), K-nearest neighbor (KNN), and Multilayer perceptron (MLP) in IoT-based systems. Finally, the impact on number of projections was practically experimented, and the sensitivity of both FLDA and QDA with regard to precision and runtime was found to be challenging. The modeling results show not only improved accuracy, but also runtime improvements. When compared with SVM, KNN, and MLP in QDA and FLDA, runtime shortens by 20 times in our chosen data set simulated for a healthcare framework. The RP filtering in the preprocessing stage of the attribute selection, fulfilling the model's runtime, is a standpoint in the IoT industry.

Index Terms: Data Mining, Random Projection, Fischer Linear Discriminant Analysis, Online Advertisement Dataset, Quadratic Discriminant Analysis, Feature Selection, Internet of Things.

Keywords: data mining, Fischer linear discriminant analysis, quadratic discriminant analysis (QDA), feature exaction and selection, Internet of Things—IoT, healthcare applications

INTRODUCTION

The importance of information technology in the age of communication is not hidden from anybody. In 2021, more than 35 billion things are connected, and lots of potentials can be utilized in Internet of things (IoT) healthcare applications. It is not unrealistic to conceive that in the near future, artificial intelligence can substitute the service-based evaluators and manipulate IoTs that are much more accurate, professional, and appealing instead of ones with various privacy gaps. They can be accessed through a form of robots that hijack their information, resulting in incorrect information circulation and also increasing the riskiness of information of healthcare services. The third wave Web x.0 is now evolving by enhancing the Internet capacity in which companies today use the fourth generation of the IoT for their enterprise resource planning (ERP) applications. This generation has reached cloud computing, multiplying its capabilities in the virtual world in terms of velocity, veracity, and variability in crowdsourcing projects, such as grid.to, or other crowdsourcing events in cyberspace, which has achieved a high synergy in terms of availability and responsiveness. The best learned lessons on services such as Uber—which already managed to attract millions of visitors—was the reason that motivated us to perform a classification algorithm on this data set of web usage in which many points of view, such as the ethical, professional, civilian's rights, and media laws, are likewise healthcare data sets and should be taken into account.

Online advertisements in widgets, banners, and plugins are always being updated by the service providers. Their components are now coded by XML[1] or AJAX[2] compilers acting on the service side, leading to optimization of the server idle time. These web services are often programmed in PHP or other frameworks, such as Perl or CSS. But the design, maintenance, and updating of such services are necessarily done as separately managed projects, in which the result is aggregated in the service according to the perception of end users and other stakeholders. For instance, the Bitcoin exchange intermediaries generally compete in a win–win or offensive strategy for advertising luxury brands, soccer competitions through reputable sponsoring channels, and specialty stores and branches on free trade zones to enter the market decentral delivering the service at any location. Here, Bitcoin miners and exchangers are thought to be among the most critical stakeholders in the affluent class. Their emotional behavior is accompanied by their high expected reliability and tangibility of the service at very high prices. During the operation of Digital Wallet, many stakeholders decide to research on the queuing systems (1), maintain their privacy on attacker behavior, or change their service's ERP system by taking advantage of a new big data system on security concerns (2, 3).

We have selected this standpoint for the selection of our data set. Therefore, in this research, we presume that the web usage features are among the most important topics in the scope of the IoT and would be studied especially for healthcare frameworks with machine learning.

In this research, the ultimate goal is to study the dynamics of the IoT-intensive systems for data mining resources, such as runtime and responsiveness, and also in the essential part of analysis regarding the transparency of structure and reliability measured by accuracy. Therefore, analysis of modeling focuses on the accuracy of Internet advertisement recognition and relies on the runtime on the unstructured high-volume data as an example of IoT systems. In this paper, we first review the literature in the field of web usage and data mining. Then, the ethical and professional aspects are discussed to link the framework to practice. Finally, the results of the modeling are represented and compared with recent works in this area. The work outlook is discussed in the conclusion, in which the proposed methodology challenges can be aggregated to IoT evaluation frameworks such as service empathy, user-friendliness, responsibility, trust, and tangibility. This leads especially to achieve the solution for startups in the IoT industry in the legal, social, and even more professional sectors, such as health.

ETHICAL AND PROFESSIONAL ISSUES IN IoT

Nowadays, online user experience has emerged among healthcare and IoT systems, demonstrating a set of secure feature locations to other applications (4). These links could be another application or a social network that is a place to discuss and critique the product or a link to a vendor partner or a public health information panel.

How do different brands in the advertising industry measure their effectiveness in online advertising and their limitations in this way, and how do they overcome it? Principally, the answer to this question depends on customer feedback. This is because customer feedback results from the customer interaction with the service through an omnichannel. Google is using web analytics widgets to display complete information about web historiography. The same widgets for details about corporate websites include a list of links to a specific brand's website announcing some related keywords (5).

In an online advertisement, another thing that brand owners consider is the emotional aspects of the customer. The customer's memories, feelings, and mood when he or she received the product or service make him or her buy again. A dynamic co-creation framework is recently developed to measure trust as a good advertising motive for adding value (6). The trust can be viewed from two dimensions, namely, the dimensions of affectional and behavioral trust. Affections are related to emotions and the atmosphere in which the service is experienced, and consumer behavior is subjective and is specific to the personality. Affectional trust has opened a new way to effectively connect customer feeling to the space in which advertisement is taking place. This can effectively be implemented in the IoT systems when the users trust the quality of service in that framework. Establishing a relationship with the customer

[1]Extended Mark-up Language.
[2]Asynchronous Java-scripts.

can be inspired by new ideas and can be considered an advantage. This connection plays a significant role, especially among startups that do not specialize in the IoT industry. By any innovation, the campaigns and technical events promote ideas that may be forgotten. This is when startup dictionaries may come across terms such as internal financing, mass outsourcing, and collaboration.

There is the same feeling from the brand owners' point of view, and he will take the necessary profit from the competitive advantage created by affective communication to the satisfied consumer. Brand loyalty is derived from a sense of satisfaction that is the result of creating shared value. The model in **Figure 1** illustrates this relationship schematically (7). Another dimension is the interaction between brands and the customer, which causes the customer to engage with the product's contents, the function of the product in terms of professional and technical specification, and even its working model for the first time on the web. Therefore, website communicators ought to complete this connection with a proper website's proper personalization, such as flexible design. Advertisement appealing capabilities are then crucial to control this interaction. In other words, customer engagement is a set of subprocesses that use customer experience in online brand communities and value creation. It is worth noting that history helps examine the background and origins of how network marketing is created (**Figure 2**). In 1925, the theory of open systems was criticized by Alfred Luca in the study of organic systems by many researchers. Fifteen years later, the idea of an open system was improved by Ludwig Von Bartalanffy, who introduced it in management, which is widely used in entrepreneurial systems today (8). This is how Peter Singe, as the father of management science, defines learning systems in his book *The Fifth Discipline*. Advances in management science, and especially knowledge management, show that all processes can be defined as knowledge-based processes.

"The process of leveraging or customizing existing knowledge to meet the needs of users who have this personal need and seeking to create and innovate new knowledge" (9)—today, the blue ocean strategy is rooted in this concept after the emergence of cyber business only two decades after the management of comprehensive systems and chaos theory was entered into the post-modernism management theory. Researchers in cyberspace have recently observed that the collaboration space or distance working leads to even higher productivity as an emerging phenomenon called fast advertisement. When a high amount of cost is saved and the promotions are effective, they tend to use Internet cryptography to collect essential information from their consumers by the specified level of difficulty. Using online advertising technology should help this industry know users' opinions and their partners. It is worth noting that even non-consumers of an IoT encourage this competition, which creates a form of conflict between different parties and increases their attractiveness. For example, according to a published press "Binance" Exchange, well-known Bitcoins exchange mediaries experienced a security breach and were hacked on May 7, 2020. Hackers use various methods, such as phishing, to obtain large customer information such as 2FA codes and API keys, among other information (10). The hackers intend to change the price of Bitcoin, and even they were able to withdraw 7,000 bitcoins (BTC) worth more than $40 million at that time, and they controlled only 2% of the exchange resources. These frauds turn into severe conflicts and problems in the long run.

This question may also be considered in online advertising given that some companies that have branded in the field of online have also entered the field of off-line. For example, Bitcoin miners from popular website Lootbits have reached off-line

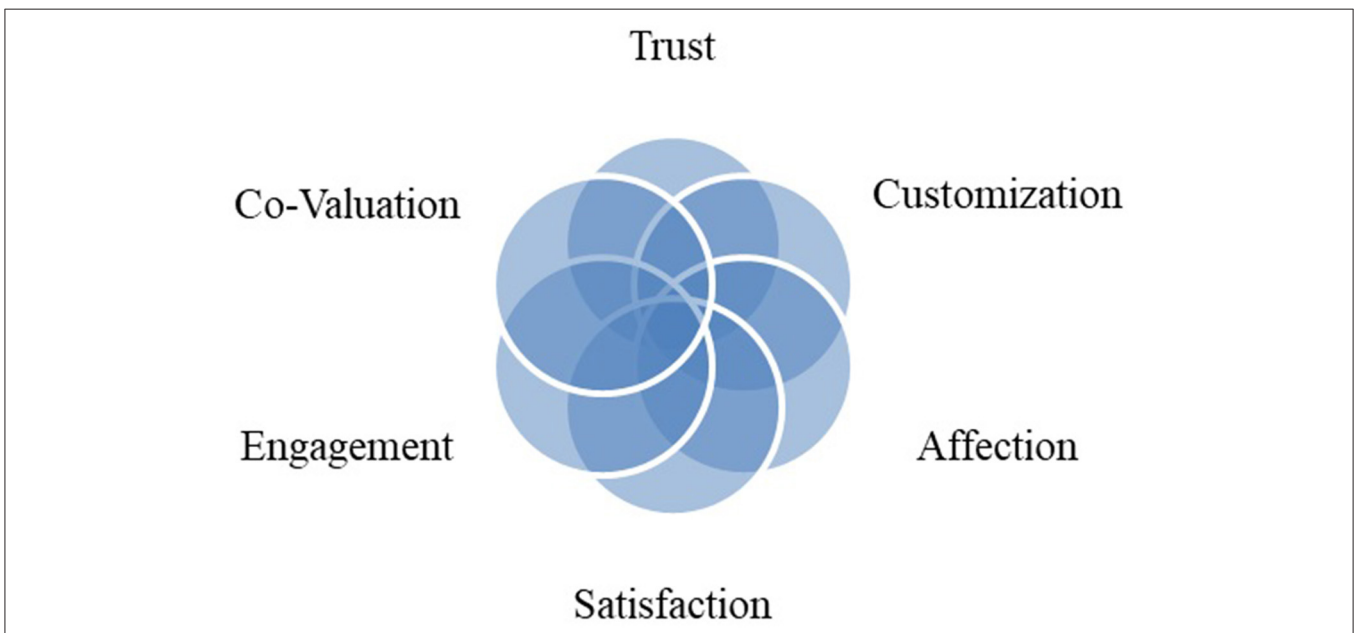

FIGURE 1 | Relationship of e-shared value, trust, and affection (7).

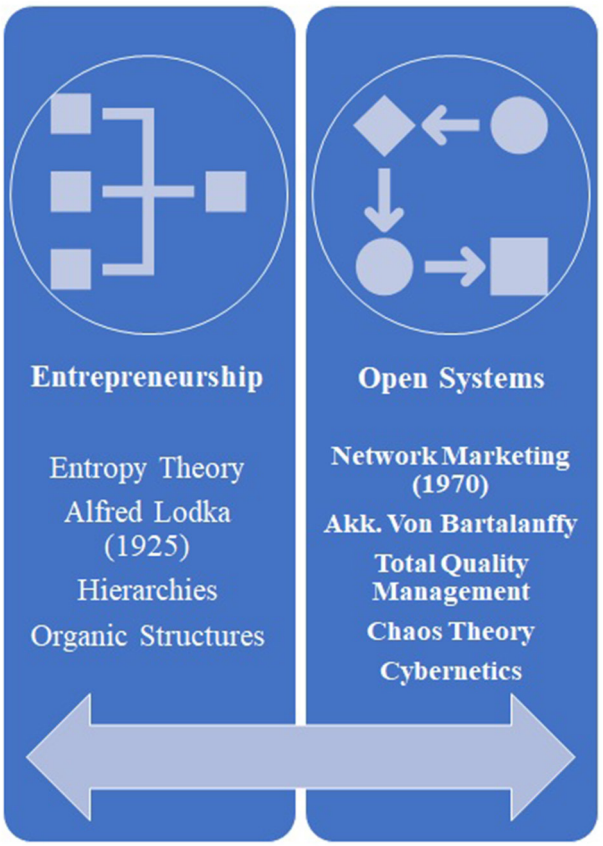

FIGURE 2 | Historical development of network marketing as the basis for the online advertisement.

activity and now operate as a gift promoter machine for soccer lotteries. Conversely, as with Paxful, there are companies that have gone online from the field of exchange business, and in the meantime, some prefer to choose a new name for their new brand, but in these cases, opponents of the existing brand believe that consumers like to register a new brand online. As a result, it subconsciously induces another brand field, shows the company's expertise, and strengthens the new name base. On the other hand, it automatically encourages the brand's stakeholders or the opponents of the new name for the brand to believe the cost of branding and the new name for the brand.

Coworking and B2B meeting groups have made significant progress in establishing virtual business offices, social networks, and telecommuting and collaboration. The argument here among startup managers is that only 1 in 10 companies succeed by developing a suitable business strategy. We should use a planner. After designing it, we can focus on a small part of the market share by differentiating or breaking the cost.

LITERATURE REVIEW

In IoT with a technological enabler, such as big data, reliability and trust have evolved a new definition. Traditionally, IT governance in the deepest layer was hierarchical. It caused lots of information silos and other inefficiency gaps. From a bottom-up point of view, citizen- and community-driven innovations are mostly needed by some stimulations and promotions. The emerging initiatives such as "Open City Dialogues" along with the government's requirements on transparency create a paradox that can best be handled by decision and policy makers (11). We believe that IoT end service users are mostly concerned about tangibility, accountability, and empathy of the service they receive. In the near future, the citizens will be experimenting with socio-regenerative developments and with emerged society rituals. Therefore, it is not surprising that incubators and sponsors of such crowd-sourced services contribute in this era, especially in the field of IoT (12).

Some of the more recent advances are using task allocation and privacy preservation algorithms. A heuristic called data aggregation error minimization (DREAM) in privacy-preserving crowdsensing uses Liyapunov stochastic programming with the random behavior of arriving sensing tasks (13, 14). It minimizes the data aggregation error of sensed tasks while preserving the privacy for a user engaging the sensing tasks.

The scientific trend of IoT has not yet finished. It covers a wide range of topics, such as neural networks, meta-heuristics' algorithms, random walks, systems dynamics, or probability and mechanical statistics. These frameworks and modeling have been recently cited through various methods and criteria in web usage, too (15–20).

For scientific research in data mining, the Yao et al. study can be mentioned in which the probability theory of websites was intended (18). In this research, it is stated that the pure usage of a website is equal to the sum of the rankings of the link pages of that website. This notation is solved by the method of Markov chain by the random walking dynamic programming algorithm. In this research, according to the experimentation of several websites with.gov extensions, the integrated methods of complexity coefficient are compared with each other. The Euclidean distances were chosen as the measurement method, and the aggregation of the ranking make it possible to accurately estimate the out-of-sample error.

In another study search engine, keywords were used for the products that were sold an e-commerce firmware (21). These rankings were then evaluated by a structural algorithm called a web dictionary, in which the frequency of that word usage was measured. For obtaining the website evaluation the retention time of users, the minimum and maximum length of the keyword, the amount of feedback, and semantics of the website were connected via a neural network applying five input layers.

In addition to using the above semantic algorithms, graph theory is also accompanied by extracting the number of webpages in the log as the nodes and the external links as the facet forming a graph. The evaluation of the website traffic activities was determined by a eugenic value vector using the chain relations of the Markov model evaluation of the website traffic activities determined by a eugenic value vector using the Markov model's chain relations. It was observed that the resulting model was convex. By calculating the eugenic factor of the site's establishment date, taking website updates and the site ranking

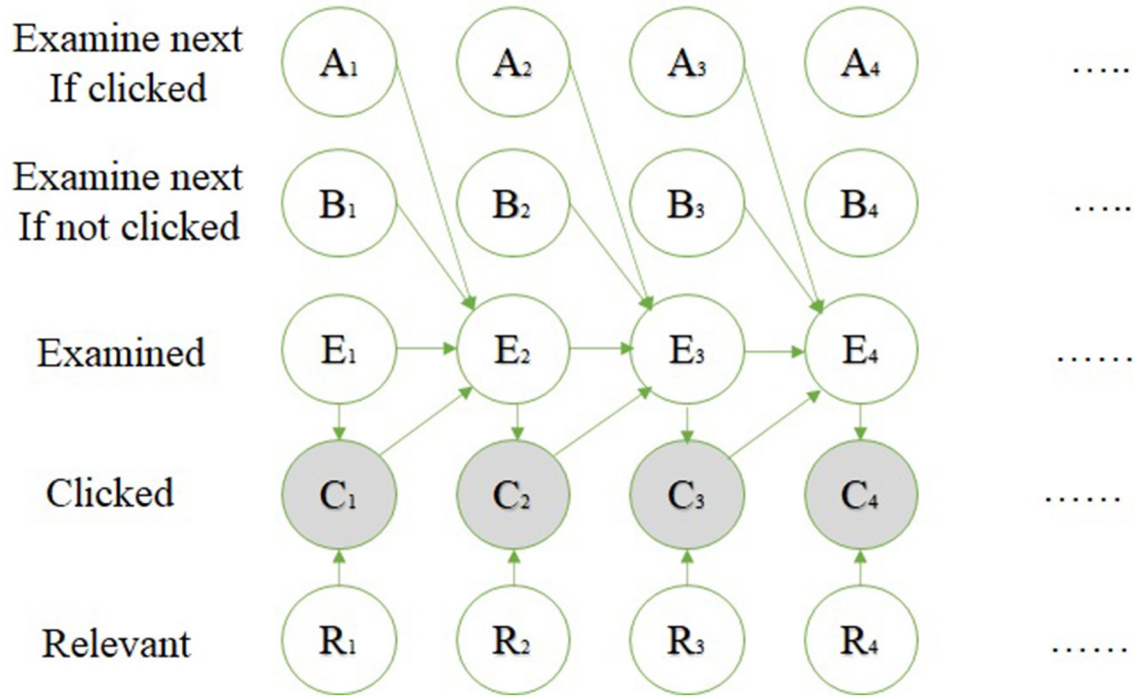

FIGURE 3 | Bayesian network (35).

relationships into account, the problem was formulated, and their time weighting in terms of added value was found.

Identifying the criteria for the success of websites through a questionnaire survey that positively increases the service level is mentioned elsewhere (22–24). Criteria, such as overall website performance, reliability, information content, and source credibility are examined separately, and the effects of other unseen characteristics were experimented. To answer the research question, structural modeling is proposed. Finally, 13 components of this study are reduced to four elements by principal component analysis (PCA). Ultimately, high-ranking websites are determined out of the 80 e-commerce websites belonging to Persian Gulf countries. In a controlled manner, these criteria are selected and finally ranked by selected individuals from selected countries with high Internet penetration rates in their countries, such as Iran, UAE, and Qatar. This data is then used to provide a theoretical framework for ranking e-commerce websites. The four elements mentioned are attractiveness, competition, engagement and retainment, indicating the amount of marketing aspect vs. the website's attractiveness at first sight.

A challenging problem in the integrated data set and the high data volume that failed in the works, as mentioned earlier, is fraud sensitivity. The data sets meet the highest standard security level by applying the most elevated standard security level with state-of-the-art machine learning to detect changes according to the algorithm's patterns. There are two methods for fraud detection: an on-the-fly schema discovery of data patterns on the client side and a solution on the data digest between the servers. Data set integration as the promising characteristics of IoT systems has enabled high security, especially in world disaster times such as the trends in virus prepandemic peak. It seems that dynamic effects are still unknown, but an agentless system, fortunately, focuses on architecture planning with monitoring an agentless system to overcome security frauds. Anyway, in intrusion cases, it is practical to perform security checks with ICMP and Ping. Both methods mentioned suffer from the low level of transparency resulting in risking usage, sharing, and processing of data sets by third parties (26, 27).

From the security point of view, this research can also explain how to detect anomalies in networks for a learning algorithm that can handle the training and testing of the data sets by an ordinary classifier (25). In this research, a binomial classification model was developed that can detect if LAN activity is in the benign or attacking category based on different attributes. The data set that is publicly available, the KDDCUP data set (28), could be used as the learning data set for testing machine learning in IoT systems. Application of different models and methods can be advantageously used for our research data set to compare the result with the advertisement sets (29). Other research models, such as the one reported in the literature, can also be helpful for the purposes of comparison accuracies (30). This data set is also discussed in the open-source data repositories by different tools and methods, and the F-score, a measure for the practical calculation of the accuracy with the consideration recall of the results, is reported to be between 0.94 and 0.96. We believe that, by selecting the appropriate preprocessing and filtering and cleaning the raw data set, it is possible to outperform this

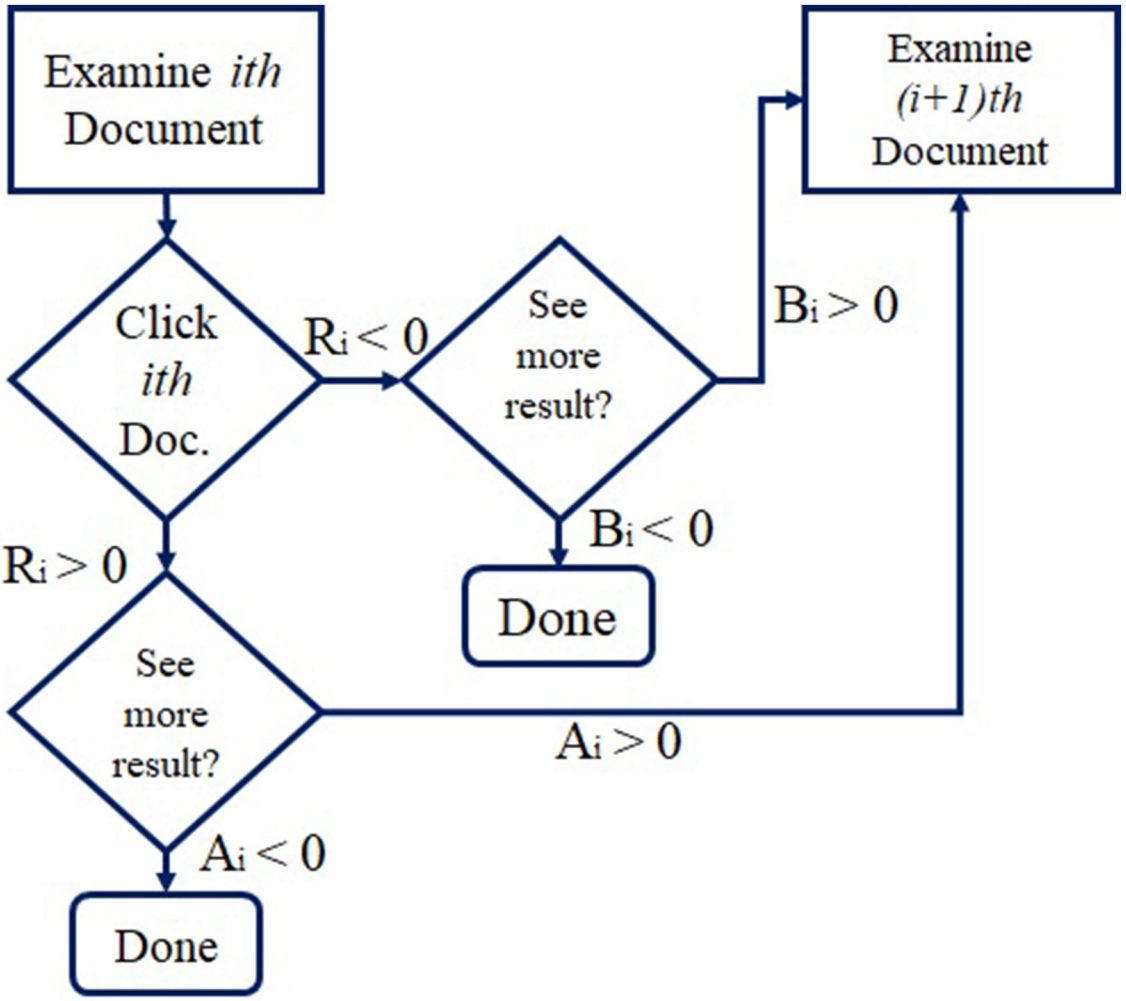

FIGURE 4 | User flow chart (35).

accuracy. It is also beneficial to hybridize the different algorithms to operationalize the same results by the least calculations and computational resources (31).

A more recent data set that was accessed from the Kaggle platform in our research is based on categorization of the attacks according to their types (32). This system's advantage relative to the binomial classes is that few overfitting risks are in the final results. The question is still unanswered as to how deep one can define each category interface to ensure the reliability of the result. Because no retrieving log file activities should be perceived as an attack, in this case, we assume that there is a difference between in- and within-group variance by the *p*-value estimates.

The other approach considered a successful one is to collect customers' intentions by mining the web server's logs to find the most linking visiting websites (17). The authors propose the use of a fuzzy web advertisement selector. Their methodology is divided into three steps: target customer clustering, fuzzy membership, and Web ad matching. For customer clustering, the authors use the neural network technique to discover backend knowledge of the web server's log files and cluster customers into different categories based on their interest. By using fuzzy rules in fuzzy inference, the authors determine the customers' categorized viewing patterns. Then, the fuzzy inference feeds the web ad selector with these patterns and enables web ad matching to suggest the corresponding advertisement to the target customer. The authors have tested their method by implementing a fuzzy web ad selector in a newspaper website. To verify the effectiveness of the fuzzy web ad selector; the authors compare click-through rate (CTR) values before and after using their method. Thus, the authors divided the newspaper web servers into two groups. One is using a web ad selector and is called the "treatment group," and the other is not using the web ad selector and is called the "control group." After running the method in newspaper websites for 2 months; there was an increase in CTR values for most sections. Businesses recognized the importance of identifying customers' needs and interests in order to provide them with right product and services. Thus, businesses are using a recommender system built to advertise products based on customer preferences. These

systems are using transaction recorders, web logs, and cookies to learn customers' interests. Recommender systems are using two approaches: a content-based and a collaborative approach. A content-based approach is dependent on customer feedback. However, the collaborative approach depends on examining users' relevance and selecting a recommended partner for the target user. Thus, the collaborative approach advertises products to target users who appear in the recommendation partner only.

These two approaches have some limitations and problems, such as having no rating or feedback for new products and the rating is based on the customer point of view and style and cannot be a standard for all users.

To overcome these limitations, the authors propose a new data mining framework that is based on social networks (33). Social networks consider a rich data set that contains a lot of information can be used for advertising systems. The authors use data sets containing customer connections and those that involve customer transaction recorders. The authors use the first data set to identify customers' subgroups (each subgroup has a group of customers who know each other as friends, relatives, coworkers, etc.). The second data set is used to predict products' liking rate according to customers' past transactions. To use both sets, the authors develop a cohesion algorithm that is used to measure the number of customers sharing common interests for each subgroup based on their past transactions. This framework can target new customers by identifying to which subgroup they belong and verifying the liking rate for that subgroup. The authors have tested their proposed framework by targeting book advertising for their university library. The authors built their own social network by using email logs for their university facilities and circulation data for facilities from the library. The authors compared their approach (group-based) with other approaches: the single-based approach (assuming each user as a group); neighbor-based approach (grouping each user and his direct neighbor); and random, which randomly chose users. This study proves that their proposed framework outperforms the other approaches.

Personalizing advertising becomes a challenge for many electronic commerce companies because of the increasing number of Internet users. In addition, companies are looking to personalize advertising to reach the maximum number of customers in the world, and this cannot be done by using the traditional approaches for targeting customers by looking to their regions, age, or gender. However, better approaches to target customers by using online advertising are by analyzing the customers' preference and interest. This can be done by following the principle of "customer-based targeting" that identifies customers' interests by IP address (geographical location), navigation habits, HTTP requests, and user profiles (34).

The authors propose the advertising remote open site agent system (*AdROSA*) for automating banner advertisements. The proposed system does not violate customers' privacy as it does not store customers' details in a database. *AdROSA* analyzes the history of Internet sessions for customers along with the current session. Also, it uses web mining techniques that consist of web content and usage mining. By analyzing the history of customers' sessions and applying clustering techniques, *AdROSA* obtains aggregated sessions (called conceptual spaces) for customers with the same navigation patterns and who click on similar advertisements. *AdROSA* uses HTML content analysis of advertising to recommend the right ad matching with customers' conceptual sessions. For example, if customers belong to sport conceptual spaces, *AdROSA* analyzes advertisements that come under a sport theme and publishes the sport ad banner for customers on their current web page. The authors have tested their system by installing *AdROSA* locally on the polish tourism's website server. The system processes eight sessions and displays advertisements based on users' conceptual space. From the following table, we can see that the user's conceptual space changes based on surfing behavior (page requests). Also, *AdROSA* displays different advertising depending on users' visiting patterns and conceptual spaces.

The click model is a method that shows what the user prefers on web searching or Internet ads. This paper focuses on the previous models' problem, which uses individual queries, including the position and relevance, not a tail query. The authors mention that it is fair to build a new model that uses multiple queries or tail queries, taking in the position, local time, user agent, etc. (35–40).

The paper shows examples of previous models used in web searching and online ads, such as

- *Relevance model*: Relevance probability depends on the fact that the user clicks the URLs on the top; if the user examines the URL, then the click depends on the user's eye tracking if it is relevant.
- *Cascade model*: Depending on that the user examines all the URLs, the click depends on the order or relevance.

The authors suggest in the paper a new model called the general click model (GCM). This model has the following features:

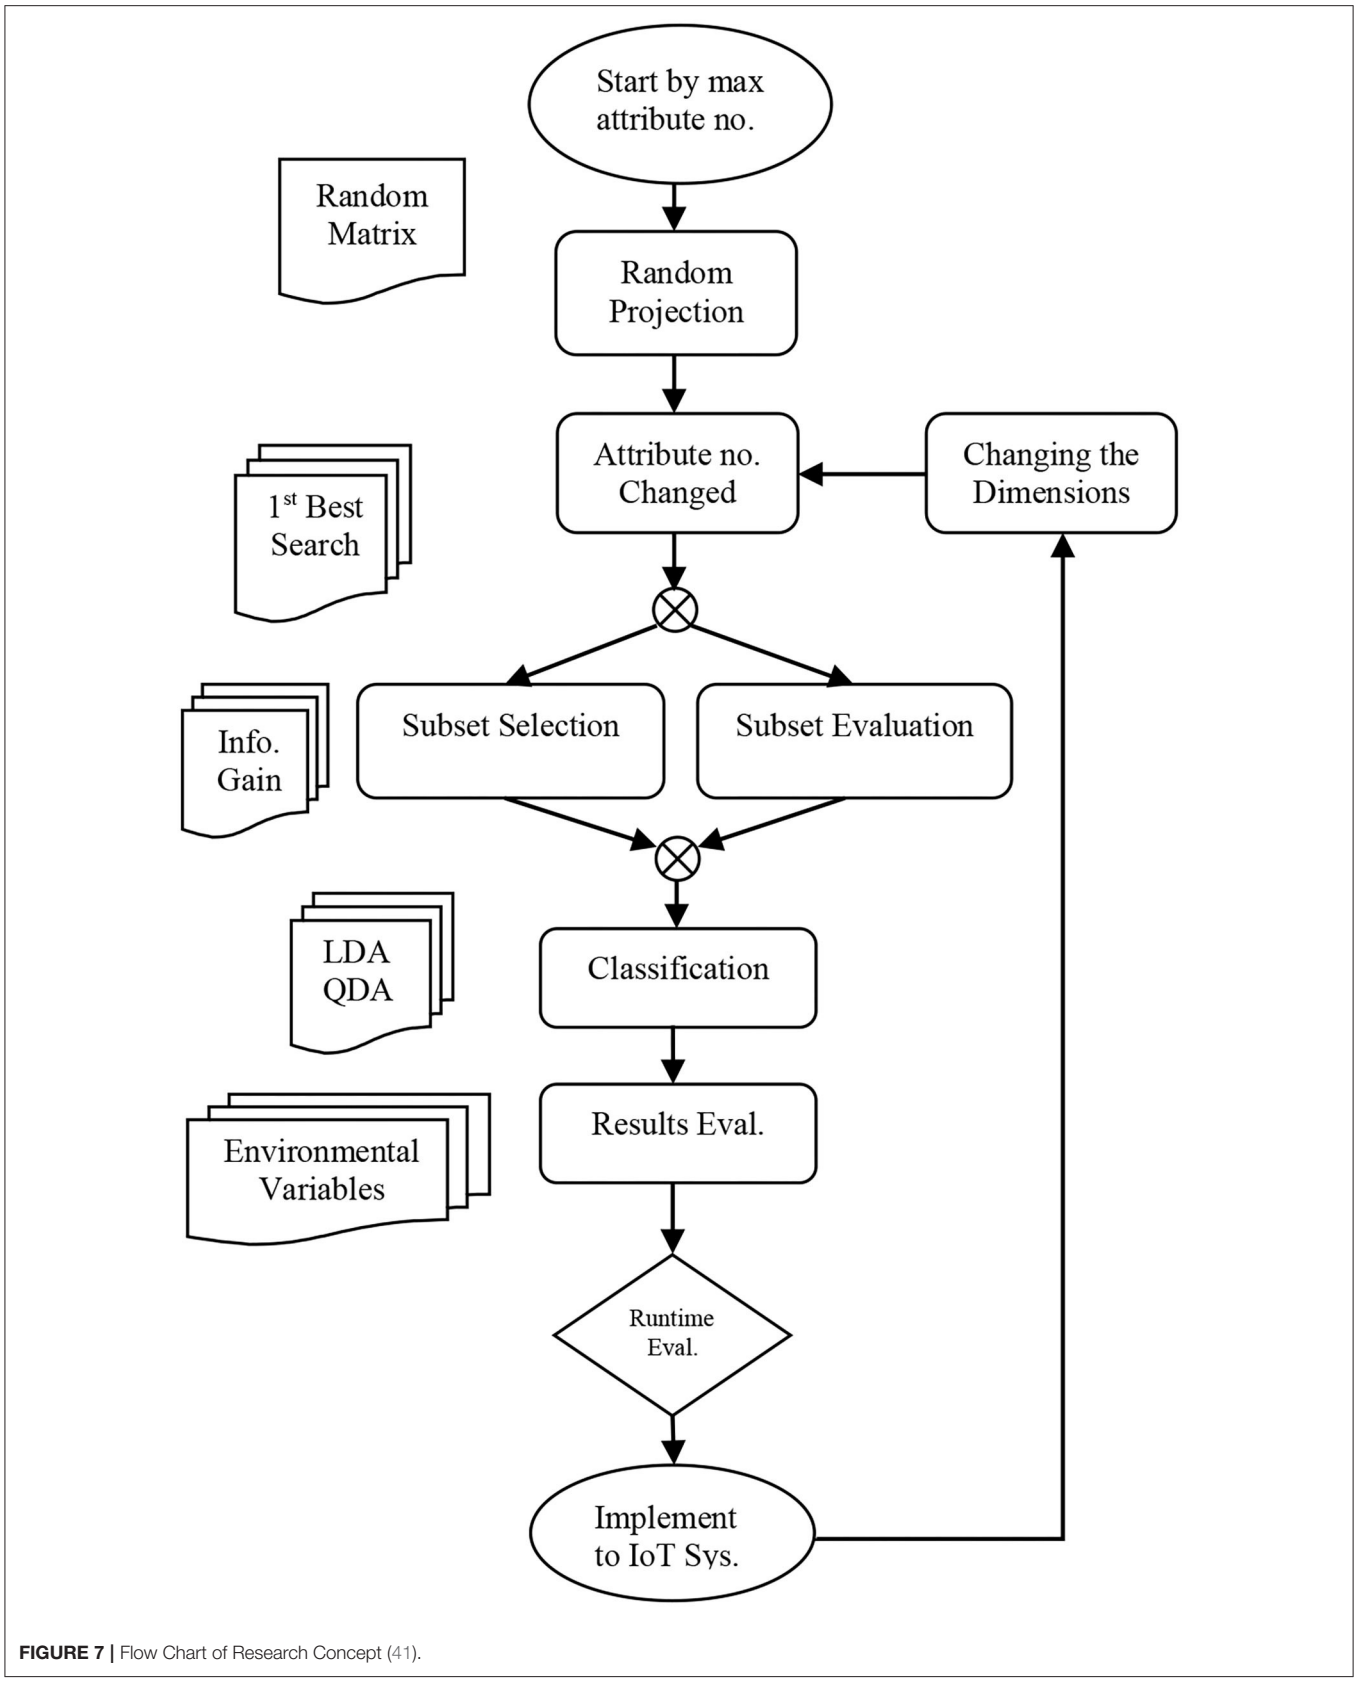

FIGURE 7 | Flow Chart of Research Concept (41).

Require: Dataset D, Attributes number(n), MSE(β)
Projection Dimensions $k= ln(n)/\beta \{d_1 d_2 \ldots d_k\}$
Subset Evaluations *s :{Cfs, Wrapper, Filter}*

1 For i:=1 to 1,2,…,s do
2 For each Subset normalize data
3 For $d' = \{d_1 d_2 \ldots d_k\}$ do
4 Do PCA and project both train and testsets into d'
5 Caculate Random Projection Matrix
6 Record the Test and Train Runtime
7 If Discrimination Experiments not significant for Normal Distribution go to 2
8 Else

10 Compare with result of without Projections End.

FIGURE 8 | Algorithm pseudocode.

- Multi-bias: Using probability between many attributes.
- Across-query learning: To use one query even if it is new by learning from other queries.
- Extensibility: The ability to add or remove attributes.
- One-pass: Using an online algorithm, the output of one session is entered into the next one.
- Application (ads): GCM outperforms past works.

GCM is a general model; the previous models, such as relevance and cascade, are a special case of this model, and it is used in the nested structure, which allows this model to deal with more than the position bias. The structure of this model dealing is shown:

- The outer model: Uses the Bayesian network, shown in **Figure 3** and the user flowchart shown in **Figure 4**.
- The inner model: The query session in this model is categorized in two types:
- User-specific attributes.
- URL-specific attributes.

The algorithm of online inference using the Bayesian network and the expectation propagation method is clear in **Figure 5**. The authors performed their experiment using two general data sets: the advertisement data set using 21 attributes and the search data set. The experiments and the results applied on the ads data set are as follows:

- Evaluation on log-likelihood measurements (empirical cross entropy) used to measure one URL impression's accuracy.
- Evaluation on perplexity, which finds the accuracy for the position.
- Evaluation on R^2 by which each 1,000 URLs are blocked.

Another paper represents the contribution selection algorithm (CSA), focusing on the attributes to be selected to maximize classifiers' performance on prior unseen data as one of the feature selections benefits (41). The CSA algorithm use the filter and the wrapper approaches; it is ranked on each step based on Shapley value by a novel ranking method. The Shapley value of the player is a weighted mean over all possible subsets in the margin. The author applies the CSA using either the forward selection or the backward elimination approaches. **Figure 6** shows the algorithm. The algorithm was applied to seven data sets, including the internet advertisements data set (ads data set). Eight compared features selection schema used in the experiment are the induction algorithm with no feature selected as the baseline, SVM, different filtering, random forests, forward selection wrapper, and classification with forwarding selection

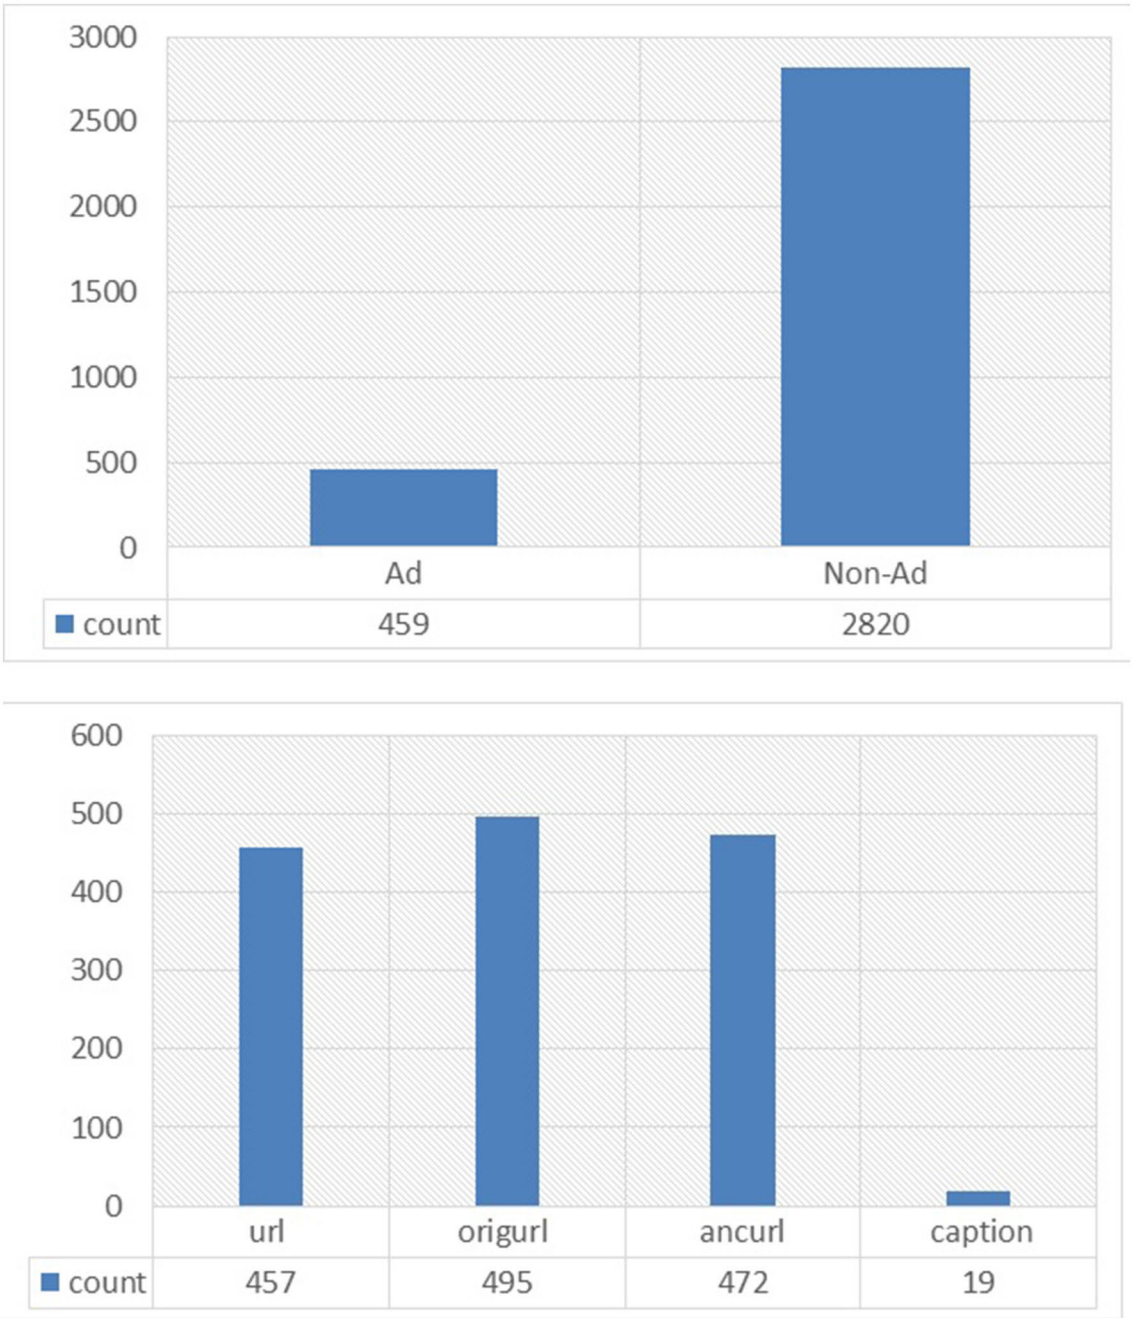

FIGURE 9 | Binomial class distribution.

or backward elimination. The results on the ads data set show that the accuracy was between 94 and 96% for all algorithms, but no feature selected by wrapper, the 1NN algorithm, was outstanding.

In another study, random projection (RP) was compared, and it is an attractive approach for dimensional reduction, compared with PCA, a popular approach (42). Five real-world data sets are used in this experiment, including the ads data set. The techniques used in the experiment to compare RP and PCA decision trees (C4.5) are nearest neighbors methods (1NN and 5NN) and linear SVM light. The authors used data sets with small sizes and others with large sizes, and they used low-dimensional data sets and other high-dimensional data sets. The ads data set was high-dimensional and large. They divided the data set into training and test subsets, depending on the size of the data set. The results show that the PCA is expensive

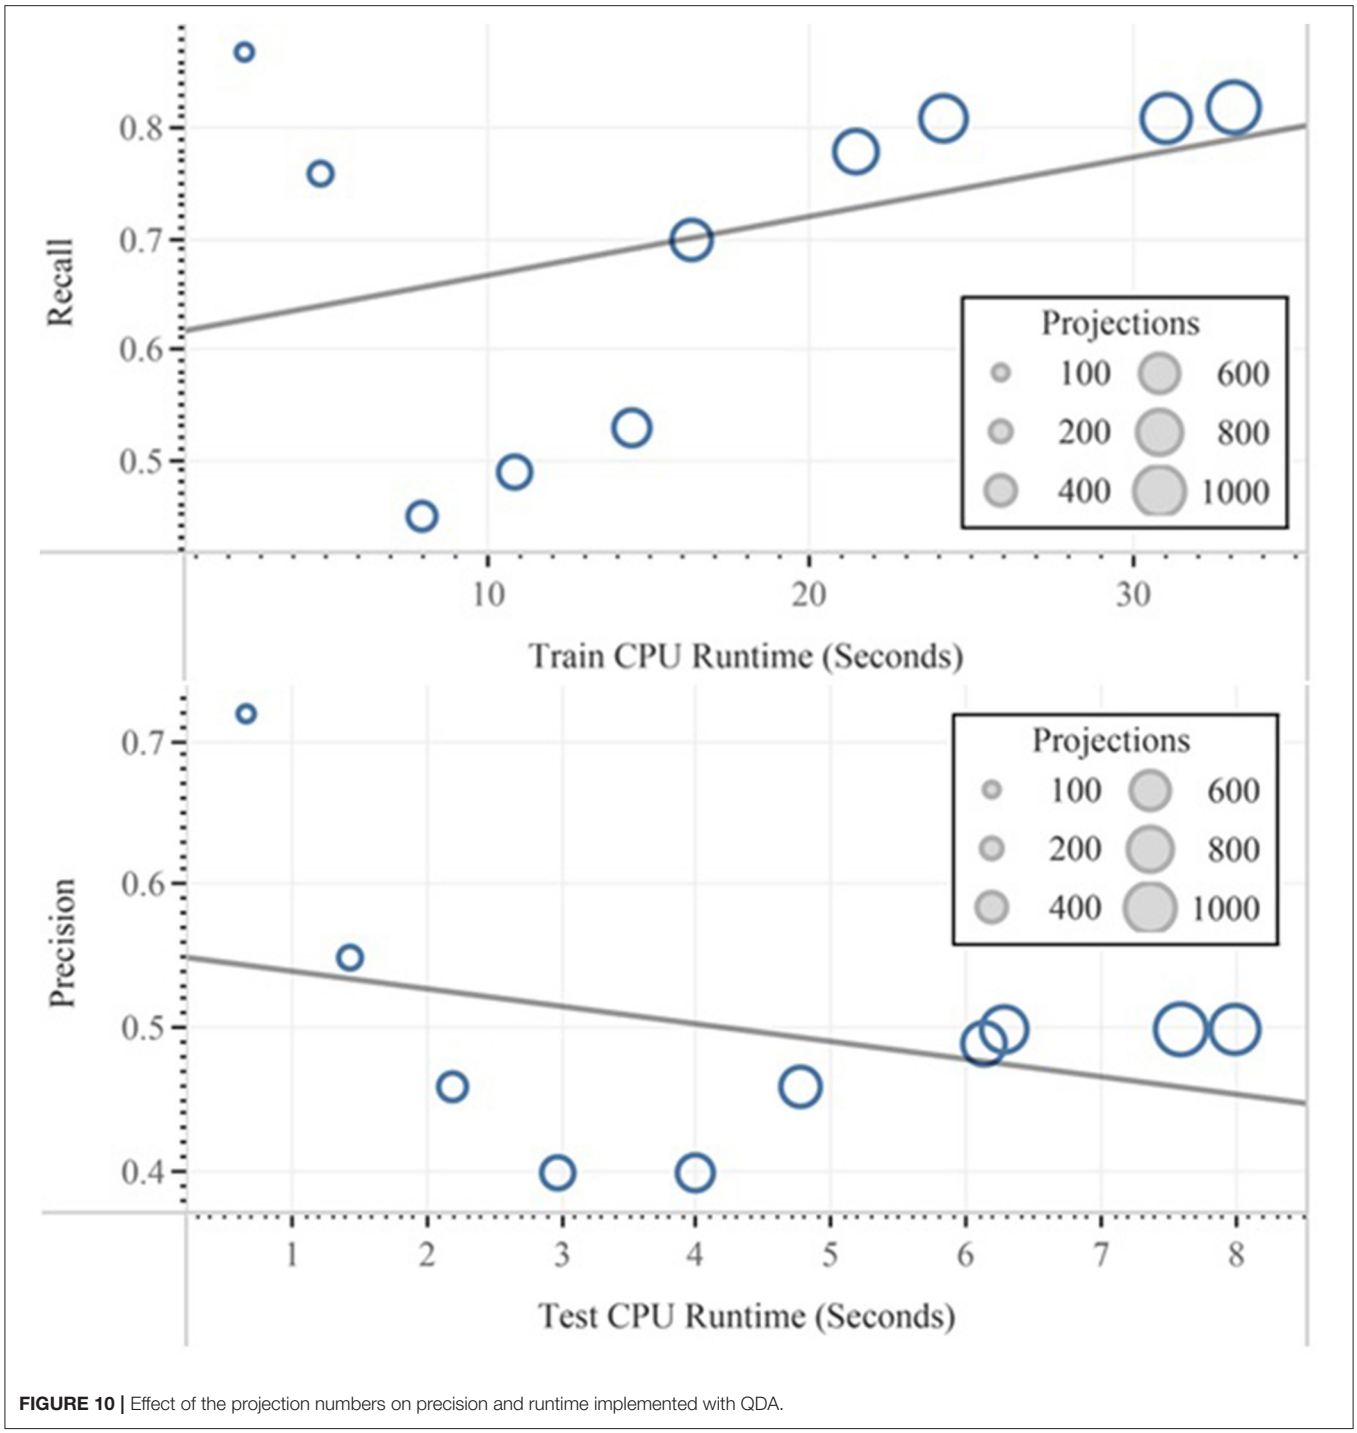

FIGURE 10 | Effect of the projection numbers on precision and runtime implemented with QDA.

computationally but gives more accurate results compared with RP, which is the cheapest computationally but has some good characteristics. Using RP improves performance by increasing the dimensions, doing the best with NN methods, and doing well with SVM. It has a problem with the decision trees (C4.5). In the **Table 1**, a summary of the research literature's methods and goals is mentioned to overview the methodologies of the literature.

RESEARCH METHOD

Discriminant analysis is widely used in engineering fields, such as electrical, vibration, and control engineering, but in this study, it is implemented in web usage and IoT (39, 43–45, 47–53). This study's objective lies in selecting a complex advertisement data set from those several hundred attributes and selecting the advertisement from a non-advertisement picture.

TABLE 2 | Classifiers accuracy for the different classification methods of each attribute selection method.

Attribute selection	Classifiers	Correctly classified instances	Incorrectly classified instances	Kappa statistic
Cfs	Decision tree (J48)	97.23%	2.78%	0.88
	k-Nearest Neighbors (IBk)	**97.76%**	2.24%	**0.91**
	Multilayer Perceptron (NNs)	96.68%	3.32%	0.86
Filter	Decision tree (J48)	97.21%	2.78%	**0.88**
	k-Nearest Neighbors (IBk)	**97.49%**	2.51%	0.90
	Multilayer Perceptron (NNs)	97.39%	2.60%	0.89
Wrapper	Decision tree (J48)	85.11%	14.89%	0
	k-Nearest Neighbors (IBk)	**85.11%**	14.89%	0
	Multilayer Perceptron (NNs)	85.11%	14.89%	0

Bold values indicates the best True Positive Rate and their kappa statistics.

According to **Figure 7**, the proposed algorithm method is performed in the form of classification problem with subset evaluation and a selection step. It is started by a maximum number of attributes followed by unsupervised filtering with RP, which is supposed to reduce the number of attributes. By reduction of attribute numbers in the Weka, a new subset is sorted with less dimension accompanied with new information gain. By reducing the attributes, it is expected to result in less runtime. The RP (described in **Figure 8**) filter uses the searching

algorithm based on the best first for a lower time budget. Switching the model to new data set with FLDA, the same method as mentioned in the research work of Pang et al., a Gaussian per binary class and concentrate on pooled covariance matrix instead of per multiclass vector-based covariance matrices and means computations, data mining resources are measured and reported (45).

We have additionally tried the quadratic form QLDA for the tuning and sensitivity analysis.

We want to concretely know how the companies that are part of the IoT systems have the possibility of competition to the highest degree for their business? Second, which part of computational resources of their data mining activities are the most important and why: algorithm, runtime, accuracy, data warehouses, services, etc., and finally, is there any model framework for ad selector application available to practically align data mining with the needs of all their stakeholders?

Data Description

The Internet advertisements data set (ads data set) collects data used by researchers about advertising in websites, and it can be categorized as a standard, high-dimensional, large, and imbalanced data set. It contains a set of advertisements as images, the geometry of the image, the anchor, the anchor text, and other image properties. The data set available in UCI contained 1,558 attributes and 3,279 instances. The predicted class in this data set

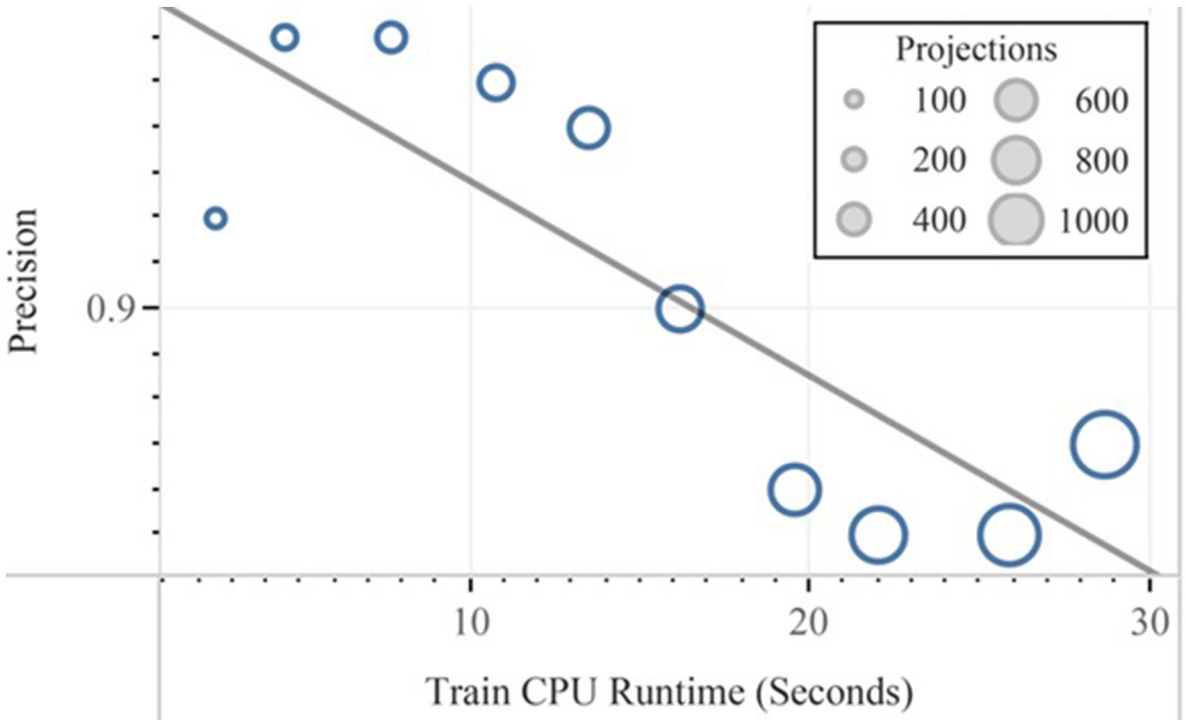

FIGURE 11 | Precision vs. training CPU runtime experimented in QDA.

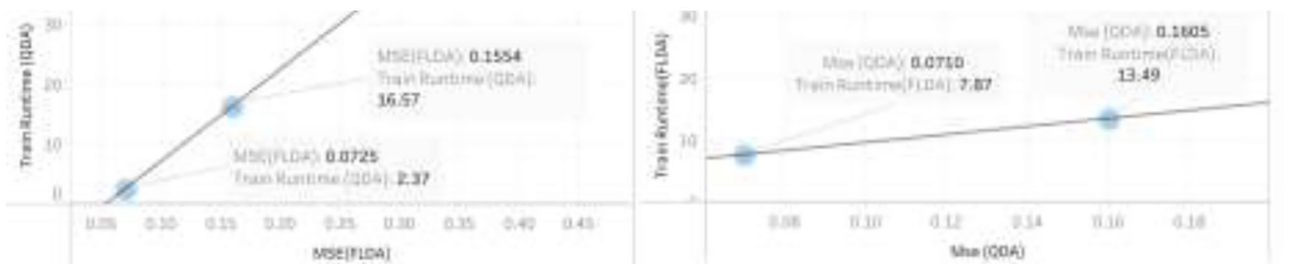

FIGURE 14 | Sensitivity analysis of mean standard error using both QDA and FLDA algorithm.

was to predict if the image is "ad" or "non-ad." The ads data set contains 2,821 non-ads and 458 ads as shown in **Figure 9**.

The ad dataset, as mentioned, contains 1,558 attributes, three of which are continuous. These are height, width, and ratio. There is 28% missing data; some of these data are from continuous attributes, which should be mentioned as "unknown." The information attributes are classified into four main categories as follows: 457 features are from URL terms, 495 features from origURL terms, 472 features from ancURL terms, and 19 features from caption terms.

Feature Selection Analysis

In feature selection, techniques are differentiated by their ability to generate other data sets from the original data from which resulted in less mean absolute error rate. In our context, this can be accompanied with the decline of the computational budget based on less runtime as well as reducing of the danger of overfitting for the IoT framework and can be later compared and approved by the above task. The only exception is that our selected data set with 2.7% error and <1% overfitting from the 10-fold cross-validation does not seem like a good candidate for the accuracy enhancement, but it can be efficiently applied for reducing the run time. This might happen on the basis of the anomaly in the distribution of the attribute's categories and also on the basis of numerical attributes. The calculation result in terms of precision and test runtime with the relevant 100 to 1,000 number of projections are represented in **Figure 10**. The data are filtered, and default settings for the calculation of the QDA were implemented.

The ads data set contains a large amount of data. The data are reduced using the attribute selection method. Feature selection or variable subset selection is the technique of selecting a subset of relevant features for classification. By removing most irrelevant features from the data, feature selection helps improve the performance of classification.

Five techniques of attribute selection were applied to the ads data set. These are Cfs, Info gain, PCA, filter, and wrapper subsets. One of the indicators of the performance of the attribute

selection is to determine the number of attributes that were selected by the given attribute selection method. In this manner, the run of the Cfs method results in selecting 24 attributes. The filter subset method gives us the minimum result to only 10 attributes. Unfortunately, the PCA method gives us a big number of attributes reaching 300 attributes. The other two methods (info gain and wrapper) failed to select attributes where it shows a full number of attributes (1,558 attributes). In conclusion, the smaller the number of attributes, the faster the results we get and the easier the model building for classification. This is in the condition of using a variety of data, which is applied in the ads data set.

The results of this work show that the combination of Cfs attribute selection method and the k-nearest neighbor method outperforms any other combination. See the below table (**Table 2**).

Classification Analysis

Classification is a data mining technique that assigns instances in a data set to target classes. The aim of classification is to accurately predict the target class for each instance in the data. Three different classification methods were used for each one of the three-attribute selections. These are the multilayer perception (NNs), the k-nearest neighbors algorithm (IBk), and the decision tree (J48). The k-nearest neighbors algorithm was set to run with $k = 1$ because there was no significant difference for higher k number. The large number of the ads data set allows us to use a Weka default value of 66% training and 34% testing set to apply the decision tree method. This is true for the other two methods of classification adopted in this work. The number of instances used for testing (34%) results in 1,115 instances out of 3,279. We started the analysis of the multilayer perception algorithm based on 1 fold in which the system divides the data automatically into 66% as a training set and 34% as a testing set. For further investigation, we redo the same technique using 10 fold cross validation (Weka default value). Using this technique, we used the whole set of instances, 10% each time as a training set. The results were significant and confirmed that the k-nearest neighbors' algorithm outperforms the other methods. Other indicators for the accuracy of classification techniques are the mean of absolute, the root mean squared, and the relative errors. All of these indicators are calculated using Weka and presented in **Table 3**. We found that the lowest mean absolute error is found in using the k-nearest neighbors (IBk) method (0.0321). The root mean squared error of it is around (0.14). This method has a root relative square error of (41.89%). An algorithm that has a low error rate is preferred as it has the most powerful classification technique.

Alternatively, the Kappa statistic (46) is used to assess the process for the classification method. It reflects the difference between the actual agreement and the agreement expected by chance; for example, a Kappa of 0.91 means there is 91% better agreement than by chance alone. Using the Kappa statistic criteria, we found that the accuracy of the three classification methods used in this study is substantial because the Kappa statistic for each one is more than 0.88 as shown in **Table 3**.

RESULTS AND DISCUSSION

As this research concern was partly on the resources relevant to the IoT, it is favorable to represent which part of computational resources of their data mining activities are impacted by the drift concept: algorithm, runtime, accuracy, data warehouses, services, etc., or is there any model framework for ad selector application available to practically align data mining with the needs of all their stakeholders. This is also important to understand the technical difference in crowdsourcing and other data sets.

In **Table 4**, the experiment results by changing the random projection on the basis of the FLDA are represented. This can be performed by the Weka experimenter module, in which the random projections are set conditionally to get the significant value for the FLDA parameters algorithm. The model performance for QDA as an evaluation method is used to assess model performance for the 10 different RP algorithms used in this work. **Table 5** represents the runtime and precision resources for the QDA algorithm. The results on these tables clearly illustrate the strength and weakness of the two methods numerically. These results are imported to the tableau software for the experimentation of these methods in regards to their runtime and accuracy sensitivity by maintaining the mean standard error in a constant Nivea.

Finally, after the feature reduction, subsequent classification with the help of linear and quadratic discrimination analyses for the class "ads" is represented. In **Figures 11**, **12**, the performance vs. runtime of FLDA and QDA are represented where their mean standard errors are equal.

The results of this work show that, in the combination of FLDA and QDA by equal mean standard error, the FLDA with shorter runtime outperforms any other combination in terms of accuracy, recall, and runtime. The runtime was decreased from 16.57 to 13.49 in addition to the decreasing of the accuracy from 96 to 94% (**Figures 13**, **14**).

CONCLUSION

This article studied the typical data mining resources such as precision, runtime and mean standard error for an IoT framework, especially healthcare applications in which reliability, responsiveness, and availability are vital. For this reason, we have applied different classification algorithms based on an Internet advertisement data set. The best algorithm for classifying is found to be FLDA with an accuracy of 94%. It has the mean absolute error at 0.16. The other classification methods gave us satisfactory results but more calculation time; however, in this work, the calculation time was decreased 20 times. These results suggest that, among the data mining techniques tested in this work, FLDA methods can significantly improve the classification methods for use in different areas, especially the IoT. This is important because, with 2% accuracy costs, the runtime can be best achieved. This is very important when there is a reported connection between ads and service reliability or, for instance, trust among empathy and anchor text. This result has been studied sizably by the feature reduction method and results were analyzed by the Fischer

linear discriminant analysis in the WEKA Experimenter module. Before recognizing the combination of the two data processing methods, the purpose of the combination should be determined, which can be used to allocate higher process time with low memory for the IoT project and drift learning. If this does not exist, we specify its constituent elements. In collective outsourcing projects, we are not opposed to technological constraints for knowledge orientation. Discriminate analysis provides a progressive framework for assessing classification techniques' performance by changing the RP attributes and other hyperparameters. This cannot only be advantageously coupled with the IoT unless the weka-based experimenter model is implemented. It is vital to include other comparison measures into the evaluation process even though using margin curves for a given data set needed more research work to determine which classification method is the best. What is its optimal decision threshold? It also required using more empirical data sets rather than using only the ads data set. This will be in the benefit of solving real-life problems in healthcare applications.

[1] General Intensive Care Unit, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [2] Key Laboratory for Critical Care Medicine of Henan Province, Zhengzhou, China, [3] Key Laboratory for Sepsis of Zhengzhou, Zhengzhou, China, [4] Department of Electrical and Computer Engineering, University of Alberta, Edmonton, AB, Canada

Background: Although numerous studies are conducted every year on how to reduce the fatality rate associated with sepsis, it is still a major challenge faced by patients, clinicians, and medical systems worldwide. Early identification and prediction of patients at risk of sepsis and adverse outcomes associated with sepsis are critical. We aimed to develop an artificial intelligence algorithm that can predict sepsis early.

Methods: This was a secondary analysis of an observational cohort study from the Intensive Care Unit of the First Affiliated Hospital of Zhengzhou University. A total of 4,449 infected patients were randomly assigned to the development and validation data set at a ratio of 4:1. After extracting electronic medical record data, a set of 55 features (variables) was calculated and passed to the random forest algorithm to predict the onset of sepsis.

Results: The pre-procedure clinical variables were used to build a prediction model from the training data set using the random forest machine learning method; a 5-fold cross-validation was used to evaluate the prediction accuracy of the model. Finally, we tested the model using the validation data set. The area obtained by the model under the receiver operating characteristic (ROC) curve (AUC) was 0.91, the sensitivity was 87%, and the specificity was 89%.

Conclusions: This newly established machine learning-based model has shown good predictive ability in Chinese sepsis patients. External validation studies are necessary to confirm the universality of our method in the population and treatment practice.

INTRODUCTION

Although numerous studies and papers on sepsis are published every year, it remains a major challenge for patients and clinicians worldwide. Between 2002 and 2012, the proportion of sepsis patients admitted to hospitals in the European ICU remained unchanged; however, the severity of the disease increased significantly (1). The standardized sepsis-related mortality rate in China in 2015 was 67 deaths per 100,000, which was equivalent to more than 1 million deaths due to sepsis (2). Despite these alarming numbers, the public seems to lack an awareness about sepsis. An adult survey found that <30% of people are aware of the severity of sepsis, which was much lower than the proportion for cardiovascular diseases, cancer, and asthma (3).

To date, the diagnosis of sepsis has largely relied on determining the presence of infection and organ dysfunction (4). In addition, screening laboratory tests are often required to confirm the diagnosis. However, laboratory testing takes time, so treatment is further delayed (5).

The early detection and prediction of patients who may develop sepsis is essential to improve the adverse consequences of sepsis. Although there are many studies on the early predictions of sepsis, such as calcitonin, C-reactive protein, white blood cells, platelets, and lactic acid (6, 7). However, disappointingly, most studies are limited in clinical prediction (8). Since sepsis is a complex clinical syndrome, it contains a wide range of multifaceted clinical and biological features; therefore, a single clinical index may not be a good reflection of the disease state (9). There is still a lack of effective biomarker combinations that can distinguish patients with sepsis from those not affected with sepsis.

Current research mainly uses data collected by bedside monitors to determine the probability of sepsis in ICU patients. Bloch et al. constructed a sepsis prediction model based on the four vital signs of mean arterial pressure, heart rate, respiratory rate, and body temperature (10). The best area under the curve (AUC) was achieved with Support Vector Machine (SVM) with radial basis function, which was 88.38%. Guillén et al. used vital sign measurements and laboratory test results to predict the likelihood of severe sepsis in patients with sepsis during ICU hospitalization (11). The study showed that the AUROC based on vital signs data was 0.84; based on vital signs and laboratory results, the AUROC was calculated to be 0.882. Calvert et al. studied the correlation between pairs and triples of vital sign measurements and the overall trend (i.e., increase, decrease, and no change) of the measurements over time to predict sepsis in the adult ICU population disease (12). Their results show that the average AUROC measurement accuracy is 0.83, but requires a larger data set, which usually requires longer processing time. Since the above studies are based on the previous definition of the Third International Consensus Definition of Sepsis (sepsis-3), our current understanding of sepsis is of limited reference value. Nemati et al. used electronic medical record data combined with high-resolution time series of heart rate and blood pressure to dynamically predict sepsis, with an area under the receiver operating characteristic (AUROC) of 0.83–0.85 (13). Although the study is based on the third international definition of sepsis (sepsis-3), its predictive power is not significantly different from previous studies.

Machine learning has been applied to multiple healthcare fields, including diabetes, cancer, cardiology, and mental health (14–17). Most of the machine learning models and tools developed in the research environment has studied the potential of prognosis, diagnosis, or clinical componentization, thus demonstrating the prospect of developing computerized decision support tools (18, 19). In general, the use of machine learning models can improve patient safety, improve the quality of care, and reduce medical costs (20).

The application of artificial intelligence in the medical field is gaining increasing recognition in the improvement of clinical practice and achievement of personalized treatment (21, 22). This study used machine learning methods to evaluate predictive clinical indicators and biomarkers related to sepsis and to establish a model that could effectively predict sepsis early, which is necessary to identify high-risk patients and may enhance the understanding and facilitate clinical management of sepsis.

Abbreviations: ICU, Intensive care unit; LDL, Low-density lipoprotein; PT, Prothrombin time; ROC, Receiver operating characteristic; WBC, White blood cells.

MATERIALS AND METHODS

Study Population

This study was a secondary analysis of a retrospective observational study conducted from 2014 to 2016 in the intensive care unit (ICU) of the First Affiliated Hospital of Zhengzhou University. The inclusion criteria were (1) infection at the time of admission to the ICU; (2) compliance with the international consensus definition of sepsis and septic shock (Sepsis-3.0); (3) age $\geq$18 years. The exclusion criteria were (1) age $<$18 years; (2) diseases without infection status such as coronary heart disease, cardiac arrest, fracture, neoplasm, cerebral infarction, and brain injury; and (3) more than three missing data. Clinical or laboratory parameters related to infection and sepsis were collected for each patient.

Statistical Analysis

The binary variables were described as counts and percentages and were evaluated using the Chi-square test or Fisher's exact test. If the continuous variables conformed to a normal distribution, they were compared using a t-test and expressed as means $\pm$ SEM. For a non-normal distribution, the Mann–Whitney U test was used. $P < 0.05$ was considered statistically significant. The ensemble model was written Python scripting language (Version 3.6.5, Python Software Foundation, Wilmington, DE, USA, https://www.python.org).

Modeling and Feature Selection

The random forest algorithm, which belongs to the category of machine learning methods and captures non-line relationships between dependent and independent variables with high flexibility and sufficient accuracy, has been successfully applied to various fields such as the estimation of the genetic effects (23), clinical deterioration prediction (24), association estimation (25), clinical outcome prediction (26), and others (27–30). In this study, we used the random forest algorithm to predict the risk of sepsis in ICU patients by analyzing laboratory/clinic data as follows: (i) lipids, (ii) liver function, (iii) hemagglutination, (iv) blood cells, (v) renal function, and (vi) electrolyte. The essential idea of the random forest algorithm is to build multiple decision trees to reduce the correlation between trees using bootstrap aggregating or bagging, which can avoid the over-fitting problem. The random forest algorithm was written in the Python scripting language (version 3.6.5, Python Software Foundation, Wilmington, DE, USA, https://www.python.org).

Generally, models with more features will achieve higher accuracy than those with fewer features. However, in clinical practice, having more features cannot always improve the performance of the model because of irrelevant or redundant features, which may mislead the models. To recognize the key features and the optimal combination of features, we performed a random forest algorithm on different subsets of the training set. In this study, we identified 55 features, which were potential candidates for sepsis prediction. Because the number of possible feature combinations was large (2^{55}), as shown in **Figure 2**, we used the Gini importance to rank the importance of all potential features (31, 32). Specifically, a high Gini importance value was a high priority for incorporation into the model. On the basis of the Gini importance value of each feature, we performed the random forest algorithm on the various feature subsets.

Validation

In this study, we used a 5-fold cross-validation to assess the prediction performance of the model because it was the most commonly used method for machine learning-based medical problem exploration (33–37). Specifically, the available training set was divided into five roughly equal-sized subsets: the training set and the validation (or internal validation) set. Four of them were applied to fit the random forest model, and the remaining one was used to estimate the accuracy of the model.

We measured the performance of the model by applying several different indices, namely (i) AUC, (ii) accuracy, (iii) precision, (iv) recall, and (v) F1-Score, which were defined as follows:

$$Accuracy = \frac{TN + TP}{TN + FP + FN + TP}$$

$$Precision = \frac{TP}{FP + TP}$$

$$Recall = \frac{TP}{FN + TP}$$

$$F1 - Score = \frac{2 \times Precision \times Recall}{Precision + Recall}$$

Here, *TP*, *FP*, *TN*, and *FN* are the number of positive samples classified as positive (true positives), the number of negative samples classified as positive (false positives), the number of positive samples classified as negative (true negatives), and the number of negative samples classified as negative (false negatives). Briefly, we used five prediction performance indices, 5-fold cross-validation for internal validation, and the testing set for external validation to estimate the performance of the model.

RESULTS

Patient Characteristics

Our database consisted of 17,005 patients admitted to the ICU. After a series of exclusions, 4,449 adult patients were included in this study, and 3,539 patients developed sepsis. The process of cohort selection is shown in **Figure 1**. A total of 55 variables, including age, sex, red blood cell count, total cholesterol, D-dimer, and other clinical or laboratory parameters related to infection and sepsis, were collected for each patient. The baseline characteristics of the included patients are shown in **Supplementary Table 1**. We then randomly divided the patients into the training and testing sets. **Supplementary Table 2** shows the basic information compared between the two sets.

Variables of Importance

Generally, the error of the model decreased with an increase in variable selection. However, increasing the number of variables was not conducive to clinical practice. In order to identify the prominent features, we used the random forest method to select variables by using various feature subsets. Therefore, the relative importance of each feature based on the fact that the features built on the tree top contributed more to the prediction of sepsis in high-risk patients is shown in **Figure 2**. It can be observed in **Figure 3** that the error value remained at a similar degree when the number of features reached 20. Therefore, we utilized a combination of 20 selected features to predict sepsis in ICU patients (shown in **Supplementary Table 3**): neutrophils%, D-dimer, neutrophils, eosinophils, lymphocytes, albumin, white blood cells (WBCs), direct bilirubin, potassium, calcium, cholinesterase, magnesium, low-density lipoprotein (LDL), prothrombin time (PT), lymphocytes, lactate dehydrogenase (LDH), basophils%, total cholesterol (TBIL), urea, and platelets (PLT).

Next, we performed a random forest classification with the same parameters (to make the comparison possible and remove the effect of the parameters) with different subsets of features to calculate the changes in AUC values. The AUC loss value changed when we set the number of features to different values (**Supplementary Table 3**).

Classification Results

As shown in **Table 1** and **Figure 4**, on average, the random forest algorithm achieved an AUC of 0.88 (±0.04), accuracy of 0.88 (±0.03), precision of 0.90 (±0.03), recall of 0.96 (±0.01), and recall of 0.93 (±0.02) in the internal validation. For the external validation, the model gave an AUC of 0.91, accuracy of 0.87, precision of 0.89, recall of 0.95, and recall of 0.92.

DISCUSSION

Early identification and treatment of sepsis is a highly complex and multifaceted challenge (38). It requires highly skilled and well-trained human experts (39). However, with the continuous emergence of AI applications in the medical field, some of these decisions will soon be replaced by machines called "intelligence" to improve clinical practice and patient outcomes (40). Most of what we call "artificial intelligence" is machine learning, which means learning from data and using this knowledge to acquire new knowledge or skills.

This study used a supervised learning method (a machine learning method) to build a predictive model, which included 20 predictors of sepsis events predicted by the random forest method. The AUC of this newly developed model was 0.91, demonstrating good discriminative power. These prediction

TABLE 1 | Internal and external validation results of the prediction model.

	AUC	Accuracy	Precision
Internal validation/validation set (95% CI)	0.88 (±0.04)	0.88 (±0.03)	0.90 (±0.03)
External validation/testing set	0.91	0.87	0.89
	Recall	**F1-Score**	
Internal validation/validation set (95% CI)	0.96 (±0.01)	0.93 (±0.02)	
External validation/testing set	0.95	0.92	

CI, confidence intervals; AUC, indicates area under the receiver-operating curves.

results suggest that the ensemble model with 20 key features is feasible and practical.

To our knowledge, most previous studies have developed models to predict the prognosis of sepsis. However, only few researchers have paid attention to the differences in the incidence of sepsis after infection, although it is important for clinical preventive intervention. Thomas et al. developed machine learning models for the early identification of sepsis risk (41); however, they did not obtain precise biomarkers that could be applied to clinicians. All calculations are trivial for a computer, which may limit generalization of the results to other hospitals and hospital systems. Other artificial intelligence systems such as random forest models may be a valuable tool to predict sepsis (8).

The variables in our model were mainly blood cells, lipids, liver function, hemagglutination, renal function, electrolyte, enzyme, and others. Interestingly, blood-related variables accounted for a large part of our model; the first five variables in **Figure 2** are related to the blood system. Neutrophils were an ideal choice for eliminating pathogenic bacteria because they store a large number of proteolytic enzymes that can rapidly produce reactive oxygen species to degrade internal pathogens. Hence, patients with sepsis often have neutrophil infiltration, and the degree of infiltration is related to tissue damage (42, 43). Other blood cells, including eosinophils, basophils, lymphocytes, and WBCs, are also associated with the body's defense against infection. For example, some studies have speculated that individuals with basophilic granulocytopenia have a weak resistance to infection and thus are more likely to develop sepsis (44). In addition, studies have shown that eosinophilia was a moderate marker for distinguishing SIRS from infection in critically ill patients newly admitted to the hospital, which suggested that eosinophilia may be a useful clinical tool for the prediction of sepsis (45). In addition, lymphocyte apoptosis has been recognized as an important step in the pathogenesis of experimental sepsis by inducing a state of "immune paralysis" that renders the host vulnerable to invading pathogens (46).

In the past decade, there has been a growing awareness about the role of the coagulation and fibrinolysis systems in the development of inflammation. Patients with sepsis may have common host reactions, such as coagulation, inflammation, and endothelial injury. Abnormal inflammatory and coagulation biomarkers were found to be associated with disease severity and mortality in patients with severe sepsis (47). Platelets are the main effector cells involved in blood coagulation and can promote the development of excessive inflammation, DIC, and microthrombosis (48). PT can reflect the coagulation function of the body, and D-dimer levels increase under hypercoagulable state (49). Therefore, changes in these substances may predict the occurrence of sepsis.

Sepsis is often associated with multiple organ dysfunction such as that involving the heart, liver, and kidney (50). Therefore, some indicators reflecting organ function may be used to predict the occurrence of sepsis. Albumin which is the most important protein in human plasma, maintains nutrition and osmotic

pressure. When liver synthesis is dysfunctional, its level usually decreases. Lactate dehydrogenase and urea are associated with cardiac and renal function, respectively. Patel et al. revealed an association between serum bilirubin levels and mortality during sepsis, suggesting that serum bilirubin may be a potential predictor of sepsis occurrence and death (51).

Previous studies have shown that lipids are also involved in the occurrence and development of sepsis. Yamano et al. found that low total cholesterol and high total bilirubin levels are associated with prognosis in patients with prolonged sepsis (52). Hofer et al. found that pharmacologic inhibition of cholinesterase improves survival in experimental sepsis, probably by activating the cholinergic anti-inflammatory pathway (53). The results of Feng's study suggest that a decrease in LDL-C levels is significantly associated with an increased risk of sepsis in infected patients, although the association was due to the presence of complications (54).

Although the association between electrolytes other than calcium and sepsis appears to be poorly studied, this study found that the decrease of potassium and magnesium is closely related to the occurrence of sepsis. We know that the critical illness itself is associated with a decrease in serum total calcium and free calcium levels, which is related to the severity of underlying diseases as measured by the APACHE II score. In addition, studies have shown that total and ionized hypocalcemia is more significantly associated with increased severity of infection, which suggested the role of calcium in predicting the risk of sepsis in patients with infection (55). Regarding magnesium and potassium, a study pointed out that ATP-$MgCl_2$ may be beneficial in sepsis (56). An increasing amount of evidence has suggested that potassium channels are involved in cardiovascular dysfunction in sepsis after systemic inflammation, cardiovascular dysfunction, and organ damage, and that potassium channels may affect the emergence of sepsis after infection (57). In conclusion, we believe that because sepsis is not a simple disease that can be predicted by a single marker, the biomarkers included in our model can be combined to predict the risk of sepsis in infected patients.

Our study has several limitations. First, this was a retrospective study, which had its own shortcomings, such as information bias. Second, the prediction model may have lacked generality because the 55 variables are still too few, and many other variables were omitted due to the loss of too many values. Generally, the more the variables included, the higher the prediction accuracy. Therefore, we hope to include more patients and variables in future prospective studies.

A model with 20 key features was successfully established to predict sepsis events in Chinese patients. This model has excellent ability to predict sepsis events in Chinese patients.

Cardiovascular disease (CVD) is considered to be one of the most epidemic diseases in the world today. Predicting CVDs, such as cardiac arrest, is a difficult task in the area of healthcare. The healthcare industry has a vast collection of datasets for analysis and prediction purposes. Somehow, the predictions made on these publicly available datasets may be erroneous. To make the prediction accurate, real-time data need to be collected. This study collected real-time data using sensors and stored it on a cloud computing platform, such as Google Firebase. The acquired data is then classified using six machine-learning algorithms: Artificial Neural Network (ANN), Random Forest Classifier (RFC), Gradient Boost Extreme Gradient Boosting (XGBoost) classifier, Support Vector Machine (SVM), Naïve Bayes (NB), and Decision Tree (DT). Furthermore, we have presented two novel gender-based risk classification and age-wise risk classification approach in the undertaken study. The presented approaches have used Kaplan-Meier and Cox regression survival analysis methodologies for risk detection and classification. The presented approaches also assist health experts in identifying the risk probability risk and the 10-year risk score prediction. The proposed system is an economical alternative to the existing system due to its low cost. The outcome obtained shows an enhanced level of performance with an overall accuracy of 98% using DT on our collected dataset for cardiac risk prediction. We also introduced two risk classification models for gender- and age-wise people to detect their survival probability. The outcome of the proposed model shows accurate probability in both classes.

Keywords: artificial intelligence, cardiac arrest prediction, machine learning, predictive analysis, risk classification, heart failure

INTRODUCTION

At present times, cardiovascular disease (CVD) is one of the most contagious illnesses. According to WHO, ∼60% of cardiac patients are Indians to suffer from CVDs. Cardiac symptoms are generally associated with dynamic changes in an individual. The vital changes in the human body may lead to cardiac problems due to misdiagnoses or improper treatment. Another sign of cardiac disease is environmental changes and lifestyles of people (1). In healthcare, CVDs are considered a vital aspect to be diagnosed as soon as possible to minimize the risk. Hence, early prediction of CVDs needs to be examined in a patient (2, 3).

Cardiovascular disease comprises heart or cardiac diseases in heart patients and is a critical challenge in the medical field. Several reasons and findings that cause cardiac arrest are observed, such as a change in personal and professional lifestyles, habits, inactive lifestyle, growing age, habitual history related to smoking, alcohol consumption, stress level, and physiological signs, such as diabetes, high level of blood pressure (BP), obesity, cholesterol, hypertension, and existing heart problems. These risk factors need early, accurate, and efficient diagnosis to prevent cardiac arrests (4–6). The risk factors can be depreciated by executing proper lifestyle activities, such as lowering salt usage, absorbing a healthy diet, prohibiting alcohol and tobacco use, and regular physical exercise (7). Medical sectors use the abovementioned vital signs to produce consequential information from data. The vital signs are generally collected from publicly available datasets, wearable gadgets, medical hospitals, or sensors. Monitoring health parameters using Internet-of-Things (IoT) is a forming trend for future well-being. IoT sensors are mostly used to collect real-time vital signs and monitor the health parameters of individuals (8). Collecting, processing, and analyzing vitals help predict risk early to tackle the problem (9, 10).

One of the broad areas of Artificial Intelligence (AI) is machine learning (ML). ML is an effective technology and efficient field, which is based on prediction purposes. Using ML concepts, we can develop models or enable human abilities and train our data collected or gathered from the past for future predictive analysis (11). Those data are further divided into training and testing, which help in predicting future possibilities. This combined technology is called ML (12). The ML algorithm needs pertinent information for training and testing. In addition, the model performance can be raised if the balanced data are given to the ML model. In addition to that, the capability and accuracy of the predictive model can be improved if relevant features are selected from a dataset. Hence, a balanced dataset and feature selection are paramount for improving model performance (13). Furthermore, for cardiac arrest prediction, the ML algorithm is used, which has been addressed in this research. Nowadays, deep learning models show prominent growth and improvement in predicting and analyzing heart diseases (14).

Several studies have shown predictions on publicly available datasets. Still, this research aims to find early risk prediction of cardiac arrest based on real-time data collected from an individual using sensors and equipment. Furthermore, the authors build a Neural Network, Bagging, and Boosting model using ML techniques by selecting relevant datasets to show which model accomplishes best. This study also aims to classify risk in different age and gender groups of people. The points mentioned below show the main contributions of the article:

- To collect real-time vital signs of an individual using sensors and equipment.
- To detect cardiac arrest by applying the ML algorithm.
- To show a comparative analysis of the various ML classifiers.
- To classify cardiac arrest risk for the coming 10 years in different age groups.
- To show survival probability gender-wise in our creation of data.

The rest of the article is assembled as follows. Section Related Work narrates research work on heart diseases along with existing methods, datasets, and techniques available. Section Proposed Work exhibits the study of the proposed study of the author. Section Methodology reveals the methodologies and algorithms used for disease risk prediction. Section Risk Classification conveys the risk classification in people. Section Exploratory Data Analysis presents the results of Exploratory Data Analysis. Section Implementation Details communicates the implementation details of all the experiments and results. Finally, section Discussion, Conclusion, and Future Work discusses and concludes the research study of the author.

RELATED STUDY

Literature Survey

This section discusses the existing article to predict and diagnose heart diseases using several techniques and datasets used with various features and classification techniques.

Ambekar and Phalnikar (1) proposed a risk model for heart disease with structured data using a Convolutional Neural Network-based Unimodal Disease Risk Prediction (CNN-UDRP) model to classify risk levels as high, low, and medium. The dataset was extracted from the UCI repository. To avoid missing values, performed data cleaning and imputation to substitute missing values and increase the performance of the model were implemented. The proposed model achieves an accuracy of nearly about 65%. Ramprakash et al. (2) developed a model using a Deep Neural Network (DNN) and χ^2–a statistical method to predict the risk of heart patients. The Cleveland dataset was used, which is publicly available on the UCI repository. In this study, DNN models Artificial Neural Network (ANN) and DNN and proposed statistical methods χ^2-ANN and χ^2-DNN were compared. The comparison shows that the proposed method χ^2-DNN was more efficient in providing an accurate accuracy of 94%. Maini et al. (5) discuss data mining techniques to detect heart disease risk at an early stage and show the importance of assigning a cloud-based approach for helping healthcare providers. Mohan et al. (6) proposed a hybrid model combination of Linear model and Random Forest (RF) technique with different features combined on publicly available datasets, i.e., Cleveland from UCI repository and compared its result with models of Naïve Bayes (NB), RF, Linear model, Deep Learning, Logistic regression, etc. From all the proposed models, Random Forest with Linear Model (HRFLM) outperforms all others with 88.4% accuracy. Shah et al. (3) used the Cleveland dataset available from the UCI repository. They implemented ML algorithms, such as Decision Tree (DT), K-Nearest Neighbor (KNN), NB, and RF for visualizing the probability of heart disease in the patients. Among all models, KNN shows the highest accuracy score of 90% in predicting heart disease.

Garg et al. (15) used an ML algorithm to predict and classify diseases of a person who is suffering from heart problems. They have used a dataset from Kaggle, which was commonly used

for prediction purposes. From the attributes, 13 main attributes, such as the age of a person, chest pain, cholesterol level, and many more, were considered to predict heart diseases. The ML algorithms used are KNN and RF. The comparison was made between the ML algorithm and RF achieves the highest accuracy with 82%. Yadav et al. (16) proposed an optimization model, namely, "Optimized DNN using Talos" deploy ML classifiers, such as DT, KNN, RF, and Ensemble model (used ANN, KNN, and Support Vector Machine, SVM), for the prediction of heart diseases. They have used the concept of dimensional reduction where only vital information of patients was considered. On comparing their model with traditional models, the proposed model provides better accuracy and prediction.

Latha and Jeeva (17) convey classification as a commonly used technique in ML algorithms, so they have tried a new technique that is an ensemble technique that combines two or more classifiers to improve the accuracy obtained by a simple classification technique. They focus on increasing the accuracy and implementation of feature selection with a different set of features. There was a significant increment in the prediction accuracy. Singh et al. (18) proposed a multisurface proximal SVM (MPSVM)-based DT, collaborated with the ensembling method consisting of Gradient Boosting and RF algorithms on Cleveland dataset from UCI repository. They have solved the 2-class problem and the 5-class problem on a dataset using the proposed method. On analyzing, the 2-class problem shows better accuracy of 91% than the 5-class problem with 73%. Sowmiya and Sumitra (19) used the Cleveland dataset from the UCI repository to implement heart disease prediction. They have applied an ant colony optimization technique for the best feature selection for the hybrid KNN classifier. This hybrid model is compared to other classification algorithms, such as SVM, KNN, NB, C4.5, and DT. Their study proposed HKNN as an effective and efficient technique for heart disease prediction.

Alotaibi (20) focused on improving the performance and accuracy of ML algorithms compared with the previous studies. In this study, the prediction of heart diseases is made using RapidMiner tool on Cleveland dataset extracted from UCI repository and compared the results with previous work that used Weka and MATLAB tools where the performance of RapidMiner tool gives higher accuracy using techniques: SVM, DT, and Logistic regression.

Nikookar and Naderi (21) proposed a hybrid ensemble method to show comparison with the primary ensemble method using SPECT heart disease dataset, consists of SPECT images based on feature vector on fuser classifier algorithm, i.e., Adaboost, MLP, Logitboost, and RF. The comparison was made between hybrid and basic ensemble classifiers where the proposed hybrid classifier shows higher accuracy. Tama et al. (22) proposed a model using a two-tier ensemble technique to detect heart disease. The developed model was implemented by ensembling gradient boosting, RF, and extreme gradient boosting (XGBoost) classifiers. The model was trained and validated on available datasets: Cleveland, Statlog, Hungarian, and Z-Alizadeh Sani. A two-step significance test was conducted to compare with the existing article and provided the highest results. Li et al. (13) developed a diagnosis system called Fast Conditional Mutual Information (FCMIM-SVM) based on classification algorithms—ANN, SVM, and Logistic Regression—to diagnose heart diseases using the Cleveland dataset. They used minimal redundancy maximal relevance, relief, most minor absolute shrinkage selector operator, etc., as a feature selection algorithm to select relevant features to get accurate accuracy. The proposed model shows a better accuracy as compared to the previously developed model. Sarmah (8) proposed a model using IOT sensors attached to the body of the patient to gather real-time data and applied the Deep learning modified neural network (DLMNN) model for heart disease prediction. The prediction from the model executes in three ways: Authentication, Encryption, and Classification. Thus, the classification shows normal and abnormal output and prescribes it in its manner. Hence, the model proposed shows improvement over the existing algorithm with providing authentication.

Chauhan et al. (10) used an ML algorithm to predict heart diseases on the Cleveland dataset publicly available and compared the result with the algorithms. Among all, ANN outperforms all classification algorithms with 85% accuracy. Pan et al. (14) proposed an enhanced deep-learning Convolution Neural Network (CNN) model that predicts and improves heart disease in a patient. This model uses the more profound architecture of the multilayer perceptron model and regularizes parameters. In addition, this system has been executed on the Internet-of-Medical-Things (IOMT) platform to provide efficient solutions for a doctor for the diagnosis of heart diseases. This CNN model is compared with other ML techniques and shows a maximum accuracy of 97%. Fitriyani et al. (7) developed a clinical decision support system (CDSS) to recognize early heart failure. They also proposed the Heart Disease Prediction Model (HDPM) for the CDSS system to eliminate noise and outlier presence. They have built the Starlog and Cleveland dataset model, which is available publicly and tested on other ML models and compared the results. The proposed model achieves 95% with Statlog and 98% with the Cleveland dataset.

Tate and Rao (23) give an idea of using wearables in form of a wristwatch, wrist band, ambulatory devices, skin response monitors, Fitbit tracker with an app installed, and many more for prediction of cardiac arrest at an early stage. These electronic gadgets help in tracking our day-to-day routine and monitoring our daily activities by keeping track of each activity. The vital information of patients can assist individuals by sending emergency alerts via web and mobile interfaces. Several studies, such as Framingham Heart Study, had developed the Cox regression hazard ratio model specifically for the sex groups for the prediction of heart diseases by estimating 10-year risk. Hence, the idea of capturing the vitals of an individual from wearables helps to get a better prediction and classification rates for detecting heart diseases. Prabhu et al. (24) proposed the CN-Based Multimodal Disease Risk Prediction (CNN-MDRP) model for risk prediction of diseases on a sizeable Medical dataset and compared the result with the algorithm that is CNN-UDRP. The performance of CNN-MDRP shows more improvement than the CNN-UDRP model for risk prediction. Shankar et al. (25) aim to predict heart diseases in an individual. They have made the

prediction based on details entered by a patient in a hospital, and the data were trained on a CNN model to find the accuracy. The data used were in structured and unstructured formats. The proposed CNN model shows improvement by comparing it with other algorithms.

Singh and Kumar (12) have calculated accuracy for predicting heart diseases using ML algorithms. The algorithms were KNN, DT, Linear Regression, and SVM utilizing Cleveland dataset from the UCI repository for training and testing. Overall, the accuracy of the KNN algorithm achieves 87% for early heart disease prediction. Amin et al. (26) have collected real-time data, i.e., the vital signs of a patient using Fitbit wearable. The data captured by the wearable were entered into an application and processed through an ML algorithm. This study aims to notify an individual whether he/she is at risk of CVD or not. The outcome of the prediction result helps doctors in diagnosis patient health. Chen et al. (27) proposed a technique for predicting the occurrence of perioperative heart diseases. The data were collected from the hospital and divided into structured data in numerical form and unstructured data in textual form. ML algorithms for numerical data gradient boosting tree algorithm and textual data topic model of text-based data model were used. The datasets were fused using a simple logistic regression model and achieved a sensitivity of 90% and specificity of 93%.

Cohen et al. (28) proposed a 1-year risk prediction model for patients with congenital heart diseases. The dataset was collected from Quebec hospitals of patients varying in age between 18 and 64 years. Multivariate logistic regression was used to predict the risk for heart diseases. The risk score was indicated between 0 and 19. Hence, the risk score model shows excellent performance. Chang et al. (29) use an ML classification algorithm to predict the vital signs of a patient for the next hour. Vital signs, such as heart rate (HR), BP, mean arterial pressure, and oxygen, were considered. Early warning signs can help nurses and doctors treat the patient before the situation degrades. ML algorithms, such as ANN, RF, Gradient Boosting, and long-short-term-memory (LSTM), were developed. The outcome shows the accuracy of ML models. Youssef Ali Amer et al. (30) have carried our experiment with vital signs of patients using wearable devices. The vital signs considered were BP, oxygen level, and HR. These vital signs were estimated every minute using mean and minimum statistical values.

Then, the ML technique of KNN LS SVM was executed to predict future values of vital signs that were monitored. The performance of implemented ML algorithm was compared with the LSTM approach, and the proposed approach shows much improvement in predicting the early warning score of vital signs. Stehlik et al. (31) have indicated re-hospitalization of HF by non-invasive and remote monitoring. Wearable sensors were placed on the chest of a person (up to 3 months), collecting and recording physiological data (vital signs). The data were uploaded on a cloud platform via a smartphone. Analytics were performed on data to detect HF exacerbation. The result shows 76–88% sensitivity and 85% specificity. An alert was shown 6 days prior for re-admission.

Jia et al. (32) use the Cox proportional hazards regression model to find the probability of risk for 10 years using the Framingham dataset. The risk factors considered were sex, body mass index (BMI), systolic BP (SBP), and diabetes. They have calculated a sex-based risk score using the Cox regression hazard equation.

Yang et al. (33) proposed a multivariate regression model for the prediction of CVDs. The prediction was made on the collection of vital information of patients from the centers of the national high-risk program by having a cardiac events assessment. The dataset consists of all information, such as BP, cholesterol level, obesity, smoking, BMI, and many more attributes were taken into consideration. The area under curve results of the multivariate regression model were then compared to other ML classification techniques, such as CART, NB, and Ada Boost. The outcome result of the multivariate regression model outperforms other methods. Made et al. (34) surveyed CVDs estimating 10-year risk in the different age groups of people. They proposed a SCORE model that uses risk factors, such as weight, BP, cholesterol level, smoking habit, diabetes, and many more. The data were collected by taking samples of men and women of age 18 and above. The 10-year risk estimation was made on statistical analysis, which estimates coronary heart diseases and no-coronary heart disease. These studies on 10-year risk scores help to prevent heart diseases in the coming future.

Comparison of Previous Findings and Proposed Study

The literature study discussed above and in **Table 1** shows the importance of the vital signs of a person in the healthcare industry to detect health-related problems. Mainly, health problems are majorly concerned with the heart, such as cardiac arrest, CVDs, coronary heart disease, and many more. In this research, the authors have depicted the detection of cardiac arrest in a person by collecting real-time data. Moreover, most of the detection and prediction of heart disease is majorly made on a public dataset consisting of shared attributes. In our contribution, the features chosen are mainly focused on cardiac arrest detection. After detecting cardiac arrest, gender-wise survival probability, and age-wise cardiac arrest risk scores are also formulated using two approaches: (1) Kaplan-Meier and (2) Cox regression model. These two methods help to provide which gender has fewer survival chances and which age group has a high probability of risk in the next 10 years.

PROPOSED WORK

This section briefly describes the novelty of the proposed work (contributions) and the articles mentioned early by some research on the same Cox regression model.

The progress in CVD risk models is ordinarily based on conventional laboratory-based predictors. The primary purpose was to develop a prediction model, which was based on a 10-year risk. To predict 10-year risk, a Cox regression proportional method was applied. A dataset from Framingham Original Cohort and SCORE of men and women aged between 30 and 62 was taken to predicate CVD risk. In this study, the CVD risk was

TABLE 1 | Comparison of literature work and proposed work.

Further, comparison is made among 6 classifiers. Also, we developed two models based on Kaplan-Meier method (For Gender-Based) and Cox-Regression Proportional Model (For Age-Based) using scoresheet	Among 6 Machine learning models-Decision Tree achieves maximum accuracy of 98%. Our proposed approach, for age-based and gender-based shows risk score (in percentage) of cardiac arrest for the next 10-years

being predicted on a gender basis (men/woman). The risk factors involved are age, sex, BMI, SBP, and diabetes.

A proposed study related to cardiac arrest prediction using the real-time dataset is classified based on gender and age. Our study has used two methods to find the risk classification probabilities among gender-based and age-based. The two methods used—Kaplan-Meier survival analysis and Cox regression model survival analysis—are considered. These two methods have their importance in analyzing risk probabilities.

Kaplan-Meier Method

This method is a non-parametric survival function for the estimation of survival probability. Kaplan-Meier method also estimates the survival curve by giving a statistical comparison between two groups: men and women.

Cox Regression Proportional Model

Cox regression proportional model does regression analysis with survival data without making any strong assumption. It calculates the hazard ratio (HR) of the covariates used in our data and is based on the equation, and it shows risk probability. Cox regression proportional model is a model that helps to find risk probability or score on more than one covariate. In general, it is a method to identify the effect of variables at some time interval on some event that occurs.

METHODOLOGY

Measuring Device

The risk factors associated with heart diseases are cardiac arrest prediction: age, gender, height, weight, BMI, BP [SBP and diastolic BP (DBP)], HR (beats per minute), and oxygen level (SPO_2%).

The above factors used in this research are collected using IOT sensors and equipment for different risk factors. The measuring device can capture the vital signs of a person needed to estimate cardiac arrest prediction. **Figures 1**–**3** show measuring device used for capturing vital signs.

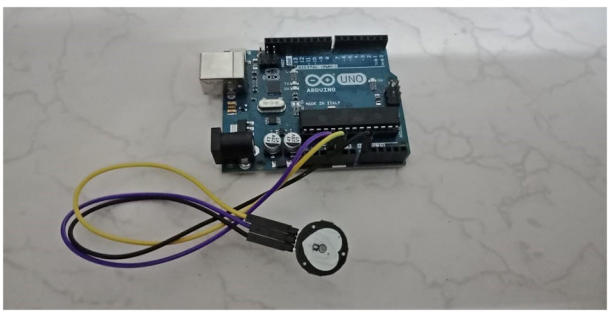

FIGURE 1 | Pulse sensor connected with Arduino.

FIGURE 2 | Sphygmomanometer.

FIGURE 3 | Oximeter.

Data Collection

Pulse Sensor

A pulse sensor is a device that is used to detect biometric pulse rate or HR, and it also keeps track of volume change. It is generally helpful for healthcare applications to capture the pulse rate of an individual. A pulse rate is detected when there is a change in blood vessel volume, and that occurs when the heart pumps blood.

For this research, we used a pulse sensor that is connected to Arduino UNO Board. Above, **Figure 1** shows the configuration of the pulse sensor and Arduino Board. A pulse rate or HR was captured from a total of 18 patients in beats per minute (BPM) at a 2 min interval.

Sphygmomanometer

A sphygmomanometer is a device used to measure the BP of a person. The connected rubber cuff with the device is wrapped around the upper arm of a patient and records the blood pressure in SBP and DBP.

For this research, we used Sphygmomanometer to measure BP. Above, **Figure 2** shows a Sphygmomanometer connected to the arm of a patient. BP was captured from the same 18 patients at every 2 min interval.

Pulse Oximeter

The pulse oximeter is a measuring device used to keep track of oxygen levels in a human body. This is an easy and painless measuring device to see how much oxygen reaches the different parts of the body. This device is generally used in hospitals and at home to determine the oxygen level in the body. It measures the oxygen level in SPO_2% form.

For this research, we used a pulse oximeter to measure the SPO_2. Above, **Figure 3** shows a pulse oximeter placed on the fingertip of a patient and the estimated oxygen level. It is a non-invasive method for monitoring oxygen saturation. Oxygen level was captured from the same 18 patients at every 2 min interval.

Dataset Description

Table 2 shows the names of attributes along with their feature description. The table also contains a range column indicating the range value mentioned in our dataset and its dataset. The dataset comprised attributes are:

- Date and time
- Gender
- Age
- Height
- Weight
- BMI
- SBP
- DBP
- HR (BPM)
- Cardiac arrest prediction—target variable.

Cardiac arrest prediction is our target variable from the features mentioned above, which is predicted in our dataset.

The target variable—cardiac arrest prediction—is labeled using the following conditions, as mentioned in **Table 3**.

Data Pre-processing

In the ML process, the processing of datasets is essential for good impersonation. Some techniques for data pre-processing are data cleaning, data integration, data transformation, data reduction, and data discretization. In our dataset, there are 540 records where the column gender is denoted as "F" and "M." These need to be processed as "0" and "1" using LabelEncoder.

Algorithm Used

Artificial Neural Network

Artificial Neural Network consists of ample neurons simulated together to form a network architecture. This architecture of the neural network is used to transform the inputs into some meaningful outputs. ANN is a supervised ML technique generally used for prediction. ANN consists of an input layer, hidden layer, and output layer linked together, forming a network. These layers are associated with numerical weights to minimize the error mathematically. For the cardiac arrest prediction dataset, the input layer consists of SBP, DBP, HR, and oxygen levels, fed to 16 neurons. These input parameters are fed into the next layer. The hidden layer consists of eight neurons and finally, after the processes, gives output to the output layer as a final result.

Random Forest Classifier (RFC)

Random Forest Classifier is a type of supervised ML algorithm used for two purposes: classification and regression problems.

TABLE 2 | Dataset description.

Sr. No.	Attributes name	Description	Value range	Type
1	Date and time	Shows person data collected on date and time	–	DD-MM-YYYY hh:mm:ss
2	Gender	Shows gender of a person	Male = 1 Female = 0	Categorical
3	Age	Shows age of a person in years	Age from 15 to 75	Numerical
4	Height	Shows height of a person in feet and inches	Height varies from 4′3′′-5′9′′	Numerical (in feet and inches)
5	Weight	Shows weight of a person in kilogram (kg)	Weight ranges from 45 to 75 kg	Numerical (in kg)
6	Body Mass Index (BMI)	Shows body mass of a person	BMI ranges from 15.1 to 38.7	Float
7	Systolic blood pressure (BP)	Shows systolic blood pressure of a person in mmHg	Normal Range must be ≥120 to ≤134 mmHg	Numeric
8	Diastolic blood pressure (BP)	Shows diastolic blood pressure of a person in mmHg	Normal range must be ≥79 to ≤87	Numeric
9	Heart rate (BPM)	Shows heart rate of a person in beats per minute	Heart rate between ≥49 to ≤84	Numeric
10	Oxygen level (SPO_2)	Shows oxygen level in a person body	Range between ≥95% to ≤100%	Numeric in %
11	Cardiac arrest prediction	Target variable to be predicted	0 = No cardiac arrest 1 = Cardiac arrest	Binary value

TABLE 3 | Labeled target variable.

Parameter	"0"—predicted label	"1"—predicted label
Systolic blood pressure mmHg	Between ≥120 to ≤134 mmHg	Below 120 mmHg and above 134 mmHg
Diastolic blood pressure mmHg	Between ≥79 to ≤87 mmHg	Below 79 mmHg and above 87 mmHg
Heart rate (BPM)	Between ≥49 to ≤84	Below 49 and above 84
Oxygen level (SPO_2)	Between 95–100%	Below 95% or above 100%

It follows the concept of ensemble learning, which combines multiple classifiers to solve complex problems and improves the performance of a model. Generally, it consists of several DTs forming a subset of a given dataset and improving the predictive accuracy of a dataset. RFC predicts the final output by comparing the prediction from each tree and based on the decision, such as majority voting; it indicates the result. For the cardiac arrest prediction dataset, the input parameters considered are SBP, DBP, HR, and oxygen level. The dataset is divided into 80% training and 20% testing set and selected the number of trees estimator 30 and function "entropy" for the information gain.

Gradient Boosting (XGBoost)

"XGBoost" stands for extreme gradient boosting and can be implemented with the gradient boosted trees algorithm. XGBoost is a supervised ML algorithm and is considered one of the most sought-after ML techniques. This is due to its high prediction accuracy and user-friendliness. Just like other ML algorithms, XGBoost can also be used for regression and classification of problems. XGBoost uses DTs as a weak predictor and minimizes the loss function using a gradient descent algorithm. In implementation, we created an "XGB Classifier" object by passing parameters subsample = 0.7, max_depth = 5, and n_estimators = 100 and by default it takes booster = "gbtree." The dataset is divided into 80% training and 20% testing set where training data are used to train a model and test part to measure its performance.

Support Vector Machine

Support Vector Machine is the best-supervised ML algorithm. It is used for both regressions and classification problems. However, for the dataset used, this algorithm is used for classification problems. For the cardiac arrest prediction dataset, the input parameters considered are SBP, DBP, HR, and oxygen level. The data are divided into 80% training and 20% testing set. We have used the Kernal value "rbf" Radial Basis Function for a non-linear classification problem.

Naïve Bayes

Naïve Bayes is a supervised ML algorithm that is used for solving a classification problem. It is generally based on the Bayes theorem and is considered one of the best classification techniques. It makes a quick prediction based on object probability. It builds a model on the classification problem and shows the high accurate result for a large dataset. For the cardiac arrest prediction dataset, the input parameters considered are SBP, DBP, HR, and oxygen level. The data are split into 80% training and 20% testing set. The model used in making a prediction is the Gaussian NB model, which follows a normal distribution for our predictor values.

Decision Tree

A DT is a classification technique used to solve a classification problem. It is a simple and widely used classification method. It is generated by providing a set of inputs in the form of a dataset. Its structure is like a flowchart that consists of Root, Sub-tree, and Leaf nodes. The algorithm starts from the root node, compares the values with the dataset attribute, and on the comparison, it follows the tree structure, i.e., branch and jumps to the next node. It continues its process until it reaches the last node, i.e., a leaf node. This helps in predicting the class of the given dataset. For the cardiac arrest prediction dataset, the input

parameters considered are SBP, DBP, HR, and oxygen level. The data are split into 80% training and 20% testing set, considering the maximum depth of tree-level to be three and attribute used "Gini" to measure purity while creating a DT.

RISK CLASSIFICATION

Survival analysis is a statistical approach for analyzing data where the outcome variable is the time till an event occurs. They are categorized into parametric, semi-parametric, and non-parametric models. For analyzing data, several survival analysis techniques are used, such as Life Tables, Kaplan-Meier analysis, Cox proportional hazards regression model, Survival trees, and Survival random forest. In this section, the different methods we used for our survival analysis are introduced.

Risk Survival Analysis Model

In this study, two models are proposed: Age_Cox_model specific for age-based survival analysis and Gender_KM_model for gender-based survival analysis. Both models are used to find probability risk in an individual. Age_Cox_model is generally based on the Cox regression model to predict the survival probability of having different ages. Gender_KM_model is based on the Kaplan-Meier estimator to analyze the survival probability based on male and female groups.

Age-Wise Classification

The age-based classification is done using Age_Cox_model analysis. The first stage of Age_Cox_model is to provide input in the form of a dataset. The next step is the pre-process the dataset to solve the categorical data such as gender. For categorical problems, the use of LabelEncoder is applied for the gender feature. The third stage is to select relevant parts for our proposed model. After selecting features, the next step is to train our model by applying the Cox regression model. The model then predicts the result, showing the importance of features and whether there are any risks. The steps of our model are described in the following pseudocode.

Step 1: Import libraries,
Step 2: Load the dataset,
Step 3: Pre-processed the data,
Step 4: Select relevant features,
Step 5: Apply Cox regression CoxFit() model,
Step 6: Predict results show feature importance and chances of risk.

The flow of the work is presented in the below diagram, **Figure 4**.

The above diagram result shows the importance and risk probability of features. **Table 4** describes that the *p*-value must be <0.05 and is considered significant.

The *p*-value of attributes age, SBP, and HR (BPM) is considered a significant covariant as values are <0.05.

On considering HR, i.e., exp(coef) shows the level of risk and have the following condition:

If HR = 1 Covariant has no effect of risk
HR <1 Covariant has fewer chances of risk
HR >1 Covariant has more options of risk.

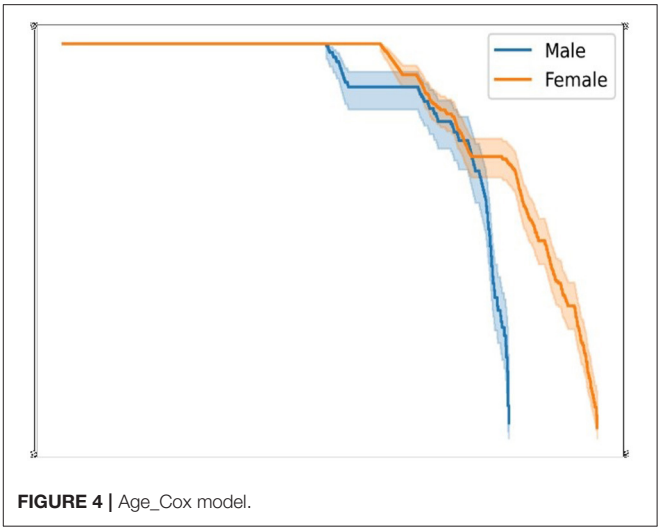

FIGURE 4 | Age_Cox model.

Hence, to know the chances of risk in our proposed work, age-based classification can be solved using the Cox regression survival analysis model formula, which is explained in the next part.

A. Age-based risk score calculation

The age-wise classification is derived from the prediction of a 10-year risk score for cardiac arrest prediction. Among the features collected, the main risk factors for cardiac arrest prediction are a Person's age, BP (SBP and DBP), HR (measured in BPM), cardiac arrest prediction as target variable, and T1 factor as a time interval. The age-wise classification for 10-year risk probability is estimated using the Cox regression model.

Table 5 represents the characteristics of risk factors that show statistical values of "total number of observations" (in each column), "number of observations with missing values," "number of observations without missing values," "minimum value" (in each variable column), "maximum value" (in each variable column), "mean value" (in each variable column), and "SD value" (in each variable column) are encapsulated.

Table 6 shows the summary statistics of events that occur while modeling risk prediction for 10 years. It shows, "total observed" = 540 total number of data or observation, "total failed" = 328 denotes the number of possible cardiac arrests, "total censored" = 212 denotes thin chances of cardiac arrest, and "Timestep" = 540 denotes the number of time steps equals to the total number of observations.

The following table indicator, **Table 7**, represents the model quality, that is, "efficiency of the model/variable fit." The most important statistic value to be noted is the probability of the Chi-square test on the log-ratio as shown in **Table 8**; on comparing, the model statistics with the defined covariates, the probability value, that is, the *p*-value must be lower than 0.05 ($p < 0.05$), to be significant. Hence, from **Table 7**, we conclude that the variables show significant information.

The following table gives information on the model. **Table 9** helps us understand the effect of our risk factors on the model. From **Table 9**, as per our collected dataset, the variable that

influences our risk survival model is SBP. From the beginning of the study, this risk variable indicates the patient has a high effect on cardiac arrest prediction. In this study, from the table, the "Value" column shows the HR, which is obtained as the estimated parameter exponent and is calculated using Equation (1).

The HR is given using the mentioned formula:

$$H(t) = h_0(t)\exp(\sum ßi X_i)(i = 1 \text{ to } r) \quad (1) \tag{1}$$

Notations are:

t = Survival time (10-year risk) (t = 10).
exp = Exponential function (exp(X)).
B_i = It measures the impact of covariates (B_1, B_2, B_3, …, B_r).
X_i = Predictor variables (X_1, X_2, X_3, …, X_r).
$h_0(t)$ = Baseline hazard rate.
H(t) = HR.

The Cox model regression has an exponential form, as seen in Equation (1).

As per our dataset, for 10 years, the term $h_0(t)$ = baseline survival rate value is considered 0.993 at mean values of covariates from the survival distribution function. Here, "t" represents an event that occurred at a time. The H(t) hazard function is determined by the set of covariates X_i = (X_1, X_2, X_3, …, X_r) and the regression coefficient $B_{i=}$ (B_1, B_2, B_3, …, B_r) that measures the impact of covariates.

In **Table 10**, the column "rho," correlates between residuals and time vector as in our above case—Kaplan Meier. The other two columns, "Chi-square" and "Pr > Chi-square," show test statistics and the associated *p*-value. Here, the *p*-values must be <0.005, and the value from **Table 10** reveals no violation of the risk assumption.

Hence, to find the survival risk score from the Cox model regression, it can be written as:

$$R(t) = 1 - R0(t)\exp(\sum ßiXi - \sum ßi\overline{X}i)\ (i = 1 \text{ to } r) \quad (2) \tag{2}$$

R(t) is the risk estimation of cardiac arrest of an individual; $R_0(t)$ is the baseline survival time at t; βi is the regression coefficient covariates values mentioned in **Table 8**; X_i is the value of the i_{th}: the risk factor value [log-transformed value – natural log (ln)]; and $\overline{X}_I$is the mean value of the covariates. Here, the i value ranges from 1 to r and denotes the risk factors considered. The cardiac arrest risk score or percent can be determined using the mentioned formula as shown in Equation (2).

The estimation of the Cox regression model is formulated from the scoresheet, and the Cox regression equation is derived. **Tables 11**, **12** show the scoresheet that represents the points allocated

B. Risk estimation from the scoresheet

As mentioned in **Tables 11**, **12**, the risk points are calculated according to the covariate's ranges. **Table 14** shows points allocated according to the risk factor involved.

C. Risk estimation from Cox regression model

As per Equation (2), risk estimation of cardiac arrest in female is given by:

Formula:

$$R(t) = 1 - R0(t) \exp\left(\sum ßiXi - \sum ßi\overline{Xi}\right) (i = 1 \text{ to } r)$$

Values for:

- $R_0(t)$ for t = 10 years = 0.993 is the baseline survival
- βi is the estimated regression coefficient (in **Table 9**)
- Xi is the log-transformed value of ith risk factor
- $\overline{X}I$ is the mean value of the covariates considered (in **Table 5**)
- R is the number of risk factors involved in predicting risk. The risk estimation of the cardiac arrest based on the Cox regression model is computed as:
- Xi is the log-transformed value of ith risk factor
- $\overline{X}I$ is the mean value of the covariates considered (in **Table 5**)
- R is the number of risk factors involved in predicting risk.

The risk estimation of the cardiac arrest based on the Cox regression model is computed as:

$$\begin{aligned}\sum_{i=1}^{r}\beta iXi &= [0.027^{*}\ln(50)] + [-0.039^{*}\ln\ (131)] \\ &+ [0.005^{*}\ln(80)] + [0.004^{*}ln\ (112)] \\ &= 0.1056 - -0.1901 + 0.0219 + \ 0.0188 \\ &= -0.0438 \\ \sum_{i=1}^{r}\beta i\overline{X}i &= [0.027^{*}43.056] + [-0.039^{*}118.961] \\ &+ [0.005^{*}78.113] + [0.004^{*}\ 87.006] \\ &= 1.1625 - 4.6394 + 0.3905 + \ 0.3480 \\ &= -2.7384\end{aligned}$$

Substituting values in Equation (2) we get,

$$\begin{aligned}R(t) &= 1 - R_0(t)\exp(\sum_{i=1}^{r}\beta iXi - \sum_{i=\ 1}^{r}\beta i\overline{X}i) \\ &= 1 - \mathrm{R}_0(10)\exp(-0.0438 - \ (-2.7384)) \\ &= 1 - (0.993)\exp\ (2.6946) \\ &= 1 - (0.993)^{\ (14.79)} \\ &= 1 - \ 0.9013 \\ &= 0.0987 \\ &= 0.0987^{*}100(\text{convertingto \%}) \\ &= 9.87 \\ &\approx 9\%\end{aligned}$$

According to the scoresheet, the point system is 9%, and the Cox regression model also gives the approximate percentage of risk 9%. Therefore, a female having age 50 may have a chance of 9% more risk of cardiac arrest in the coming 10-year risk prediction.

Gender-Wise Classification

The gender-based classification is done using Gender_KM_model analysis. The first stage of Gender_KM_model is to provide input in the form of a dataset. The next step is to pre-process the dataset to solve the categorical data such as gender. For categorical problems, the use of LabelEncoder is applied for the gender feature. We divide our dataset into two groups: male and female and apply the Kaplan-Meier analysis model. The model then predicts the result, showing prediction probability in each gender at an event time. The steps of our model are described in the following pseudocode.

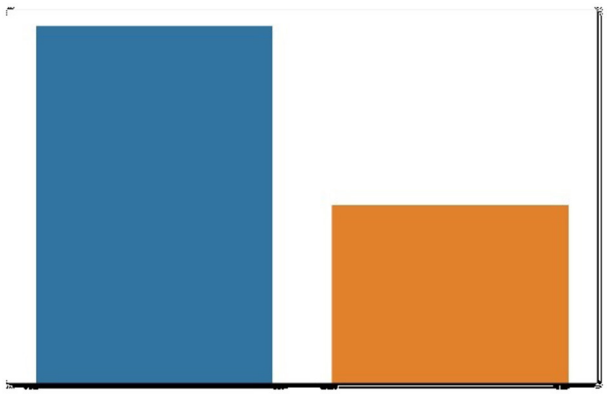

FIGURE 5 | Gender_KM model.

Step 1: Import libraries
Step 2: Load the dataset
Step 3: Pre-processed the data
Step 4: Divide dataset into two groups: male and female
Step 5: Apply Kaplan-Meier KaplanMeierFitter() model
Step 6: Predict results shows probability in each gender at an event time.

The flow of the work is presented in the below diagram, **Figure 5**.

A. Gender-based estimation of risk probability

The gender-wise risk classification can be estimated using a non-parametric survival estimator called the Kaplan-Meier method. It is useful in determining the survival probabilities of an individual and gender-wise. As per our collected dataset, survival function estimator S(t) can be given as:

$$\mathrm{S(t)} = \Pi(1 - \mathrm{di/ni})(\mathrm{i} : \mathrm{ti} <= \mathrm{t}) \tag{3}$$

Where,

S(t) = gives survival probability
t_i = time at when an event occurs
d_i = number of events occur (e.g., at risk of cardiac arrest) at time ti
n_i = number of individuals who have survived (e.g., not at risk of cardiac arrest) at time t_i

The Kaplan-Meier estimator helps to find the probability or survival rates of adjusted covariates. In our dataset, our estimation is to classify risk according to gender (male and female). We have divided our data into two groups: male and female. Our target is to notice any significant difference in probability or survival rate if data are divided into two groups based on gender. Based on gender split, we come up with survival probability in men and women based on Equation (3), which is shown in **Tables 15**, **16**.

The survival probability/risk of an individual (male/female) is estimated based on the time interval. On predicting survival probabilities in both genders using object creation of Kaplan-Meier we get,

kmf_m.predict (900) = 0.89061… ≈ 89%
kmf_f.predict (900) = 0.92205… ≈ 92%

Here, predict (900) indicates predicting survival or risk probability at 900-time intervals. The male probability of surviving is 89%, and the female probability of surviving is 92%.

From the above observation, we can conclude that the survival probability of women is higher compared to men. Men are at higher risk than women. Below, **Figure 6** shows the survival probability of men and women at a given time t.

EXPLORATORY DATA ANALYSIS

Figure 7 shows the number of female and male data in our dataset from the figure. We can conclude that there are 150 "men" and 350 "women."

Figure 8 shows a correlation graph among attributes, using the syntax:

data.corr( )

Figure 9 shows counts of cardiac arrest prediction "1" and "0" in each gender, male and female. We conclude that 100 "men" are prone to cardiac arrest, and around 75 "men" are risk free of cardiac arrest. Similarly, more than 200 "women" are prone to cardiac arrest, and ∼140 "women" are risk free from cardiac arrest.

Figure 10 shows the various age distributions. It is observed from the bar plot that 25 years of people are seen more following 17 and 63 years of people are found more.

Figure 11 shows the distribution of age, and it seems to be normally distributed.

IMPLEMENTATION DETAILS

Experimental Setup

In this research, we implemented six supervised ML algorithms to evaluate the possibility of cardiac arrest and the performance of a classifier in a classification problem. For evaluation, the real-time dataset was collected using sensors and equipment as described in section Methodology. The dataset consists of 10 attributes, among which five main attributes, i.e., the vital signs of the patient, are mainly considered. For experimental execution, the "Data Streamer" tool was used in this study to collect the pulse rate every 2 min. Data Streamer is an open-source tool used to collect live data supporting capturing, analyzing, and visualizing real-time sensor data in Excel.

As described in section Methodology, the next step uses an ML model: ANN, RFC, XGBoost, SVM, NB, and DT classifier. Before applying the model to our collected data, the collected dataset was imported using "read_csv()," and then the data was pre-processed as discussed in section Methodology. In the next step, we did feature selection using "StandardScaler()" where the vital signs of a patient were majorly considered. Furthermore, the dataset was

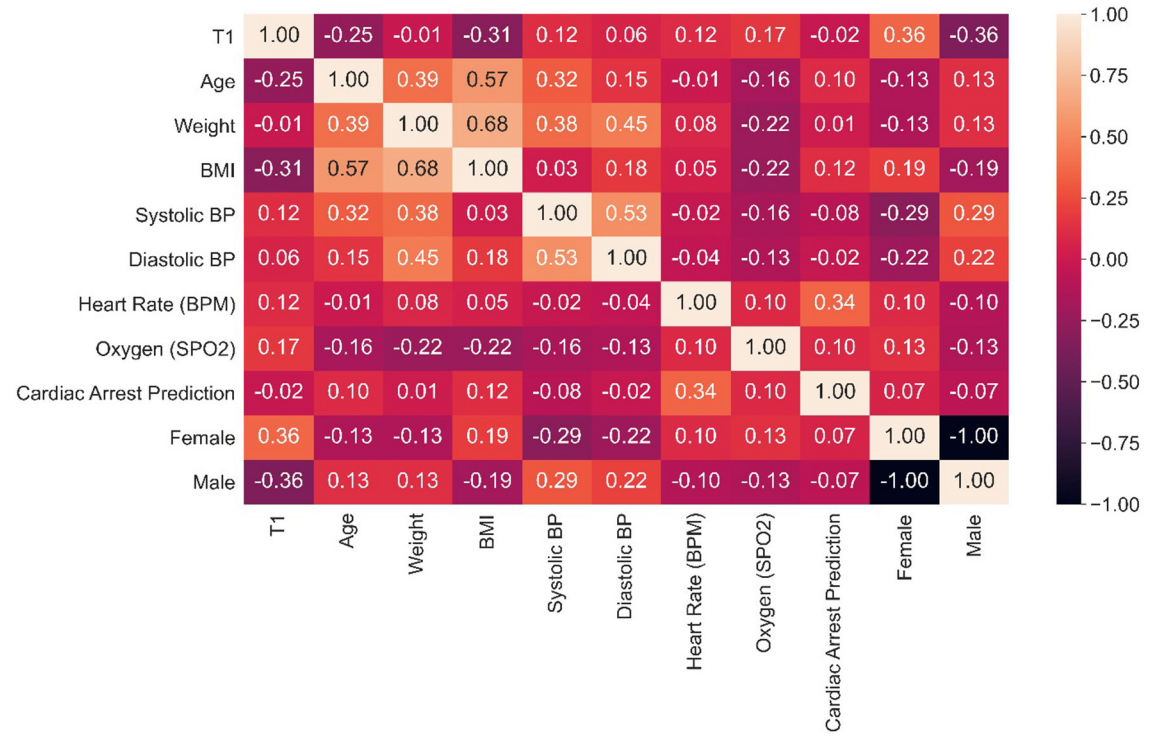

FIGURE 6 | Men/women survival probability graph.

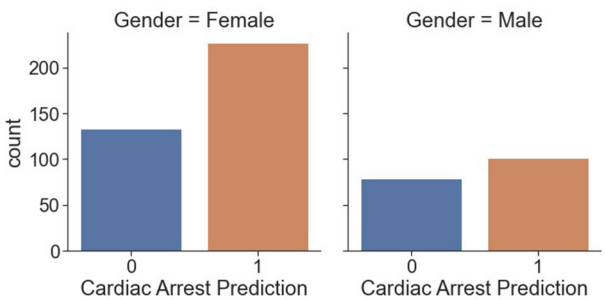

FIGURE 7 | Counts of men and women.

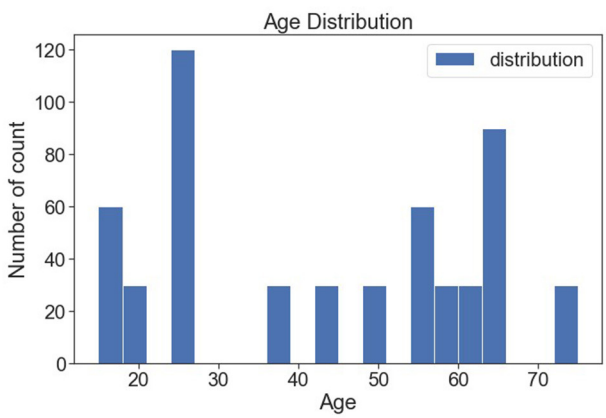

FIGURE 8 | Attributes correlation matrix.

split up into 80% training and 20% testing set. Then, models were applied to these data to check model accuracy. In the next phase, to test the performance of the classifier, various experimental metrics were computed. The contribution part of our research involves gender-wise analysis of risk/survival probability using the Kaplan-Meier algorithm, and age-wise risk probability for 10 years was formulated using the "XLSTAT" add-in tool in Excel. XLSTAT is an open-source software used to analyze, customize, and display results in Excel. Hence, the experiments discussed above have been carried out using Anaconda software in a Jupyter notebook python environment using ML libraries on an Intel(R) Core (TM) i5-3320M CPU @ 2.60 GHz system.

Evaluation Metrics

The evaluation metrics of the model are formulated with the confusion matrix. For this, the calculation of values is measured based on:

- True positive (TP) = number of occurrences that are correctly determined.
- False negative (FN) = number of occurrences that are incorrectly predicted and not required.

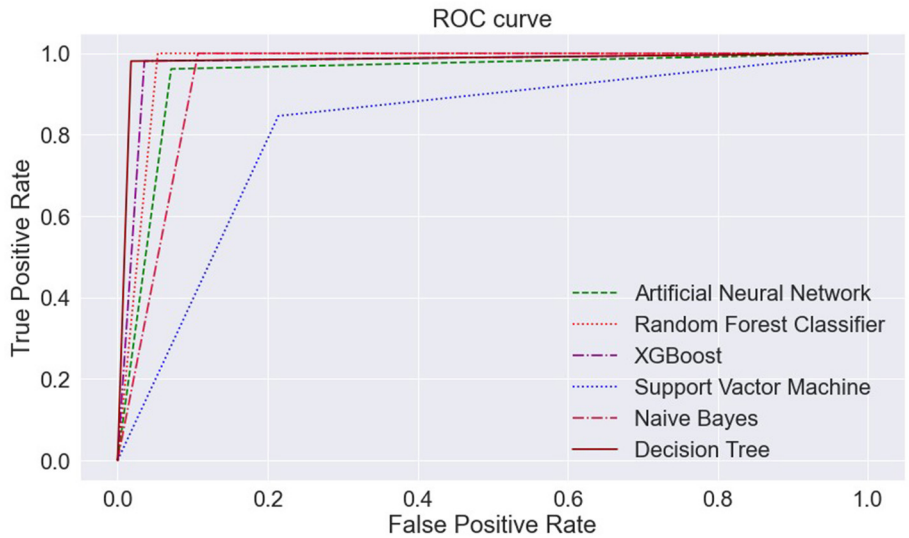

FIGURE 9 | Counts of cardiac arrest in men/women.

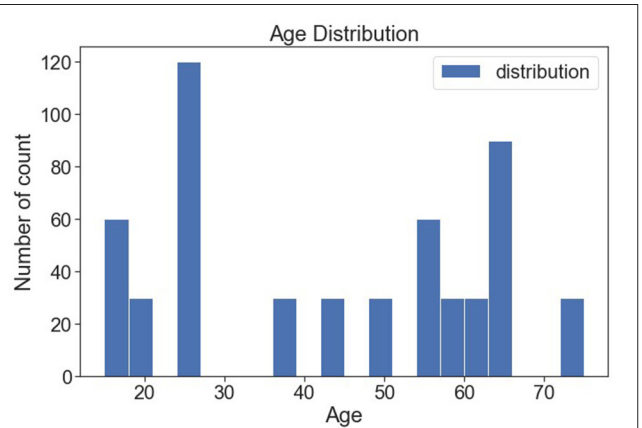

FIGURE 10 | Age-wise distribution.

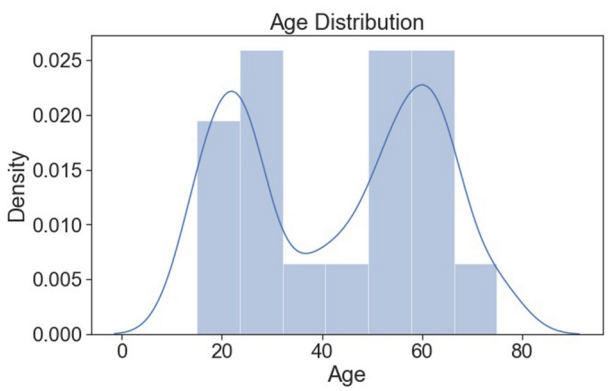

FIGURE 11 | Age distribution (normalized).

- False positive (FP) = number of occurrences that are incorrectly predicted.
- True negative (TN) = number of occurrences that are correctly predicted and not required.

Based on this parameter, we have calculated four measurements with the given formula:

- Accuracy = $TN + TP/TN + TP + FN + FP$
- Precision = $TP/TP + FP$
- Sensitivity (Recall) = $TP/TP + FN$
- F1 Score = $2^*(Precision^*Recall/Precision + Recall)$

These measurements help to know the cardiac risk associated with heart diseases.

Results

After executing the ML model on the collected dataset, we found the accuracy, sensitivity, precision, and F1-score of each algorithm, as shown in **Table 14**. These measurements were calculated with the support of confusion matrix value TP, TN, FP, and FN for each algorithm shown in **Figures 12A–F**.

Table 17 shows the Precision, Recall, F1- score, and overall accuracy of ML algorithms. The value for Precision, Recall, and F1- score is calculated against 2—the class problem of having cardiac arrest risk and no cardiac arrest risk. The label "0" has been used for no risk in cardiac diseases, and "1" has been used for risk in cardiac disease.

Hence, **Table 17** concludes that the DT outperforms all ML algorithms achieving overall 96% accuracy.

Figures 13A–F portrays the area under the curve (AUC) and receiver operating characteristic (ROC) curve. ROC curve depicts

		1	1.00	0.89	0.94

the graphical appearance to measure the model performance. It shows the true negative, and true positive values plotted at distinct levels of the threshold.

The AUC curve represents the aggregate measures of performance at different threshold values. It also describes the probability value from the classification model to get an accurate result. If the AUC curve value shows 0 value, it predicts wrong results, and if 1, it means an exact model. Here, in **Figure 14**, the accuracy of all three classification models reaches 1 value, which means our prediction accuracy is highly accurate.

DISCUSSION, CONCLUSION, AND FUTURE WORK

Discussion

This study is aimed to detect and predict whether the patient is prone to cardiac arrest or not. This research was carried out using six ML classification algorithms, namely, ANN, RFC, XGBoost, SVM, NB, and DT classifier on a real-time collected dataset. Different tools were conducted for analyzing and classifying data on Intel(R) Core (TM) i5-3320M CPU @ 2.60 GHz system.

Dataset was split up into 0.8% training and 0.2% testing set, and then data pre-processing was done. To get the result, ML algorithms were applied to datasets to get the accuracy of the result. The results—accuracy, Precision, Recall, and F1-score—were generated using Python programming on Jupyter notebook.

Figures 15A,B show the scores. Precision, Recall, and F1-scores of the patients having no risk or chances of cardiac arrest and patients with a risk of cardiac arrest. These scores help us to understand the measure of relevance of accuracy.

Comparing both charts, we conclude that "DT" reaches the maximum accuracy based on the scores retrieved from Precision, Recall, and F1 scores.

Furthermore, the main contribution of our research work shows an effective and efficient method for the prediction of cardiac arrest risk in gender-wise and different age-wise people in terms of survival probability. The method Kaplan-Meier shows statistical analysis in gender for showing the chances of survival probability. The result obtained by applying the Kaplan-Meier model to our collected dataset shows that female survival probability is more than that in men, as shown in **Figure 6**. Another method, Cox regression analysis, is another statistical analysis method that shows prediction/survival probability for the next 10 years of risk in cardiac arrest for different age groups. We can use this model to see cardiac risk in an individual. In addition, this method helps identify whether a person is at risk in the coming next 10 years using the score sheet displayed above.

Conclusion

This study contributes classification techniques for detecting and comparing gender-based and age-based probability for cardiac arrest survival. The main objective of our work is to

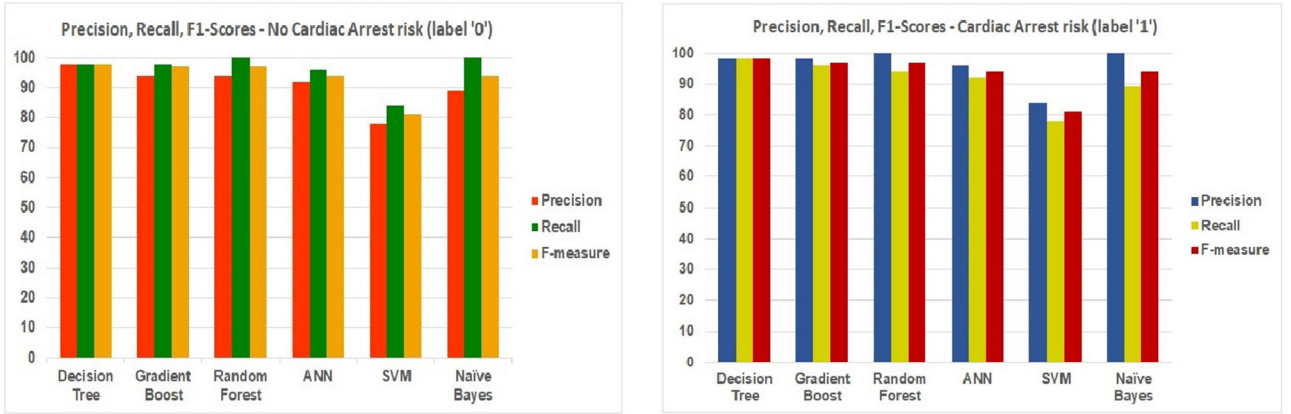

FIGURE 15 | ML models—Precision, Recall, and F1-scores—for **(A)** label "0" **(B)** label "1."

recognize cardiac arrest in a patient as early as possible using an ML model. Apart from that, our main contribution shows survival probability in an individual with gender-based and age-based using two effective methods: Kaplan-Meier and Cox regression methods. From the result, in detecting cardiac arrest risk in gender-based survival probability, female patients of our collected record show higher chances of survival than male patients. While in detecting cardiac arrest risk in age-based survival probability, patients with age 30 and more may have chances of cardiac risk as per our proposed model. From our classification model, the predicting results of the DT outperform the other ML classifiers.

Future Study

This study can be further extended by adding more diseases and making predictions using different classifier models. In addition to that, we can add more features, and predictions can be made on a larger dataset.

Deep Learning-based Sentiment Analysis and Topic Modeling on Tourism During Covid-19 Pandemic

Ram Krishn Mishra[1], Siddhaling Urolagin[1], J. Angel Arul Jothi[1], Ashwin Sanjay Neogi[1] and Nishad Nawaz[2]*

[1]Department of Computer Science, BITS Pilani, Dubai Campus, Dubai, United Arab Emirates, [2]Department of Business Management, College of Business Administration, Kingdom University, Ar Rifā, Bahrain

The Covid-19 pandemic has disrupted the world economy and significantly influenced the tourism industry. Millions of people have shared their emotions, views, facts, and circumstances on numerous social media platforms, which has resulted in a massive flow of information. The high-density social media data has drawn many researchers to extract valuable information and understand the user's emotions during the pandemic time. The research looks at the data collected from the micro-blogging site Twitter for the tourism sector, emphasizing sub-domains hospitality and healthcare. The sentiment of approximately 20,000 tweets have been calculated using Valence Aware Dictionary for Sentiment Reasoning (VADER) model. Furthermore, topic modeling was used to reveal certain hidden themes and determine the narrative and direction of the topics related to tourism healthcare, and hospitality. Topic modeling also helped us to identify inter-cluster similar terms and analyzing the flow of information from a group of a similar opinion. Finally, a cutting-edge deep learning classification model was used with different epoch sizes of the dataset to anticipate and classify the people's feelings. The deep learning model has been tested with multiple parameters such as training set accuracy, test set accuracy, validation loss, validation accuracy, etc., and resulted in more than a 90% in training set accuracy tourism hospitality and healthcare reported 80.9 and 78.7% respectively on test set accuracy.

INTRODUCTION

The tourism sector globally plays a significant role in long-term economic development. A huge movement of tourists from one place to another for leisure, business, family, or friend has connected the globe as a single village. Tourists like to visit the places for their happiness or business. Tourism is held accountable for many factors, such as it increases income, and helps in the development of many other industries (Manzoor et al., 2019). The advantages of travel and tourism extend well beyond their direct effects on GDP and employment; they also include indirect benefits through supply chain links to other industries and create induced effects. As per the report (Poole & Misrahi, 2020), the tourism industry contributed 10.3% to global GDP, and domestic travel accounts for the bulk of worldwide Travel and Tourism spending in 2019, accounting for 71.3% of total spending globally, with foreign tourists accounting for the remaining 28.7%. Many countries focus on foreign tourism because of its cash generation. Domestic tourism may be a vital instrument for generating employment, economic growth, poverty reduction, and infrastructure upgrades.

The Covid-19 has caused the globe to face a significant and complex dilemma (Aburumman, 2020). It has turned out to be a health issue, and it has also ruined the entire corporate process. Travel and tourism have been severely impacted in the corporate world (Alamanda et al., 2019). Due to the total lockdown enforcement by every country, every stakeholder in the tourist sector cannot revive. Tourism is a significant and growing source of revenue in the economy. According to UNCTAD research released on June 30, 2021, a drop in international tourism caused by the coronavirus pandemic may cost the world economy more than $4 trillion in 2020 and 2021 (*COVID-19 and Tourism - An Update*, 2021). Prior to the Covid-19 pandemic, travel and tourism had grown to be one of the most significant sectors in the global economy, accounting for 10% of global GDP. Only 25 million individuals traveled abroad in 1950, at the dawn of the jet era. By 2019, that figure had risen to 1.5 billion, and the travel and tourism industry had grown to nearly unfathomable dimensions for many nations globally.

Among the G20 nations, the hospitality and travel industries account for 10% of employment and 9.5% of GDP on average, with Italy, Mexico, and Spain accounting for 14% or more of GDP. A 6-month disruption inactivity may directly lower GDP by 2.5–3.5% (*IMF F and D.,2021*).

The hospitality sector has been put under tremendous strain due to the exponential decline in personal and business travel, resulting in reduced occupancy and revenue per available room. During the lockdown phase, 98% of global international tourists had declined in May 2020 as compared to 2019 which leads to a big loss in hospitality (UNWTO., 2020). This equates to a drop of 300 million tourists and a loss of 320 billion dollars in international tourism revenues, which is more than three times the loss experienced during the global economic crisis of 2009. Oversupply, declining hotel prices, low consumer sentiment, travel restrictions, and the delay of key global events are all causing severe operational and financial difficulties for industry players. As a result, In Malaysia, hotel owners have been compelled to cut expenses by taking actions such as reducing staff numbers and wages, forcing workers to work without pay, and closing hotels entirely (Foo et al., 2020).

Passengers' behavior has shifted as a result of the Covid-19 problem, travel limitations, and the ensuing economic crisis, resulting in a significant decrease in demand for airline services. As measured by revenue per passenger kilometers, passenger air transport was down 90 percent year on year in april 2020, and it was still down 75 percent in August, according to IATA (IATA, 2021.). The decline in economic activity and trade had an effect on freight, the freight service was almost 30% lower year on year in april and was still around 12% lower in August. To fight against the spread of the coronavirus, travel restrictions have been imposed in all nations. Airport closures, suspension of incoming and outgoing flights, and nationwide lockdowns are just a few of the measures governments are doing to combat the epidemic. Following the pandemic's spread in the first two quarters of 2020, at least 93 percent of the global population lived in countries with coronavirus-related travel restrictions, with almost three billion people living in governments that imposed entire border bans on foreigners.

According to the research jointly published by UNCTAD, 2021a and the UN World Tourism Organization (UNWTO), international tourism and its closely related industries incurred a 2.4 trillion dollars loss in 2020. The tourism sector may face a similar loss this year, and that the tourist industry's recovery would be dependent on the global uptake of coronavirus vaccinations (Global Economy Could Lose over $4 Trillion Due to COVID-19 Impact on Tourism | UNCTAD,2021b, n. d.-a). Due to the mounting losses in many countries, Covid-19 vaccines are more prevalent in certain countries than others, tourist losses in most industrialized countries are minimized but aggravated in underdeveloped countries. According to the research, the tourist industry is expected to recover faster in nations with high vaccination rates, including the United Kingdom, the United States, France, Switzerland, and Germany. However, many experts predict that recovery to Pre-Covid international visitor arrival levels would not occur until 2023 or later, according to the UNWTO ("UNWTO World Tourism Barometer and Statistical Annex, December 2020," 2020).

The study examines the perceptions of Twitter users in the Covid-19 pandemic concerning two tourism sub-domains: hospitality and healthcare. The research was carried out using deep learning algorithms and Natural Language Processing (NLP) methods. The research objectives are to identify the common similar shared terms related to tourism sub-domain healthcare and hospitality using a topic modeling. We find the most significant themes in each sector and reveal hidden semantic patterns inside both sectors. This will aid us in locating and comprehending the most widely discussed issues in the area. This research also looks at the direction of people's feelings towards tourism healthcare and hospitality during the covid-19 outbreak by calculating the sentiment score and classifying in the different emotional categories. Now that it has been trained on real-world data, this model may be utilized in prediction of user's emotions on new tweets. Lastly, we will talk about the study's challenges and issues and the contributions of this research in possible future works. The structure of the research is organized in a systematic flow, **section 2** describes the literature review, **section 3** methodology, **section 4** experimental result, **section 5** discussion and at the last conclusion and future scope.

LITERATURE REVIEW

The literature review discusses the domains related to the research study. It also provides a panoramic overview of the theoretical studies done in the tourism subdomain. Some relevant studies which are related to this research study's methodology have been pondered upon. Along with that, the theoretical studies have been discussed accordingly. It provides a rich source of information. Therefore, an extensive review of literature has been done in the area of social media, sentiment analysis, topic modeling, deep learning, and tourism during the pandemic crisis.

The highly contagious coronavirus continues to wreak havoc on the tourism sector, raising serious questions about its present and long-term survival. The infection has resulted in the loss of millions of jobs. India has a hospitality industry which is one of the largest

tourism industries of the world and provides employment to lakhs of people. Ever since the Covid-19 started, India's hospitality and the airline industry suffered a massive loss in revenue and has resulted in a 30 percent dip in tourists. Being a top tourism destination, Malaysia has suffered a net loss of 5.5 million USD in hotel cancellations alone due to growing concern about the raging virus (Foo et al., 2020). Kuala Lumpur is one of the top tourist destinations for many people around the world. On top of that, the losses incurred are far greater when the government of Malaysia shut its doors by banning international flights. A study was conducted on a cross-regional comparison of the effects of covid-19 on the tourist sector. The authors of the study concluded that the tourist industry is vulnerable to global crises (Uğur & Akbıyık, 2020). With the dissemination of the news, passengers opt to postpone or delay their journeys on the same day. Comments on the benefits of travel insurance and refunds due to trip cancellations were among the issues that further in-depth studies discovered. An algorithm for sentiment analysis and fake news classifications has been proposed in the studies (Hakak et al., 2021). Another study provided a random forest approach for predicting the patient health during Covid-19 (Iwendi et al., 2020) (Khan et al., 2020). The Deep learning approaches provide to deal with sensitive data specifically healthcare such as early detection of diabetic (Gadekallu et al., 2020) where prediction and model accuracy should be more accurate. Once the model is ready, optimization help to find the ideal iteration and finalizing the model with proper perfections (Agrawal et al., 2021).

With regards to social media and then amount of data it generates every day, twitter users are said to create around 15 GB of data each day. It is widely utilized by the general people, who use it to express their opinions (Pandey et al., 2019)on a variety of public topics (Srivastav et al., 2020) and to voice their complaints to businesses and government agencies. Since tourism is one of the biggest industries in terms of generating revenue towards a country's economy and at the same time most of the data is generated from various social media websites. A study (Alaei et al., 2017) has employed various sentiment analysis techniques in tourism, which are examined and evaluated in terms of datasets used and performance on key assessment measures. Facebook has been witnessed to be used by the Korean government for the promotion and growth of tourism (Hoon et al., 2016). Due to the Coronavirus pandemic, a huge transformation towards online usage has been witnessed along with a sudden increase in Twitter usage. Social media is a rich source of information for tourists planning for any travel strategy. Machine learning and deep learning have played an important role in the field of medical image processing where machine learning algorithms have been used to classify Covid-19 affected individuals (Bhattacharya et al., 2021) and classifying the severity of Covid-19 diagnosed patient using neuro fuzzy techniques (Ayoub et al., 2021; Iwendi et al., 2021). Another study on how deep learning is being used for healthcare delivery in low and middle income countries has been done where the authors have explained how pneumonia detection using state-of-the-art deep learning algorithms can be utilized to help those countries with limited facilities and resources (Williams et al., 2021).

A study in (Kaushal & Srivastava, 2021) has taken a rather interesting approach to study the impact of Covid-19 on the tourism industry by taking on the interviews with 15 participants in senior positions in the hospitality industry. The study takes a qualitative approach to research, with email interviews serving as the primary method of data gathering. Email interviews are becoming more frequent in qualitative research, and given the present climate of social distance, it is deemed most suited for the current inquiry. Email interviews are also considered to be less expensive than telephonic or face-to-face interviews, yet they can generate detailed information from participants. We all are aware of the fact that the coronavirus indeed emerged in the sprawling capital of Central China's Hubei province–Wuhan. The study aimed to assess the impact of coronavirus outbreaks on the Chinese tourism sector (Yang et al., 2020). Global visitors have abandoned their plans to visit China, while Chinese tourists are barred from visiting other countries. The fast spread of the Coronavirus in China has put a halt to people's daily lives. This concern has influenced the country's tourism sector both locally and abroad. According to the conclusions of the study, because of the danger from the virus, outsiders are afraid to interact with the Chinese population.

Countless individuals have lost their jobs as a result of the epidemic. Businesses are facing difficulties in returning to pre-covid levels, and they are looking for new revenue-generating techniques. While looking for new methods, it is critical to pay attention to the conversations taking place on social media to grasp the emotion. This may give suggestions for the development of new revenue-generating initiatives for firms. In a study (Jeong et al., 2019) on the topic modeling and sentiment analysis of social media data, the authors of this paper presented an opportunity mining technique for identifying product possibilities. An opportunity algorithm based on the significance and satisfaction of product subjects identifies the opportunity value and improvement direction of each product topic from a customer-centered perspective. We must be ready to adapt to new conditions in these unusual times when a whole country's economy has stalled due to a lack of tourism revenue. Businesses, too, should adapt by adopting the aforementioned strategy to develop new ways and items to market for increasing their revenue stream and attracting tourists.

METHODOLOGY

Many techniques were utilized in the research to delve deeper and gain a better understanding of the Covid-19 epidemic's impact on high-level tourist firms, including topic modeling, sentiment analysis, and deep learning classification. The authors have divided the tourist data into four categories: hospitality and healthcare. **Figure 1** illustrates a high-level overview of the many techniques taken by the authors to understand the impact of the tourist industry.

The datasets for each sector have been saved in a CSV format with four attributes: datetime, tweet id, text, and username.

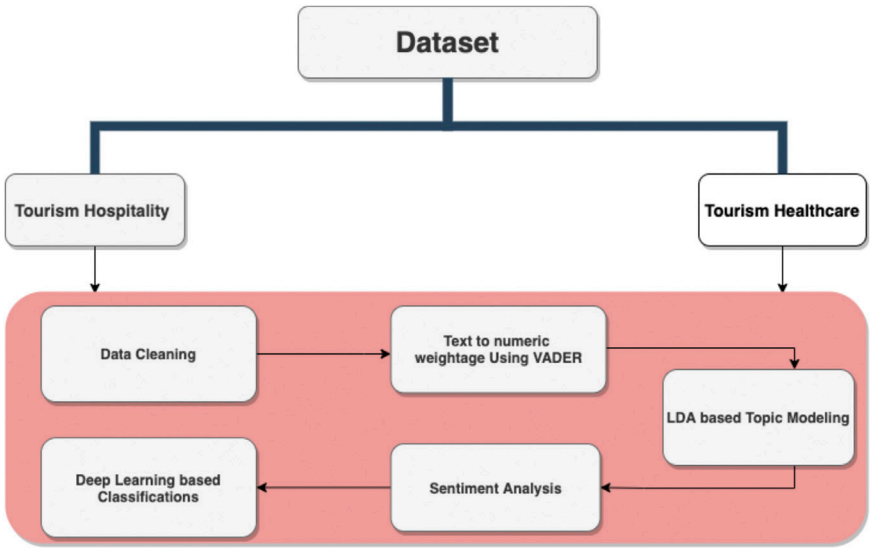

FIGURE 1 | Processing structure.

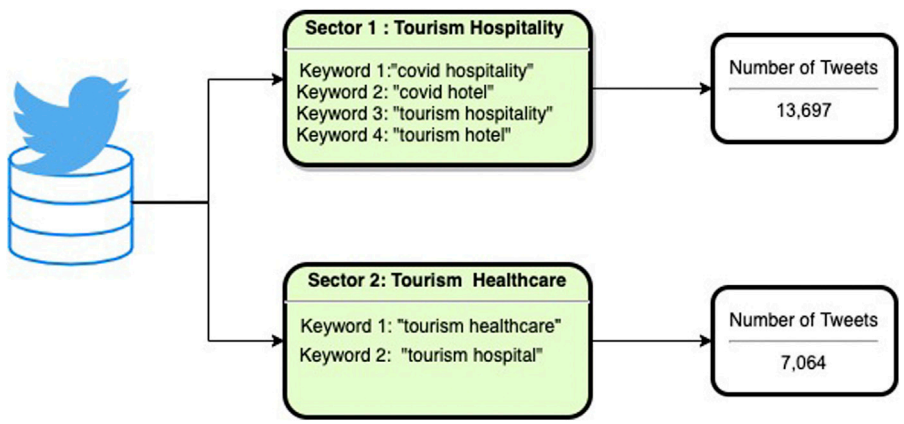

FIGURE 2 | Data collection.

Data Collection

Over the course of 8 months, we have gathered a total of 20,761 tweets pertaining to tourism, healthcare and hospitality. The data was gathered with the help of the Tweepy library, an open-source Python program that connects to the Twitter database. The timeline of the tweets was between april 2020 and December 2020, when the Covid-19 virus began to spread all around the world, forcing governments to seal their borders and ensure travel restrictions. **Figure 2** depicts the data collecting strategy. Since the main purpose is to understand how the tourism sector has been affected by the coronavirus, it has been segmented into two parts.

The tourism hospitality business is the first segment, with 13,697 tweets. The tourism healthcare services is the second segment that is helping the people during pandemic time. We found 7,064 tweets about healthcare using the keywords' tourism healthcare', and "tourism hospitals". We focused on collecting these two sectors to identify the interdependencies between the similar kinds of topics shared in twitter.

Data Preprocessing

One of the most important aspects of data analysis is ensuring that the acquired data is machine-readable. Words, photos, and videos are incomprehensible to machines; they can only understand 1 and 0s. To be able to give an input of 1 and 0s, we must go through many phases. The data must be pre-processed, which demands the use of a method known as data cleaning, which entails transforming raw data into a machine-readable format. We need to clean the big text dataset, which is made up of tweets, to remove any discrepancies and avoid having inconsistent data. The study's approach to data cleansing is straightforward. The study made use of Excel's inbuilt duplicate data removal feature and removed all complete tweet duplicates. Duplicate data can have

little to adverse effects on the machine learning model. When duplicate data was observed, the training data might have the same instances again and again. i.e. there will be multiple same values of dependent and independent variable combinations. Hence, when the proposed model learns from this data, the study will get very high accuracy on in-sample testing but out of sample testing will be much lesser, i.e., the study will have an over-fitted model.

Furthermore, we moved ahead to clean the data in much more detail by using python's open-source package called Regex which is nothing but regular expressions. The research study created a custom python script that takes in the tweets as a whole and by using regular expression (ThompsonKen, 1968). Then it started with removing special characters, while converting all the tweets to lowercase mainly because machine learning models might treat a word which is at the beginning of a tweet with a capital letter different from the same word which appears later in the same tweet but without any capital letter. This might lead to a decline in accuracy. So, therefore lowering the words would be a better trade-off. Punctuation along with leading and trailing white spaces in the tweets were also removed.

There are data cleaning steps that should be done specifically in Twitter such as removing user mention '\text [at]', removing HTTP links, removing emotions, the 'rt' character which displays when a user retweets a tweet.

NLP Techniques for Data Cleaning

As mentioned earlier, machine learning models struggle in understanding the raw text, and this is why there are a couple of natural language processing sub-techniques that we incorporated:

Tokenization

The basic components of natural language processing are tokens. Tokenization is the process pf breaking down a large chunk of text into smaller tokens. Tokens can be words, characters, or sub words.

The most frequent technique of processing raw text is at the token level, because tokens are the building blocks of Natural Language. RNN, GRU, and LSTM, among the most common deep learning architectures for NLP, analyze raw text at the token level as well. Unstructured data and natural language text are broken down into bits of information that may be regarded distinct parts using a tokenizer. The token occurrences in a document can be utilized to create a vector that represents the document. An unstructured string (text document) is instantly transformed into a numerical data structure appropriate for machine learning.

In tokenization, the authors needed to identify the words that constitute a string of characters, and it is the most basic step to proceed in processing textual data. This is important because the meaning of the text could easily be interpreted by analyzing the words present in the text (Webster & Kit, 1992). The study performed tokenization before removing stop words.

Removal of Stop Words

Stopwords are the most common words in any natural language. For the purpose of analyzing text data and building NLP models, these stopwords might not add much value to the meaning of the document. On removing stopwords, dataset size decreases and the time to train the model also decreases. A python list was created which contained all the words that fall under the category of stopwords for removing them. Removing stop words can potentially help improve the performance as there are fewer and only meaningful tokens left. Thus, it could increase classification accuracy.

Topic Modelling Process

The goal of the analytics industry is to extract "Information" from data. It's challenging to get relevant and needed information with the rising volume of data in recent years, much of which is unstructured. However, technology has created some effective ways for mining through data and retrieving the information that were needed.

Topic Modelling is one such text mining approach. As the name implies, a technique for automatically identifying themes contained in a text item and deriving hidden patterns displayed by a text corpus. As a result, wiser decisions may be made.

Topic modeling is distinct from rule-based text mining techniques that rely on regular expressions or dictionary-based keyword searches. It's an unsupervised method for spotting and tracking a group of words in huge groups of texts. Using a probabilistic model, topic modeling finds abstract themes that recur in a corpus of documents. It's commonly used as a text mining technique to uncover semantic patterns in large amounts of material. The Latent Dirichlet Allocation (LDA) statistical model was used to find themes in a collection of documents (in our example, a corpus of tweets).

Latent Semantic Structures

Latent semantic analysis (LSA) is a statistical model of word usage that allows for semantic similarity comparisons across bits of textual information. LSA's basic premise is that there is some underlying, or "latent," structure in the pattern of word usage across texts and that statistical approaches may be used to estimate this latent structure. In this scenario, documents may be regarded as contexts in which words appear, as well as smaller text pieces such as individual paragraphs or phrases.

On the basis of massive corpus studies, Latent Semantic Analysis (LSA) creates a high-dimensional vector representation. However, LSA analyzes co-occurrence across the corpus using a defined window of context (e.g., the paragraph level). The co-occurrence matrix is then subjected to a factor analytic approach (singular value decomposition) to produce a smaller set of dimensions. Words that are used in comparable contexts, even if they are not used in the same context, have similar vectors as a result of the dimension reduction. Nonetheless, their vector representations in LSA would be comparable (Landauer et al., 2009). This foundation makes it possible to compare larger chunks of text, such as the meaning of phrases, paragraphs, or whole texts.

As a theoretical model and a technique, LSA has been used to characterize the semantic relatedness of linguistic units. Its results on conventional vocabulary and subject matter exams overlap those of humans, it replicates human word sorting and category judgments, it simulates word-word and passage-word lexical priming data, and it adequately evaluates textual coherence and learnability of texts. Our methodology incorporates Latent Dirichlet Allocation (LDA), which employs the latent semantic structure for textual similarity comparison as previously mentioned.

LDA Based Topic Modelling

In this research, the authors have used the LDA model to perform topic discoveries from the existing tweets. Latent Dirichlet Allocation (LDA) is a statistical generative model using Dirichlet distributions (Jelodar et al., 2017).

The authors begin with a corpus of D documents and decide how many X topics we want to uncover from it. The topic model and D documents, represented as a mixture of the X topics, will be the outputs. LDA finds the weight of connections between documents and topics and between topics and words. The advantage of LDA is that it leverages feature information to construct a new axis, reducing variance and increasing class distance between the variables.

LDA focuses primarily on projecting the features in higher dimension space to lower dimensions. The three steps for achieving this are:

1) To begin, we must determine the separability between classes, which is defined as the distance between the mean of two or more classes. The between-class variance is the term for this is given in **Equation (1)**.

$$S_b = \sum_{i=1}^{g} N_i * (\bar{x}_i - \bar{x})(\bar{x}_i - \bar{x})^T \quad (1)$$

2) Second, we must compute the distance between each class's mean and sample. Within-class variance is another name for it which is shown in **Equation (2)**.

$$S_w = \sum_{i-1}^{g} (N_i - 1) * S_i = \sum_{i-1}^{g} \sum_{j-1}^{N_i} \left(x_{\bar{i},j} - \bar{x}\right)\left(x_{\bar{i},j} - \bar{x}\right)^T \quad (2)$$

Where:

S_b = Seperability between the classes.
S_w = Distance between each class's mean and sample.
N = Number of instances.
$\bar{x}$= Mean of the input data points.

3) Finally, a lower-dimensional space must be created that increases variation across classes while minimizing variance within classes. P, commonly known as Fisher's criteria, is a lower-dimensional space projection.

We utilized the pyLDAvis package for our research, which is an open-source Python framework for interactive topic model visualization.

Sentiment Calculation Using VADER

Lexicon and Rule-Based Sentiment Calculation

For this work, Valence Aware Dictionary and Sentiment Reasoner (VADER) based sentiment calculation were used. VADER is a vocabulary and rule-based sentiment analysis tool that is tuned in to social media sentiments. It is an open-source utility that is completely free (Bonta et al., 2019). Word order and degree modifiers are taken into account by VADER as well. It is a text sentiment analysis model that's sensitive to both emotion polarity (positive/negative) and intensity (strong). It is included in the NLTK package, and the biggest advantage about it is that it can be used on unlabeled text data right away. The model automatically gives us a dictionary which contains the scores of each sentiment i. e negative, neutral and positive. These scores are calculated based on a metric called polarity. The range of polarity is [−1,1], with -1 indicating a negative feeling and one indicating a positive sentiment. The intensity of a word affects whether it has any effect on the next word. Adverbs are utilized as modifiers in English, such as "very good," which employs a lexicon-based method. In certain situations, the values are precisely equal to zero. A sentiment score will be assigned based on the polarity value, and the computation will be done in such a way that if the score is less than 0, the sentiment will be reported as negative. Positive sentiment is returned if the polarity is greater than 0. The score will be 0 in all other situations, and the sentiment will be neutral. There is another score returned by VADER and that is the compound score. Compound score is simply the sum of all the sentiment scores and it ranges from [-1,+1] where -1 indicates extremely negative score and on the other hand +1 indicates extremely positive score. We have used this metric primarily to understand the sentiments of the users (Hutto & Gilbert, 2014).

The main advantage of utilizing a lexicon-based approach is that it is much easier to understand and update by people. Using this method, the semantic orientation may be gathered and classified as neutral, positive, or negative. Sentiment analysis is a technique for extracting subjectivity and polarity from text, whereas semantic orientation assesses the content's polarity and strength. This approach uses adjectives and adverbs to indicate the text's semantic direction (in our case it is a tweet). The sentiment orientation value is then calculated by mixing adverbs and adjectives. Furthermore, the entire value is derived from a single source. Finally, a pooling technique is used to assess the sentiment of the tweets, which takes the average of all sentiments.

Classification of Sentiments Using LSTM RNN Algorithm

Long Short-Term Memory Networks (LSTMs) are a kind of RNN that can learn long-term dependencies. They work tremendously well on a large variety of problems and are now widely used. Neural Networks are a strong technology that may be used for image identification and a variety of other tasks. One of the model's limitations is that it has no memory connected with it. This is a difficulty while dealing with sequential data such as text or time series. RNN solves this problem by incorporating a feedback glance that acts as a memory. As a result, the model's previous inputs leave a trace. LSTM expands on this concept by including a short-term and long-term memory component (Sherstinsky, 2018).

All recurrent neural networks are made up of a series of repeated neural network modules. This repeating module in conventional RNNs will have a relatively basic structure, such as a single tanh layer. LSTMs are specifically intended to prevent the problem of long-term reliance. They do not have to work hard to remember knowledge for lengthy periods of time; it's virtually second nature to them. The entire architectural explanation of LSTM Network having different input and output layers and dealing with sequential information it combines forget gate, input gate, and output gate (Yu et al., 2019).

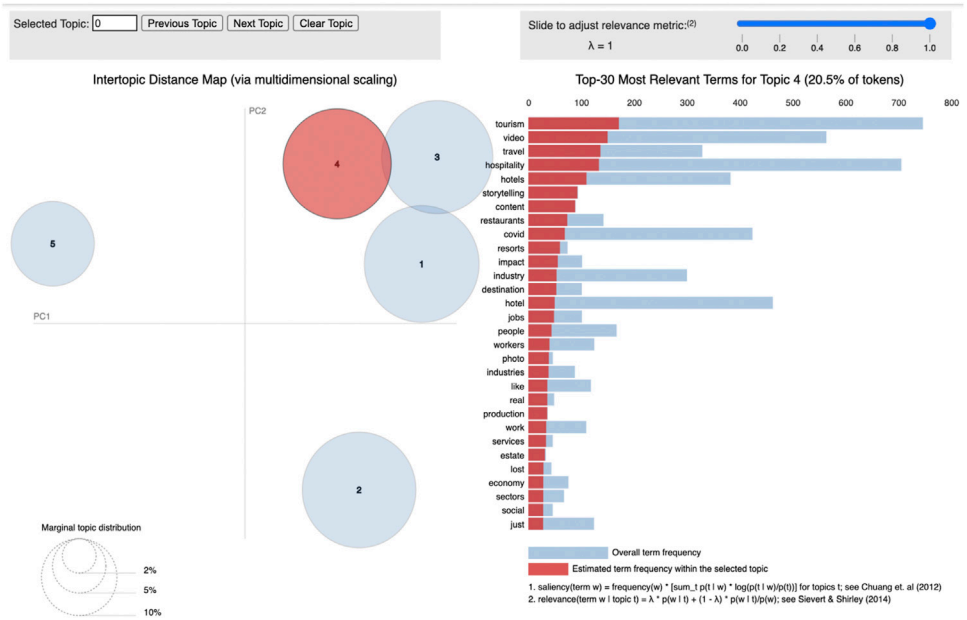

FIGURE 3 | Interactive topic modeling visualization for tourism hospitality sector.

In the case of RNN, the input is divided into two sections, and it must process multiple inputs while only performing one forward computation (Sherstinsky, 2018). This does not occur in the BP network. One of the two segregated inputs is the calculation's output, while the other is the variable present in the trained sample. RNN manages continuous data, specifically lists and sequences. This is what the characteristics mean. As a result, RNN and LSTM are particularly well-suited to dealing with the aforementioned data. However, there are a few questions to consider when using RNN. The gradients are exploding and disappearing, which is a big concern. Since the RNN is made up of several BPNNs, the calculation requires a variety of activation functions, such as sigmoid. These activation functions change the value in a certain set, such as [0, 1], and so on. Furthermore, these functions limit the spectrum of their derivatives.

LSTM has many uses and is used in many types of research, including forecasting stock markets, sentiment analysis, music generation, forecasting tourism demand, time series prediction, controlling robots, speech recognition, handwriting recognition, semantic parsing, and much more.

In some cases, we will have to examine recent data in order to complete the work at hand. Consider a vocabulary model that predicts the next word based on the ones that came before it. Recurrent Neural Network (RNN) can learn to utilize prior experience in situations when the period between historical information and the area where they're needed is brief. Because the RNN has a long-term dependency, the LSTM was included to help with this. The LSTM architecture is a kind of RNN that is capable of learning long-term relationships as well as solving the vanishing/exploding gradient problem. When working with huge volumes of data, LSTM can model and extract valuable information from social media data extremely effectively. Hence, we decided to use the LSTM RNN model since it had approximately 20,000 tweets.

Many attempts have been made to address the problem of vanishing gradients by modifying vanilla RNNs such that gradients do not expire as sequences become longer. The most popular and effective of these projects has been the long, short-term memory network, or LSTM. LSTMs have virtually supplanted regular RNNs in terms of popularity. LSTMs are also widely used to analyze social media data.

EXPERIMENTAL RESULTS AND ANALYSIS

This section discussed about the experimental results and analysis of the research study.

Depiction of Topic Modeling for Tourism Hospitality

Hovering over the first subject in **Figure 3** is the pyLDAvis interactive topic modeling visualization for the tourist hospitality industry. This figure reveals that there are 5 cluster themes connected with the sector, and the red bar represents the most common terms in each subject. The blue bar represents the overall phrase frequency of that specific word across all themes combined. Another thing to keep in mind is that if any of the clusters overlap or are physically adjacent to another cluster, it suggests that the topics contain comparable terminology.

The key themes in the first topic cluster include terms like Covid, hospitality, hotels, and industry. This implies that the Covid-19 epidemic has caused the hospitality industry to close its doors, resulting in billions of dollars in lost revenue (*Global Economy Could Lose over $4 Trillion Due to COVID-19 Impact on Tourism* | *UNCTAD.,2021c*, n. d.-b). It was observed that

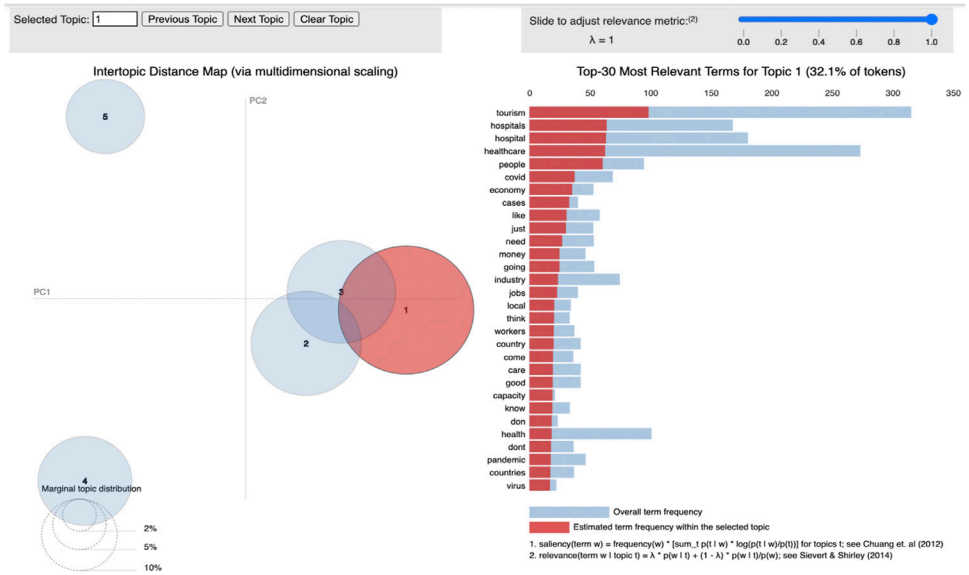

FIGURE 4 | Interactive topic modeling visualization for tourism healthcare sector.

restaurants, hotels, and resorts have been the most negatively impacted businesses owing to a variety of factors including.

1) Lack of visitors due to Covid - 19,
2) Loss of consumers (tourists) from other regions of the nation due to the pandemic.

We also discovered that employees and workers in the restaurants, hotels, and other sub-sectors were laid off in large numbers as a result of management choices made due to a shortage of finances. Another finding from the second subject cluster was that the same management implemented new methods to keep their company afloat by integrating new survival marketing tactics.

Depiction of Topic Modeling for Tourism Healthcare

Figure 4 depicts the tourism healthcare industry as an interactive graphic. The medical tourism industry was also impacted by the outbreak. By completing topic modeling, it was observed that the third topic cluster led us to Thailand, where it was learned that Thailand had made gradual steps to reopen for medical tourism, allowing restricted numbers of patients to visit the nation for treatment from the end of July 2020 (Tatum, 2020). Medical tourists and up to three others who can accompany them must follow strict standards, which include confirmation of negative Covid-19 testing granted no more than 72 h before departure, repeated tests while in-country, a 14-days hospital quarantine, and other anti-infection measures. The government is responding to the changing climate by leveraging digital technology to extend and improve telemedicine services, fostering a more hospitable business environment to encourage medical investment and innovation, and advancing its sophisticated healthcare infrastructure.

Histogram of Sentiment Compound Score for Each Sector

Figure 5 explains the compound range of sentiments. As per depiction, the compound range varies between -1 and +1. **Figure 5A** shows tourism hospitality's sentiments where positive rates are higher than negative. Tourism healthcare in **Figure 5B** has more positive ranges and the highest frequency is between 0.5 and 0.7 and most of the tweets belong to the positive side.

Sentiment bar Plot for Each Sector

Figure 6 is a bar plot depicting the number of feelings expressed in the various sectors of the industry taken into the study. The bulk of the feelings are positive, as seen in the graph. In the instance of the tourism hospitality sector in **Figure 6A**, VADER sentiment analysis revealed that about 6,300 + emotions were positive. One of the reasons for the increase in positive tweets is that when covid-19 hit the globe, there was an inflow of tweets praising the hospitality sector, particularly the hotel industry, collaborating with the government for a win-win situation. Passengers had to go through obligatory institutional quarantine, and the government was having trouble accommodating all of the quarantine passengers. The hotel sector offered the government a feasible alternative for directing travelers to quarantine themselves in hotel rooms, therefore increasing their revenue.

The ideal situation can be seen in the healthcare sector bar plot **Figure 6B**, where a country's GDP drop, which led to substantial system reorganization, can be linked back to a huge number of positive tweets. The negative tweets may be linked back to numerous industry owners whose businesses were harmed as a result of the lockdown, adversely impacting the country's economy. Another reason is that prominent influencers and celebrities, notably in India, began tweeting about the

TABLE 1 | Comparison of LSTM RNN Model Based on Epoch size.

Sectors	Epoch size	Loss	Training set accuracy (%)	Test set accuracy (%)	Validation accuracy (%)
Tourism Hospitality	5	0.225	91.1	80.3	79.7
	10	0.043	98.4	80.4	80.4
	15	0.011	99.6	80.9	80.9
Tourism Healthcare	5	0.168	93.7	78.1	78.1
	10	0.029	99.1	78.7	78.7
	15	0.007	99.3	76.1	77.7

country's economy tanking and the prime minister being held accountable.

A country like India, which is developing and has a lot of promise, may also be the reason why individuals began to tweet that shutting the country's borders at an early stage would have saved a lot of lives and prevented further spread of the virus.

Violin Plot of Compound Score for Each Sector

The violin plot of all the sectors is shown in **Figure 7**. A typical observation is that the violin plot of all positive sentiments has a higher degree of fluctuation, particularly in the hospitality sector. This means that the compound score from the range of 0.2–0.5 is higher, indicating that there are more tweets in that area. In these plots, the straight line denotes that the class belongs to neutral sentiment, which has a compound score of 0. If the violin plot has a wider region, as it does in the instance of negative emotions in the tourism economic sector, it indicates that the composite score of all negative sentiments follows a consistent range.

LSTM RNN Model Results

The input/output of the model with 85% of total data for training and 15% have been kept for testing purpose shown in **Figure 8**. **Table 1** summarizes the full experimental findings and comparisons of the LSTM RNN deep learning model for three epoch sizes: 5, 10, 15, and 20 for each tourism sector. To begin, an epoch size of 15 obtained the maximum accuracy of 80.9 percent and a loss of 0.011 in the tourist hospitality sector. Secondly, the model performed well in the tourism economy sector, with an accuracy of 75% and a loss of 0.043, which is 5% less than the preceding sector's performance. Furthermore, in the fifth and 10th epochs, the final sector which is healthcare obtained an accuracy of 76.1 percent. Lastly, with the increase in the epoch size of 20, we saw that the model started overfitting the dataset. Hence, we went for the optimal epoch size of 15 which indicates the robustness of the model.

Overall, the deep learning model performed admirably and accurately categorized most of the sentiments, suggesting that we could depend on the model for future sentiment classification predictions.

Table 2 compares the random forest and support vector classifier, two common machine learning algorithms. When we examine the findings of **Table 1** and **Table 2**, especially the test set accuracy, it is apparent that the deep learning algorithm performs well in the hospitality industry. The SVC algorithm, on the other hand, does have a little higher accuracy in the healthcare sector. Another thing to remember is that the test set accuracy refers to the tweets on which the model has not been trained. The LSTM RNN

algorithm was chosen primarily because neural networks are a very powerful technique for text and image classification. One of the model's shortcomings is that it has no memory, which is an issue for sequential data such as text or time series. RNN solves this problem by introducing a feedback glance that acts as a memory. As a result, the model's previous inputs leave a trace. LSTM expands on this concept by including a short-term and long-term memory component. As a result, LSTM is an excellent tool for anything involving a sequence. Because the meaning of a word is determined by the words that came before it. Because of this, we chose the LSTM RNN algorithm and took advantage of its memory feature. Both approaches have a test accuracy that goes hand in hand, as we observed before when comparing the results acquired by machine learning and deep learning (**Tables 1**, **2**). This is primarily due to the size of our dataset. Because we were constrained by the Twitter API's request limits, LSTM RNN, a deep learning algorithm, requires a large amount of data to reach its full potential.

Cluster Inter-dependency Between Healthcare and Hospitality

In topic modeling, the study retrieved the information of common terms which are widely used during the Covid time. Firstly, the clusters of top tweets in healthcare and hospitality were extracted with the help of the LDA approach. It can be observed in **Table 3** that top similar terms used during pandemic times are “covid” and “tourism” and even other words such as hospitals and hospitality have been used maximum times by social media users. It can be seen in **Figures 3**, **4** that the clusters were five in numbers namely - Cluster 1, 2, 3, 4, and 5. The top six tweet terms were taken from both the keywords-based topic namely - healthcare and hospitality. The Inter Topic Distance Map was done with the help of multidimensional scaling. The table provides a panoramic view of similar terms in both sectors. This provides the food for thought of cluster interdependency calculation. Six out of the top 30 salient terms were selected in the table. The priority was given based on the maximum percentage of the salient terms.

Our approach for this research have been proposed with three aspect, first topic modeling which shows that what kind phrases are being used during the pandemic, and this approach will helps to find the trending issues related to tourism healthcare and hospitality. Second, we used a deep learning technique based on the LSTM RNN algorithm to classify twitter users' emotions. In the hospitality and healthcare sectors, one may utilize our model, which was trained on

real-world data, to assess public opinion and identify any problems that may emerge in any hot zones of a country where the government can assist, be it with medical supplies or tending to stuck tourists. Lastly, we tried to find the similar terms interdependency in the cluster which acts as an extra advantage to analyse what kind of words are maximally being used between the two sectors.

DISCUSSION

This research work aims to extract and analyze tweets about coivd-19 from tourism sub-domains healthcare and hospitality from all around the world. The Covid-19 has had the greatest influence on the tourism domain, and visitors who had planned a vacation to another nation away from their regular surroundings have been trapped inside their homes.

The authors began by performing sentiment analysis with a very distinctive approach called VADER, which has the largest benefit of requiring very little data cleansing since it recognizes the magnitude of the words. After the analysis, it is found that the positive sentiments were the highest in all of the sectors which briefly means that In the next few years, it will have a substantial and beneficial influence on worldwide tourism. It also offers the possibility of transforming our affected planet into a greener one. Furthermore, we used topic modeling to discover patterns such as word frequency and distance between words. A topic model clusters comparable feedback as well as phrases and expressions that appear frequently. With this knowledge, it is possible to immediately infer what each group of texts is discussing. Each document in the LDA model is seen as a conglomeration of themes from the corpus. According to the model, each word in the text is related to one of the document's subjects. Lastly, implementation of the state-of-the-art deep learning algorithm and testing the model with different epoch sizes helped in providing a robust sentiment prediction model.

Hospitality

The hospitality industry has taken huge hits in terms of revenue, and massive layoffs occurred because of Covid-19. By implementing topic modelling, it is seen that the restaurants, hotels, and resorts are among the highest sectors facing difficulty. The proposed deep learning model has achieved the highest values of test set accuracy of 80.9 percent, which is the maximum among the epoch sizes between 5 and 10. Apart from test accuracy, the authors captured the loss and training set accuracy of 0.011 and 99.6 percent, respectively. The hospitality sector has contributed to providing shelters for tourists with the alliance of government agencies during lockdown phase. Many hotels came forwards to facilitate the best services for covid victims during the quarantine phase. This has resulted in sharing of positive narrative by tourists when they are isolated during lockdown periods.

Healthcare

Healthcare to tourists is a critical component in which the best medical treatment is provided to foreign tourists and visitors. The tweets for tourist healthcare were collected from visitors who were trapped in various nations and how they handled and shared their experiences on social media data. On an epoch size of 10, the created deep learning model for the tourism sector can produce the best results. The study provided various implications for practice. The Twitter analysis can be done to check the impact of various other crises on tourism domains. The sentiment analysis using VADER can be a boon for many researchers. The tourism economy has witnessed a huge halt due to travel restrictions. The study has provided a panoramic view of the analysis during the coronavirus crisis which can help in paving the foundation for the implementation of efficient remedial measures to sustain after the covid-19 pandemic. The social media analysis helps the healthcare admirative agencies to analyze the tourist sentiments and prioritize the urgency patients due to covid complications.

CONCLUSION AND FUTURE SCOPE

Social media platforms are a medium for sharing opinions and thoughts. Analysis of these thoughts may help to get ready for upcoming travelers once the Covid-19 situations will normalize. The study has a future scope of research. A post-crisis study can also be done after the Covid-19 pandemic is over. This can help provide a birds-eye view of the overall impact of the coronavirus on tourism domains.

In view of the Covid-19 pandemic, Twitter data of tourism two sub-domains: hospitality and healthcare were selected and extracted accordingly. Analysis is done through sentiment visualization and deep learning algorithms. Sentiment visualization is presented with the help of bar and violin plots. This study provides a strategic practical framework to sustain during the Covid- 19 pandemic which revolves around the deep learning analysis of social media. Finally, the LSTM RNN model prediction has a number of applications, one of which is allowing government officials to monitor social media sites such as Twitter in order to better understand their citizens' sentiments so that they can make choices and act in the best interests of the country and people.

One of the paper's future scopes is to see whether the topic modeling suggestion can be expanded to other sectors like airline and economy to see what kinds of comparable words are impacting and influencing the healthcare and hospitality industries. We were limited in the quantity of data we could collect because of the Twitter API's request restriction, which was one of the study's constraints. The LSTM RNN approach would be considerably more robust with a much larger dataset.

Forecasting Dengue Hotspots Associated With Variation in Meteorological Parameters Using Regression and Time Series Models

*Seema Patil and Sharnil Pandya**

Symbiosis Institute of Technology, Symbiosis International (Deemed University), Pune, India

For forecasting the spread of dengue, monitoring climate change and its effects specific to the disease is necessary. Dengue is one of the most rapidly spreading vector-borne infectious diseases. This paper proposes a forecasting model for predicting dengue incidences considering climatic variability across nine cities of Maharashtra state of India over 10 years. The work involves the collection of five climatic factors such as mean minimum temperature, mean maximum temperature, relative humidity, rainfall, and mean wind speed for 10 years. Monthly incidences of dengue for the same locations are also collected. Different regression models such as random forest regression, decision trees regression, support vector regress, multiple linear regression, elastic net regression, and polynomial regression are used. Time-series forecasting models such as holt's forecasting, autoregressive, Moving average, ARIMA, SARIMA, and Facebook prophet are implemented and compared to forecast the dengue outbreak accurately. The research shows that humidity and mean maximum temperature are the major climate factors and exhibit strong positive and negative correlation, respectively, with dengue incidences for all locations of Maharashtra state. Mean minimum temperature and rainfall are moderately positively correlated with dengue incidences. Mean wind speed is a less significant factor and is weakly negatively correlated with dengue incidences. Root mean square error (RMSE), mean absolute error (MAE), and R square error (R^2) evaluation metrics are used to compare the performance of the prediction model. Random Forest Regression is the best-fit regression model for five out of nine cities, while Support Vector Regression is for two cities. Facebook Prophet Model is the best fit time series forecasting model for six out of nine cities. Based on the prediction, Mumbai, Thane, Nashik, and Pune are the high-risk regions, especially in August, September, and October. The findings exhibit an effective early warning system that would predict the outbreak of other infectious diseases. It will help the relevant authorities to take accurate preventive measures.

Keywords: dengue fever, climate change, machine learning, prediction, time series forecasting, regression model

INTRODUCTION

Climate change is variations in climate variables such as temperature, humidity, precipitation, rainfall, wind speed, etc. Climate Change occurs due to natural activities such as variations in the sun, volcanic explosions, or human activities like the emission of carbon dioxide and other greenhouse gases that cause global warming. Infectious diseases are categorized into foodborne, airborne, waterborne, and vector-borne infectious diseases. Vector-borne infectious diseases are transmitted to humans by a microbe, called vectors, such as mosquitoes, ticks, flies, etc. Dengue is a vector-borne infectious disease carried by mosquito vectors that is most susceptible to meteorological conditions. According to WHO, this pandemic spreads over 128 countries across the globe and increased eight times over the last 20 years affecting 4.2 million people in the year 2020. **Figure 1** shows the effects of climate change on disease vectors.

For understanding the spread of dengue, studying climate change and its effects specific to the disease is necessary. Temperature, rainfall, humidity, wind speed are the significant meteorological factors for the spread of dengue fever. Identifying the relationship between variation in these climatic factors and dengue incidences helps to predict the disease outbreak more accurately. An association has been found between the climatic parameters and dengue incidences for the selected locations in the proposed system. Machine Learning plays a vital role in developing a predictive model to understand the influx of dengue. Previously different classification and regression techniques were implemented for the prediction of dengue outbreaks for different locations. Considering varied geographic topography with changing climatic conditions and frequent disease outbreaks in the past, there is a need for better and accurate predictive models for early surveillance systems and improved prevention strategies. The following points highlight the paper's significant contributions:

- To collect climate and dengue incidence data for the selected locations for the past 10 years
- To identify the correlation between variations in climatic parameters and dengue incidences
- To implement various predictive models and show a comparative analysis based on different evaluation metrics
- To predict different climatic regions at risk in the future based on its climatic conditions

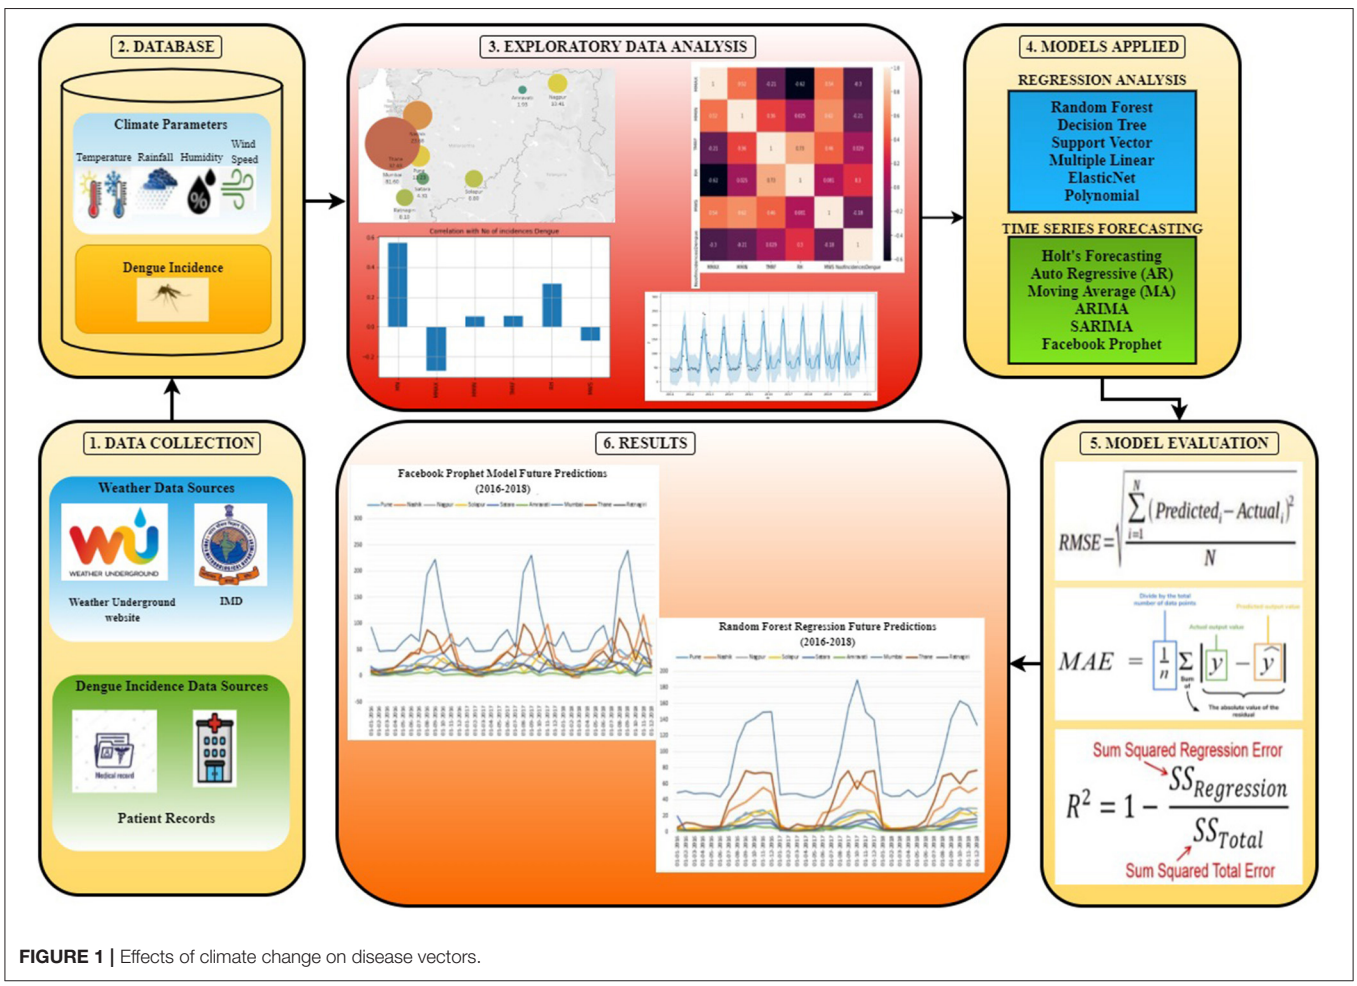

FIGURE 1 | Effects of climate change on disease vectors.

The following sections of the paper are organized as follows: Section Related Work describes related research work carried out for identifying the relationship between climate factors and vector-borne infectious diseases along with existing predictive modeling techniques available and its limitations. Section Proposed Work narrates the proposed system for dengue forecasting with variation in climate change. Section Methodology exhibits the methodologies used for forecasting dengue disease outbreaks. It includes different subsections such as data collection and integration, data preprocessing, exploratory data analysis, model execution, and evaluation metrics. Section Results and Discussion discusses details of predictive analysis and results. Finally, Section Conclusion, Limitations, and Future Work presents and concludes the author's research work.

RELATED WORK

Significant research has been carried out for understanding the association of meteorological variables with dengue incidences. This section describes the existing work related to the prediction of dengue incidences based on climatic factors using several machine learning techniques with its advantages and limitations.

Salim et al. (1) proposed a study to predict dengue outbreaks based on weekly dengue incidence data for the Selangor state of Malaysia. Several Machine Learning algorithms such as CART, ANN, SVM, and Naive Bayes create a predictive model. It has been found that the support vector machine model (SVM) best predicted dengue outbreaks. This research provides categorical output instead of continuous output. Liu et al. (2) implemented a unique approach for forecasting dengue incidences in Guangzhou, China. They integrated SVM-MLP machine learning approaches (3) with environmental features such as water collection sites, dustbins, etc. It performs better than models based on standard features (Temperature) alone. More standard features in addition to temperature and rainfall could be considered for better training of the ML Model. The SVR-based model Tanawi et al. (4) is proposed to predict dengue incidences in DKI, Jakarta. They concluded that SVR with a linear kernel provides better results than SVR with a radial kernel. Recently Mudele et al. (5) proposed a technique that uses a recurrent neural network (RNN) for forecasting the dengue mosquito vector population. This model is compared with random forest and k nearest neighbor for two Brazilian cities. They proposed that other deep learning models should be considered for the study (6–15). Mohapatra et. al. (16) investigated the effect of climate parameters on malaria outbreak using multilayer Perceptron and J48 classifier using WEKA tool. The results show that J48 is the most suitable model than MLP and has better accuracy and less error (RMSE). Also, temperature and humidity are more significant climate parameters than rainfall, and monsoon and post-monsoon are the peak periods for the outbreak. However, other factors such as demography, immunity within the population, society's socio-economic structure, availability of affordable public health facilities are not considered during the research (17). Cheng et al. (18) proposed distributed lag non-linear model to investigate the association between extreme weather events such as floods, heatwaves, high humidity, and dengue epidemic. The researcher implemented the model on daily dengue incidences and climate

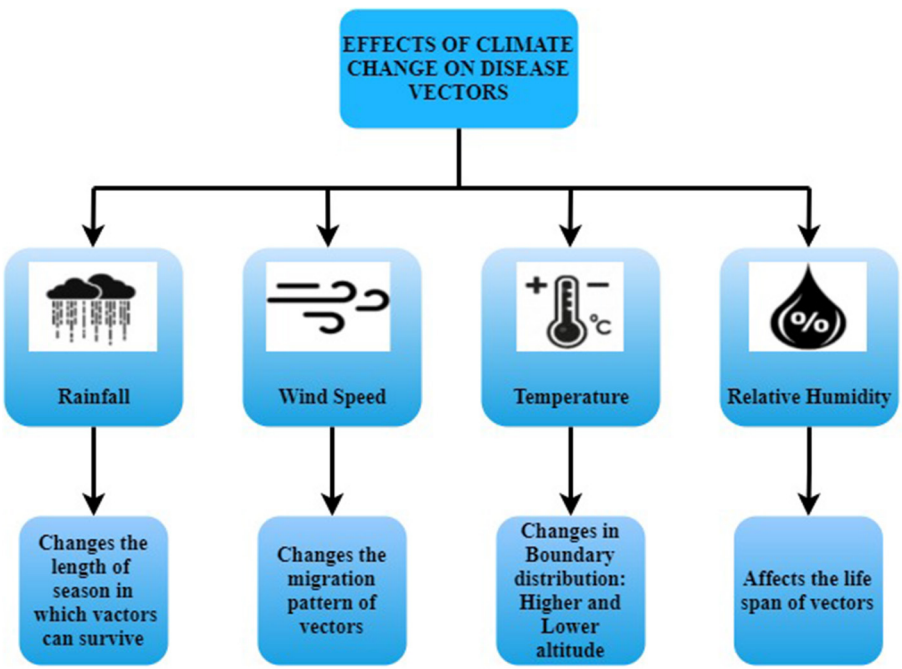

FIGURE 2 | Schematic overview of the proposed system.

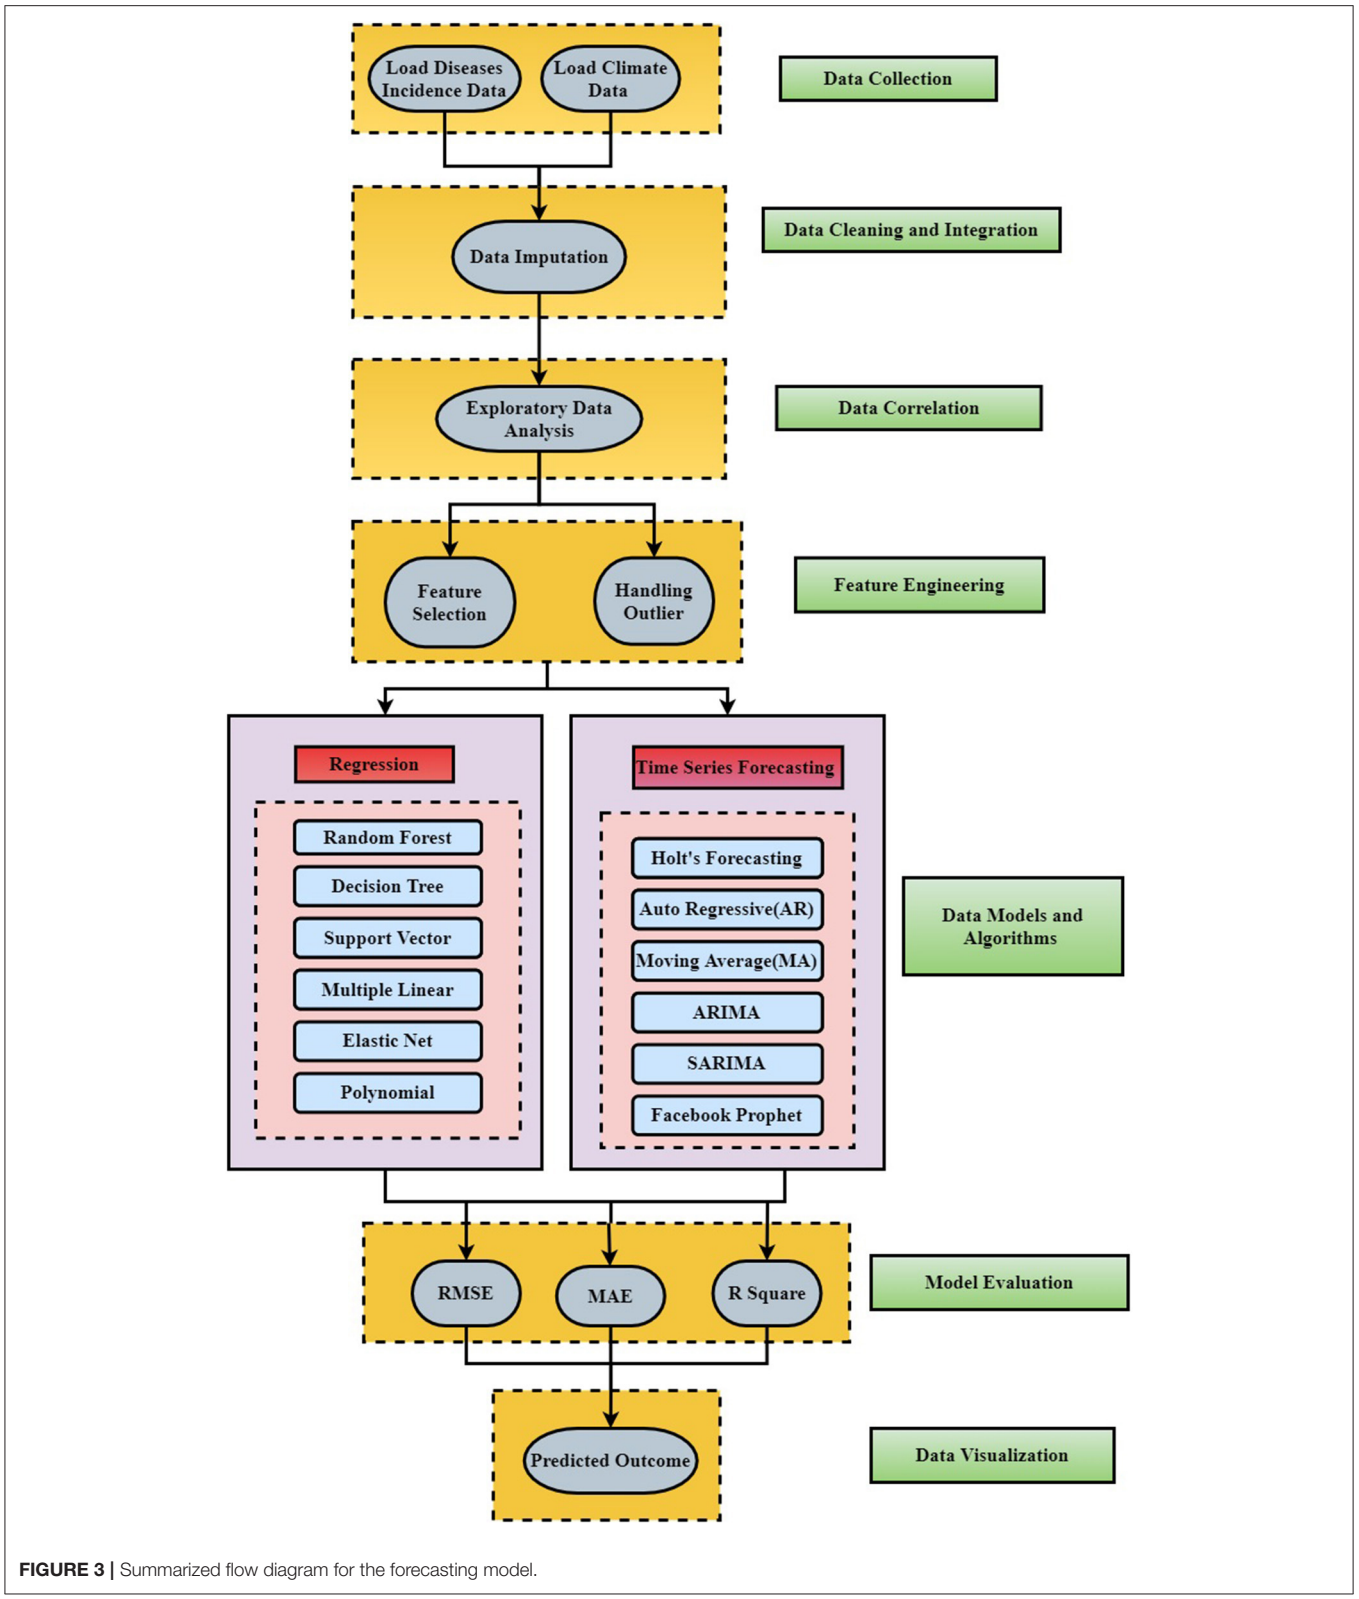

FIGURE 3 | Summarized flow diagram for the forecasting model.

factors such as temperature, humidity, and rainfall for different cities of China. The threshold for each climate parameter is calculated, and risk for dengue outbreak is identified for the extreme weather events. The limitation of the research is that

other time-variant factors such as changes in mosquito density, population movements and habits, and vector control measures are not considered for the study (19).

Xu et al. (20) analyzed dengue incidences data considering different meteorological factors. They proposed long short-term memory (LSTM) based recurrent neural network predictive model to predict monthly dengue cases using climate data for 20 Chinese cities. LSTM model shows the best performance for forecasting dengue incidences. But it is time-consuming compared to other models such as the backpropagation neural network and gradient boosting machine model. Appice et al. (22) formulated different strategies such as Auto Encoding, Window-based Data Slicing, and Cluster Analysis to discover temporal dynamics in temperature and dengue variables. They proposed a new multi-stage Machine Learning model called AutoTiC-NN (22) to find trend patterns between historical data of temperature and dengue in Mexico. The study proved that the model outperforms both in regression and time series forecasting analysis. Benedum et al. (23) compared machine learning, regression, and time-series models to forecast dengue cases and outbreaks in Peru, Puerto Rico, and Singapore. They concluded that Random Forest regression provided better results than Poisson Regression and ARIMA for short-term predictions while ARIMA was better for long-term forecasts. Nkiruka et al. (24) proposed a malaria incidence classification model (MIC) using climate parameters for six countries of Africa over 28 years. The research used k means clustering for outlier detection and the XGBoost model for classification. The proposed model is compared with other classification models such as ARIMA, SARIMA, SVM and showed the best results compared to other models.

Anno et al. (21) have integrated Spatiotemporal Hotspot analysis, RS Data, and a Machine Learning approach to develop a climate-based forecasting model to deliver early warning messages to the relevant public health authorities in Taiwan. This study uses two climate parameters (Rainfall and Temperature) to predict dengue outbreaks. Stolerman et al. (25) provide a better understanding of the long-term effects of climate conditions on the Aedes Aegypti (dengue causing mosquito) population. They have developed a new data-driven method using SVM algorithms to identify climate signatures that predict Dengue epidemics in Brazil. This research uses the binary threshold to classify epidemics/non-epidemics based on the Brazilian Ministry of Health. Two climate parameters (Frequency of precipitation and average Temperature) are used. Carvajal et al. highlighted the use of time lags of meteorological factors to predict dengue incidences. They concluded that Tree based Machine Learning methods (Random Forest, Gradient Boosting) performed better than conventional statistical techniques (GAM, SAIMAX) to predict a temporal pattern of Dengue incidences in Manila, Philippines. They also suggested that Relative Humidity is one of the most critical climate factors for their RF-LG model. All the variables are trained with keeping lag time in consideration to give an early outbreak prediction. Thus, this model cannot be used to predict an immediate output (17, 19, 26, 27). Despite continuous research, due to the varied topography of India, especially Maharashtra state having different climatic regions, there is a need to develop an accurate and enhanced predictive model for effective forecasting (2, 28–36). It will help the medical researcher and public health department promptly respond to the dengue outbreak and undertake corrective majors.

PROPOSED WORK

Figure 2 shows a schematic overview for dengue forecasting using regression and the time series model. It includes data sources and collection for both Climate parameters and dengue incidences. This is followed by data cleaning and integration in which missing data are imputed using the mean of the month data imputation technique. Exploratory data analysis is performed to find the correlation between climate parameters and dengue incidences. Feature engineering is carried out for feature selection and handling outliers. The impact of climate change includes indirect effects such as rising sea and temperature levels, extreme weather events such as droughts, floods, heatwaves, etc. The direct impact of climate change includes endurance, reproduction, or distribution of disease vectors which may affect human health. The climatic variations help in transmitting disease pathogens that may lead to infectious diseases (5, 16–19, 26, 27, 37–42).

Furthermore, the data is then split into training and testing data sets where training data is used to train different Machine Learning models–Regression Analysis and Time Series forecasting. These models are evaluated based on three evaluation metrics–Root Mean Square Error, Mean Absolute Error, and R Square Error. The models are compared to determine which models work best for different cities based on their geographic locations. Finally, locations at risk and outbreak period are predicted. Various visualization tools and techniques are used to represent the data and results effectively.

Novelties and Contribution of the Proposed Work

The effect of the variation in climate factors with varied topography on infectious diseases such as dengue is an exciting research area. The proposed work illustrates the detailed analysis of the climate and health data for different locations of Maharashtra state of India. It includes finding a correlation between monthly climate factors such as mean minimum temperature, mean maximum temperature, mean wind speed, relative humidity, etc., with dengue incidences for different locations. These locations have diverse geographic topography and weather conditions. Based on the analysis, forecasting of dengue outbreaks is performed using time series and regression models. The performance of these models is compared using various evaluation metrics and identifies the best suitable models for the study. This research will help design an effective surveillance system that will accurately monitor and control the dengue outbreak in a timely manner.

Methodology

Figure 3 shows the detailed workflow and layered architecture for the construction of the dengue forecasting model. The following sub-section (Data Sources and Collection, Data

Cleaning and Integration, Exploratory Data Analysis, Feature Engineering, Model Execution, Model Evaluation) elaborates different data sources and data collection process along with data preprocessing techniques implemented such as data imputation for missing values, climate and health data integration, feature selection, and outlier detection. Exploratory data analysis is performed to identify the correlation between climate parameters and dengue incidences using different visualization techniques such as heat maps, feature plots, etc. It also depicts different time series and regression machine learning models applied along with model evaluation metrics. Finally, dengue outbreak is forecasted for different cities of India for the next 3 years.

TABLE 1 | City wise population and weather conditions.

Division name	City	Population (in Lakhs)	Weather conditions
Konkan	Mumbai	125	Tropical, wet, and dry climate
Konkan	Thane	18.9	Tropical monsoon climate
Konkan	Ratnagiri	3.27	Tropical
Pune	Pune	31.2	Hot, semi-arid climate
Pune	Solapur	9.51	Dry, arid, and semi-arid climate
Pune	Satara	3.26	Tropical, pleasant climate
Nashik	Nashik	14.86	Mild tropical climate
Nagpur	Nagpur	24.1	Tropical Savanna climate
Amaravati	Amaravati	6.47	Tropical, wet, and dry climate
Aurangabad	Parbhani	3.07	Tropical, hot, and wet climate

Data Sources and Collection

Climate Data

Maharashtra has diverse climatic regions like Kokan, Khandesh, Desh, Vidarbha, and Marathwada. Based on the intensity of the disease and varied climatic conditions, nine cities like Mumbai, Thane, Ratnagiri, Pune, Solapur, Satara, Nashik, Nagpur, and Amaravati have been selected for the study. Monthly climate data is collected from Indian Meteorological Department (IMD) for 10 years from 2009 to 2019. The parameters in consideration are attributes such as Monthly Mean Maximum Temperature (MMAX) (°C), Monthly Mean Minimum Temperature (MIN) (°C), Total Monthly Rainfall (TMRF) (mm), Relative Humidity (RH) (%), and Mean Wind Speed (MWS) (km/h). **Table 1** shows different region-wise locations of Maharashtra state along with population and climatic conditions.

Health Data

The monthly dengue disease incidence data is collected from the National Vector Borne Disease Control Program (NVBDCP) for targeted cities of Maharashtra state mentioned in the climate data section for 10 years from 2009 to 2019. The data collected is in excel format, having inconsistent and missing values. The climate and disease incidence data are integrated into the CSV file for all the nine targeted cities, and data preprocessing is performed. **Figure 4** shows the map of Maharashtra state with region-wise selected cities for the study.

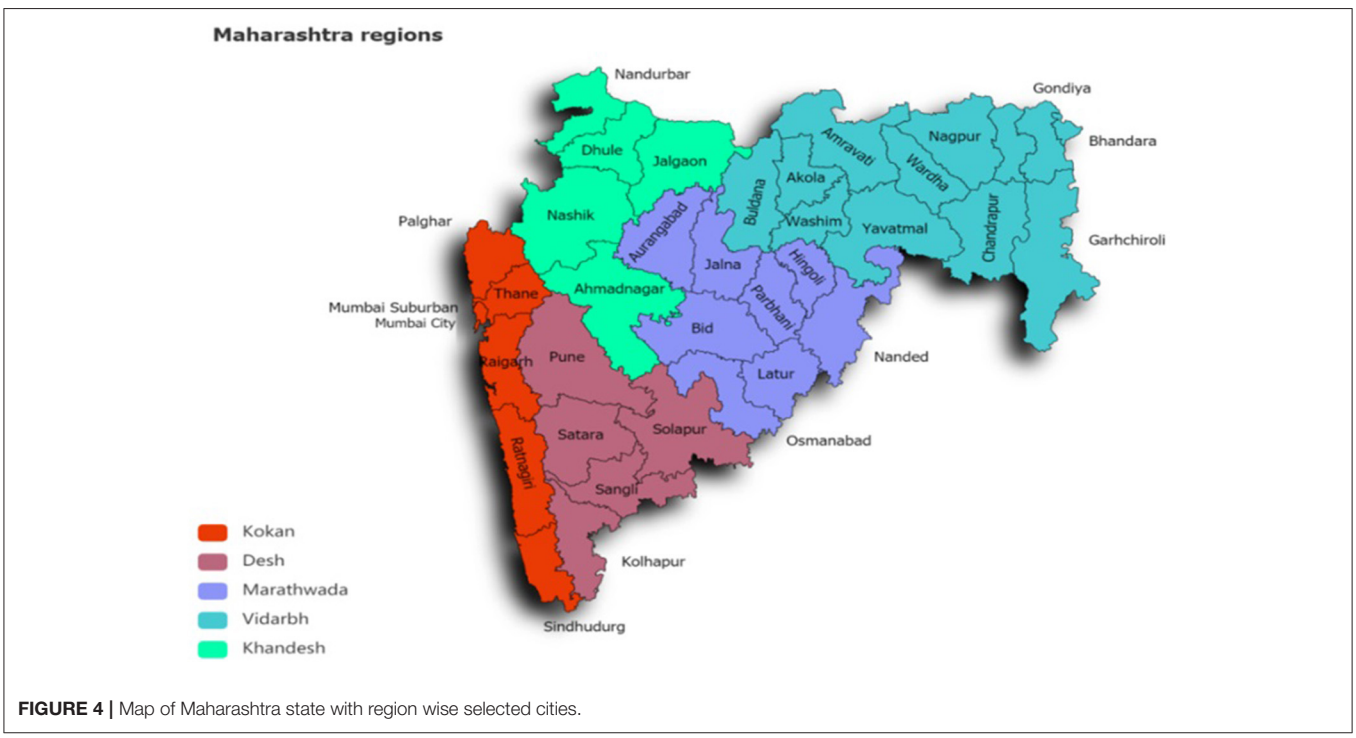

FIGURE 4 | Map of Maharashtra state with region wise selected cities.

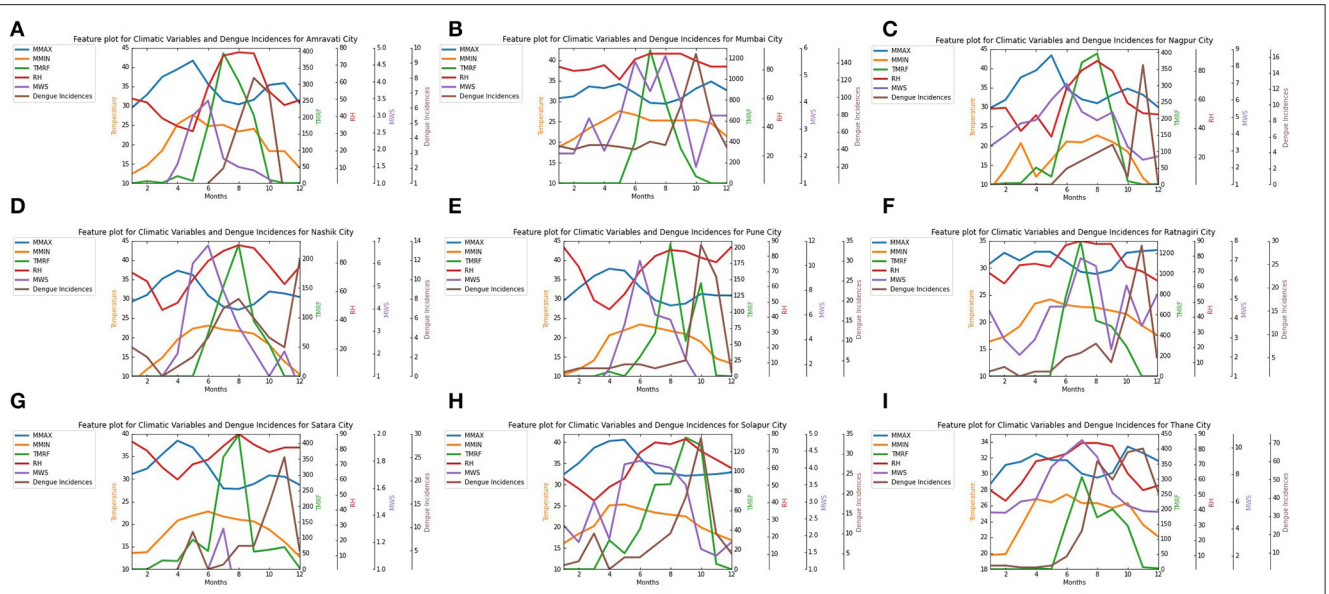

FIGURE 5 | City Wise Features Plot for climate variables monthly mean minimum temperature, mean maximum temperature, Average rainfall, Relative humidity, Mean wind speed, and monthly dengue incidences for nine selected cities in Maharashtra from 2009 to 2019. **(A)** Amravati, **(B)** Mumbai, **(C)** Nagpur, **(D)** Nashik, **(E)** Pune, **(F)** Ratnagiri, **(G)** Satara, **(H)** Solapur, **(I)** Thane.

Data Cleaning and Integration

To create the dataset, climate and dengue incidences data are collected and integrated. The dataset generated had inconsistent values due to the diverse nature of weather and health data. For each targeted city, a few irrelevant attributes are removed from the dataset during integration. The resulting dataset consists of missing values, especially in climate parameters. Data cleaning is performed to identify missing values. The data imputation technique is used to clean the dataset. The missing data were imputed using the mean of the Month Imputation technique. In this method, the missing values are replaced with an average of the previous values of the same month throughout different years. The mean of the month imputation function is given by:

$$\text{Vest} = (\sum \text{Tj} = 1\text{Vij})/\text{T} \quad (1)$$

$$\text{Vest} = (\text{Vij1} + \text{Vij2} + \text{Vij3} + \ldots.. + \text{VijT})/\text{T} \quad (2)$$

The estimated value Vest for the missing attribute is calculated by the averaging sum of values (Vij) of the variable for the ith month of the year j, where T is the number of available data for that year. In the present study, the mean of Maximum temperature "MMAX" for August 2016 was missing in the given dataset from 2009 to 2019. The estimated value is calculated by an average of previous values of the same month throughout different years. This value was treated as a data point in place of the missing value.

Exploratory Data Analysis

Once the dataset is cleaned, exploratory data analysis is performed to analyze attributes and summarize its characteristics using statistical techniques to discover useful patterns and graphical representation. City-wise feature graphs are plotted as shown in **Figures 5A–I**, and it is determined that each parameter for every city has a lot of variations, and there is no fixed pattern. So the correlation between each climate parameter and dengue incidences is found for all targeted locations to check which parameters are more significant.

Pearson correlation is performed on the dataset to determine the association between climate variables and dengue incidences, and heat maps are generated for each targeted city. Pearson correlation is a parametric test that measures the degree of relationship between two variables. It is the most suitable correlation technique based on the method of covariance and deals with numeric values. The person correlation function is given by Manogaran and Lopez (7):

$$r = \frac{\sum_{i=1}^{n} (ai - a)(bi - b)}{\sqrt{\left[\sum_{i=1}^{n} (ai - \overline{a})^2\right]\left[\sum_{i=1}^{n} (bi - \overline{b})^2\right]}} \quad (3)$$

Here, the Pearson correlation coefficient function is employed to determine the relationship between the climate parameters and the number of dengue cases. Climate variables are monthly mean max temperature (MMAX), mean minimum temperature (MMIN), Rainfall (TMRF), Relative Humidity (RH), Mean Wind Speed (MWS).

Correlation between climate factors and dengue incidences shows that each climate variable affects the dengue incidences differently. The mean maximum temperature (MMAX) is negatively correlated with the incidences of dengue despite the locations. This implies that as the maximum temperature decreases, incidences of dengue have increased. Mean minimum temperature (MMIN) is weakly/moderately positively correlated

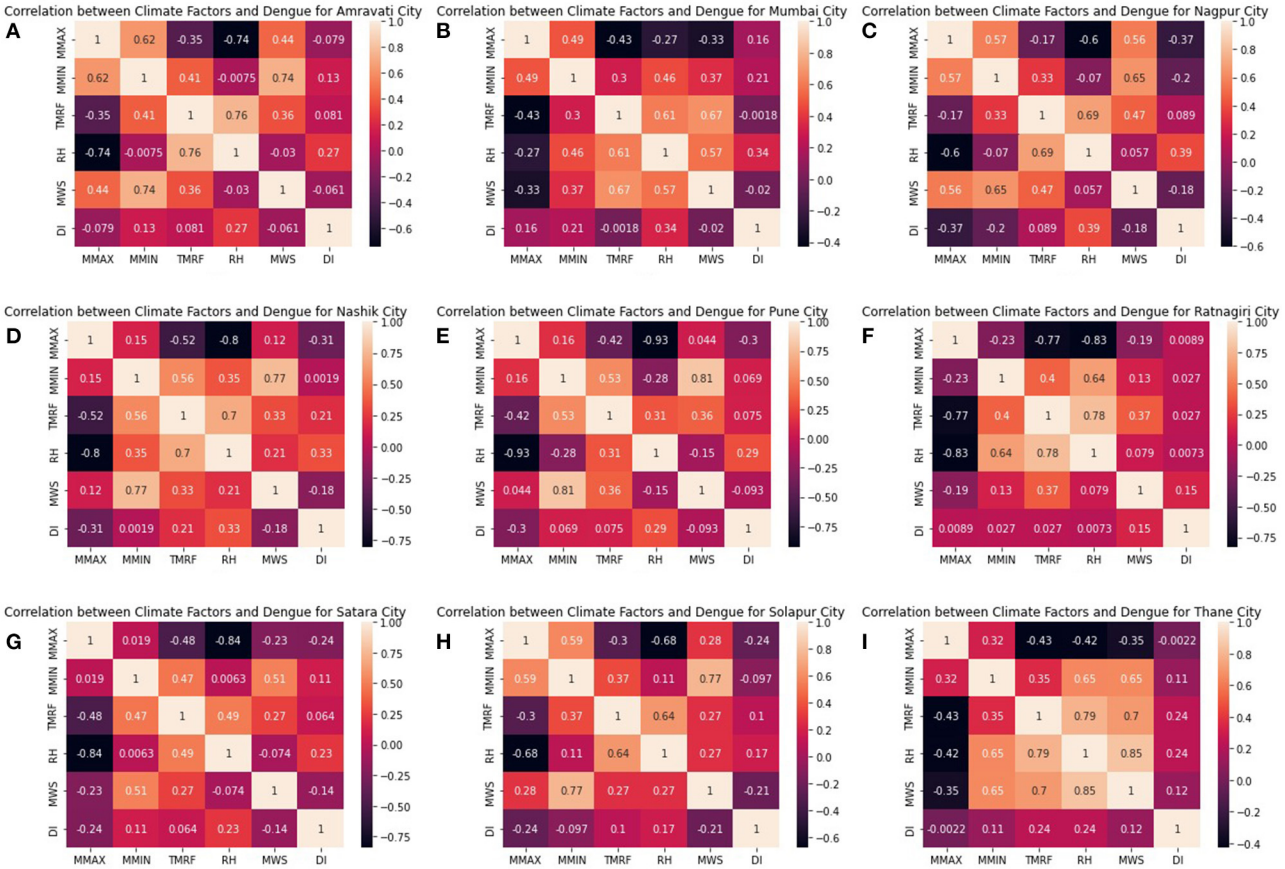

FIGURE 6 | Correlation of monthly mean minimum temperature, mean maximum temperature, total monthly rainfall, relative humidity, mean wind speed climate parameters, and monthly dengue incidences: **(A)** Amravati, **(B)** Mumbai, **(C)** Nagpur, **(D)** Nashik, **(E)** Pune, **(F)** Ratnagiri, **(G)** Satara, **(H)** Solapur, **(I)**Thane.

with dengue incidences except for Nagpur. Relative Humidity (RH) is the primary climate factor and exhibits a strong positive correlation with dengue incidences for all locations of Maharashtra state. Similarly, total monthly rainfall (TMRF) is moderately positively correlated with incidences of dengue. As humidity or rainfall is increased, cases have shown an increase for all selected cities of Maharashtra. Maximum incidences occur between June to September, where the average rainfall is between 150 and 350 mm. Mean Wind speed (MWS) is a less significant climate factor and weakly negatively correlated with dengue incidences.

Figure 6 shows city-wise graphs of the Pearson correlation of each climate parameter with the dengue incidences. These graphs are further used for feature selection based on results generated to identify the significant climates factors.

Feature Engineering

The data quality is of utmost importance for developing a predictive model with better accuracy and faster performance. For this purpose, a few data preprocessing techniques are applied, such as outlier detection and feature selection, to improve the data quality. The meteorological data consist of extreme values for specific periods, such as extreme wind speed, rainfall, and humidity. Outliers in the dataset can reduce predictive modeling performance. So the final dataset was normalized to uniform into the same scale.

Feature or attribute selection is the process of selecting the most relevant attributes in a dataset that helps train the model faster, reduces overfitting, and improves the accuracy of the predictive model. Minimal redundancy maximum relevance feature selection technique is used for attribute selection on the dataset to select attributes with high correlation and low variance. For determining the relevant features, two measures are calculated: redundancy and relevance. The following equation is used to find the mean of logical values of each climate parameter for the selected city in terms of dengue incidences:

$$\bar{c}_l = \frac{1}{n_i} \sum_{k=1}^{n_i} C_{ik} \tag{4}$$

Where, $\bar{c}_i$: Means of climate parameter i, n_i : Number of climate parameters, C_{ik}: the kth value of climate parameter i.

The below equation shows a variance of the climate parameters triggered by dengue incidences:

$$C_i^2 = \frac{1}{n_i} \sum_{k=1}^{n_i} (C_{ik} - \bar{c}_l)^2 \tag{5}$$

TABLE 2 | Dropped variables.

City	Dropped variables
Amravati	N/A
Mumbai	TMRF
Nagpur	N/A
Nashik	MMIN
Pune	TMRF, MMIN
Ratnagiri	MMAX, RH
Satara	TMRF
Solapur	N/A
Thane	MMAX

The minimal redundancy condition for the redundancy measure can be expressed by:

$$\min R(D),\ R = \frac{1}{|d|^2} \sum_{yi;yj \in d} I(yi; yj) \tag{6}$$

Where, min R (D) is the minimal redundancy for redundancy measure R, $|d|$ is the number of features in the subset of feature D, and I (yi; yj) is the mutual information between feature i and j.

The maximal relevance condition for the relevance measure can be expressed by:

$$\max RL(D, a),\ RL = \frac{1}{|D|} \sum_{yi \in d} I(yi; a) \tag{7}$$

Where max RL (D, a) is the maximal relevance for relevance measure RL and target activity a and I (yi; a) is the mutual information between the feature i and target activity a.

The smaller the value of the redundancy measure, the better the criteria for selection. Similarly, the higher the value of relevance measure, the better the feature selection. After exploratory data analysis is performed on the dataset considering several feature variables such as MMIN, MMAX, TMRF, RH, and MWS, different climate variables with high redundancy and low relevance are dropped for few cities under study, as shown in **Table 2**.

Model Execution

Regression is a supervised learning statistical method used to estimate the relationship between a dependent and one or more independent variables to determine trends in the data. It is used in the prediction of continuous values. The following regression models are implemented to predict dengue incidences across different cities based on climate parameters in the proposed system.

Support Vector Regression

It is the regression technique used to predict continuous ordered values. Some commonly used keywords in SVR are the kernel, hyperplane, boundary line, and support vectors. The primary purpose of SVR is to consider as many data points as possible within the boundary lines, and the hyperplane (best-fit line) must contain as many data points as possible. It is easy to implement and shows high prediction accuracy with excellent generalization capability. It can handle outliers very well.

Multiple Linear Regression

It is an extension of simple linear regression that models a linear relationship between more than one independent variable and a single dependent continuous variable. It is a technique for fitting a regression line through a multidimensional space of data points.

ElasticNet Regression

Elastic net is a type of regularized linear regression that includes two well-known penalties, the L1 and L2 penalty functions. The advantage of the elastic net model is that it permits a balance of both penalties, resulting in a more excellent performance on particular tasks than a model with either one or more penalties.

Polynomial Regression

Polynomial regression is a type of linear regression that estimates the connection as an nth degree polynomial. It is an example of multiple linear regression. Because Polynomial Regression is sensitive to outliers, the existence of one or two of them can have a negative impact on the results.

Decision Tree Regression

It is a regression model that breaks down a dataset into smaller subsets forming a tree with decision nodes and leaf nodes. Decision trees are very easy to visualize and reduce the uncertainty in the prediction. However, overfitting and underfitting are common problems with decision trees. If the hyperparameters are incorrectly set, the decision tree's output can vary dramatically.

Random Forest Regression

Random forest is the most commonly used machine learning technique that gives excellent results in predicting disease incidences based on climate conditions. It comprises many decision trees, each with the same node but different inputs, resulting in various leaves. It combines the results of the average of various decision trees. Overfitting can be avoided in the model by using Random Forest regression to create random subsets of the dataset.

Along with regression, the proposed system also used time series forecasting models to predict dengue incidences. Time series data is a sequence of different data points that measure a specific variable over an ordered period. In this method, time-series data extract meaningful statistics and other data characteristics to generate forecasts of our target variable. Different time series forecasting models are applied as given below:

Holt's Forecasting: It is time series forecasting method that depicts trends and seasonality from historical data. It is simple to implement and evolve with changing business requirements.

Auto-Regressive (AR) and Moving Average (MA): Autoregression forecasting technique predicts future values using previous values in time series. It demonstrates linear relation between future and past values. It is used to forecast recurring patterns in the data. The moving average method uses an average of several past points to predict future points. In this

method, short-term fluctuations and the effect of extreme values are reduced.

Auto-Regressive Integrated Moving Average (ARIMA): ARIMA model is a popular time series forecasting model which uses its lags to predict future values. It uses dependent relation between past observation and current observation. It involves subtracting recent observations from previous period observations several times. It is broken down into its subtypes to increase the accuracy of incidence predictions based on climate variability. This model does not support seasonal data.

Seasonal Auto-Regressive Integrated Moving Average (SARIMA): When seasonal components are added to the ARIMA model, then it is called SARIMA. It supports univariate time series data. Additional four seasonal elements in SARIMA are P, D, Q, and m, where P is seasonal autoregressive order, D is seasonal difference order, Q is moving average order, and m is the number of time steps (17).

TABLE 3 | Rudimentary observations.

Climate parameters	Rudimentary observations
Relative humidity	For RH > 55%, Number of incidences increases
Monthly maximum temperature	For temp 30°C < MMAX < 35°C, Number of incidences increases
Monthly minimum temperature	For temp 18°C < MMIN < 25°C, Number of incidences increases
Mean wind speed	For MWS < 2.5 kmph, No of incidences increases
Total monthly rainfall	For rainfall, 150 mm < TMRF < 250mm, No of incidences increases

Facebook Prophet Model

The Facebook prophet is a relatively new time series forecasting model developed in 2017 by the Facebook data science team as open-source software. In this model, irregular observations are permitted in the dataset as it ignores temporal data dependence. It is accurate, fast, and shows excellent performance as compared with other time series forecasting models. The prophet equation is given by:

$$x(t) = c(t) + s(t) + h(t) + u(t) \tag{8}$$

Where x(t) is forecast value, c(t) is the trend, i.e., change over a long period, s(t) is the seasonality, h(t) is the effect of the

holiday, u(t) is unconditional changes or error. This model works best with time series with substantial seasonal influences and historical data from multiple seasons. It is robust to outliers and handles missing values very well. This model gives the best performance for six out of nine cities to forecast dengue incidences based on climate variations in the proposed system.

Model Evaluation

Once all regression and time series forecasting models are trained, the performance of the models is evaluated using three evaluation metrics: Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and R Square Error (R^2). RMSE is the Standard Deviation of predicted errors. Lower RMSE values indicate better models. RMSE is evaluated by the Equation (2):

$$\mathrm{RMSE} = \sqrt{\sum_{i=1}^{\mathrm{N}} (\mathrm{x_t} - \bar{\mathrm{x}}_\mathrm{t})^2 / \mathrm{N}} \tag{9}$$

Here, xt is actual dengue incidences for time t and $\bar{x}_t$ is the predicted number of incidences by the model.

Mean Absolute Error (MAE) is the difference between the actual values and the predicted values. Lower MAE values indicate better models. MAE is evaluated by Equation (1):

$$MAE = 1/n \sum_{i=1}^{n} |\mathrm{X_i} - \mathrm{X}| \tag{10}$$

R Square Error (R^2) is also known as the coefficient of determination. It tells us how well a model fits on a dataset. It indicates how close the regression line is to the actual data. The R^2 value closest to 1 is considered to be the best value. The equation given below evaluates the value of R^2 (20):

$$R^2 = 1 - \frac{\mathrm{SS}_{\mathrm{Regression}}}{\mathrm{SS}_{\mathrm{Total}}} \tag{11}$$

RESULTS AND DISCUSSION

Based on the exploratory data analysis, it was observed that each climate variable affects the dengue incidences differently. The average temp range in Maharashtra state is between 26 and 43°C. As shown in **Figures 6A–H**, histogram graphs generated after performing Pearson's correlation shows that mean maximum temperature (MMAX) is negatively correlated with the incidences of dengue despite the locations. This implies that as the maximum temperature decreases, incidences of dengue have increased. Mean minimum temperature (MMIN) is weakly/moderately positively correlated with dengue incidences except for Nagpur. Relative Humidity (RH) is the primary climate factor and exhibits a strong positive correlation with dengue incidences for all locations of Maharashtra state. Similarly, total monthly rainfall (TMRF) is moderately positively correlated with incidences of dengue. As humidity or rainfall is increased, cases have shown an increase for all selected cities of Maharashtra. Maximum incidences occur between June and September, where the average rainfall is between 150 and 350 mm. Mean Wind speed (MWS) is a less significant climate factor and weakly negatively correlated with dengue incidences. **Table 3** shows rudimentary observations for all five climatic parameters. The performance of all the regression and time series forecasting models for each city is evaluated and compared.

Tables 4–12 present city-wise performance comparison for all regression and time series forecasting models. The best fit values for each metric are highlighted in bold.

Table 5 shows that decision tree regression gives the least values for RMSE, MAE, and R^2 compared to other regression techniques. At the same time, the Facebook prophet gives the least values for RMSE, MAE, and R^2 compared to other time series models for Mumbai city of Maharashtra. Similarly, **Table 6** shows that the random forest model gives the best values for all performance metrics, whereas the AR model gives the least values for RMSE (5.5) and MAE (4.28) for Nagpur city. **Table 7** shows that Random forest demonstrates the best performance for metrics RMSE (24.16), MAE (18.88), and R^2 (0.21) for Nashik city. **Table 8** shows that random forest gives the best performance for metrics RMSE (14.4), MAE (9.44), R^2 (0.25), and Facebook prophet gives the best performance for metrics RMSE (9.3), MAE (6.7), R^2 (0.64) for Pune city. From all the performance **Tables 4–12** and result analysis, it has been observed that Random Forest Regression is the best-fit regression model working on five out of nine cities, i.e., Nagpur, Nashik, Pune, Ratnagiri, Satara, whereas Support Vector Regression shows the best performance on two cities, Thane and Solapur. Facebook Prophet Model is the best fit time series model that worked on six out of nine cities in time series forecasting. For the rest of the cities, various combinations of ARIMA models worked as the best fit.

Figure 7 shows predictions for nine targeted cities using Random forest regression, and **Figure 8** shows the predictions using the Facebook prophet time series model for 36 months from the Year 2021 to 2023. A hot spot map of Maharashtra state is created, as shown in **Figure 9**, using Tableau to compare the average number of monthly cases across our selected cities to visualize these results. The figures show that Mumbai is the most affected city, with monthly average dengue cases going up to more than 80, while Amravati is

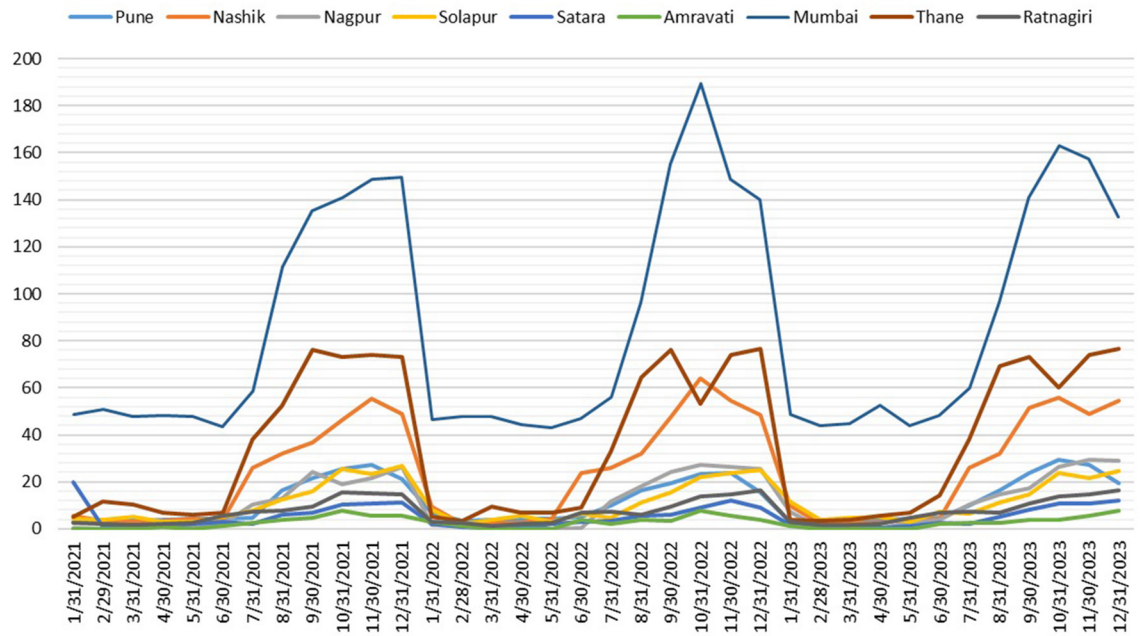

FIGURE 7 | Predictions for random forest regression model (X-axis: Date and Y-axis: Dengue cases).

the least affected location of Maharashtra. Other cities are ranged between 5 and 35 cases. Also, Thane, Nashik, and Pune are the cities at high risk, especially in August, September, and October.

CONCLUSION, LIMITATIONS, AND FUTURE WORK

Conclusion

This research paper proposed a framework that can predict dengue incidences across different cities of Maharashtra based on climate parameters. Different meteorological variables like MMIN, MMAX, RH, TMRF, etc., are given as input, and the number of Dengue incidences is produced as output by the proposed system. Nine cities with varied climatic conditions were selected based on geographic regions. A correlation between meteorological parameters and dengue incidences was found out. The proposed system implemented 12 different regression and time series models for the prediction of dengue outbreaks. The performance of all the models is compared using root mean square error, mean absolute error, and R square error evaluation metrics. The result analysis shows that Random Forest outperforms the other Regression models for five out of nine cities. Facebook Prophet Model is the best fit time series forecasting model for six out of nine cities. The system also predicts the high-risk geographic regions from the year 2021 to 2023. It has been observed that Mumbai, Thane, and Pune are the hot spots in Maharashtra, especially from July to October. The medical researchers, public health departments, and health geography analysts can utilize these research results to take the necessary preventive measures based on these predictions.

Limitations

The study only considers climate factors. Non-climatic factors such as the demography, immunity within the population, society's socio-economic structure, availability of affordable public health facilities, and other environmental modifications initiatives are not considered for the study. Also, there is scope to add additional time-variant factors such as changes in mosquito density, population movements and habits, and vector control measures. The study is limited to a few cities of Maharashtra state of India to analyze monthly climate and dengue incidence data due to the unavailability of weekly or daily reports that could have helped better predictions.

Future Work

The result of the research will be helpful in designing an effective surveillance system that will effectively monitor and control dengue outbreaks. An output platform like a website can be created to assess the latest climate change parameters, disease outbreaks, and future projections. Future work can involve more extreme geographic regions of India along with daily or weekly

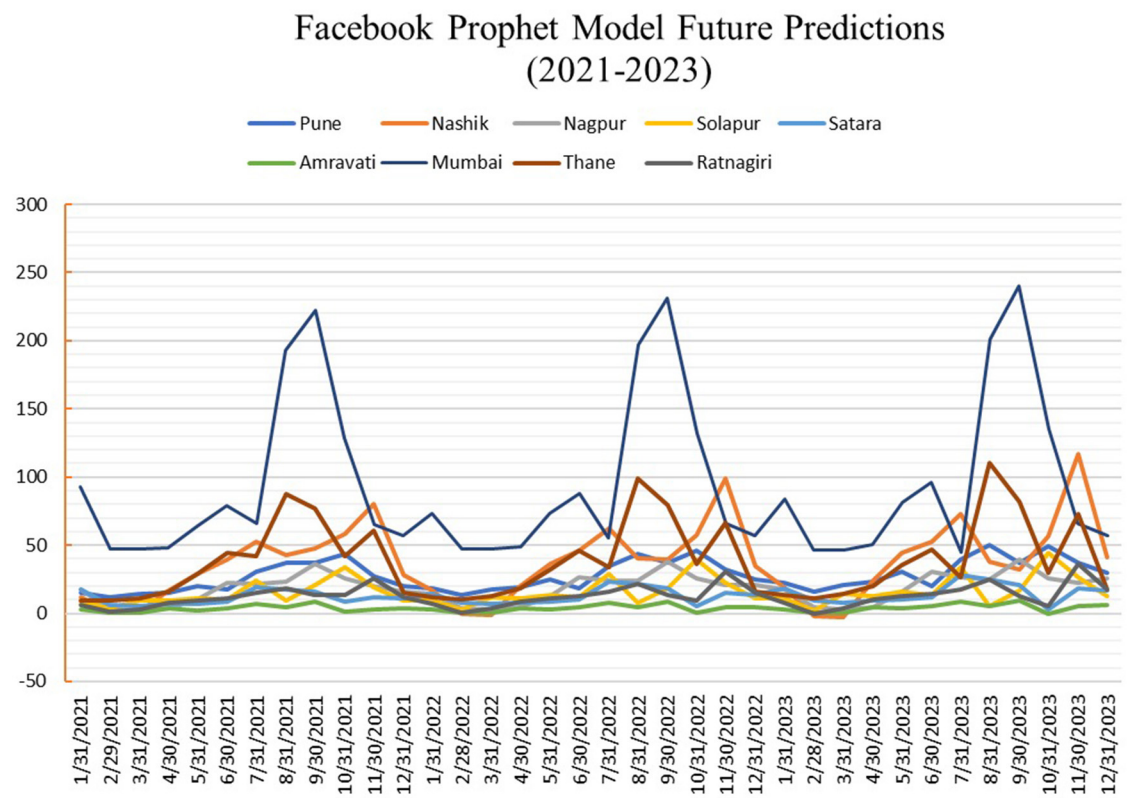

FIGURE 8 | Predictions for Facebook prophet model (X-axis: Date and Y-axis: Dengue cases).

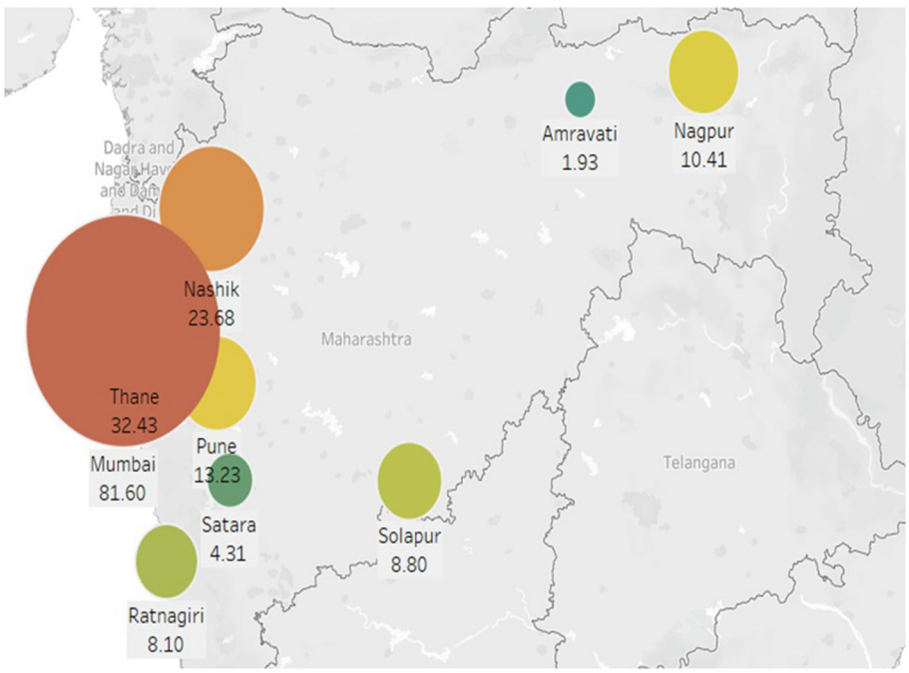

FIGURE 9 | Monthly average incidence hotspot map.

climate data analysis. Vulnerability groups such as age, gender, health status, occupation of the patients can be considered to enhance the surveillance system for better planning and preparation to avoid a future outbreak.

COVIDSAVIOR: A Novel Sensor-Fusion and Deep Learning Based Framework for Virus Outbreaks

Sharnil Pandya, Anirban Sur and Nitin Solke*

Symbiosis Institute of Technology, Symbiosis International (Deemed) University, Pune, India

The presented deep learning and sensor-fusion based assistive technology (Smart Facemask and Thermal scanning kiosk) will protect the individual using auto face-mask detection and auto thermal scanning to detect the current body temperature. Furthermore, the presented system also facilitates a variety of notifications, such as an alarm, if an individual is not wearing a mask and detects thermal temperature beyond the standard body temperature threshold, such as 98.6°F (37°C). Design/methodology/approach—The presented deep Learning and sensor-fusion-based approach can also detect an individual in with or without mask situations and provide appropriate notification to the security personnel by raising the alarm. Moreover, the smart tunnel is also equipped with a thermal sensing unit embedded with a camera, which can detect the real-time body temperature of an individual concerning the prescribed body temperature limits as prescribed by WHO reports. Findings—The investigation results validate the performance evaluation of the presented smart face-mask and thermal scanning mechanism. The presented system can also detect an outsider entering the building with or without mask condition and be aware of the security control room by raising appropriate alarms. Furthermore, the presented smart epidemic tunnel is embedded with an intelligent algorithm that can perform real-time thermal scanning of an individual and store essential information in a cloud platform, such as Google firebase. Thus, the proposed system favors society by saving time and helps in lowering the spread of coronavirus.

1. INTRODUCTION

The COVID-19 outbreak has given sleepless nights to the entire world for the last 6 months. In recent times, an economy-driven country such as India has recorded more than 1,500,000 cases (1). Considering these facts, researchers are putting enormous efforts into developing innovative solutions to deal with the current pandemic. Furthermore, according to WHO reports, the

WHO has put enormous efforts into assisting various developed and developing countries in terms of masks, ventilators, hospital beds, face shields, and other essential health equipments (2). Furthermore, the WHO has also prepared strict guidelines for lock-downs, social-distancing, and testing of COVID-19 suspects. In developing countries, such as India, along with the physical efforts of doctors, nurses, and the paramedical staff, the government has utilized digital technologies in a variety of ways, such as "Aarogya–Setu app," which can assist citizens in identifying near-by COVID-19 patients using Bluetooth and GPS based remote tracking technologies. However, looking at the impact and the spread of coronavirus, fellow researchers need to put more effort into designing and developing COVID-19 solutions (3–7). It is a fact that fellow researchers have proposed various innovative approaches to deal with the current precarious situation, including automatic sanitizer systems for the disinfection of medical equipment and individuals, thermal scanning guns, and many more. However, the development of COVID-19 assistive systems has remained an open issue for fellow researchers (8–10). In addition to this, various state governments have formulated strict health prevention policies and have made genuine efforts to disinfect various geographical regions using various sanitizers, such as disinfectants and insecticides. The government has also executed numerous health-awareness campaigns for the well-being of society. In some cases, the government has also penalized mischievous individuals who have attempted to break the health and safety procedures. It has also been recorded that the police have to patrol in the surrounding areas to ensure strict adherence to health and safety precautions, such as wearing a mask, maintaining social distancing etc. However, it is also observed and predicted by the world's health experts that society will not have access to coronavirus vaccination in the near future. So the fellow researchers need to keep on developing efficient and effective solutions to avoid unwanted circumstances (11). For this purpose, we have carried out a detailed and rigorous analysis of the existing methodologies and identified certain research gaps. It is also imperative that if the situation continues to persist for a longer time, we have to learn to live with the given problems by keeping ourselves and sound at the workplace. To resolve the discussed issues, in the undertaken study, we have presented a deep learning and sensor-fusion-based approach for detecting a face mask and real-time body temperature for COVID-19, which is term as "Smart Facemask and Thermal scanning kiosk" throughout this paper. The presented deep learning and sensor-fusion-based approach is designed to detect an individual with or without mask conditions and notify security personnel by raising the alarm. Moreover, the smart tunnel is also equipped with a thermal sensing unit embedded with a camera, which can detect the real-time body temperature of an individual concerning the prescribed body temperature limits as prescribed by WHO reports. The presented article is organized as follows: Section 2 discusses the state of the art methodologies. Section 3 discusses the necessity of the presented system, section 4 and 5 discusses the design and experimental setup, architecture design, sensing arrangements, deployments, and the detailed workflow of the presented system. Finally, section 6 provides the concluding remarks.

2. RELATED WORK

Yang and his team have proposed an object detection auto-masking neural network for capturing discriminative objects. In this study, a variety of simulation-based study has been carried out. The proposed system is not tested in a real-time environment (12). Joshi R. has presented a health kiosk model using Computational Fluid Dynamics (CFD) simulation-based studies. However, the presented approach has been tested under the simulation environment only (13). Fan and his fellow researchers have proposed an auto-lung segmentation system to detect CT-scans of coronavirus patients. However, the proposed system did not facilitate the scanning of face-masks and the body temperature of humans (14). Maurya and his team have presented an innovative method for disinfecting humans. However, the proposed system did not facilitate any kind of face-mask and body temperature scanning (15). Ghayvat and his team have presented a system to keep the track of social-distancing policies between two persons. For this purpose, the proposed system has used smart cities, such as ITS infrastructures. However, the proposed system did not discuss any kind of scanning approach for the human body and face-masks (2). Abbas and his fellow mates have presented a chest X-ray scanning system of COVID-19 suspects. However, the presented system is not capable to do thermal scanning of a human body or identifying obscured faces (16). Apostolopoulos and Mpesiana have presented a chest X-ray scanning system of COVID-19 suspects. However, the presented systems were not capable to do thermal scanning of a human body or identifying obscured faces (17). Poon and his research team have proposed a system that is capable to carry out obstetric and gynecological scans. The main purpose of the presented system was to do scanning of medical equipment (18). Kim and Lee have presented a respiratory illness scanning system to detect diseases, such as COPD. However, the proposed system did not facilitate thermal scanning and the detection of obscured faces (19). Ucar and fellow researchers have presented an AI-based CT-scan scanning system to detect coronavirus symptoms. However, the presented system did not discuss anything like detecting body temperature or face-masks (20). Kwon and fellow researchers have presented a human scanning system to detect COVID-19 like symptoms for a drive-through. However, the presented system did not discuss anything like detecting body temperature or face-masks (21). Majid et al. (22) researchers have presented a sensor-fusion based wearable device that can scan and disinfect human hands from coronavirus infections (22). Takagi and Yagishita have presented a detailed comparison and discussion of various health and safety policies related to COVID-19 issues. However, the system did not propose any system for COVID-19 like diseases (23). Farman and team have presented a geofencing based real-time tracking system for COVID-19 patients. However, the presented system did not discuss any scanning mechanisms for the current pandemic situations. However, the system was not

designed for the disinfection of healthy patients (24). Lippi and fellow researchers have analyzed and discussed numerous bio-safety policies and precautions. However, the presented system did not discuss any scanning approaches for humans (25). Mahammedi et al. (26) have presented a novel solar power-based system to disinfect things such as mobile, key, wallet, and many more. However, the system did not possess the capability to perform any kind of scanning. Pandya et al. (27) have presented a novel face-detection system that can detect a human with fully or partially covered faces. However, the system did not possess the capability to detect face-masks. Ghayvat et al. (28) have presented a sensor-fusion based smart aging system to monitor the elderly well beings. However, the system did not facilitate the scanning of faces and body temperature of a human.

3. NECESSITY OF A SMART FACE MASK AND THERMAL SCANNING KIOSK

Recent fellow researchers have made efforts to implement a cost-effective pandemic tunnel to disinfect humans from COVID-19 like infections. In this study, an IoT based sensor fusion assistive tunnel has been presented, which can disinfect an individual from the possibility of coronavirus infections. The major contributions of the presented system are as follows: a deep learning and IoT based sensor fusion assistive framework has been proposed to do real-time detection of individuals with face-mask and without face-mask conditions. In the presented research work, a solar-powered smart tunnel has been presented, installed and deployed at the entrance of the Symbiosis institute of technology, Pune. The contributions of the proposed work are as follows:

1. The presented system can also detect an outsider who is entering the building with or without mask conditions using You Only Look Once 4 (YOLOv4) computer vision algorithm (29) and notifies the security control room by raising appropriate alarms.
2. The presented smart face-mask detection and thermal scanning kiosk can function using solar energy during the day, and it functions using a solar power bank at night time. This functionality has been provided by light-dependent resistor (LDR) sensing unit placed in a tunnel.
3. The smart tunnel also provides the facility to do real-time attendance of all the staff entering the smart tunnel, along with thermal scanning and face-mask detection.
4. In the end, web and mobile interface has been designed to provide daily, weekly and monthly reports of the recorded body temperatures of individuals, along with in-out timestamp values. The investigation results validate the performance evaluation of the presented smart face-mask and thermal scanning kiosk. The presented smart tunnel is embedded with an intelligent algorithm that can perform real-time thermal scanning of an individual and stores the essential information in a cloud platform, such as google firebase.

4. DESIGN AND EXPERIMENTAL SETUP

In the experimental setup, each sensor is placed in different positions in the house, with a single ESP8266 attached to it, where the basic data processing takes place. ESP8266 comes with a Wi-Fi module attached to it, using which the processed data is then transferred logged into the Raspberry Pi B+ server. To avoid data duplication of erroneous data, pre-processing of sensor data is done at the ESP8266 level, thus ensuring

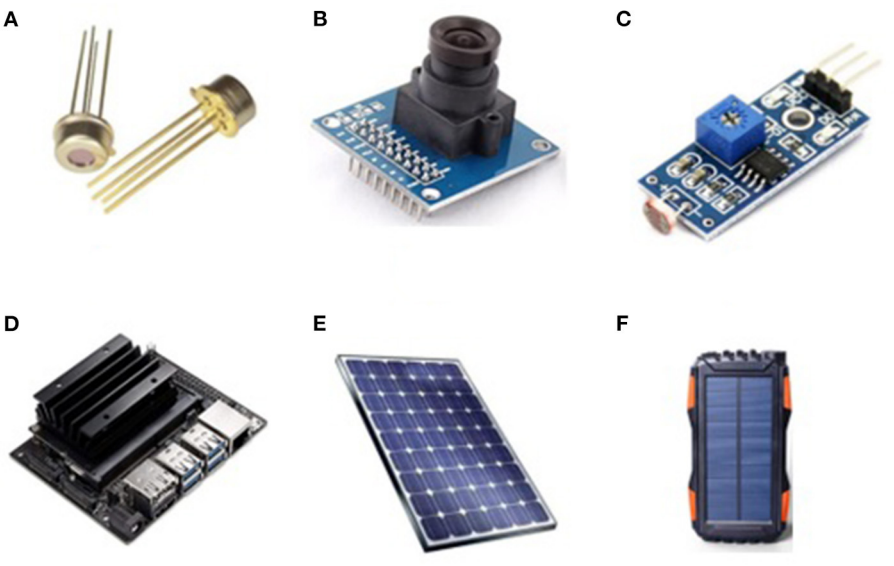

FIGURE 1 | Design and experimental setup of a smart epidemic tunnel **(A)** thermopile temperature sensor a Robocraze OV7670 **(B)** 300KP VGA Camera **(C)** an LDR sensing unit **(D)** a NVIDIA Jetson Nano **(E)** a solar cell **(F)** a solar power bank.

that Raspberry pi is only used as the local server where clean data is stored in the whole setup. Logged Data is periodically sent to the Cloud storage to ensure backup of data is kept in case of any system failure, along with the logs of whole systems working, which can also be later on utilized for systems debugging. The presented smart tunnel is an extended version of the smart epidemic tunnel, which had facilitated the ultrasonic sensor-based sanitizer system and timestamp-based notifications. In the presented research work, we have proposed a customized smart face-mask and thermal scanning kiosk equipped in a previously presented smart epidemic tunnel. The presented system is flexible enough to be placed outside public spots such as malls, university buildings, companies, bus-stop, hospital ICU units, vegetable markets, railway stations, and many more. **Figures 1A–F** represent a design and experimental setup used in the conducted experiments such as a Thermopylae sensor, a VGA camera, LDR sensing unit, Netson NVIDIA controller, a solar cell, and a solar power bank. **Figure 2** represents a prototype design of the presented smart face mask and thermal scanning kiosk equipped in a smart epidemic tunnel.

5. METHODOLOGY

Fellow researchers have made efforts to implement a cost-effective pandemic tunnel to disinfect humans from COVID-19 like infections. In this study, an IoT based sensor fusion assistive tunnel has been presented, which can disinfect an individual from the possibility of coronavirus infections. The major contributions of the presented PWP system are as follows: (i) a deep learning and IoT based sensor fusion assistive framework have been proposed to do real-time detection of individuals with face-mask and without face-mask conditions. In the presented research work, a solar-powered smart tunnel has been presented, installed, and deployed at the entrance of the Symbiosis institute of technology, Pune. (i) The presented system can also detect an outsider who is entering the building with or without mask conditions using YOLOv4 computer vision algorithm and notifies the security control room by raising appropriate alarms. (ii) The presented smart face-mask detection and thermal scanning kiosk can function using solar energy during the day, and it functions using a solar power bank at night. This functionality has been provided by an (LDR) sensing unit

placed in a tunnel. (iii) The smart tunnel also provides the facility to do real-time attendance of all the staff entering the smart tunnel, along with thermal scanning and face-mask detection. (iv) In the end, web and mobile interface has been designed to provide daily, weekly, and monthly reports of the recorded body temperatures of individuals, along with in-out timestamp values. The investigation results validate the performance evaluation of the presented smart face-mask and thermal scanning kiosk. The presented smart tunnel is embedded with an intelligent algorithm that can perform real-time thermal scanning of an individual and stored the essential information in a cloud platform, such as google firebase. In the pandemic situation, a smart face-mask and thermal scanning kiosk have been presented, equipped in a smart epidemic tunnel. The presented research work is an extended version of the smart epidemic tunnel. In the presented research work, we have added certain novel features to enhance the presented system's performance. The presented deep learning and sensor-fusion based assistive technology (Smart Facemask and Thermal scanning kiosk) will protect the individual using auto face-mask detection and auto thermal scanning to detect the current body temperature. The presented smart tunnel is embedded with an intelligent algorithm that can perform real-time thermal scanning of an individual and stored the essential information in a cloud platform, such as google firebase. Furthermore, in the conducted experiments, the YOLOv4 computer vision algorithm has been applied to detect individuals with face-mask and without faced-mask conditions. Furthermore, the presented system also facilitates a variety of notifications such as an alarm if an individual is not wearing a mask and detects thermal temperature beyond the standard body temperature threshold such as 98.6°F (37°C). Furthermore, a solar power bank is also used for storing solar energy, which the proposed system will utilize at night. In the end, the investigation results validate the performance evaluation of the presented smart face-mask and thermal scanning kiosk.

5.1. The Layered Design of a Smart Face-Mask and Thermal Scanning Kiosk

Figure 3 represents an architectural design of the presented novel deep Learning and sensor-fusion-based approach for detecting

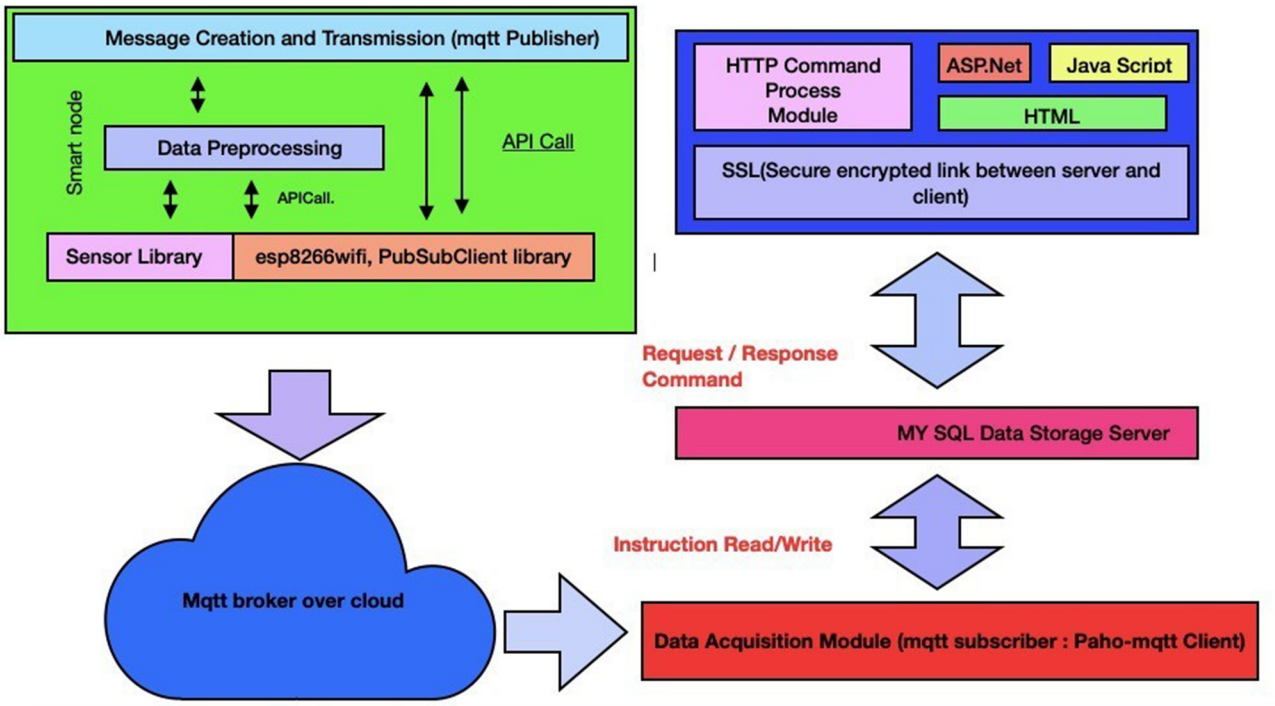

FIGURE 4 | A back-end design of a smart face-mask thermal scanning system.

a face mask and real-time body temperature for COVID-19 outbreak situations. The extended version of the presented has been placed at the Symbiosis Institute of Technology, Pune, which has been implemented for performing auto-face mask detection and thermal scanning of various Symbiosis stakeholders such as faculty members, students, and external visitors. The presented architectural design contains five layers: (i) physical (sensing) layer, (ii) communication and networking layer, (iii) cloud computing (google firebase storage) layer, (iv) data processing layer, and (v) application layer. The main purpose of the physical sensing layer is to detect the body temperature of individuals who are present in the projection areas of a VGA camera equipped in the presented thermal scanning kiosk. This sensing layer contains various sensing units such as the LDR sensing unit and a thermopile temperature sensor. Furthermore, this layer also contains an intelligent NVIDIA Netson controller, along with a solar cell and a solar power bank. A YOLOv4 computer vision algorithm has been installed in an NVIDIA Netson controller to detect humans with face masks and without face-mask conditions. In addition to this, this layer also facilitates a solar power backup using a solar cell during the day-time and a solar power bank during the night time. Again, in the day-time, the presented smart face-mask and thermal scanning kiosk start functioning using a solar cell.

5.1.1. Sensing Layer

The main purpose of the physical sensing layer is to detect the body temperature of individuals present in the projection areas of a VGA camera equipped in the presented thermal scanning kiosk. This sensing layer contains various sensing units, such as the LDR sensing unit and a thermopile temperature sensor. Furthermore, this layer also contains an intelligent NVIDIA Netson controller, along with a solar cell and a solar power bank. A YOLOv4 computer vision algorithm has been installed in an NVIDIA Netson controller to detect humans with face masks and without face-mask conditions. In addition to this, this layer also facilitates a solar power backup using a solar cell during daytime and a solar power bank during nighttime. Again, in the daytime, the presented smart face-mask and thermal scanning kiosk start functioning using a solar cell.

5.1.2. Communication and Networking Layer

The networking and communication layer is responsible for interfacing and transmitting information between a physical(sensing) layer, cloud services layer, and an application layer using a broker architecture of an MQTT protocol. Furthermore, it transmits scanned body temperature values, timestamps, and the count of people wearing or not wearing a face mask on a google firebase platform. **Figure 4** represents a back-end design of a smart epidemic tunnel.

5.1.3. Communication and Networking Layer

The networking and communication layer is responsible for interfacing and transmitting information between a physical(sensing) layer, cloud services layer, and an application layer using a broker architecture of an MQTT protocol.

Furthermore, it transmits scanned body temperature values, timestamps, and the count of people wearing or not wearing a face mask on a google firebase platform. **Figure 4** represents a back-end design of a smart epidemic tunnel.

5.1.4. Cloud Computing (Google Firebase) Layer

The cloud computing layer facilitates the storage of the temperature values of individuals scanned using a thermal sensing unit with timestamp values and the count of people with face-mask and without face-mask variations. Furthermore, it keeps track of various individuals who have accessed the smart face-mask and thermal scanning kiosk during the day or night timings. In the conducted experiments, the Google Firebase cloud computing platform has been used for storage purposes.

5.1.5. Processing Layer

The processing layer fetches the temperature and face-mask related values from the Google Firebase database *via* MQTT broker architecture. This layer performs two essential operations: (i) the processing layer detects the body temperature of individuals using a thermal sensor placed in a smart thermal scanning kiosk (ii) it also facilitates two essential bifurcation of the people who are wearing or not wearing face-masks using a YOLOv4 computer vision algorithm deployed in an NVIDIA Netson controller. Eventually, the processed information will be passed on to the application layer for generating various reports.

5.1.6. Application Layer

The application layer received organized information from the processing layer and represented it in various graphical and tabular representations. Furthermore, the application layer also consists of the web and mobile interface, which provides daily, weekly, and monthly updates such as timestamp-based temperature detection reports, the count of people wearing or not wearing face-masks, and the number of individuals who have access to the presented face-mask and thermal scanning kiosk during the day and night timings.

6. THE DETAIL WORKING OF THE FACE-MASK AND THERMAL SCANNING KIOSK

As shown in **Figure 5**, the presented smart system performs two key operations during this phase: (i) it also facilitates the bifurcation of the people based on a variety of face mask conditions such as with and without face mask conditions using a YOLOv4 computer vision algorithm deployed in an NVIDIA Netson controller. (ii) The presented smart system can detect the body temperature of individuals present in the projection areas of a Robocraze OV7670 300KP VGA camera using a thermopile temperature sensing unit.

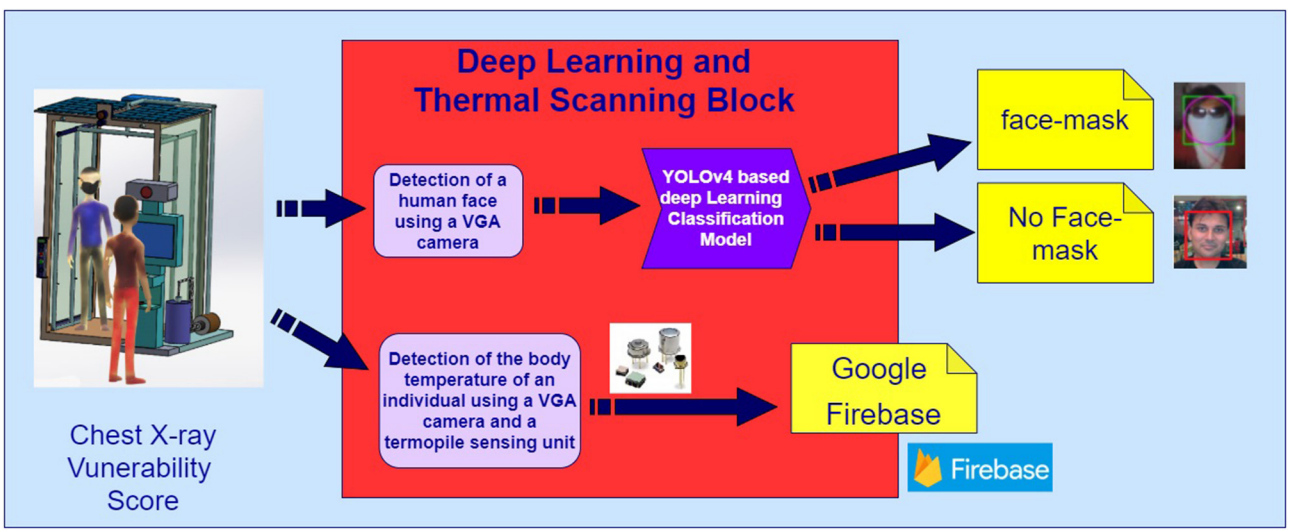

FIGURE 5 | A topology design of a smart facemask and thermal scanning system.

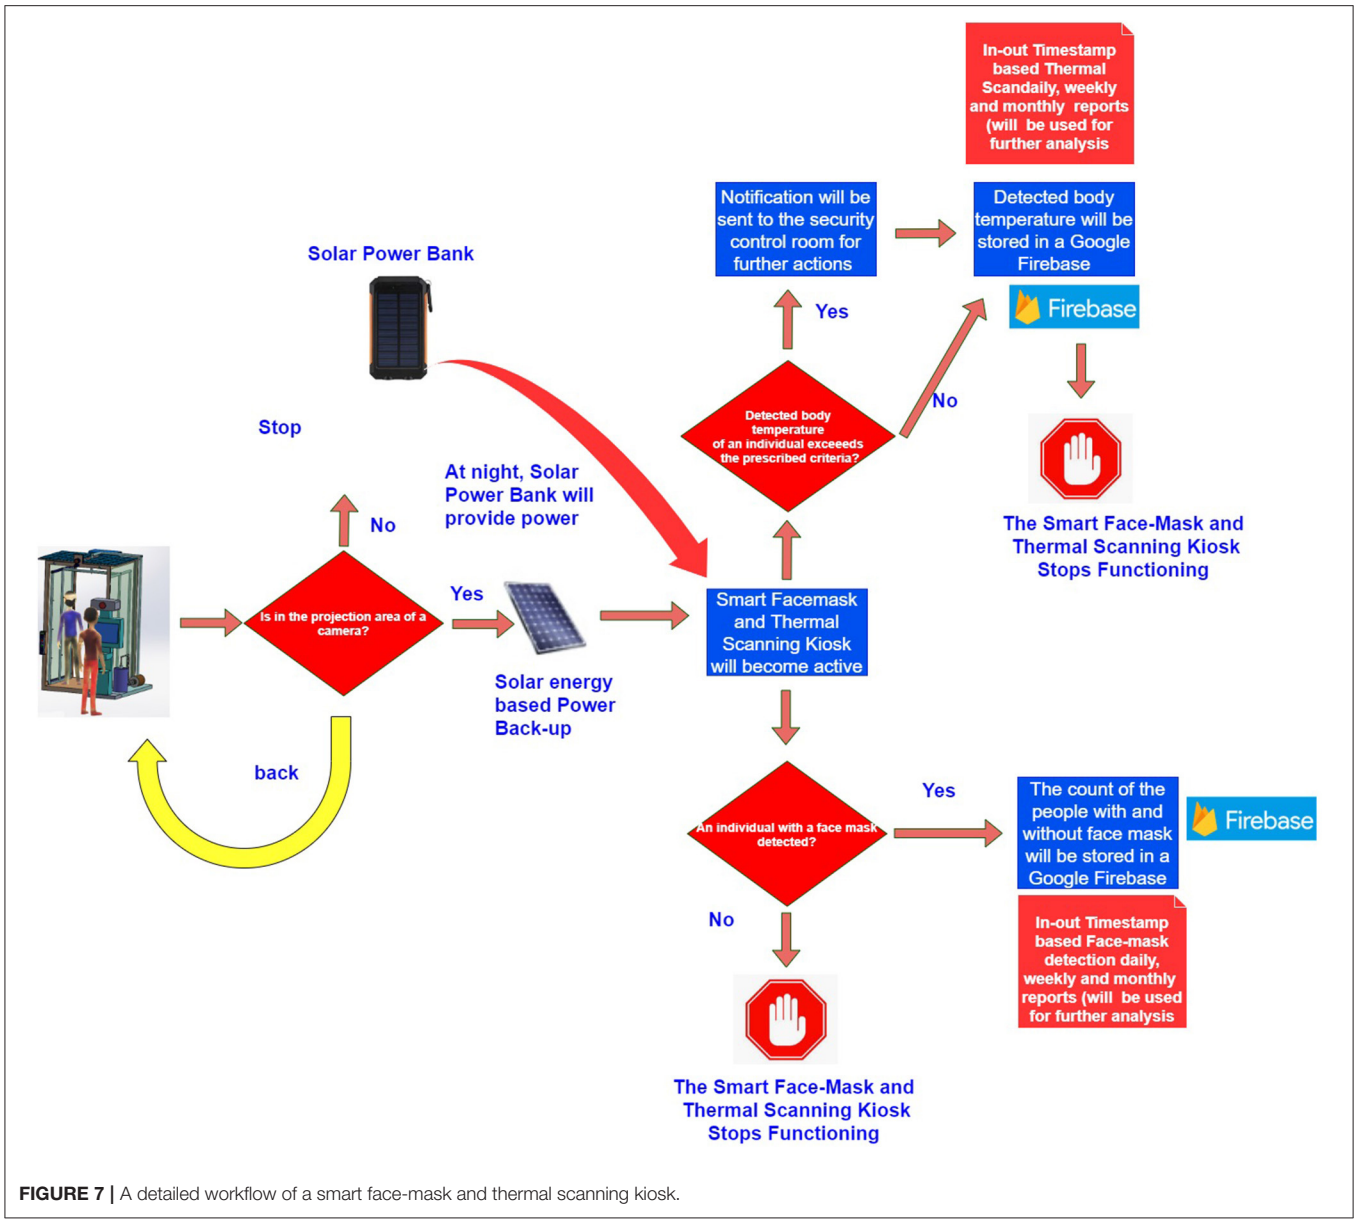

FIGURE 7 | A detailed workflow of a smart face-mask and thermal scanning kiosk.

6.1. The Detailed Working of the Face-Mask Detection Methodology

The face-mask detection feature becomes active when an individual comes into the projection area of a VGA camera, as shown in **Figure 6**. In the conducted experiments, we have used a customized dataset of 1,000 face samples. After an individual is detected by a VGA camera placed in a smart kiosk, a YOLOv4 computer vision algorithm deployed in an NVIDIA Netson controller process the captured frame; during this phase, a YOLOv4 algorithm makes the use of cross-stage partial connection and separates the feature maps in two different parts: (i) the first part of the feature map bypasses the dense block and directly moves toward the transition block. (ii) The second part went through the dense block and reached the transition block. This kind of design increases the efficiency of the YOLOv4 algorithm by reducing the complexity of the presented approach. In addition to this, the YOLOV4 algorithm also utilizes cross-stage-partial connections with CSPDarknet-53 feature extraction methodology, which enables the presented algorithm to achieve very high objection detection accuracy. **Figure 7** represents a YOLOv4 methodology, and **Figure 8** represents a detailed workflow of the presented smart face-detection and thermal scanning kiosk. As shown in **Figure 8**, after an individual is detected by a VGA camera placed in a smart kiosk using a YOLOv4 computer vision algorithm, it will process the captured frame of an individual to identify whether the captured individual is wearing a face-mask to protect against COVID-19 or not. Then, the algorithm will transmit the processed information to

the Google Firebase and generate various timestamp-based daily, weekly, and monthly reports in both scenarios.

6.2. The Detailed Working of the Thermal-Scanning Methodology

The thermal scanning feature of a presented smart kiosk starts functioning when an individual is detected in the projection area of a VGA camera. Once an individual is detected, the presented system will scan their body temperature using a thermal sensor and compare it with the standard body temperature threshold such as 98.6°F (37°C). If the presented kiosk records body temperature of an individual beyond the prescribed limits, it will immediately notify the security control room for further action. Otherwise, timestamp-based records of scanned body temperatures will be stored in Google Firebase for further analysis in both scenarios. The YOLOV4 methodology is divided into two parts: (i) the first part bypasses the dense block and directly moves toward the transition block. (ii) The second part goes through the dense block and reaches the transition block. This kind of design increases the efficiency of the YOLOv4 algorithm by reducing the complexity of the presented approach. In addition to this, the YOLOV4 algorithm also utilizes cross-stage-partial connections with CSPDarknet-53 feature extraction methodology, which enables the presented algorithm to achieve very high objection detection accuracy. **Figure 7** represents a YOLOv4 methodology, and **Figure 8** represents a detailed workflow of the presented smart face-detection and thermal scanning kiosk.

7. RESULTS AND DISCUSSIONS

In this section, a detailed discussion of the obtained results of the presented smart face-mask and thermal scanning kiosk for two different approaches (i) the YOLOv4 based face-mask detection methodology (ii) thermopile temperature sensor VGA camera-based body temperature detection methodology.

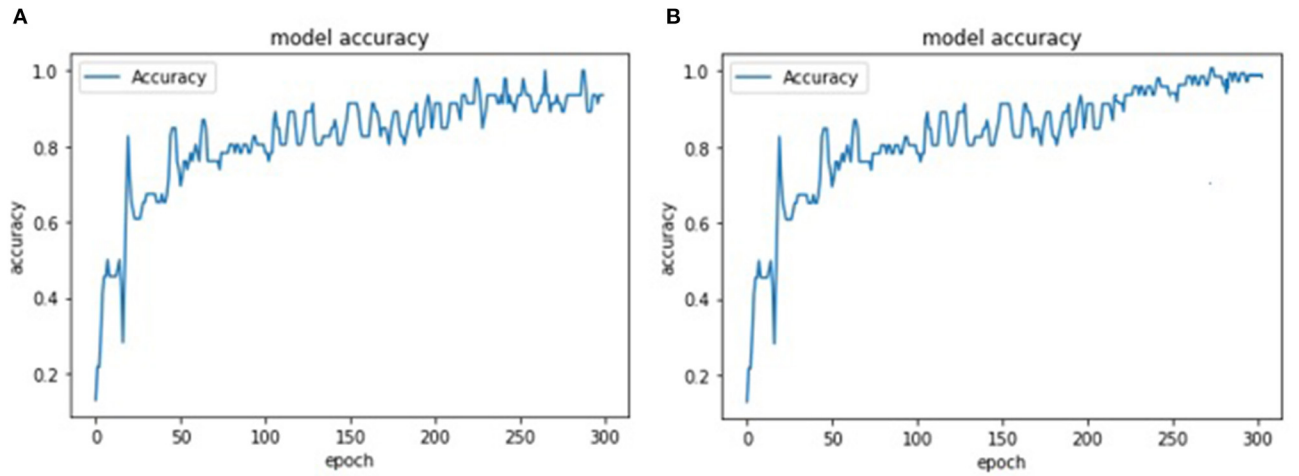

FIGURE 9 | A comparison of a YOLOv4 training and testing accuracy metrics **(A)** training accuracy **(B)** testing accuracy.

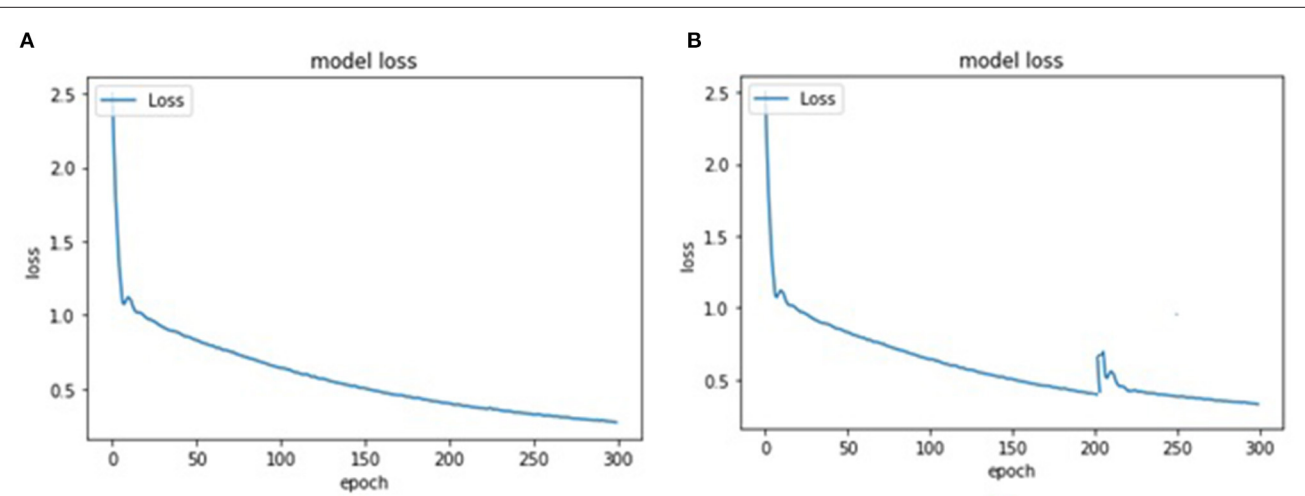

FIGURE 10 | A comparison of a YOLOv4 training and testing accuracy metrics **(A)** training loss **(B)** testing loss.

7.1. Results Discussion of the YOLOv4 Based Face-Mask Detection Methodology

Figure 9 represents training and testing snapshots of the presented YOLOv4 deep learning methodology. A customized dataset of 1,000 face images was used in the conducted experiments and trained using the YOLOv4 methodology. As described in section 5.2.1, in the conducted experiments, we have used CSPDarknet-53 feature extraction methodology along with the presented YOLOv4 deep learning approach. As shown in **Figure 9**, we have modified the presented YOLOv4 algorithm to achieve high accuracy in detecting individuals with and without face-mask conditions. Based on the conducted experiments, the presented YOLOV4 methodology has recorded face-mask detection training and testing accuracy of 97.17 and 96.12%, as shown in **Figure 10**. As shown in **Figure 11**, based on the conducted experiments, the presented YOLOv4 deep learning algorithm has recorded very minimal training and testing loss, around 1.83 and 2.88%, respectively. **Figure 12** depicts face-mask detection samples detected using the YOLOv4 algorithm.

7.2. Results Discussion of the Thermal Scanning Based Body Temperature Detection Methodology

In the conducted experiments, we have performed real-time testing of more than 800 individuals to validate the performance of the presented body temperature detection methodology. The presented methodology has utilized a Robocraze OV7670 300KP VGA camera and thermopile temperature sensor to identify individuals exceeding the prescribed standard threshold such as 98.6°F (37°C). **Figure 13** represents the real-time thermal scanning results of more than 800 individuals concerning the recorded body temperature. Furthermore, it also depicts the

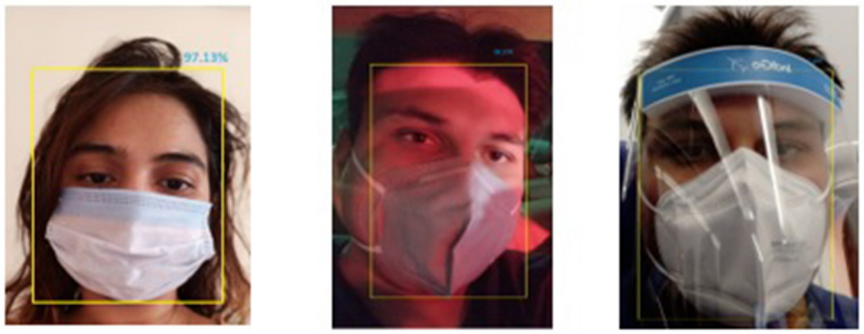

FIGURE 11 | A testing sample of YOLOv4 face-mask detection.

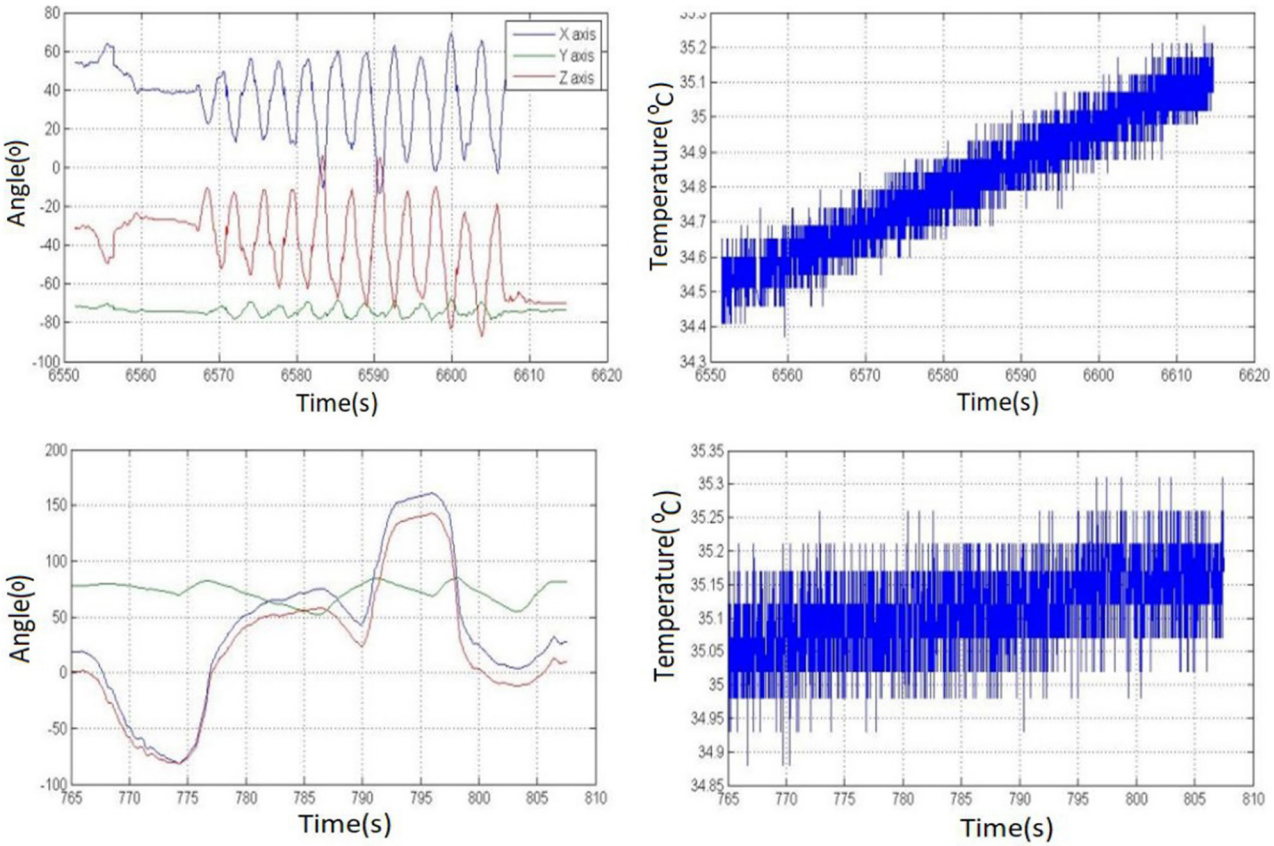

FIGURE 12 | Real-time thermal scanning results of more than 800 individuals.

graphical representation of the number of individuals who a VGA camera has captured from various angles. The presented thermal scanning mechanism has recorded a validation accuracy of 92.01% thermal scanning kiosk. Furthermore, the presented interfaces present the daily, weekly, and monthly reports of the counts of individuals, along with in-out timestamps fetched from the google firebase cloud computing platform. Furthermore, it also keeps track of the consumed power and also provides information on power usage reports.

7.3. The Web and Mobile Interface of a Smart Face-Mask and Thermal Scanning Kiosk

Figure 13 represents a GUI-based web and mobile interface design of the presented smart face-mask and thermal scanning kiosk. The presented interfaces present the daily, weekly, and monthly reports of the counts of individuals, along with in-out timestamps fetched from the google firebase cloud computing

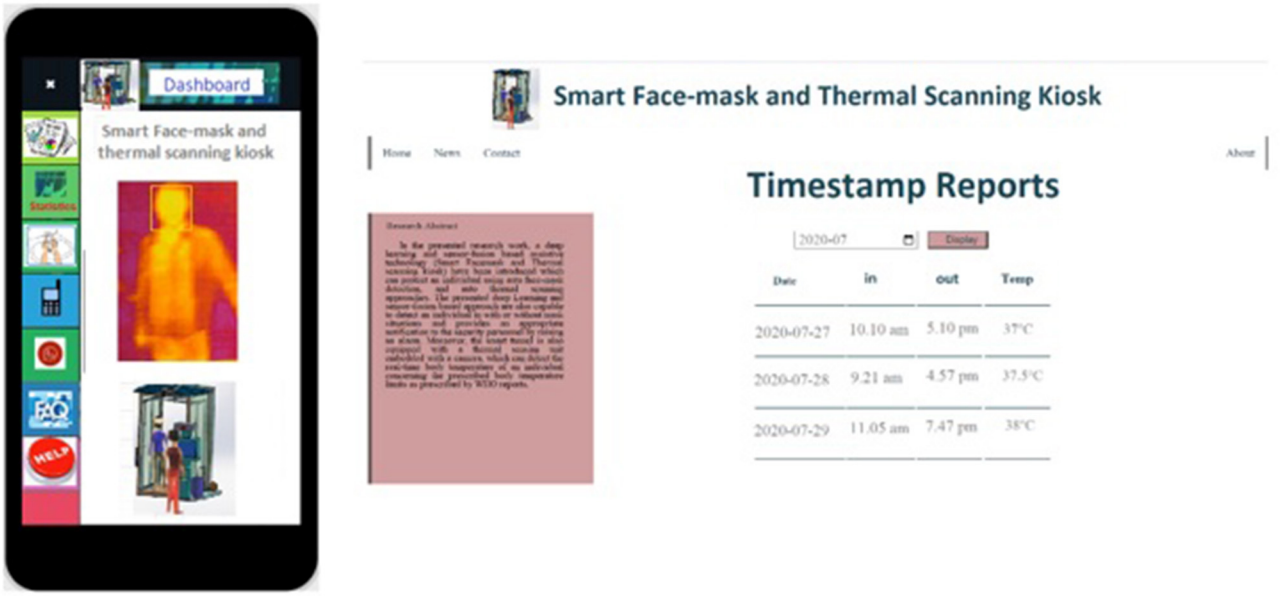

FIGURE 13 | The web and mobile interface of a smart face-mask and thermal scanning kiosk.

platform. Furthermore, it also keeps track of the consumed power and also provides information on power usage reports.

8. CONCLUSION AND FUTURE ENHANCEMENTS

This study presents a deep learning and sensor-fusion-based assistive technology (Smart Facemask and Thermal scanning kiosk) to detect individuals with and without mask conditions. The presented research work is an extended version of the smart epidemic tunnel presented previously. In the undertaken study, the presented smart face-mask and thermal scanning kiosk have facilitated two essential tasks (i) the bifurcation of the people based on a variety of face mask conditions such as with and without face mask conditions using a YOLOv4 computer vision algorithm deployed in an NVIDIA Netson controller. In addition, (ii) it can also detect the body temperature of individuals present in the projection areas of a Robocraze OV7670 300KP VGA camera using a Thermopylae temperature sensing unit. The investigation results validate the performance evaluation of the presented smart face-mask and thermal scanning mechanism. The major findings of this study are as follows: (i) The presented system can detect an outsider who is entering the building with or without mask conditions and notifies the security control room by raising appropriate alarms. (ii) The presented smart face-mask detection and thermal scanning kiosk can function using solar energy during the day, and it functions using a solar power bank at night. This functionality has been provided by an LDR sensing unit placed in a tunnel. (iii) The presented smart kiosk also provides the facility to do real-time timestamp-based attendance of all the staff entering the smart tunnel, along with thermal scanning of the body temperature and face-mask detection. Based on the experiments, the presented YOLOV4 methodology recorded face-mask detection training and testing accuracy of 97.17 and 96.12%. Furthermore, the presented thermal scanning mechanism has recorded a validation accuracy of 92.01%. (iv) In the end, web and mobile interface has been designed to provide daily, weekly, and monthly reports of the recorded body temperatures of individuals, along with in-out timestamp values. In the future, the proposed research work can be extended with various scenarios, such as obscured faces, half, or fully obscured human faces with plastic, leather, or any other materials.

Upadhyaya AM, Hasan MK, Abdel-Khalek S, Hassan R, Srivastava MC, Sharan P, Islam S, Saad AME and Vo N (2021) A Comprehensive Review on the Optical Micro-Electromechanical Sensors for the Biomedical Application. Front. Public Health 9:759032. doi: 10.3389/fpubh.2021.759032

This study presented an overview of current developments in optical micro-electromechanical systems in biomedical applications. Optical micro-electromechanical system (MEMS) is a particular class of MEMS technology. It combines micro-optics, mechanical elements, and electronics, called the micro-opto electromechanical system (MOEMS). Optical MEMS comprises sensing and influencing optical signals on micron-level by incorporating mechanical, electrical, and optical systems. Optical MEMS devices are widely used in inertial navigation, accelerometers, gyroscope application, and many industrial and biomedical applications. Due to its miniaturised size, insensitivity to electromagnetic interference, affordability, and lightweight characteristic, it can be easily integrated into the human body with a suitable design. This study presented a comprehensive review of 140 research articles published on photonic MEMS in biomedical applications that used the qualitative method to find the recent advancement, challenges, and issues. The paper also identified the critical success factors applied to design the optimum photonic MEMS devices in biomedical applications. With the systematic literature review approach, the results showed that the key design factors could significantly impact design, application, and future scope of work. The literature of this paper suggested that due to the flexibility, accuracy, design factors efficiency of the Fibre Bragg Grating (FBG) sensors, the demand has been increasing for various photonic devices. Except for FBG sensing devices, other sensing systems such as optical ring resonator, Mach-Zehnder interferometer (MZI), and photonic crystals are used, which still show experimental stages in the application of biosensing. Due to the requirement of sophisticated fabrication facilities and integrated systems, it is a tough choice to consider the other photonic system. Miniaturisation of complete FBG device for biomedical applications is the future scope of work.

Even though there is a lot of experimental work considered with an FBG sensing system, commercialisation of the final FBG device for a specific application has not been seen noticeable progress in the past.

Keywords: optical MEMS (optical micro electro mechanical system), microcantilever, fibre bragg grating, pressure sensor, intraocular pressure, blood pressure, urodynamic, orthodontic

INTRODUCTION

Micro-opto electromechanical system or optical micro-electromechanical system combines optical components with micro electromechanical system technology. The micro-level mechanical elements with micro-level motion manipulate the optical signals by actuation provided by electronic structures in a system called micro-opto electromechanical system (MOEMS). Many people are working on optical micro-electromechanical system (MEMS) technology to develop sensitive sensors. Electronic devices size varies from millimetre, micrometre, to nanometre, but mechanical element size ranges from four to five times the electronic devices. This requires sophisticated fabrication technology for optical MEMS. To fabricate the optical MEMS sensor, the technology involved are bulk micromachining, deep x-ray lithography, and surface micromachining. Microfabrication consists of, the process of generating micro ma-chines. Functionality testing of optical and electronic structures is the first phase of MOEMS device fabrication. In this context, the development and analysis of a mechanical element is the second phase of MOEMS device advancement. The third phase involves material deposition, etching, and pattern. The optical design process consists of choosing suitable geometry and assessing optical. Electromechanical design involves various mechanical factors such as stiffness, material parameter, electrostatic, and thermal. MOEMS device design depends on different parameters. Different factors that need to be considered during the design of optical MEMS are mechanical, electrical, thermal, ecological, biological, optical, and chemical aspects based on different applications. The shape and dimension considered during the design of optical MEMS play a significant role in the proper working of optical MEMS devices. Stress distribution due to different geometrical aspects and optimization is a factor that influences the MOEMS design. **Figure 1A** shows the MOEMS overview chart (1).

Strength, stiffness, hardness, wear resistance, abrasion, creep, and fatigue resistance of the material used during the design are parameters evident in the sound optical MEMS system. The refractive index, an optical property, is the governing factor of any MOEMS device. In the optical design, we know that if the refractive index changes directly affect the performance of any optical MEMS structures, then the particular assignment of refractive index is a must before analysis. The optical MEMS sensor consists of two main parts: (1) the micro sensing element and transduction unit, which powers the supply unit with optical media, and (2) the micro sensing element, which senses the input signals and converts them into output in the required form of the transduction unit. Different types of optical MEMS sensors that are possible in a real scenario are displacement, temperature, bio-sensor, chemical, optical, and pressure sensors. The optical MEMS system can also act as a microactuator by actuating micro actuating elements (2). **Figure 1B** shows the different types of optical MEMS systems.

This analysis aimed to research the literature on photonic MEMS in biomedical systems. We investigated different studies providing different backgrounds and their relationships. The following research questions (RQ) are specified. RQ1: "What are the major issues regarding using photonic MEMS?" RQ2: "What key success factors are applied to methods that influence performance enhancement?" RQ3: "What are the research gap and scope to design the optimum photonic MEMS devices in the biomedical application?"

MATERIALS AND METHODS

This research relied on a systematic review of the MOEMS and its application in the biomedical field. Parallel understanding of available research associated with optical MEMS, such as the basic principle of optical MEMS, different design configurations involved, and its future scope of improvements, were discussed. There are three key phases in this review paper. First, the principle of MOEMS and the different types of optical MEMS. Second, the specific application of optical MEMS. Third, the challenges towards optical MEMS with the current market trend and future scopes. Research papers associated with the basics of optical biosensors, integrated optical sensors, and optical MEMS for biomedical applications, and articles explaining the current status of optical MEMS sensors in the market were selected to help answer the research questions.

Different methods are employed in the design of optical MEMS. It involves modelling MOEMS as the sensor, modelling MOEMS as the actuator, modelling different substrates, beam propagation techniques, computational opto electro mechanics, and high fidelity modelling of the electromagnetic field.

High fidelity modelling of MEMS based on vertical cavity surface emitting method uses Laguerre Gaussian equation. This involves single, double, and multimode equations in consideration.

$$E(r,z) = E_o \frac{w_o}{w(z)} \frac{w_o}{w(z)} \exp\left(\frac{-r^2}{w^2(z)}\right) \frac{-r^2}{w^2(z)}$$
$$\exp\left(-ikz - ik\frac{r^2}{2R(z)}\frac{r^2}{2R(z)} + i\zeta(z)\right.$$

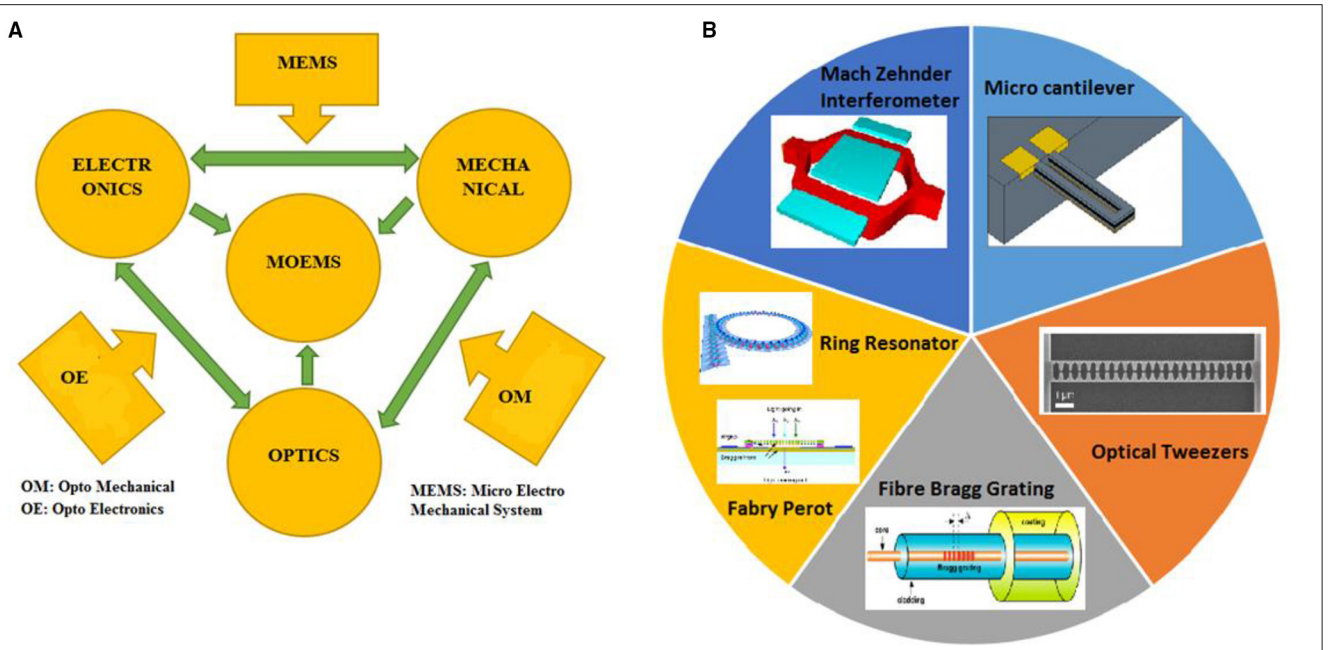

FIGURE 1 | (A) MOEMS overview chart, **(B)** different types of Optical MEMS.

Maxwell equations are used at the beginning of every optic problem.

$$\text{i.e., div D} = \rho, (2)\text{div B} = 0, (3)\text{curl E} = \frac{\mathbf{dD}}{\mathbf{dt}} + \mathbf{J}\frac{\mathbf{dD}}{\mathbf{dt}} + \mathbf{J}$$

where ρ is charge density, J is current density, E is the electric field, B is the magnetic field, and D and H are field quantities that are proportional to E and B, respectively. The last technique involved considering in the design and modelling of optical MEMS is the beam propagation technique. This technique uses Helmholtz time-dependent diffusion equation.

$$(-\nabla^2 - \frac{\omega^2}{\mathbf{v^2}}\frac{\omega^2}{\mathbf{v^2}})\, \text{q(x)}$$

Many optical MEMS devices incorporate different types of materials for sensing or actuating sensing layers. Different types of micro sensing or actuating elements are thermal forces, electrostatic forces, piezoelectric materials, and shape memory that alloys along with optical MEMS integration in a different environment. Photonic sensing layers silica, optical fibre made up of silicon, are the materials, considered in the optical sensing system. Germanium and gallium arsenide are also used in other conditions like thin films. Along with the other materials, the sensing system also consists of polymer materials. Photonic MEMS as actuator involves movable and fixed sensing elements, cold or hot arm in terms of thermomechanical actuation. **Figures 2A,B** show different sensing systems with MOEMS.

Major types of optical MEMS such as FBG sensor, optical microcantilever sensor, Mach-Zehnder interferometer (MZI),

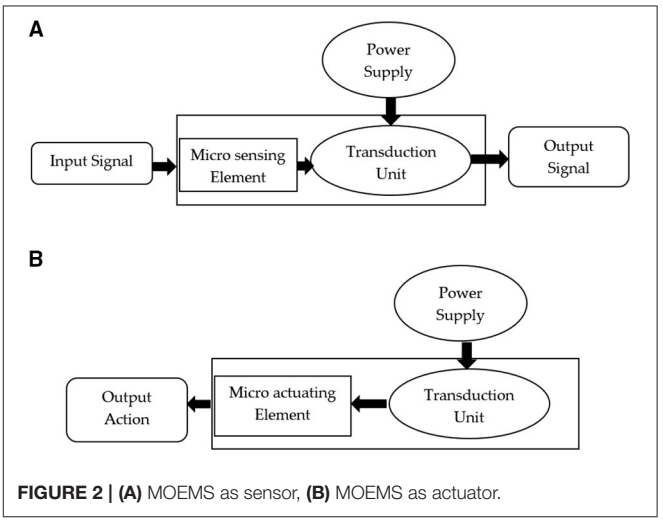

FIGURE 2 | (A) MOEMS as sensor, **(B)** MOEMS as actuator.

and photonic MEMS with microfluidic channels, as well as their applications, were discussed here. It was categorised based on its approach to integration with MEMS application and principle of operation, among others. Most of the works of literature in optical MEMS-based microcantilever sensors incorporated with photonic crystal sensing layer, ring resonator structures, and optical readout techniques were discussed. MZI is integrated with the photonic sensing layer or diaphragm for sensing the deflection in the sensing arm. The level of maturity of FBG techniques has reached to commercial stage since they are widely explored in different biomedical applications. Recent

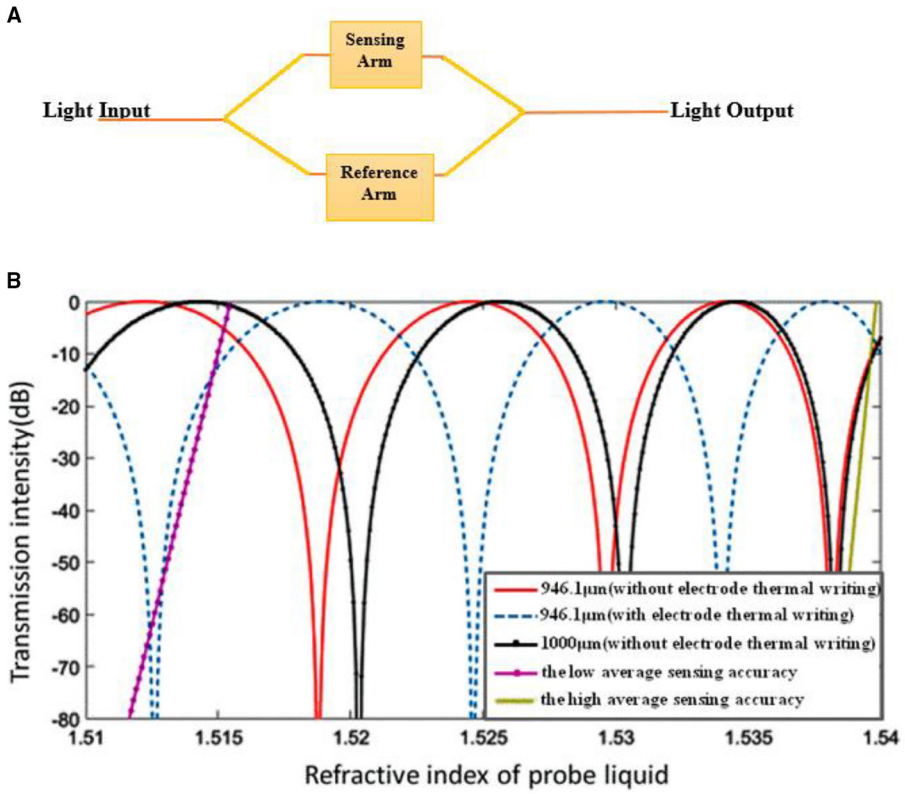

FIGURE 3 | (A) Mach-Zehnder Interferometer working process, **(B)** intensity of sensor with various length and refractive index of core (6).

advancements in photonic MEMS with microfluidic channels and its design and fabrication were also discussed in this study.

TYPE OF OPTICAL MEMS SENSORS WITH APPLICATION

There are various types of optical MEMS sensors. Depending on the application, different sensing mechanisms had been reported and presented in this manuscript. This section explained the basic principle of all possible optical sensing schemes used in optical MEMS.

Types of Optical MEMS Sensors

Optical MEMS Based Mach-Zehnder Interferometer

Photonic devices generally have extreme sensitivity to the environment and manufacturing, having wide applications. It is a device used to measure the change in phase shift between two beams. In this context, MZI with high sensitivity has three core fibres proposed by Ding et.al. The MZI is considered an optical MEMS sensor that was bringing properties such as elongation or shortening of the core made possible by applying force. Overall bending sensitivity of 15.35 and 3.11 nm/m was obtained (3). MZI is also used to propose the potential measurement of the trajectories of joint angle. Two core trapezoid cone structures have been used for the simultaneous measurement of pressure and temperature. Developed high sensitive MZI for this purpose was sensitive to laboratory seismic noise. A possible micromechanical structure with electro-optical function has been investigated with an In-P material with an integrated optical stress sensor to reduce the seismic noise (4). In another work, Jindal and Raghuwanshi discussed the photoelastic effect induced phase shift during the transmission of light in MZI. Due to maximum pressure at the centre of the diaphragm, the centre portion attached to the MZI gets deflected and brings out the shift in phase and intensity variations. Theoretical analysis of micromachined differential pressure sensor clamped with circular diaphragm and FBG sensor embedded in MZI has been analysed, wherein the sensitivity of this pressure sensor was about 0.2 pm/pa (5).

The Mach-Zehnder Interferometer shown in **Figure 3A** consists of a light input and output and a sensing and reference arm. Left Y-junction which have light input splits the light beam called as a beam splitter and right junction combines the light and called as beam combiner. Two straight waveguides between two Y-junctions locate the sensing arm at one end and the reference arm at the other ends. Output unit, the right end of Y-junction, gives the phase shift, i.e., $\Delta\Phi$. Polarised light from laser source passed to two arms of MZI, through input waveguide. Transmission of light through the sensing arm reacts with a biochemical molecule and the overall refractive index changes with the refractive index of the reference arm. Intensity modulation is obtained in the output due to variation in the

overall refractive index of a sample in the sensing arm relating to a reference arm with a normal refractive index of the medium. If $\Delta\Phi$ is the shift in phase, λ is a wavelength, and d is the length of the sensing arm, the effective refractive index is denoted by n_{eff} (7). Equations 1, 2 indicates that MZI sensor output intensity is equal to the oscillating function of interferometer phase change difference.

$$Iout = I_{sen} + I_{ref} + 2\sqrt{I_{sen}I_{ref}}(\Delta\varphi + \Delta\varphi 0) \quad (1)$$

where I_{sen} and I_{ref} are the intensity of light passing through the sensing arm and reference arm.

$$\Delta\Phi = 2\pi/\lambda.\Delta n_{eff}\text{sensing arm} \quad (2)$$

The sensitivity of the MZI is denoted by $\Delta O/\Delta n$, where ΔO is output power change and Δn changes in refractive index. The phase shift is obtained by Equation 2. In another work, PB Patel and co-authors evaluated a novel optical MZI (OMZI) with rib waveguides. The complete structure has been designed with a silicon rib waveguide. The rib width of the OMZI structure was optimised, and the effect of the rib width on wave propagation was monitored. Change in resonant peak wavelength for refractive index variation due to rib width optimizations was also analysed. It was observed from the results that mono mode behaviour was developed with the rib width of 4 μm and height of 5 μm. The rib waveguide was analysed for wavelength variation of 630 to 1,310 nm (8). In this context, Lin considered a novel electrode temperature writing waveguide based on changing refractive index for the applied heat. Different mode conditions were considered in this sensor design (6). Transmission intensity for the various refractive index of probe liquid is presented in **Figure 3B**.

In another work, Yadav et al. discussed optical waveguide-based biosensors on the subwavelength grating which were investigated with a single TE mode in 1,400 to 1,500 nm. The interferometer bend radius of 50 μm was maintained. Two-dimensional FEM simulation was performed with the Comsol Multiphysics software tool. The reference arm was considered with silica material and sensing arm incorporated with air material. There were 2-fold increases in sensitivity after including the sub-wavelength range (9) compared with the MZI proposed with single-mode fibre. Single-mode fibre was coated with methylcellulose. It has shown a humidity sensing range of 45–8% RH. A sensitivity of 0.094% RH was obtained during the simulation. An increase or decrease in the relative humidity has shown the difference of intensities up to 0.03 dB (10). Highly sensitive silicon MZI based ultrasound sensor was discussed by Ouyang et al. In this sensor, one end of the sensing arm was integrated with a thin membrane and another end of the arm was used as a reference. The ultrasound wave was excited on the sensing layer of the interferometer. The low detection limit of 0.38m Pa/Hz was obtained. In preliminary experimental conditions, the image wire phantom was formed. The properties and sensing characteristics of the sensor showed promising application such as ultrasound imaging (11). In this context, high temperature-sensitive MZI was designed with a system of optical fibre offset splicing techniques. The designed sensor has shown sensitivities for external refractive index up to −17,335 nm/RIU and temperature for 32 pm/C. The sensor was constructed with a quartz capillary sandwiched process. The sensitivity of the sensor achieved was 21.2 nm/RIU. The authors concluded its application in many biomedical and industrial concepts (12). It is observed from **Figure 4** that sensitivity changing for change in the refractive index.

In another work, Luan et al. discussed a highly sensitive lab on-chip optical ring resonator. Different types of optical ring resonator structures were considered, such as doped silicon-based dual ring resonator system and phase-shifted FBG-based interferometry system. Sensitivity was compared with different configurations (13). In this context, Wang et

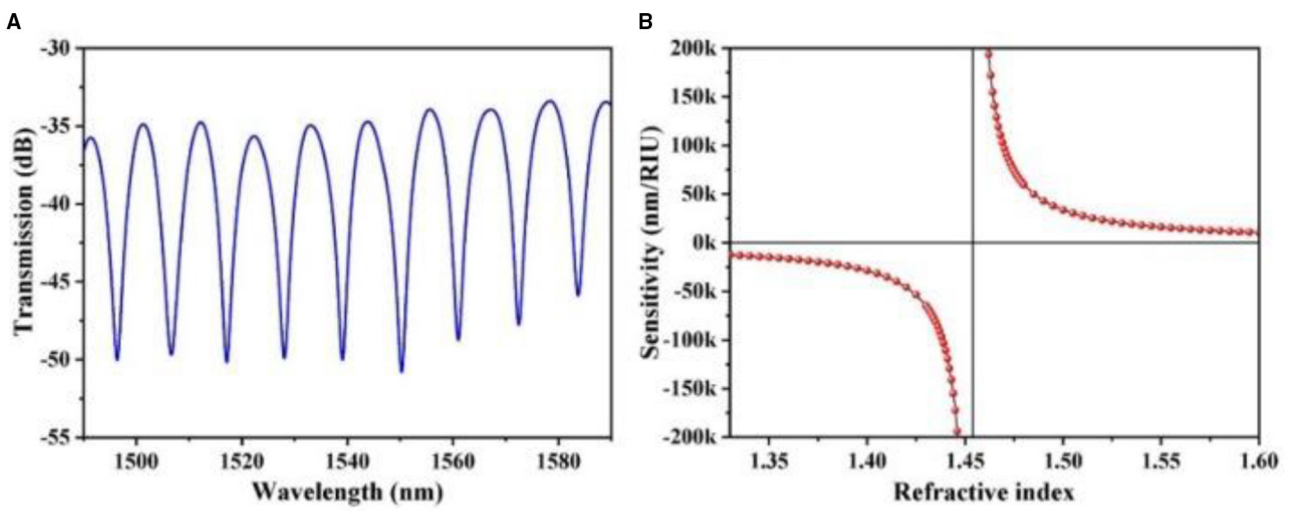

FIGURE 4 | (A,B) Transmission spectra and sensitivity calculation of Machzehnder Interferometer (12).

al. developed an MZI-based sensor for continuous respiratory monitoring. During the development of the MZI-based respiratory monitoring system, it was adequately scrutinised for its respiration rate, tidal volume, and minute ventilation. The designed sensor was constructed with a flexible arch-type structure feature with curvature sensitivity of 8.53 dB/m (14, 15). The study of Zunic et al. designed a MOEMS ultrasonic sensor for photoacoustic imaging. MOEMS sensor was designed and developed with the integration of the MZI. The model was designed and simulated in Comsol Multiphysics. Analysis has been conducted for different materials assigned to layers. Different materials assigned were Si, SiO2, Si3N4, and SMMA. The sensor was designed to operate at 1 MHz (16). The MZI was designed for measuring glucose in serum. The light that was propagating through the sensing system which detected the serum sample with a specific concentration of glucose was analysed. The output power obtained was linear until it reached the value of 1.358 (17).

Optical MEMS Microcantilever

Micro-electromechanical system microcantilevers have wide applications in many biomedical aspects, especially most of MEMS biosensor integrated with microcantilever system because of its flexibility in mass sensing, benefits of EMI insensitivity, and micro-sized fewer circuitry parts (18). Several micromechanical structures were configured with the microcantilever sensor which were widely used for label-free biosensor applications. It has been used in many applications and research studies, including the fabrication of monolithic Wheatstone bridge circuits (18, 19) are the analysis of electrical responses of MEMS piezoresistive microcantilevers. Microcantilevers have been widely used in medical applications such as the induced mass change technique for glucose detection (20–22). Microcantilever sensor work is mainly based on maximum surface stress generation due to applied force at the cantilever tip. Combining optical systems with micro cantilever makes the optical sensor system work effectively for change in deflection and maximum surface stress. In terms of label-free sensing, variety of methods can be integrated with microcantilever sensors. They are (1) photonic crystal structure, (2) MZI, (3) optical ring resonator waveguides, (4) FBG, etc. Label-free sensing uses protocols of change in refractive index due to change in surface density instead of a change in mass. In this review, we discussed microcantilevers, which have undergone micromachining technology. Cantilever deflection is highly sensitive to change in maximum stress developed at the surface of the cantilever. Biomolecules, DNA, and Protein molecules can be captured by the targeted surface of the cantilever coated by the adsorption layer of the material, which increases the surface stress. Adsorption in one side of the cantilever brings out differential stress for each deflection of the cantilever. The electrical and optical methods of cantilever readout methods are in commercialisation. Still, the optical system of the cantilever sensor has more advantages than electrical due to its simplicity, lightweight, small size, EMI Insensitivity, less circuitry complexity, reliability, and linear results (23). In this context, Lee et al. discussed a nanomechanical cantilever sensor integrated with a photonic crystal microcavity resonator. Resonant wavelength shift was observed for each increment of applied force. It has shown a promising future of application in the detection of biomolecules (24). In another work, Xiang and Lee proposed optical readout chemical sensing based on microcantilever sensors. Photonic crystal microcavity resonators integrated with microcantilevers in a fluidic channel for chemical sensing with water and air were investigated. Microcantilever sensitivity in both air and water for the designed cantilever was analysed, wherein minimum detectability obtained in water was less than in the air (25). Microcantilever was used for the detection of specific biomolecules. Overall geometry was designed, allowing simple microfluidic delivery channels to make adsorb to the surface of microcantilever (26). An optical readout mechanism was used for analysing the optical MEMS sensor. Ptolemy-II is a tool considered for experimental validation of designed optical MEMS sensors. Microcantilever was integrated with many other photonic technologies for the development of optical MEMS-based sensors. Photonic crystal microcavity with micro cantilever is applicable in a different biomechanical application. Optimising photonic crystal structure integrated with micro cantilever cavity for label-free biosensing application has more scope in improving sensitivity. Variation of ring thickness and ring radius is an essential factor affecting the overall sensitivity of the ring resonator integrated with the microcantilever. From **Figure 7A**, we can see the microcantilever array is embedded with microfluidic channels for analysing the chemical solution (30, 31). **Figures 5A–E** shows different methods of optical system integration with Microcantilever including a microfluidic channel.

In this context, Steven et al. discussed carbon nanotube-based carbon mechanical resonators. It has been used to detect different molecules in the air. The length of the cantilever ranges from 500 μm to 5 mm. The porosity of carbon resonators varied with a density of 102–104 kg/m^{-3}. Significant applications in biomedical disease detection and pathogens in air and gas environments have been analysed (32). SU-8 polymer material based microcantilever designed and analysed for disease detection. From the evolution of SU8 Polymer-based surface stress microcantilever. The selection of material, geometrical design parameters, and challenges faced in the current market are discussed (33). By considering different materials, maximum deflection for each specific material of microcantilever is analysed. Microfluidic channels have been designed and analysed for blood flow and viscosity generation for the same sensor configurations. Pressure-induced on microcantilever due to an increase in blood viscosity is investigated. The performance of different microcantilever sensors for different materials is carried out. They concluded that SU8 polymer material gives the best displacement and strain distribution range along the microcantilever (34).

Photonic Crystal Pressure Sensor

The photonic crystal is an optical nanostructure that affects the photon motion much similar to the motion of electrons affected by the ionic lattices. Photonic crystal structures are susceptible to change in refractive index by mechanical deformation. A minute change in deflection causes the overall refractive index

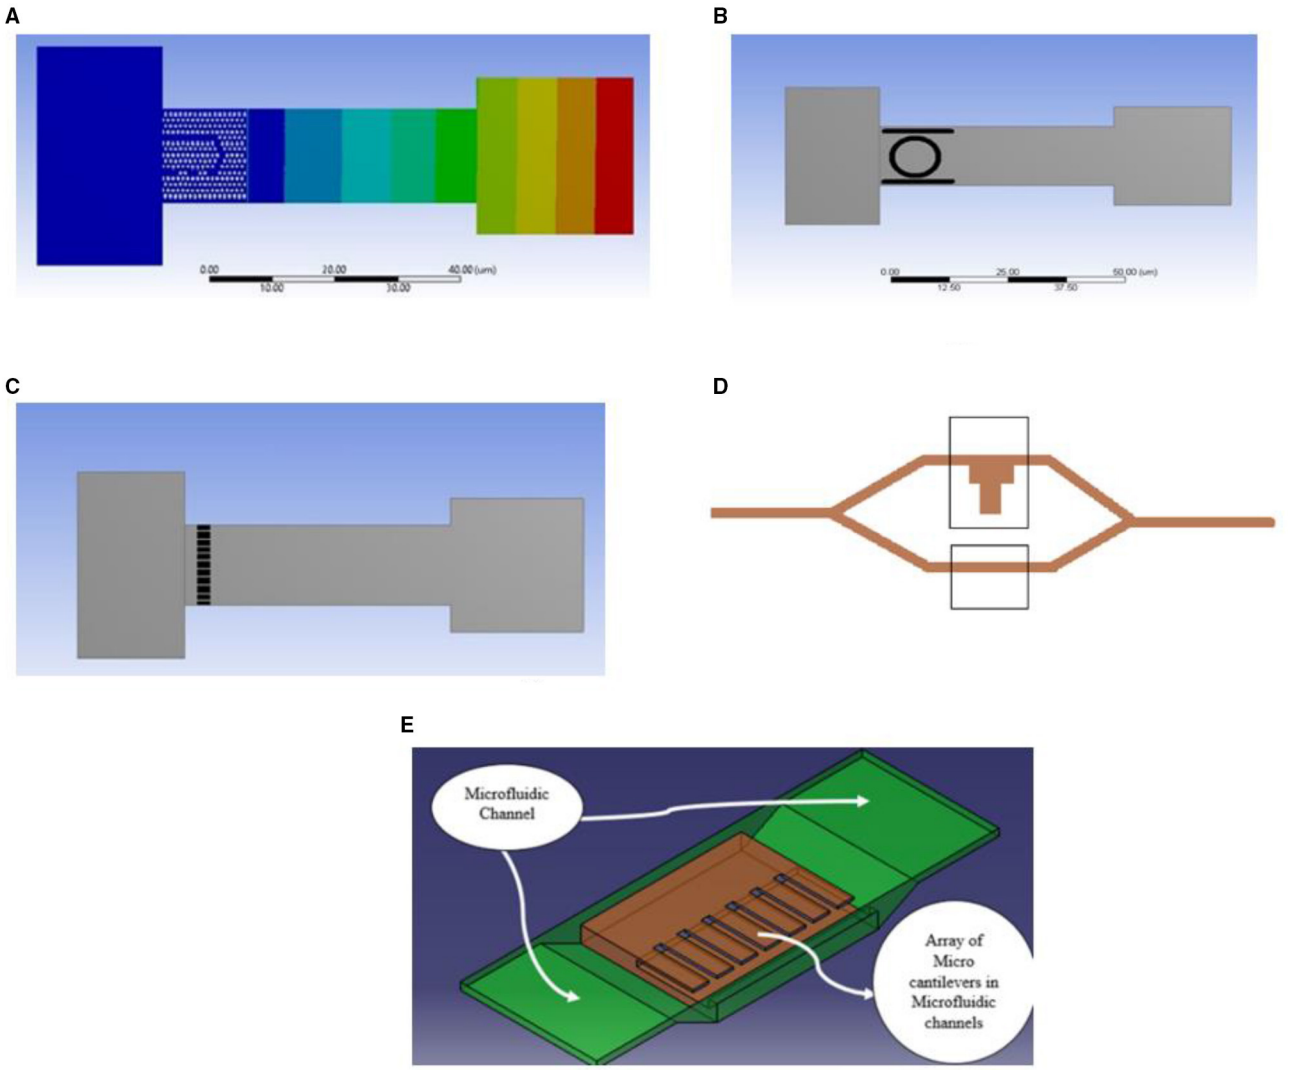

FIGURE 5 | Presents the various Microcantilever: Photonic crystal integrated Microcantilever **(A)**, ring resonator integrated Microcantilever **(B)**, FBG integrated Microcantilever **(C)**, MZI Integrated with Microcantilever **(D)**, array of Microcantilever with the microfluidic channel **(E)**.

of the structure to change. Agarwal et al. discussed a photonic crystal-based micro-opto electro mechanical system sensor in this context. Sensor configuration consists of the integration of a photonic crystal sensing layer in a bridge-type silicon structure. In this context, two cases of sensing structures were investigated, i.e., in the first case, the bridge structure was fixed at one end, while in the second case, it was fixed at both the end. The pressure is applied at the centre of the bridge in the second case. In the first case, the pressure was applied at the free end tip of the sensing structure. The pressure is applied from 0 to 400 MPa for both sensing configurations. The analysis observed that the structure fixed at one end shows higher sensitivity of about 68.296 nm/MPa. Structure fixed at both ends shows a sensitivity of 0.134 nm/MPa. The figure shows the resonant peak obtained for the structure fixed at one end. We can see from **Figure 6** that there is a distinct shift in wavelength for the different pressure range from 0 to 400 Mpa. The wavelength range obtained for structure with one end fixed is 1,550 to 1,535 nm (35). The peak resonant wavelength for each pressure increment is shown in **Figures 6A–C**.

In another work, a hybrid dual-core photonic crystal fibre-based pressure sensor was designed. Elliptical and circular shaped air holes were constructed in photonic crystal fibre pressure sensor configuration. Under different applied pressure, the mode behaviour of the sensing configuration was analysed. The sensor was designed for hydro pressure applications. It was found that a sensor length of 6 cm have sensing range from 0 to 1,000 MPa (37). In this context, Rajasekar et al. discussed a hexagonal photonic crystal ring resonator structure for sensing pressure and temperature. The pressure range considered was 0.04–6 GPa and the temperature range obtained was 5–540°C Bandgap analysis of each sensing configuration was carried out to monitor the range

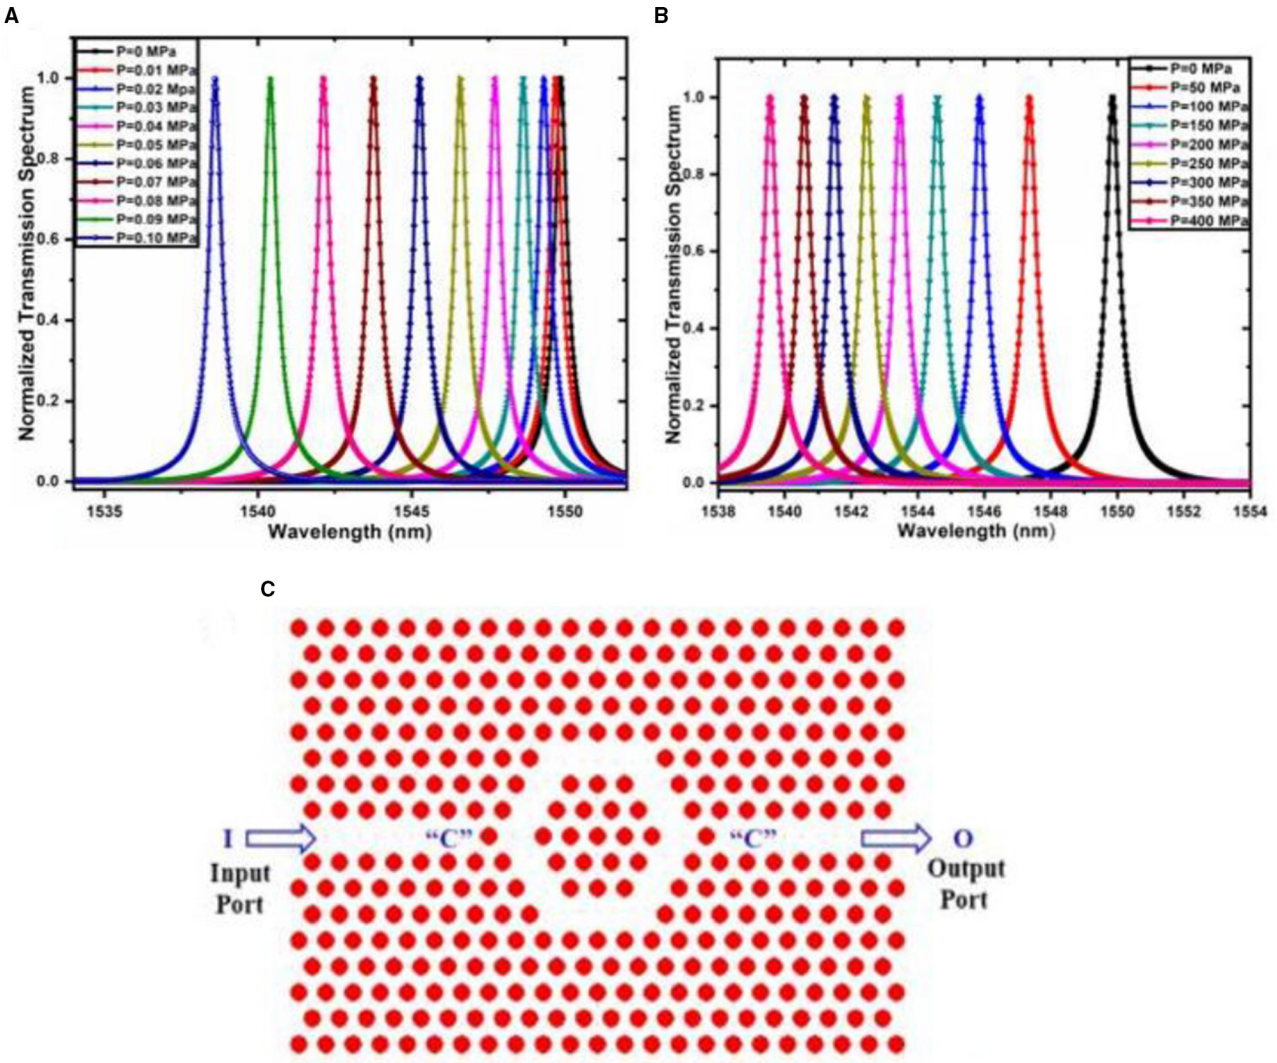

FIGURE 6 | Peak resonant wavelength for sensing structure **(A)** fixed at one end. **(B)** Fixed at both the end (35). **(C)** Hexagonal photonic crystal ring resonator-based pressure-temperature sensor (36).

of frequency. 2D hexagonal photonic crystal resonator arranged with a circular rod in air configuration was considered during the analysis. In another work, a 2D hexagonal lattice of six hexagonal-shaped rings of hexagonal lattice sensing configuration was micromachined on tip of the microcantilever. The concept of using a microcantilever tip is to get a wide range of pressure. The pressure was applied from 1 to 10 Mpa with a resolution of 10 MPa (36, 38). The hexagonal ring resonator has shown better sensitivity up to 250 nm/MPa. The modified refractive index after applying pressure for 2D photonic crystals was calculated by the following Equation 3 (36).

$$n = no - (C_1 + 2C_2)\sigma \quad (3)$$

where no is the refractive index at zero pressure, C1 and C2 are photoelastic constants and σ is the stress generated at the sensing structure due to pressure. **Figure 6B** shows the photonic ring resonator structure.

Fibre Bragg Grating Sensors

Fibre Bragg Grating has a unique characteristic to perform as a sensing system. The core of the FBG is exposed to intense laser light. Refractive index increases as there is an increase in exposure to the laser light. In this context, Werneck et al. discussed the basic principle of FBG sensors. A periodic change in the refractive index in the core segment of optical fibre was grating fibre. Refractive index variation due to applying pressure or temperature led to pitch change in FBG. The most common choice of fibre optic-based sensor is FBG sensors. The ultrasonic laser inscribing process generated the periodic refractive index on a core segment of optical fibre. An FBG suitable for measuring strain in a product or device has experienced pressures

throughout the process. The multiple FBG sensors could be embedded under any structure to get the spectrum shift from the FBG interrogator. The most application of FBG sensors was based on the structural health monitoring system. In structural health monitoring, FBG sensor placement is the most crucial part of the research. Since there is an application of the thermal or structural load on the FBG sensor, installing an FBG sensor inside the structure requires prior knowledge of the structural behaviour. The FBG sensor placement study was conducted in many mechanical applications like the placement of fibre in the tensile test specimen, placement of fibre in wings of the aeroplane for structural health monitoring, or in the case of rail monitoring, during the movement of train wheel for a specific period. From a biomedical point of view, most blood pressure measurements and temperature measurements were in progress with the FBG system. In many applications, the FBG sensor was used as non-invasive. Most FBG Interrogators will provide the raw data in the form of voltage; the same is converted in wavelength for each change in microstrain and feed rate of FBG sensor (27).

The study of Bonefacino et al. discussed ultra-fast polymer optical FBG inscription for medical devices in this context. The fibre consisted of polymethyl methacrylate material. The extraordinary result was obtained during the experimentation. New dopant diphenyl disulfide causing positive refractive index change was utilised during the process. This made sensitivity high when FBG was considered with PMMA to compare with silica fibre. The sensitivity of the FBG sensor obtained was -55 pm$^{\circ}C^{-1}$ (39). The strain from the FBG sensor was also used to calculate the curvature and torsion of fibres. The catheter was used for reconstruction techniques. The FBG embedded catheter was used as a shape sensor. The maximum reconstruction error found was 1.05 mm. The authors concluded that shape sensing with flexible biomedical instruments is feasible with the FBG sensor (40).

Along with these applications, the uses of FBG in civil engineering applications, biomedical applications, military, and marine applications were discussed. Depending on the type of application, FBG is designed with long or chirped grating, which is uniform and tilted (40, 41). In this context, Zheng et al. discussed 3D hydrogel actuators driven by light and generated by two-photon polymerization. The photoresist of gel was produced by Fe_3O_4. The size of the hydrogel actuator was 26 μm and the response time of the sensor was 0.033 s. The designed actuator has good controllability and repeatability (42). On-chip optomechanical sensing configuration has been established. Sensor configuration consisted of a dual-channel integrated waveguide and directional coupler. The dynamic range of the sensor was 30 nm with displacement imprecision of 45 fm/Hz (43). In another work, Linh et al. proposed an FBG-based optical pressure sensor. The pressure sensing element was constructed with Fabry-Perot based pressure sensor. Fabry-Perot pressure sensor with a different cavity length was optimised. Obtained pressure sensitivity was -0.672 rad/MPa. The proposed sensor was having a very high-temperature sensing ability (44). In another work, optical fibre-based pressure sensing application system was developed for pulse transit time measurement. Pulse transit time measurement system is helpful in cuffless blood pressure measurement. Electrocardiograms and photoplethysmographs had been monitored with a pulse transit time system. Plastic optical fibre was deployed as a transport medium in the chest part of the human to monitor the pulse pressure. Research work carried out here considered pulse transit time (PTT) in three different positions, i.e., finer, wrist, and foot (45). Complementary metal oxide semiconductor (CMOS) MEMS-based membrane nanomechanical sensor is designed and developed for molecule detection. Results shows that small molecules significantly impact the human body, wherein detecting such a molecule is challenging in many sensing systems. This membrane bridge sensor is used to detect phenytoin in different concentrations. The detection limit of this sensor is 4.06 $\pm$ 0.15 μg/ml. It is used as a biosensor as well chemical sensor. In this context, Raghuwanshi et al. carried out a sensitivity analysis for TiO_2-coated FBG sensor for chemical detection. A TiO_2-based FBG sensor was developed with Cu-Vapour-based laser writing. The thickness of the coating has been optimised to get better sensitivity and FBG design parameters. The sensor was able to detect the minute change in adulteration with accuracy 0.01 ppm (46, 47). In the study of LV, C and co-authors, they discussed invasive FBG based pressure sensors for palpation of tissue surgery. The finite element method has been used to analyze the static and dynamic performance of the sensor configuration. Optimum sensor design output has been given to 2.55 mN. The pressure range considered was 0–5 N (48). In another work, the effectiveness of sensing configuration has been presented by Khan et al. for the pose measurement system of different medical instruments by FBG sensor. The results of the FBG sensor were converted to strain. Strain calculations were made by comparing strain gauge parameters. Mean error in the orientation and position was observed to be <4.69 mm and 6.84°. Different poses of catheters and many other medical instruments by experimental data were obtained (49). In this context, Antunes discussed the mechanical testing of dental resin. In real-time usage of dental resin, resin materials had undergone failure due to the shrinkage polymerization. This caused the breakage of gaps, which interfaced the dental resin with the tooth. A laboratory experiment was conducted to cheque the ability of different resin materials and their failure point by using an FBG sensor. The FBG sensor was placed in the dental model (28). Variation of strain concerning time with FBG sensor is shown in **Figure 7B**. **Figure 7A** shows the FBG sensor processing system. Performance comparison of different sensors is shown in **Table 1**.

Figure 7C shows the temperature variation during resin polymerization in dental material. The shift in wavelength was obtained for change in these parameters. Strain dependence of FBG sensor can explain with the following mathematical expression (4) and (5) (29).

$$\Delta\lambda/\lambda_0 = n_{eff}/\Lambda_(eff_\Lambda) = (1 + (1/n_{eff})\delta n_{eff}\delta\varepsilon)\Delta\varepsilon = (1 + p_e)\Delta\varepsilon \quad (4)$$

$$\Delta\lambda\lambda_0 = k\Delta\varepsilon \quad (5)$$

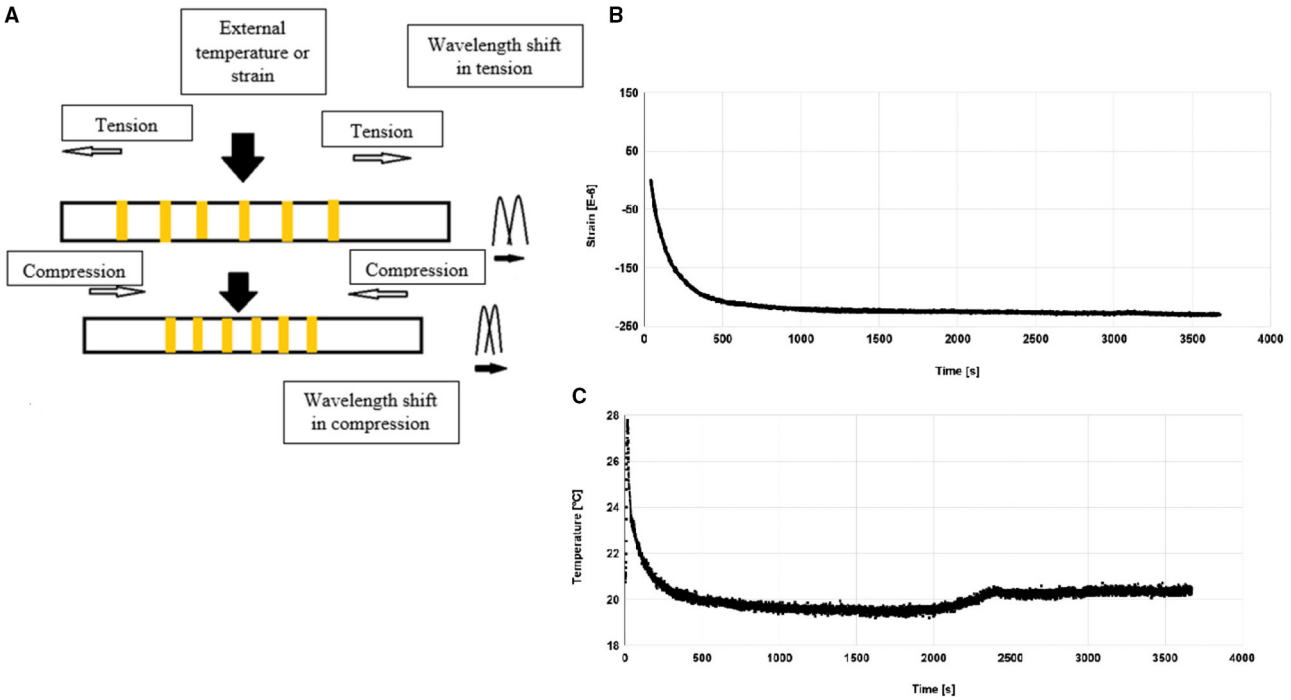

FIGURE 7 | (A) Fiber bragg grating working process during the application of pressure (27). **(B)** Strain evolution of bulk flow resin during polymerization (28). **(C)** Temperature evolution of bulk flow resin during polymerization (29).

where k = k factor of bragg grating, pe = photo elastic constant = 0.21, and $\Delta\lambda/\Delta\varepsilon = 1.2$ pm/(μm/m) - Strain sensitivity for FBG at 1,550 nm

Fibre Bragg Grating as temperature dependent has below expressions;

$$\begin{aligned}&\Delta\lambda/\lambda_0\\&= \Delta n_{eff}/\Lambda_(eff_\Lambda) = (1/\Lambda(\Lambda/\delta T) + (1/n_{eff})\delta n_{eff}\delta T)\Delta\varepsilon\\&= (\alpha+\zeta)\Delta T \qquad (6)\end{aligned}$$

α – coefficient of thermal expansion
ζ- thermo-optic coefficient
$\alpha = 0.55 \times 10^{-6}/°C$
$\zeta = 5.77 \times 10^{-6}/°C$.

Application of Optical MEMS

Miniaturisation of devices or various micro mechanical elements is a critical concept in developing new optical MEMS technology. Optical MEMS are the microdevices that measure and manipulate various mechanical parameters such as pressure, temperature, shape, stress, strain, etc. Optical MEMS has plenty of applications in present days, e.g., in industry, biomedicine, automobile, and aviation. In this paper, we selected the critical application of optical MEMS in the biomedical field. The primary application discussed here was dental, human spinal disc, optical MEMS in the human respiratory system, the optical fibre in gait motion, blood pressure measurement, and bladder pressure monitoring, among others. Detailed discussion on the advancement of optical MEMS in the stated different applications is presented below. Most of the applications had used optical fibre-based FBG sensing systems (Section Fibre Bragg Grating Sensors) for real-time applications. Microcantilever integrated different types of photonic crystal structures (Section Optical MEMS Microcantilever) were modelled and simulated for various applications. **Figures 8A–D** shows the Optical MEMS sensors applications in the human body.

Dental Application

Incorporating the optical sensor for the dental caries monitoring in the dental application is a new innovative technique. Evaluating the dental filler materials and monitoring the structural behaviour of braces and aligners are essential criteria in dental health monitoring. Recent dental structural behaviour evaluations monitored by the FBG technique were discussed in this review. Evidence suggests that orthodontic tooth movement and biting force can be monitored with photonic MEMS technologies. The work of Silvia et al. proposed a 3D intraoral scanner to map the 3D image in dental restoration accurately. Dental caries is a major problem in dentistry. Global disease study in the year 2016 has been predicted that in the total world of population, wherein 3.5 billion people have been remarked with oral diseases such as tooth decay. Cracked tooth caries are complex tissue lesions that severely affect the quality of life of a person. It has remained a mystery to solve the non-invasive method to detect the cause of caries and crack of the tooth in humans.

[a]*Not reported.*

Nevertheless, early detection of caries is made possible by FBG based optical sensor (53). **Figure 7** shows the optical MEMS application overview.

In another work, Pyo et al. discussed the feasibility of using optical coherence tomography in dentistry. Analysis has been carried out by changing the fringe numbers, clarity of dental images has been investigated with optical coherence tomography (OCT). OCT has more advantages for exploring a more complex tooth portion (50). Hybrid technology called photoacoustic imaging high-resolution ultrasound could also project deep tissue with high contrast optical images. **Figures 8A,C**, show dental scanned images. Strain patterns for different orthodontic devices were evaluated. Regarding this, an orthodontic appliance with a disjunctor bar on the left side and without a disjunctor bar

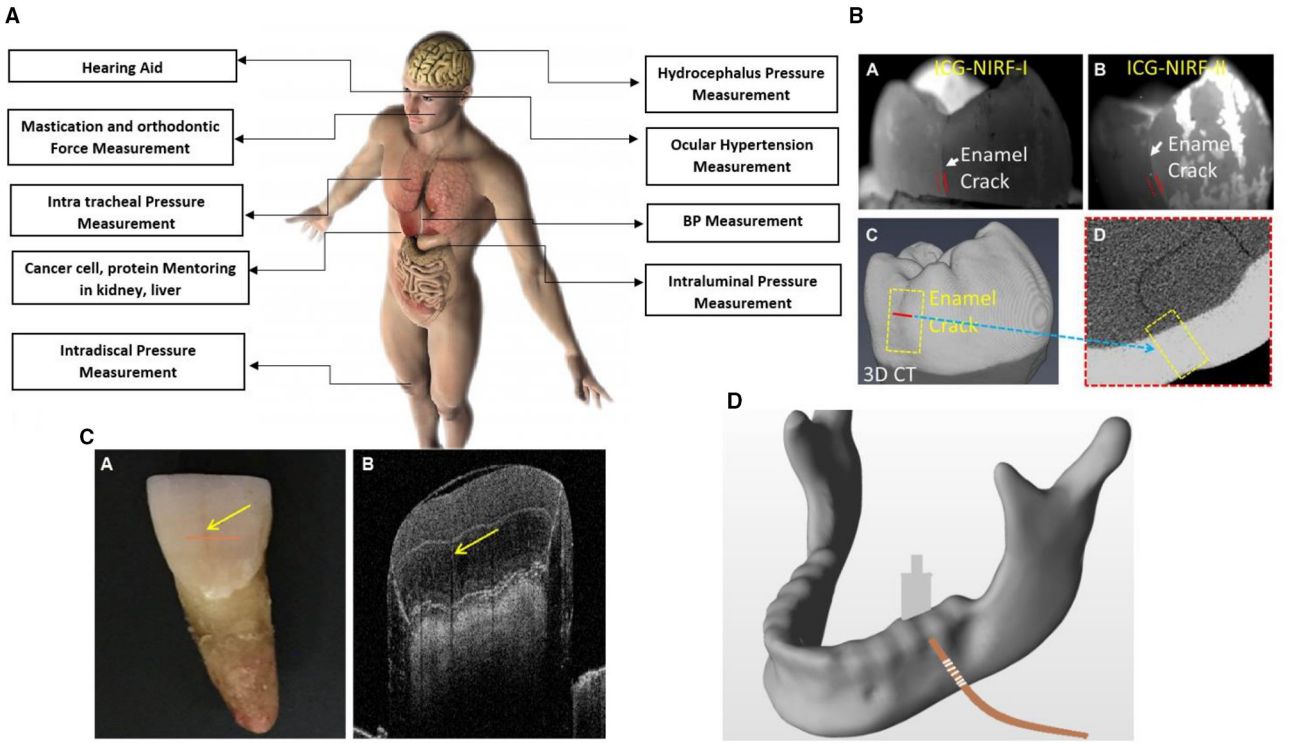

FIGURE 8 | (A) Optical MEMS sensors application in the human body (50). **(B)** Dental X-Ray imaging of cracks by green near infrared imaging (51). **(C)** Dental OCT imaging (53). **(D)** FBG integration with human mandibular (52).

was compared for strain pattern obtained for transferred forces to the dental arch, teeth, or maxilla (54). **Figure 8D** shows the placement of the FBG sensor human mandibular model. In this context, the FBG sensor was used to measure material expansion because of a dental implant. The effect of thermal strain on FBG sensors has been widely studied. The hardening phase of the material expansion process has been investigated concerning the optical MEMS sensor. Electromagnetic interference (EMI)-insensitive, small dimension bite force device has been developed by FBG technology for measuring. Obtained results showed better resolution compared with the traditional devices available in the market. The optical system was also used in strain measurement of the tibia in bone for decalcification. The different bone sample has experimented for different percentage of decalcification. Since there is a loss in calcium percentage in bone, an increase in strain behaviour was observed. Better resolution over the result was obtained compared with QCT, QUS, and DEXA. These traditional techniques had the drawback of inaccurate values and exposure to radiation (51, 55). In another work, the surface roughness of rot carriers was analysed using optical profilometry. A total of 20 extracted teeth from a patient was examined for root caries, and surface roughness was analysed with profilometry. This clinical study was carried out to protect the non-cavitated surface from cavitation by prior accession of the status of a tooth. In the dental clinical examination, there was no clinical test process to detect hard tissue. This need in the dental field is the reason for the development of optical polarisation imaging systems. This imaging system could assist in dental calculus caries and cracked tooth (52, 56).

Strain Monitoring Human Spinal Disc

The degenerated human intervertebral discs exhibit more compressive stress, tensile stress, and strains. Load distribution on the spinal disc is important for the proper functioning of the lumbar motion of the human body. In this context, Newwell et al. evaluated the use of the FBG sensor in human spinal cord mechanics. Understanding the pressure distribution of the intervertebral disc is a major key point in the clinical diagnostic of disc strain. The biomechanical structure of the spine consists of the intervertebral disc, as shown in **Figures 9A–C**, between superior and posterior parts of the spine consist of an intervertebral disc. In the study of Newwell et al., biomechanical action took place between these parts. Finite element mandrel was developed with encapsulation of FBG sensor within it. FBG sensor was incorporated with the intervertebral disc part. Compressive or tensile force applied on the intervertebral disc has generated the strain. Encapsulated FBG sensors had undergone pressure that brought the change in the grating period. Functional units of the spinal cord experienced compressive load. FBG sensor

incorporated in intervertebral disc and linearity, sensitivity, and hysteresis for each compressive stress was investigated. The porcine intervertebral disc (IVD) pressure has been validated with an FBG sensor for accuracy. Needle mounted strain gauge sensor was inserted into the nucleus. Even though the invasive measurement method was divisive, this method could undergo accurate pressure measurement in the IVD. Functional units of the spine were compressed for 0–500 N force. The substantial potential has been exhibited by FBG sensor with IVD pressure monitoring by sidestepping the controversial nature of invasive methods (58, 59). In another work, Yamaji et al. evaluated the device for analysing the motion of the lumbar. The device consisted of stretchable strain sensors. It was observed from the clinical survey that lower back pain was common in most people in the world. In this study, the stretchable device for lower back motion was analysed. Six strain sensors were used in the human spinal cord in the non-invasive method. Sitting postures were the major cause of most spinal cord diseases. In such cases, detection of the wrong posture could give major advantages. Many wearable devices had been investigated for different applications, wherein the sensitivity of the sensor achieved as high as 0.2 nm/$\mu\varepsilon^{-1}$ (60, 61).

Monitoring Angular Motion of Joint and Gait Analysis Application

Diagnosing issues causing pain during walking or implementing or evaluating pain for treatments is paramount in physiotherapy treatments. Monitoring the angular motion of the joint helps in restoring correct patterns and abnormalities. In this context, Padma et al. proposed a goniometer device with FBG encapsulated for dynamic angular motion of joint. Rotational motion of join in the affected human body was converted into strain variation. Developed FBG sensor was able to detect the range of angular motion from 0 to 200°. The resolution obtained was in the range of 0.06°. Elbow joint and ankle joint measurements were carried during the experimentation. The sensor device was used to measure the angle between the shin and thigh for various cantilever strain variations. Knee angle measurement device was also validated for a range of motion of joint angle in gait analysis with traditional sensors. Sensitivity switching mode was made available to obtain various levels of sensitivity action mode. Low sensitivity mode, medium sensitivity mode, and high sensitivity mode were developed in the device. They also used polymer optical fibre for joint angle measurement. The obtained results were compared with a resistive goniometer and polymer optical fibre sensor (57, 62). In another work, an electro goniometer was used to measure the joint angle. The goniometer was embedded with an FBG sensor to get the angular motion details. However, the drawback

of this device was the fixed hinge and fixed centre of rotation which caused a problem during the measurement of angle in joint with more bend. Alternative fibre optic-based device with the technique of intensity modulation and laser beam methodology was developed. The prototype developed had a range of angular rotation up to 90° with a standard deviation of 0.1°. The developed sensor has high reliability, sensitivity, speed, and flexibility (63). In this context, JR Galvao discussed gait analysis with FBG sensor. Gait analysis is the study of the motion of a human or animal body using the eyes of the observer through various study devices for the measurement of motion with body mechanics. Sport and medicine are the widely used area of gait analysis. The walking process, steps in walking, body posture, and walking velocity are the different parameters depending on the gait analysis result. Different gaits of horses had been studied using the instrumentation of the FBG sensor. Early injury diagnosis of horses and retirement of horses were investigated in the said study. Initially, the FBG sensor was used without any encapsulation and embedded in each limb of the horse. In the second step, FBG was encapsulated with composite fibre and embedded in the limbs. The second step involved digital image processing techniques to get proper images of compressive or tensile forces. Both FBG sensing and digital image processing had shown good agreement for biomechanical study and evaluation of FBG sensors for horse dynamic training and competitions (64, 65). Furthermore, the study of Domingues et al. discussed an insole FBG-based optical fibre pressure sensor. Internet of Things technology was incorporated with this application. An optical fibre-based foot pressure system was integrated with the Internet of things for e-health assessment. Accuracy of the system was varied with normal walking and patients with diabetes. Polymer optical fibre was embedded in the foot plantar surface. An array of polymer optical fibre has placed foot insole and experimented for different gait cycles. Four different FBG sensors characterised by four different wavelengths had been used. The FBG sensor was positioned at different positions of insole, i.e., first, second, third, fourth, and fifth metatarsus. Finite element analysis (FEA) was carried out for the insole model. The high sensitivity of 0.000492 nm/KPa was obtained for the developed system. The insole was embedded with multiplexed FBG-based sensor. The designed system was allowing complete gait motion assessment with a multiplexed FBG sensor network. Assessment results of the insole would be sent to a physiotherapist to monitor the conditions of the patient (66–69).

Respiratory Pressure Monitoring

Monitoring of respiratory system reduces the severe illness during consideration of clinical response. Exploring the possibilities of good respiratory monitoring sensors such as the FBG system is vital in the present scenarios of chronic respiratory diseases. In this context, Padma et al. discussed a breath pattern analyzer based on the FBG technology for communication assistance for people having restricted communication ability. In emergency medicine for people with spinal cord or brain injuries, or patients in the intensive care unit, critical life-supporting system is required. The FBG breath pattern analyzer was used for the patient to communicate with the outside world, where specific breath patterns were trained by FBG breath pattern analyzer. During emergency assistance, the patient could be communicated for specific purposes. The developed device was an alternative to the brain-computer interface, where specific instruments were used to obtain the brain responses (70). In this context, Krehel developed a textile-based respiratory system. In this system, highly flexible polymeric textile fibre was embedded with an optical fibre pressure sensor, and the pressure applied on optical fibre has shown a distinct shift in wavelength. The device was analysed with different setups with an optical fibre pressure sensor. Half oval with a length of 60, 180, and 240 mm, as well as half oval with additional bends and with additional bend and cross fibre is cosnidered in the design. The pressure was monitored with a human torso. This comparison with different setups was made to assess the utility of this monitoring device (71). In another work, Nishiyama et al. discussed and evaluated respiration and body motion during sleep with FBG technology. This investigation is essential to understand the human breathing pattern during sleep and detect the motion of the body, sleep habits, etc. The optical fibre pressure measurement system was embedded in a conventional bed. Pressure changing due to breath and roll over in bed was monitored throughout the process using plastic optical fibre-based respiratory monitoring system. Plastic optical fibre was used as a sensor to measure the rate of breathing. This optical fibre pressure sensor has been placed in tape form in the chest of the patient to monitor respiratory movements. The input and output signal from the optical fibre pressure sensor was obtained as intensity modulation. The pressure sensor was tested in a chest in normal status, sitting, and lying condition. The proposed sensor has provided different possibilities in respiratory monitoring within the MRI system (72, 73). In this context, Massaroni et al. discussed the method of measuring respiratory rate by the contact-based method. Different respiratory rates were recorded with the help of sensing element. The complete details discussed were about the contact-based methods, monitoring airflow pressure, air humidity, air movement, chest wall movement, and sound. Differential flow metre, turbine flow metre, anemometer, and fibre optic sensor were used during the process. MEMS-based pressure sensor for simultaneous monitoring of breath pressure and pulse wave was analysed. The real-time experiment was conducted on nasal pressure to monitor the pressure developed at the nasal airways. The MEMS-based pressure sensor pad was attached to the human nose. Eyeglasses was attached the sensor pad to the nasal part (74, 75). In another work, polymer optical fibre-based respiratory rate monitoring sensor has been analysed. In this work, a stretchable strain sensor was made wearable around the stomach. During respiration, inhale and exhale process, the stomach would expand. The sensor would measure the strain generated by expansion. Infrared light was passed through the stretchable grating fibre (76).

Photonic MEMS Microfluidic System

Optical MEMS with microfluidic concepts involves techniques of lab on chip-based sensors. The system consists of optics and fluidic systems with mechanical actuation. Microfluidic

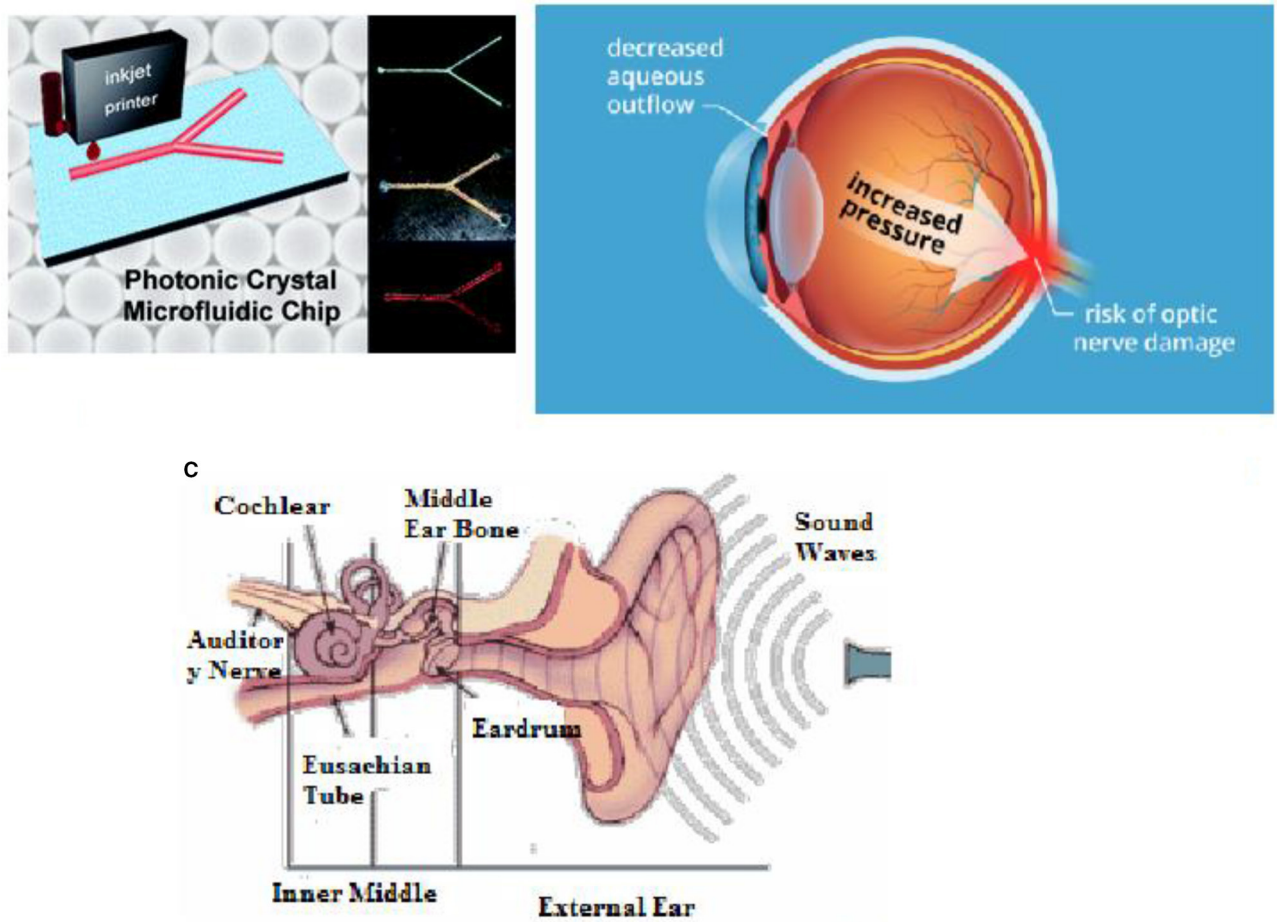

FIGURE 10 | (A) Microfluidic channel with photonic crystal integration (81). **(B)** Intraocular pressure development in the eye (82). **(C)** Human cochlear system (83).

channels are a vital component of photonic MEMS for any biosensing applications to introduce any type of fluid for sensing. In this context, Jeiang et al. discussed an FBG-based Fabry-Perot pressure sensor in a lab on a chip that included microfluidic channels. As the different polystyrene microparticle size varies, the wavelength shift was observed. Sensor systems presented ease of fabrication methods and label-free detection methods. The sensor was demonstrated in polymethyl siloxane chips. It was also monitored that experiments and analytical results fitted very well within the context and avoided the waste of samples (77). In another work, the FBG sensor was integrated into the microfluidic channel. It provided opportunities for dynamic measurement of the physical and chemical properties of fluid passing through the channel. In another work, Weizhi et al. discussed a photonic crystal-based microfluidic channel fabricated with the inkjet printing process. Photonic crystal with the different coloured colloidal microfluidic channel was successfully integrated into a single chip. The fabricated microfluidic channel has the advantage of rapid fabrication possibility, and colourimetric was the add-on properties of photonic crystal based microfluidic channel (78, 79). In this context, Nunes et al. discussed silica-based 1D photonic crystal in opting fluidic systems. It comprised of photonic crystal with the integration of a microfluidic channel. By considering the nanopillar configuration of the photonic crystal, biofluid was injected into the microfluidic channel during the analysis. In the stage of the simulation, the refractive index was taken into account. The shift in resonant wavelength has been observed during the propagation of light due to a change in the overall refractive index profile of the sensing structure with the microfluidic channel. The author has proposed the sensor for biochemical applications (80). **Figure 10A** shows the integration of microfluidic channels with photonics. In another work, Khoshnoud et al. discussed the use of MEMS-based biomedical sensors.

Micro-electromechanical system devices are used to detect triglycerides, glucose, and are used for the measurement of pressure during surgeries, counting the blood cells, sensing in the thermal fluid, and electromagnetic fields (84, 85). In

this context, Quack and Sattar discussed a nanoscale photonic integrated circuit to explore optomechanics. In this work, the authors mainly focused on reducing power consumption due to the movement of mechanical parts within the system. Due to the minor modulation in the effective refractive index, it was possible to get the required consumption of power. The authors also discussed the recent achievement of MEMS enabled silicon photonic systems (86). In another work, an optofluidic pressure sensor integrated with a microfluidic channel was developed. Optofluidic pressure sensor made up of Fabry-Perot resonator system was integrated with a fluid flow wall. The sensor obtained high-quality factors and high sensitivity with a good detection limit. The sensitivity of the sensor was 12.46 nm/MPa with a detection limit of 8.2 bar. A silicon photonic mid-infrared system with microfluidic channels was integrated. In this system, silicon on the insulator layer was developed. The author focused on increasing sensitivity by increasing the length of the interaction of light with structure, intensity, and reducing noise (87, 88).

Measuring Intraocular Pressure

Intraocular pressure (IOP) monitoring is an essential aspect of the human eye to avoid the risk of glaucoma and to provide clear vision to a person. Pressure build-up within the eyes optic nerves is the leading cause of glaucoma. Glaucoma damages the optic nerve, and if untreated, may lead to vision loss, which then makes a person blind. In this context, Lee et al. developed a micro-sized optical implant for *in vivo* intraocular pressure monitoring. Sensors were mounted in intraocular lenses for continuous monitoring of pressure. Sensors were tested with New Zealand white rabbits, and in this way, continuous intraocular pressure measurement was made possible. In another work, intraocular pressure sensor was used with the technology of a flexible photonic crystal membrane.

Periodically, micro-structured 1D photonic crystal on polydimethylsiloxane was considered in the experimentation process. The estimated limit of detection was about 160 Pa. The micro-size compatibility of these sensors has been rendered as a favourable application for glaucoma. **Figure 10B** shows intraocular pressure development. IOP sensor was integrated into keratoprostheses, and the proposed sensor has given 2 mm/Hg accuracy (89–92). In the study of Han et al., they discussed an optical aberrations effect on intraocular pressure measurement with small optical elements in this context. Elevated intraocular pressure is a significant risk factor for glaucoma. To monitor this, the implantable optical pressure sensor was incorporated *in vivo* with rabbit eyes. Optical aberrations relationship with intraocular pressure sensor performance was monitored. It was concluded that sensor readout accuracy decreases as the magnitude of optical aberrations increases. The accuracy of signal to noise ratio obtained was 0.58 ± 0.32 mmHg and 15.57 ± 4.85 dB[3]. In another work, Truong et al. developed a portable handheld reader for monitoring intraocular pressure. Reflected light

[3]Available online at: https://www.allaboutvision.com/conditions/hypertension.htm (accessed July 27, 2020).

from the intraocular pressure sensor forms fringed and it was captured using a camera. Three different handheld readers were used to analyze the better quality fringes and patterns. It was concluded from the results that DSLR based reader has high-quality fringes compared with others. Monitoring of intraocular pressure with optical coherence tomography is a novel technique. Hypertension can lead to glaucoma. Frequent control of IOP monitoring corneal deflection either by direct contact or non-contact process is the current procedure involved in clinical treatment. The relationship between OCT images and the IOP sensor was developed by capturing the bovine eye (81, 93).

Blood Pressure Measurement

Daily monitoring pulse rate is essential to success to meet fit and healthy lifestyles, especially for people with cardiovascular diseases or weight loss. FBG based system is widely applicable for monitoring pulse signals because of its micro size and high sensitivity to external pressure. The study of Katsuragawa et al. evaluated FBG based non-invasive blood pressure sensor. Systolic pressure and diastolic pressure pulse were measured in a single FBG pressure sensor. FBG sensor was kept at the right wrist and right elbow. Results were validated regarding blood pressure values. The device developed had good agreement with standards of sphygmomanometer. In this context, Opsens' OPP-M developed a cardiovascular blood pressure monitoring system using a fibre optic sensor. Dynamic temperature measurement was also made possible with this device, and less moisture was induced during the monitoring process. A reduction in size makes the device more favourable for invasive cases. Devices possessed immune to electromagnetic interference, magnetic resonance imaging, and any other invasive surgery instruments. The integration of the sensor was made easy with a cost-effective strategy. The optical fibre pressure sensor used an optical detector, light source, signal processing module, etc. It was observed that the blood pressure measurement based fibre optic system is reliable and faster in terms of sensitivity and quality factors. Most promising technologies and improvements carried under optical MEMS systems for blood pressure measurement applications used the concept of FBG system, fibre optic system, optical ring resonator, photonic crystal membrane, and interferometers (94, 95). Silica optical fibre-based FBG sensor was designed and discussed for strain measurement. Induced pressure by pulse waves from human arteries is the signal for the FBG sensor. Since silica optical fibre may undergo fatigue fractures, plastic optical fibre was introduced to resolve this issue. Pulse waveform from the human arteries was obtained. Based on the results obtained, the measurement of waveform plastic optical FBG was the better solution compared with others in terms of accuracy and sensitivity (96)[4]. In another work, Katayama et al. proposed wearable blood pressure measurement for tracing the sudden change in human blood pressure in the arteries. FBG optical pressure sensor was embedded in the textile or garments for the easy measure of pressure waves form in the human body. The partial least square method was followed for calibrations of pulse waveform and induced FBG pressure. The sensing accuracy obtained by this sensor was comparable to conventional sensors (82, 96, 97)[4].

Bladder Pressure Monitoring

We know that pressure is a critical parameter that is used to represent the state of all organs in the body. Hence the measure of pressure is very crucial in the medical field. The conventional system uses the fluid base wherein the pressure is indirectly transmitted from the required organ. These often have a delay in measurement since fluid lines are used as a medium of measurement. The traditional methods of measuring pressure have always proven to have minor errors. Usually, there are no sensors places in the body of a patient since it limits the movement of a patient. Hence, pressure is measured when the person is hospitalised or before and after a problem. Due to these factors, we do not have any constant measuring of pressure in the human body, and it does not reveal the underlying problems faced by people. In this context, Poeggel discussed the urodynamic analysis for evaluating the dysfunction of the lower urinary tract during the filling and voiding process of the bladder. Pressure measurement of the bladder during this process made the urologist provide a required treatment to a patient based on individual diseases. The technique was based on two optical pressure sensors and a temperature sensor. A real-time pressure measurement system was made possible by this method. To overcome this difficulty, we can design lightweight, small-sized, and efficient MEMS. MEMS can be used with minimal efforts using invasive techniques that can continuously monitor the condition of the patient all throughout. Urinary incontinence, which is the involuntary loss of urine from the bladder, occurs in ∼10% of the male population worldwide. This procedure was performed by a skilled professional. The procedure consisted of inserting a catheter into the urethra of a patient into the urinary bladder, where there is a transducer in one end. The pressure and the reference pressure were measured in the rectum through fluid lines. The target pressure of the urethra was compared with the reference pressure of the rectum and analysed. It has a substantial margin of error due to the movement and measurement errors, however, pressure is a vital parameter to measure the performance of organs. For effective diagnostic, high quality and high resolution in measurements is necessary. In organs such as the urinary bladder, water-filled lines have their limitations and have still been practised throughout the decades. We should make use of the advancement in photonic MEMS, which offers a very small pressure sensor with precision and accuracy. We could conclude that there are more limitations to the values measured with water-filled lines. Hence, an in-target pressure sensor from the organs is much advanced and reliable in detecting any changes. In the meantime, optical fibre measurement systems are also considered for monitoring the temperature. The system consists of an encapsulated fibre optic pressure sensor and a Fabry-Perot pressure sensor. The optical fibre used in this case is FBG pressure sensors. The optical fibre pressure measurement system is compatible with the

[4]*Opsen's Solution*. Available online at: https://opsens-solutions.com/ (accessed July 20, 2019).

clinical phase. The whole system is compared with the traditional biocompatible urodynamic measuring system (98).

Cochlear Implant Application

Deafness affects about 10% of the general population, and the rate increases to more than 30% for those aged over 65. However, a hearing prosthesis such as a cochlear implant can provide shearing and significantly improve the quality of life. It is the most important advancement in the treatment of hearing impairment. In another work, Yao developed a fibre optic-based bending sensor for cochlear implantation. It has proved a great success in providing implantation for deafness in children and adults. Implantation using a cochlear electrode array is a complex surgical process, and there is a chance of damage to the inner wall of the cochlear, i.e., scala tympani. Since the electrode has to bend at various angles, and if the electrode does not bend at the required angle, damage to the cochlear may be severe. To avoid this, researchers developed a bend sensor for implantation surgery (99). In this context, Balster has investigated hearing restoration by optical stimulation alternative to electric stimulation. Activation of the auditory system was made by light fibre insertion into the coiled cochlea. Light fibre force measurement was conducted, and results were compared with traditional electric stimulation study. The results showed that minimal painful implantation surgery optical stimulation was considered feasible (100). In another work, fibre optic-based intracochlear pressure measurement system was developed. A 81 μm-diameter superluminescent diode (SLED) and other modes of optical fibre were embedded inside the transducers. These cochlear fibre optic sensors were helpful for early monitoring of hearing loss, as well as the sound pressure measurement of temporal bones and mechanical stimulation of the intracochlear system (83, 101, 102).

The work of Starovoyt et al. discussed optical coherence tomography for intracochlear structure. Studying the temporal bone by using OCT was the main aim of the authors. The authors focused on obtaining high-resolution images using optical coherence tomography qualitative and quantitative characteristics of intracochlear structures. The importance of OCT images in intracochlear implant surgery was explored. Implantable sensors for hearing devices and wearing the external hearing aid causes discomfort for most people. Different designs of the implantable sensor were evaluated and compared (103–105). **Figure 10C** shows the view of the human cochlear system. Key applications of optical MEMS sensors are presented in **Table 2**.

Other Applications

The study of Samavati et al. discussed the development of the COVID-19 virus diagnosis kit using a novel Go- decorated Au/FBG sensor. The saliva of a patient is considered a favourable testing specimen for COVID-19. In this study, salivary samples was collected from different types of people. The FBG-based probe has been used to detect the COVID-19 virus. The FBG probe was immersed in healthy saliva and saliva with the COVID-19 virus. The FBG probe detected the presence of the virus. The density of the virus was 1.2×10^8 copies/ml in saliva. The maximum change in wavelength observed was 1.12 nm and an intensity change of 2.01 dB (106). In this context, Sharath U designed and developed different types of FBG devices for novel medical applications. The author designed an FBG pulse recorder for cardiology applications and individual bite force monitoring devices. Bite force in men and women has been differentiated with the help of this device (107). By considering the same concept, author Jha et al. proposed an FBG sensor-based glove to monitor the flexure of 10 finger joints. The author evaluated the accuracy and repeatability of all 10 sensors. The FBG-based glove has been designed and tested with an FBG interrogator. Stroke patients were benefitted from the device developed (108). Similarly, in another work carried by Alwin T and co-authors, FBG sensor was used as a multi ocular sensor. In this case, FBG was utilised for sensing temperature, pressure, and chemical concentration (109). The human respiration rate was monitored with FBG based sensor with an Arduino interface. The respiration rate was also calculated during coughing and handshaking. Compared with an electric sensor, FBG-based sensor has shown prominent results (110). In this context Tavares et al. embedded an FBG sensor in a wheelchair. This wheelchair was mainly used to monitor the ulcer in bone areas of the seat. The FBG sensor was also used for sensing dorsal flexion and extension movements. Spending the time in job for many hours with bad posture will lead to back musculoskeletal disorders. Thus, FBG sensing that was developed has shown promising results for future fabrication (111, 112).

In another work, the authors developed a system for monitoring soft finger deformation, which was driven by shape memory alloy with an FBG sensor embedded. Firstly the structural and mechanical properties of a finger were considered for analysis. The central wavelength for change in curvature of material due to shape memory alloy deformation was monitored with FBG sensors. Soft finger deformation was analysed with ABAQUS software for analysing the FEA simulations (113). In this context, Mo et al. designed optical sensing needles for tissue identification. Optical sensing needles were used for minimally invasive surgery. Optical sensors were mainly used because of their immune to magnetic resonance. Intensity-modulated Fabry-Perot interference was considered for optical needles. Developed optical sensing needles were successfully implemented in the medical field (114). Application of intravascular catheterization was used in minimal vascular surgery considered distal force sensing system. The designed sensor has shown higher repeatability and stability. With the distal tip force sensor, it was obtained from the result that the stability of each flexure movement could be controlled with the FBG-based sensor (115). Non-invasive methods to measure wrist angular handgrip devices had been developed to measure the handgrip strength of humans with muscular-skeletal disorders. Handgrip strength was measured in different angular positions. The FBG sensor was encapsulated in the mechanical package and its variation in strain with peak resonance wavelength was monitored for various ranges of applied pressure (116).

Lower back pain is one of the most common muscular-skeletal disorders affecting workers. Video terminal workers are the most affected people with lower back pain. Prompt detection of wrong

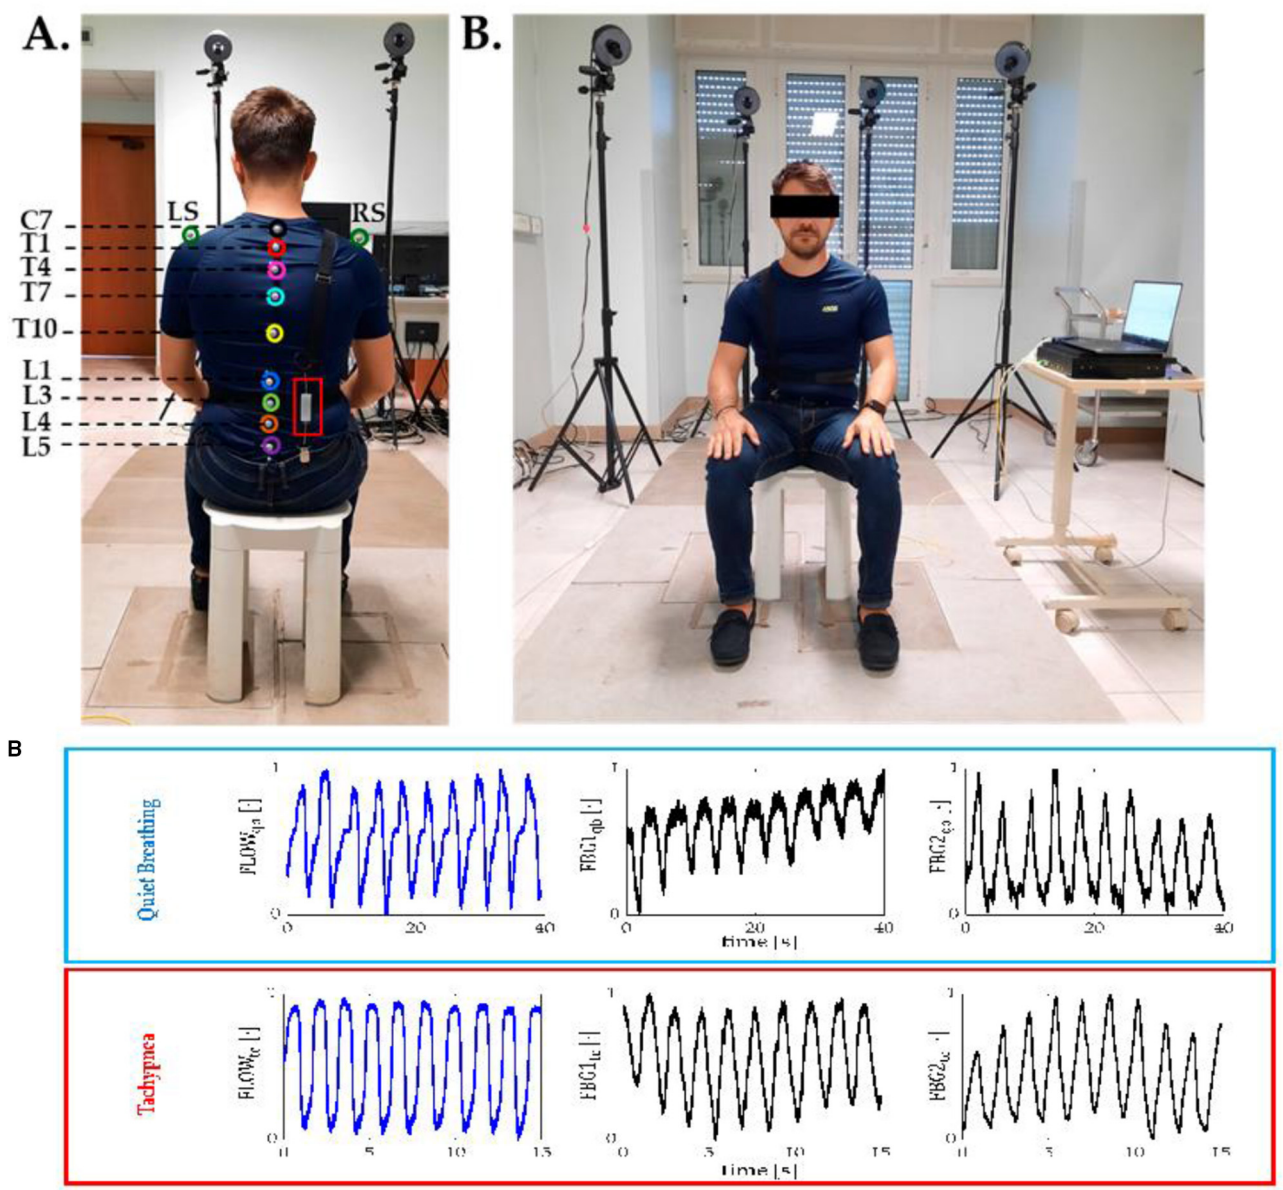

FIGURE 11 | (A) Back view showing the posterior part of the wearable devices with embedded sensor and and front view showing the anterior part of the embedded sensor (118). **(B)** Signal collected by flow meter and FBG during quite breathing and tachypnea (119).

seating postures is more critical. A lumbar movement monitoring device has been developed with FBG sensing technology. The sensitivity of the FBG device developed was 0.20 nm/mε^{-1}. This is the first device with silica embedded FBG sensing technology for lumbar motion monitoring for worker safety to overcome lower back pain. **Figure 11** shows the wearable device installed in person back for experimental purposes. The study of Lo Presti et al. considered an FBG sesor embedded in silica gel for monitoring neck movements and respiratory frequency. Neck movements during flexion-extension were investigated. In the meantime, FBG sensors were embedded in the human chest and monitored during quiet breathing and tachypnea (61, 117). **Figure 11A** shows the different views of a person with a wearable device for experimentation.

In the same context, FBG sensors are used in human gait analysis, including diagnosis, rehabilitation, and sports. The FBG sensor encapsulated in the mechanical package was used to monitor the extension and flexion movement. This evaluation is useful in monitoring walking disorders and pathologies. FBG wearable system was developed with flexible polymer matrix is

TABLE 3 | Summary of application.

Sl. No	Application	Summary of results
1	Dental	❖ Prediction of dental carries using optical sensor ❖ Incorporation of FBF sensor for dental carries ❖ Strain pattern evaluates for different parts of dental region ❖ Evaluation of dental filler material with FBG ❖ Evaluation of biting force with FBG sensor
2	Intervertebral disc	❖ Load distribution over intertribal disc during tensile and compressive stress has been monitored. ❖ Incorporation of FBG sensor spinal cord in different sitting position
3	Lumbar motion	❖ Load distribution over lumbar disc during tensile and compressive stress has been monitored. ❖ Incorporation of FBG sensor in lumbar position
4	Joint angle, gait analysis, insole pressure	❖ Integration of FBG sensor in insole for foot pressure monitoring in diabetic and arthritis patients. ❖ Embedding the sensors in insole and checking pressure distribution for different types of foot and in different experimental conditions such as walking, standing, climbing, age, and sex and in different patients.
5	Communication assistance	❖ Development of communication assistance based on eye blinking integrated with FBG sensor signals
6	Pulse wave and respiratory, body pressure	❖ Different pressure points of the body are monitored with FBG sensor ❖ Respiratory pressure is monitored with FBG sensor using wrapping the FBG sensor based belt around chest
7	Intraocular	❖ Optical fibre based sensor has been used to detect the glaucoma in patients
8	Urodynamic measurement	❖ Optical fibre has been incorporated with catheter to
9	Microfluidic system	❖ FBG sensor has been integrated with different microfluidic channel for biosensing applications
10	Handgrip	❖ FBG sensor for integrated with gloves, designed handgrip models,

embedded with FBG arrays as knee embrace. The developed FBG wearable system has shown sensitivity up to 3.944 nm-mm^{-1} (120). **Figure 11B** shows the signal collected by the flow metre and FBG during experimentation. In another work, Ran et al. proposed an FBG-based immunosensor for cardiac biomarkers. The concept of temperature cross-sensitivity was considered during the development of proof of concept. The tool was used to identifying acute heart diseases. In a similar case, FBG sensors were embedded in T-shirts to monitor the respiratory rate during cycling. Massaroni et al. proposed an FBG sensing system embedded in cloth for monitoring human body breath monitoring. Twelve FBG based sensors were embedded in the T-shirts. Four volunteers were considered during the study (49, 118, 119, 121–125)[5]. FBG sensors are also used to measure the pose of different medical instruments used in surgery, wherein FBG sensors are embedded in catheters. Flexible movement of catheters during surgery is monitored with an FBG sensing system (126–128). **Table 3** shows the summary of the application. **Figure 12** shows the major application of optical MEMS.

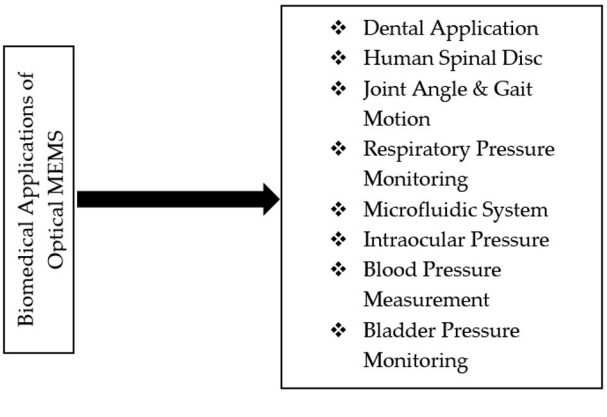

FIGURE 12 | Major applications of optical MEMS in biomedical.

KEY IMPACTS AND THE CHALLENGES OF THE OPTICAL MEMS FOR THE BIOMEDICAL APPLICATION

The authors investigated crucial factors of the optical MEMS sensing system by considering many research papers and concluded three key elements. These key factors are based on optical MEMS devices, optical MEMS applications, and current optical MEMS technology trends. A detailed analysis of these critical factors is grouped in **Table 4**. Conventional MEMS sensor uses piezoelectric or shapes memory alloy, transducers to convert physical phenomena and into electrical signals; these signals are scaled, conditioned, and digitised to the required applications. Despite their advantages, these sensors are impractical to use in all applications. Instead, the optical MEMS sensor offers excellent solutions to many challenges faced by MEMS sensors. Sometimes, the optical MEMS sensor works similarly to the MEMS sensor but uses light instead of electricity and silica glass instead of copper. It was observed from the literature that most biomedical applications use optical fibre or FBG technologies for monitoring pressure, temperature, and many other physical parameters. Different optical MEMS systems, such as photonic integrated microcantilevers, MZI, and ring resonators, can penetrate as emerging technology until laboratory testing costs and complexity and reliability issues of these

TABLE 4 | Critical factors of optical MEMS.

Key factors for the optical MEMS methods/designs	References	Total studies
Key factor 1	(1–49)	49 papers
Key factor 2	(50–104, 129)[12345]	60 papers
Key factor 3	(49, 118, 119, 123–128)	28 papers

sensing systems are resolved. Critical success factors of the optical MEMS till 2020 include evaluation of sensor performance such as its sensitivity, Q factor, detection limit, Optimization of various sensing structures, etc. **Table 4** shows that research work carried out extensively with optical sensing systems such as photonic crystal structures, MZIs, and optical microcantilevers. Performance enhancement of various optical MEMS sensing structures has been carried out. It was possible to successfully implement the FBG and an optical fibre sensing system in many real-time applications. Still, authors are provided scope for improvement in much research work. Feasible sensitivity and detection limit is achieved based on a specific application. Most of the sensors were designed and analysed with transverse electric mode. It is noted that real-time implementation of other sensing systems apart from FBG and optical fibre sensor requires plenty of sensing system characterisation. **Figure 13** shows major applications of optical MEMS in biomedical.

Three critical factors are identified in the survey of optical MEMS for biomedical applications, and are clearly distinguished as Key factors 1, 2, and 3. Research articles on Key factor 1 highlighted the issue of pre-fabrication stages, such as design and simulations. Performance evaluation of sensors in terms of sensitivity, detection limit by design optimization, modified refractive index, and different material assignment for the sensing structure is discussed in Key factor 1. Applications in which optical MEMS sensors have been successfully implemented is considered as Key factor 2. From Key factor 2, it is observed that there is substantial usage of optical fibre sensors, FBG, and MEMS-based optical coherence tomography, optical MEMS actuators, etc. survey on the present market status of optical MEMS are discussed in Key factor 3. The optical MEMS design and testing phase faces technical challenges in the presence of mechanical elements during the integration process involving flow, pressure, movement, and analysing temperature. The combination of the multi-function device makes the design and testing complex during the development process of the optical MEMS sensor. Most organisations have no access to the fabrication facility, even if there is interest in exploring the technologies. Packaging can be expensive and knowledge of fabrication challenging aspect in the case of optical MEMS.

An overview of optical MEMS market growth in 2019 offers a complete analysis for better understanding the completion in the market and implementing the same in research activities. The optical MEMS market fragmented in different major companies like S.T. Microelectronics, Analogue Devices, Freescale Semiconductor, Texas Instruments, Boston Micromachines, and Memscap. As shown in **Figures 14A,B** below, the maximum market size of optical MEMS in the current era in the field of Biomedical Engineering is preceded by Defence and Security and Smart structures. The least volume of the market is observed in the small structures. Under the optical MEMS category, the original product is the projection system, microbolometers, MZI, optical cantilevers, ring resonators, and FBG sensors.

The fibre optic sensor market is projected in 2017 to be $1,008 million in 2021 and reaching above $1,033 million in 2023. Most commercial efforts focused on medical and military applications. Due to the continuous improvement in the FBG writing system, there is an increase in demand. Among the different types of FBG types, uniform FBG type is expected to have compound annual growth rate over 14% as forecast in upcoming days. Photonic crystal biosensor, optical ring resonators type of sensing system has shown less trend presently due to sophisticated experimental setup and more importantly because of the technology readiness level of photonic sensing devices. Most of the photonic crystal sensor has to be cascaded which leads to the difficulty over fabrication. Bringing out the photonic sensing system in the main market, except for fibre optics-based sensors, takes few years of time due to this challenging process involved. The global market of photonic crystals has reached up to $43.119 billion during 2015 and it will be $60.230 million during 2022. Photonic crystal sensing research has got attention from other academicians, as well as from scientists. Research filed such as industrial telecommunications, biomedical field, LED display, and optical sensing technology has shown remarkable growth with photonic crystal from the past few years.

Obstacles for the growth of the optical MEMS device mainly include design complexity, reliability, fabrication access, packaging facility, and knowledge of fabrication. The optical output parameters such as Q-factor, sensitivity, and transmission efficiency mainly depend upon the final packaging of the device. Since the optical MEMS technology involves more moving parts controlling the device, accuracy requires expertise in a multidisciplinary field. Despite these challenges in optical MEMS technology, it overcomes many disadvantages faced by MEMS technology, such as high sensitivity, less power consumption, EMI Insensitivity, and lightwave manipulation can be more comfortable with moving mechanical elements. The device-level design, fabrication, or packaging complexity is due to less exposure to optical MEMS technologies. Simplifying the device design and packaging process is the scope in the optical MEMS technologies. **Figures 14A,B** shows the curret trends of optic MEMS sensor in market.

Simplifying moving micromechanical parts in terms of size is essential for increasing the efficiency and performance of optical MEMS. Design and optimization of moving mechanical elements essential criteria to build the integrated optical sensing system. Using the sophisticated fabrication lab software tools for pre-checking the final model and packaging for reliability, the accuracy of readings is the primary solution to speed up the final fabrication to bring the device technology to commercial status. This technique mainly applies to the

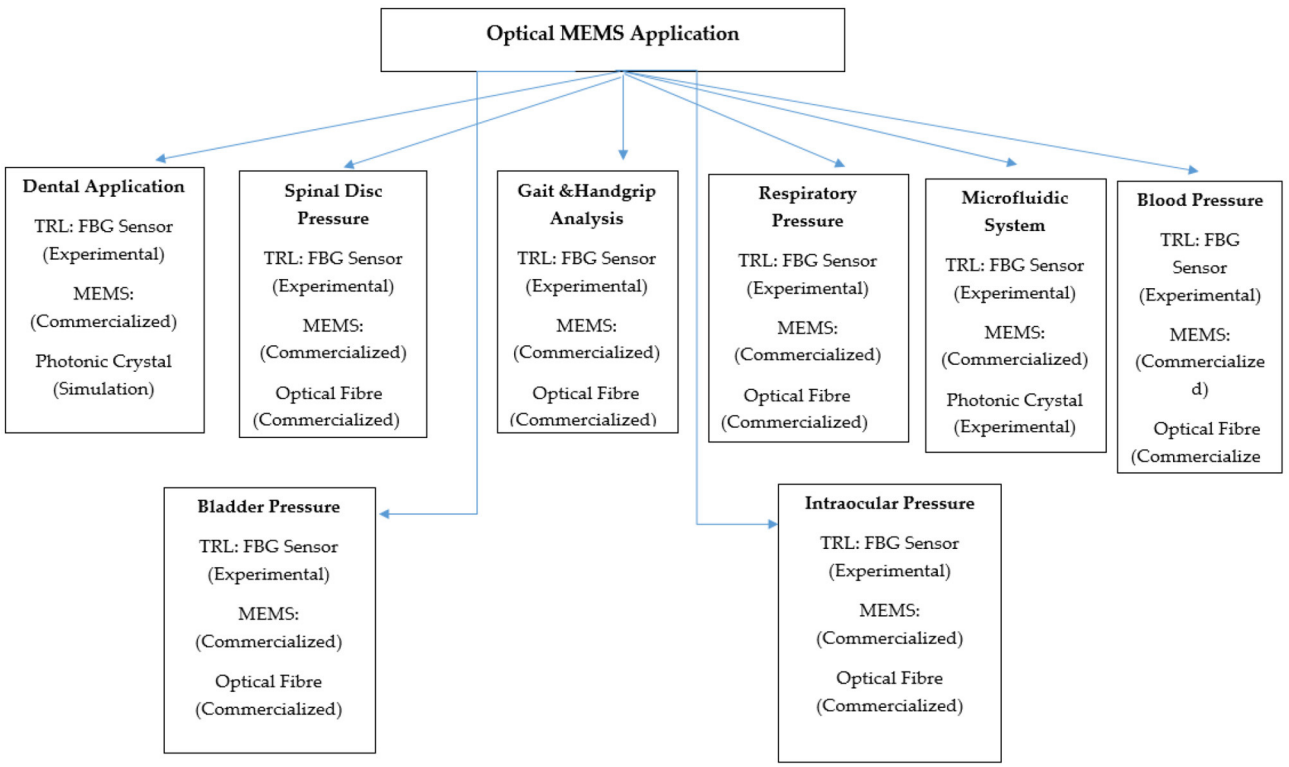

FIGURE 13 | Major applications and TRL (technology readiness level) of optical MEMS sensing system in biomedical.

photonic sensing system in the technology readiness level as experimental such as photonic crystal, photonic ring resonators, and MZI. In the case of FBG based sensing system, miniaturisation of FBG interrogator device in the form of chip will increase the demand in the market. Accurate debugging and design tuning, preparing virtual prototypes, Gathering practical feedback at the time of designing are the factors making up the successful implementation of the product. Designing the photonic integrated circuit with photonic crystals sensing technology and optical resonators or MZI is always challenging; actual implementations are possible with 3D emulators. This process shows how the microchip will work in 3D visualisation and helps the final working of the product after packaging. There will be unpredictable and immeasurable errors that have to be overcome for ease of fabrication. High tolerance needs to be maintained in the design for achieving targeted output. Coupling problem, temperature influence, controlling size, and position of holes are critical parameters affecting sensor performance due to the requirement of nanometer precisions scale.

SCOPE OF FUTURE WORK

The focus of this review was to explore the recent advancement of optical MEMS sensors and their application in the biomedical field. Key and important issues with optical MEMS had been identified. Using high sensitive MOEMS sensor for the harsh environment have operational and stability issues. There is always scope for developing sophisticated MOEMS sensing structures by analytical and simulation models to improvise the sensitivity, stability, and printable or packaging issues. Optomechanical sensors with high sensitivity could be developed by considering different mechanical properties, stiffness, the mass of sensing material, etc., thereby increasing response frequency for sensing pressure and displacement. The operational stability of the MOEMS sensor could also be increased by the coating of the sensing layer with different materials. There is always scope to investigate the integration of optical sensing layers with composite and organic materials to make packaging easier. Even though the FBG sensing system has reached commercialisation, the miniaturisation of the FBG system such as interrogator is the requirement of the present scenario to bring compact devices in the market.

- ❖ Variety of Photonic MEMS sensing systems have been considered in the literature, but minimal sensing system is implemented in biomedical applications due to sophisticated fabrication feasibility.
- ❖ There is a lot of scope for optimization of photonic MEMS sensing structure for implementation in biomedical applications since most of the photonic MEMS system, apart from optical fibre, is implemented in telecommunication.
- ❖ Fibre Bragg Grating is a mature technology and has plenty of scope for incorporating in biomedical applications

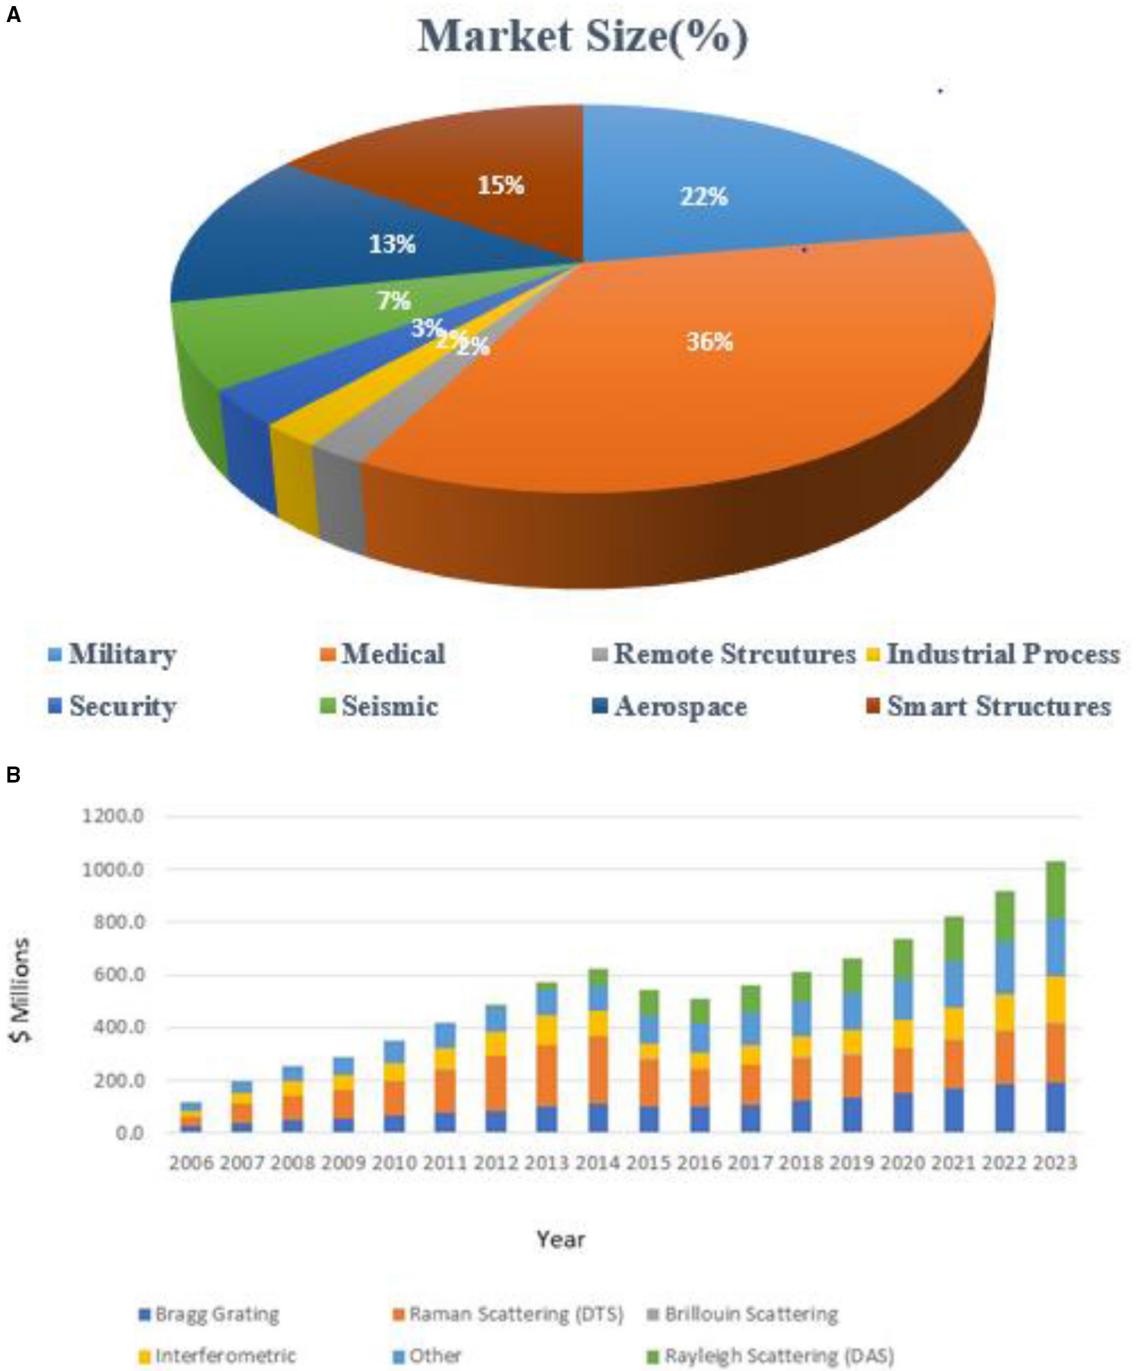

FIGURE 14 | (A) Presents trend of Optical MEMS market (127). **(B)** Optical MEMS market growth until 2023 (127–133).

to increase the accuracy, sensitivity, and durability of medical instruments.

- ❖ Recently published articles show possible future work in terms of design, different experimental conditions for specific applications.
- ❖ The obstacles to overcome soon include collecting experimental data, fabrication knowledge, and lack of fabrication facility.
- ❖ Dynamic analysis of each moving mechanical element is necessary before integrating these elements into the optical system to obtain more accurate results.
- ❖ Design and packaging, testing, sensing, latching, controllability, and reliability are the main challenges in developing optical mems sensors.

❖ Optical MEMS helps accelerate the deployment of different sensing systems in the biomedical field and other structural health monitoring fields.

CONCLUSION

This article reviewed different optical MEMS sensors and their application in the various biomedical fields with future trends and growth. To assist clinicians in knowing about the recent developments under optical MEMS, a clear possible visualisation was provided to implement the same technologies in the biomedical field. This paper has investigated the necessary information about optical MEMS, and its possible applications in the biomedical field have been assembled and discussed in detail. With many research articles under microcantilever-based optical MEMS diaphragm, interferometers under different forms were limited to simulation stages, but still showed possible future improvement towards improvising sensitivity with novel structure with experimental setups. Photonic crystal sensing and optical ring resonators had shown more discussion on developing mathematical modelling and numerical simulations. Structural optimization in terms of material properties, geometrical changes, and possible applications has been considered. Experimental techniques were considered in the field of photonic crystal, ring resonator, and MZI technologies. However, readers who are interested in readings of these photonic technologies would find plenty of unique design properties assigned during the structural optimization. Designers had increased their horizons towards finding new solutions for ease fabrication by simple designs with practical outputs. In the near future, photonic sensing technologies will control, integrate the network, and find real-time measurements in different biosensing applications. From the literature, it was also observed that most biomedical applications discussed here use the non-invasive method of parameter monitoring. There is always a possibility of the improvement of non-invasive clinical diagnosing with the optical sensor. Irrespective of complexity in fabrication, optical MEMS has consistently shown high operation speed, high optical efficiency, optical precision, reliability, readability, and scalability. Significant properties the optical MEMS material should incorporate are high stiffness, high fracture strength, fracture toughness, temperature, and chemical inertness. It was also found that optical coherence tomography major equipment used in biomedical image study. Although researchers had understood optical MEMS and experimented with a different application, implementation of the same in reality has not been possible in many cases due to sophisticated technology, lack of experimental setups, and the requirement of testing its consistency in performance. Since there are various fibre optic FBGs sensors, choosing the appropriate coating material for a suitable application is critical. As per the market survey, it was seen that there will always be an increase in demand for optical MEMS sensors with technical advancement.

NextGen Public Health Surveillance and the Internet of Things (IoT)

Kirti Sundar Sahu[1], *Shannon E. Majowicz*[1], *Joel A. Dubin*[1,2] *and Plinio Pelegrini Morita*[1,3,4,5,6]*

[1] School of Public Health Sciences, University of Waterloo, Waterloo, ON, Canada, [2] Department of Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada, [3] Institute of Health Policy, Management, and Evaluation, University of Toronto, Toronto, ON, Canada, [4] Department of Systems Design Engineering, University of Waterloo, Waterloo, ON, Canada, [5] Ehealth Innovation, Techna Institute, University Health Network, Toronto, ON, Canada, [6] Research Institute for Aging, University of Waterloo, Waterloo, ON, Canada

Recent advances in technology have led to the rise of new-age data sources (e.g., Internet of Things (IoT), wearables, social media, and mobile health). IoT is becoming ubiquitous, and data generation is accelerating globally. Other health research domains have used IoT as a data source, but its potential has not been thoroughly explored and utilized systematically in public health surveillance. This article summarizes the existing literature on the use of IoT as a data source for surveillance. It presents the shortcomings of current data sources and how NextGen data sources, including the large-scale applications of IoT, can meet the needs of surveillance. The opportunities and challenges of using these modern data sources in public health surveillance are also explored. These IoT data ecosystems are being generated with minimal effort by the device users and benefit from high granularity, objectivity, and validity. Advances in computing are now bringing IoT-based surveillance into the realm of possibility. The potential advantages of IoT data include high-frequency, high volume, zero effort data collection methods, with a potential to have syndromic surveillance. In contrast, the critical challenges to mainstream this data source within surveillance systems are the huge volume and variety of data, fusing data from multiple devices to produce a unified result, and the lack of multidisciplinary professionals to understand the domain and analyze the domain data accordingly.

Keywords: real-time data, rapid surveillance, data source, big data, innovation

INTRODUCTION

The function of public health systems is to understand and respond to health trends affecting populations (1). This is achieved through public health surveillance, that is, the ongoing collection and analysis of population health indicators. Traditional surveillance data collection can be cumbersome, expensive, and slow, often relying on paper-based and digitally extracted data sources. Social media and crowdsourcing are data sources that can be leveraged for surveillance data (2, 3). Sources like Twitter, Facebook, Google, and Reddit have been successfully used to explore behavior and health outcomes (4–6). These are now being accepted as potential data sources across several health domains (7, 8).

Another promising data source is the increasing number of devices (e.g., smart home monitors, wearables) and the technology to interconnect them. Internet of Things (IoT) technologies have become mainstream within communities and individual households (9). Wearables and sensors can track personalized parameters of healthy living, including sleep, physical activity, and sedentary behavior (10, 11). These devices can provide insights into population health, disease management, and active assisted living services (12, 13). IoT data has several advantages over traditional surveillance data: high volume and frequency of data collection, data triangulation, real-time availability, and minimal acquisition effort.

Existing literature discusses the potential use of the IoT data sources for different purposes within multiple domains including healthcare. Among healthcare domain, area specific application can be seen for pediatric, geriatrics, chronic disease supervision, private health, and fitness management (14, 15), but no single study exists to put together the views to utilize the IoT data with specific emphasis on public health surveillance.

This article summarizes the existing literature on the use of IoT as a data source for surveillance. We discuss the shortcomings of current data sources and how IoT can meet the needs of surveillance. Challenges facing the large-scale application of IoT data to surveillance are also explored.

PUBLIC HEALTH SURVEILLANCE AND CHALLENGES WITH EXISTING DATA SOURCES

Public health recommendations focus on the social determinants of health and health equity (16). Surveillance is the process by which ongoing health data are collected, analyzed, and reported, and it is critical to informing public health services. In 1968, the World Health Organization listed 10 essential data sources for surveillance (17) (**Figure 1**: Traditional data sources) that at the time relied on paper-based data collection and manual data entry. Surveillance capability has evolved enormously alongside advances in technology. It now includes digital data extracted from several sources (**Figure 1**: Modern data sources), offering reduced processing time, fewer errors, and reduced lag between data collection and its use.

The above said, surveillance data are still often obtained from questionnaire-based surveys online surveys, in-person or telephone-based interviews (18), and such data collection requires enormous resources and funding (19, 20). Data quality can be compromised by declining response rates (18), recall bias (21), and low granularity of the data (22) as in the traditional data collection system, there is a limited number of subjects provide their inputs. Without complete and comprehensive information, the value of the data reduced. For example, fewer subjects with a smaller *n*, really only impacts the precision of the estimates that come from surveillance. To further explain, the system might not get very precise incidence estimates, which may or may not be a problem depending on the goal of the system. The bigger issue with declining response rates is that they usually do not happen at random and meaning you're a less representative set of results. This is an issue if the factors that lead to making it into surveillance also relate to the issue you are trying to measure with the surveillance system. Current data used for the surveillance have challenges like missing data, under-reporting, inconsistencies, invalid data, illegible handwriting, non-standardization of vocabulary, measurement error, and inappropriate fields (23). Traditional data sources used in surveillance are often delayed. For example, at least 1 year is required for getting a Canadian Community Health Survey (CCHS) update. "Public Health Ontario" in Canada affirms interdependent gaps within surveillance, insufficient data to build comprehensive health indicators (24), and an absence of existing mechanisms to capture some of healthcare's vital components.

Current surveillance relies on both prospective and retrospective data collection, analysis, and reporting (25). The current pandemic has highlighted the essential need for real-time public health surveillance to improve the evidence-based decision-making process (26). Our evolving knowledge about chronic diseases, their risk factors, and management also demands the modernization of surveillance (25). Real-time responses to emerging public health threats require real-time and systematic data collection.

NEXT-GENERATION DATA SOURCES FOR PUBLIC HEALTH SURVEILLANCE

Researchers have attempted to build and analyze health indicators using innovative data sources (27–29). They are exploring the use of smartphones (30), online searches (31), social media (7), wearables (32), ambient sensors (33), electronic health records (EHRs) (27, 34), medical-administrative records (27), and pharmacy sales (28) to broaden the scope of surveillance.

As a source of surveillance data, information technologies are potentially advantageous because their near-universal uptake by a significant portion of the population creates vast quantities and varieties of data (22). For example, wearable data from six billion nights has been used to understand sleep duration, quality, and change in pattern with time (35, 36). Effective use of big data for surveillance requires innovative analytical methods such as data integration (32) and data visualization (28, 37, 38). Big data analytics is becoming mainstream in public health, integrating knowledge and skills from health informatics and biostatistics (39).

THE INTERNET OF THINGS AS A NOVEL DATA SOURCE

The Internet of Things (IoT) is a technological innovation through which devices can communicate with each other in real-time through an internet connection (40). For example, several household devices are interconnected to achieve a common objective, such as monitoring temperature or motion (40). Integrated devices can include different sensors, mobile phones, mobile applications,

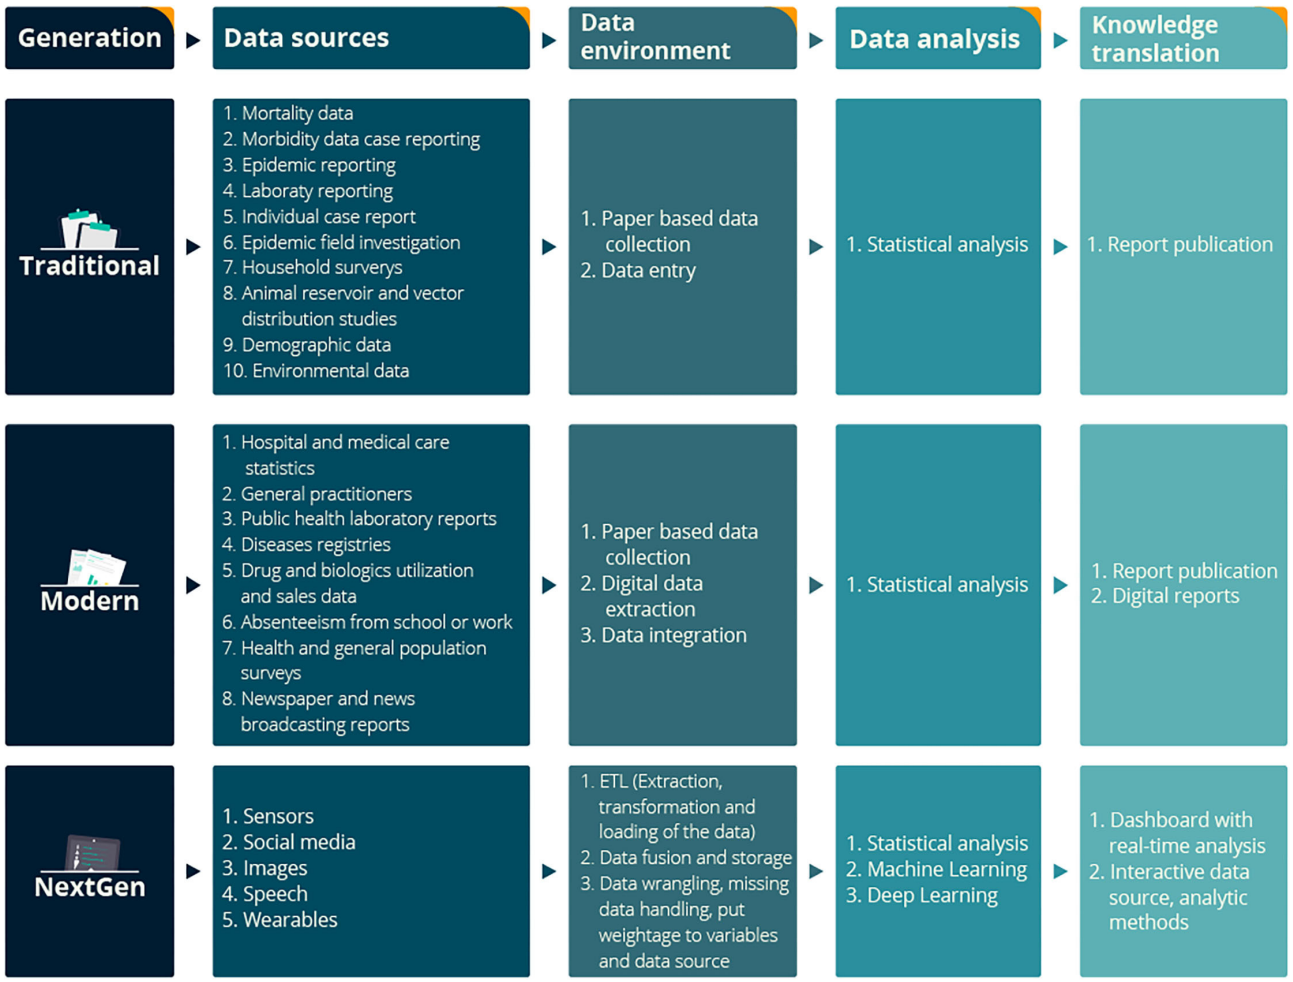

FIGURE 1 | Conceptual framework of NextGen Public Health Surveillance with Traditional, Modern, and NextGen data sources. Traditional and modern data sources extracted from Declich and Carter (17).

wearable devices, and Radio-Frequency Identification (RFID) tags (40).

IoT devices have accelerated data collection (13, 41). Connectivity among people, machines, and organizations increases as device availability and affordability improve (22). This increase in connectivity is because of the ease of use of the devices, user-friendly designs, and internet speed. These parameters reduced the time gap within communication, broaden the scope of communication by providing different choice, be it audio visual, text, or hybrid of multiple methods. People can interact with the machines and vice versa, which was not possible earlier due to lack of technological progress. In 2011, the number of interconnected devices overtook the actual number of people globally (42). The potential for data generation is exponential (41). As the IoT data has already been successfully used in multiple setups to monitor individual health outcomes and report on environmental conditions, some of the best use cases has been described below.

Use of IoT Data to Support Individual Health Outcomes

The management of chronic conditions has traditionally relied on patients interacting with their healthcare providers in person. However, patients spend most of their time outside the clinic. IoT monitoring provides an opportunity to collect real-time health information between patient-healthcare provider interactions.

Smart devices, such as wristbands, with IoT technology have been developed to measure individual physiological data, including physical activity (10, 43), sedentary time (44), oxygen saturation (45–47), heart rhythm (45, 46), muscle tremors (48), spinal posture (49), brainwaves (50), sleep (51), diet (52, 53), electrodermal activity monitoring for sympathetic response (44) and oral health care (54). With regards to specialized medical care, IoT technology has been used to cater to the need of cardiovascular (18), cardiopulmonary (18) and ophthalmology (55). With regards to different categories of populations, IoT has been used to help to monitor indicators related to women's health (56), including pregnancy (57), soldiers at the country borders

(58), nursing care at the hospitals (59), the elderly population in the long-term-care homes (60), persons with neurological conditions at the rehabilitation center (49), and also for persons with respiratory complaints including asthma (61).

IoT devices have a multipurpose use within the healthcare field, such as their capabilities can range from providing prenatal care to rehabilitation to monitoring seniors or athletes. IoT devices have successfully provided real-time health information on maternal and fetal health between regular appointments (57). By monitoring vital signs using sensors, IoT platforms have been designed to provide people with diabetes with feedback and notifications to mitigate the risk of complications (62–64). Additionally, wearable devices have been used to detect falls and changes in behavioral activity for seniors living independently (65–68). Monitoring systems have also been developed to evaluate sports rehabilitation (69–72). IoT can support individual outcomes by allowing patients to manage their health outside of the clinical setting.

Use of IoT Data to Monitor Environmental Conditions

The IoT can also monitor environmental conditions in areas where we live, work, and play. Monitoring air purification in hospital settings plays a role in mitigating hospital-related infections (73). Monitoring air quality is already used to quantify climate change impact (74) and has the potential to help mitigate its impact in the future (75). IoT has been employed to monitor hospital circulating air volume, ozone concentration, temperature, humidity, and leaked ultraviolet intensity (73). Preventive behavior like hand washing can also be monitored (76). Indicators of healthy outdoor environments, such as water pollution and air quality, have been another target of IoT health research (61, 77, 78).

THE INTERNET OF THINGS IN PUBLIC HEALTH SURVEILLANCE

IoT data has been successfully used in other health domains but has not yet been fully used in public health. In response to the pandemic, the 2020 Riyadh Declaration made several recommendations to address the shortcomings in global public health response systems (79). The Declaration prioritized the need for scalable and sustainable digital health technologies and the adoption of health intelligence (79). There is a growing interest in using IoT data for building public health indicators at various levels (80–82).

Advantages of IoT in Public Health Surveillance

IoT data have the potential to overcome shortcomings of current surveillance. IoT data sources provide high-frequency data with greater usability, and much of the device infrastructure for surveillance is already in place (i.e., smartphones, wearable technologies, internet access). Currently, worldwide more than three billion smartphone users (83), 722 million users of several kinds of wearable devices (84), and more than 1.2 billion smart-home connected devices exist (85). IoT data benefits from essential features like high granularity (22), objectivity (32), and validity (86). These "user-generated data ecosystems" are being generated with minimal effort by the device users and researchers. To date, the monetary cost to participants and researchers is low, suggesting that public health monitoring costs would likewise be minimal (87, 88). Finally, IoT enables near real-time data collection (89). This can significantly reduce the time gap between health events, data collection, reporting, and intervention.

Here we have assessed IoT's current attributes using the framework for evaluating public health surveillance by Groseclose et al. (90), which outlines nine features of surveillance systems to consider (**Table 1**). As summarized in the table, the major advantages of IoT data sources appear to be high-frequency data collection, the potential to have syndromic surveillance, zero effort data collection method, high volume, and variety of data. The major disadvantages appear to be lack of representativeness within a single data source, private players' involvement as the data owner, the need for a high technological system to store, clean, and analyze the data, and interoperability. In addition to the above points, data privacy concerns of users are a potential disadvantage of acceptance of this technology from the user point of view (81).

Challenges to Using IoT in Public Health Surveillance

The challenge now is how to access and analyze the data being gathered. Some IoT companies create sharable, research-oriented data sources, such as "donate your data" from ecobee, a smart thermostat company in Canada (91). ecobee's smart home products include motion and temperature sensors, and research teams have access to longitudinal data from thousands of households with a data granularity of 5 min intervals.

Other IoT companies publish studies from their own smart devices using artificial intelligence algorithms for population-level measurements. For example, Fitbit wearables recorded sleep data from over six billion nights of its customers' sleep (35), the most prominent sleep dataset ever collected. Similarly, Oura Health used IoT data gathered from their Oura ring, a wearable sensor that tracks key signals from the human body (sleep, heart rate, skin temperature, physical activity), delivering critical insights to help an individual harness their body's potential daily and also to monitor vital health indicators (92).

Another hurdle is the ability to fuse data from multiple devices to produce a unified result. Several research projects have focused on making IoT data fusion viable in the real world by designing computing infrastructure and data fusion techniques (89, 93). Real-time IoT analysis from multiple health monitoring devices may overwhelm current computational capabilities, such as using multiple devices to monitor each football player's physiological indicators during a game (94). A distributed computational framework to handle complex computational needs was developed by Higinio et al. for health surveillance (94).

TABLE 1 | Analysis of IoT as a data source for public health surveillance, using Groseclose et al. (90)[#] framework for evaluating public health surveillance.

Attributes (definition)	Features of IoT data
Simplicity *"The system's structure and ease of operation. The system should be as simple as possible."* (90)	• Data collection/extraction from users without complex interactions using Application Programming Interface (APIs) that the manufacturer often provides. • Easy access to the data, which is often collected by passive sensors, minimizing the burden for the user. • IoT systems rapidly generate large volumes of data in real-time, creating challenges associated with managing, hosting, and analyzing big data. • Diverse types of data being generated: numeric, images, text, or audio. • Collects vast amounts of data from the same individual, often supporting longitudinal analysis.
Flexibility *"Ability to adapt to changing information needs or technological operating conditions with little additional time, personnel, or allocated funds."* (90)	• Application Programming Interfaces (APIs) make it easy to adapt to the technology to the end-users being used, type of data, type of database, type of storage, and security requirements. • New IoT data sources that use APIs can easily be integrated into systems, also affording changes in a data structure as technologies evolve. • Changes in case definition can be updated in algorithms rather than requiring changes to data collected since systems can access the raw data. • The system can be automated to generate alert systems without manual effort which can help public health officials identify potential signals for future outbreaks early.
Data quality *"Completeness and validity of the data recorded in the system."* (90)	• IoT data often suffers from missing, inaccurate, and incomplete data. • Wearable sensors that require participants to recharge and remember to interact with the device often have larger volumes of missing data. • Ambient sensors often generate continuous and complete datasets as they are always connected, powered on, and streaming. • Technology development is leading to improved data quality across all IoT sensors.
Acceptability *"Willingness of persons and organizations to participate in the system."* (90)	• IoT technologies are pervasive, and in the community, a part of the population is already using those technologies to generate data. • IoT adoption is accelerating in the last decade and is predicted to be much higher in the near future. • Recent advancement in technology used "skin interfaced sensors" not only monitor physical activities and vital signs but also keep track of molecular biomarkers of the human body (104). • Users need to agree to share their data, as it has already been collected.
Sensitivity *"At the level of case reporting: the proportion of cases of a disease or event detected by the system. Ability to detect outbreaks over time and evaluation of surveillance system."* (90)	• IoT sensors, in most cases, do not focus on the detection of specific diseases such as COVID-19 or influenza but rather on symptoms like fever, abnormal heart rate, or change in gait pattern. • IoT technology is ideal for supporting syndromic surveillance by collecting data about healthy behaviors and health variables in real-time. • IoT technology will collect data that is often indirectly associated with health and health risk behaviors (e.g., indoor motion data to quantify sleep patterns, phone mobility data used to quantify response to COVID-10 policies). • IoT will provide extensive participant data with a higher likelihood of the presence of events. • The longitudinal nature of the data can detect future anomalies using Artificial Intelligence models within the healthcare sector and send alerts to policymakers. The longitudinal and continuity nature of the data will provide richer insights into population behaviors, which increases the likelihood of getting the events of interest.
Positive predictive value *"The proportion of reported cases that actually have the event under surveillance."* (90)	• The proportion of the presence of IoT within the community is increasing and predicting the true positive cases will be easier using IoT data by identifying early alerts. • The detection of specific diseases is possible, as technologies such as lab on a chip (106, 107) allow for real-time detection of pathogens and contaminants. • Positive predictive value seems to be in a disadvantageous position with the current IoT data environment, but this might change in the future.
Representativeness *"Ability to accurately describe the occurrence of a health-related event overtime and distribution of the population by place and person."* (90)	• Large number of participants can provide access to data who were not represented in the traditional data collection method. • IoT technologies are ubiquitous, highly pervasive, and are generating data 24/7. • Data mining from sensors already owned by the population generates a biased sample, with data from the wealthier and more physically active part of the population. • Studies can supplement biased samples by deploying targeted studies to collect data from under-represented subgroups of the population.
Timeliness *"Reflects the speed between steps in a system."* (90)	• Data is often collected at high frequencies, often affording access to data in the near real-time. • An increase in the data's granularity and the longitudinal nature of the data can provide richer insights, for instance, faster alerts of anomalies for specific health issues, and support the creation of innovative indicators. • In the near future, the IoT data source may become helpful to identify future pandemic and climate-related emergencies. Immediate assessment of the impact of policy changes (for example, "work from home" during the pandemic) can be possible using IoT data. • Improvement from traditional data sources where data collection often happens once yearly or less frequently.
Stability *"Ability to rely on the system for availability and to collect manage and provide data without failure. Ability to be operational when needed."* (90)	• Private cloud systems can provide the necessary data security and maintain the users' privacy. • Redundant, always available, more stable public health surveillance platforms/systems can be built using private cloud solutions, having the capacity to collect uninterrupted data without failure. IoT manufacturers and IoT data custodians can deliver such redundant and stable systems for their consumers' everyday use. • The disadvantage of these IoT data manufacturers is ever-changing company environment (for example, corporate and big private entities) might not provide a stable source of data. The alternative source of data should be listed as a backup plan to support and strengthen when required.

[#] *Groseclose et al. (90).*

The use of each smart devices' computing capabilities effectively shared advanced health monitoring applications (94).

Regarding technical challenges related to IoT, some of the critical issues are energy optimization, hardware compatibility, security, and data connectivity (95). A recent study by Iwendi et al. in 2020 shows that there are certain highly specialized algorithm such as a "hybrid meta-heuristic algorithm" has the potential to optimize the energy consumption of the sensors related to wireless sensor networks (95).

Aberration detection identifies unusual incidents or information trends with possible significance to clinical or public health (96). Methods for detecting such aberrations have also evolved significantly. Current modeling methods can now analyze individual surveillance data collected from different sources and integrate multiple covariates (97). The algorithms used for signal recognition have improved over the last decade and are now better equipped to utilize advanced informatics to capture surveillance data aberrations (96, 97) accurately.

In 2018, Faverjon C. and Berezowski J. elaborated on IoT data's utility for aberration detection (97, 98). Two studies have shown that user data from wearables (Fitbit and the Oura ring) could detect early signs of COVID-19 infection (99–103). Evidence shows the risk of hospitalization related to COVID-19 can be calculated from self-reported symptoms and predictive physiological signs by combining different health and behavioral data from consumer wearable devices; this may help identify pathological changes weeks before observation using traditional epidemiological monitoring (99, 100). As described in the study using Fitbit wearable, it has the potential to detect almost half of COVID-19 positive cases 24 h before participants reported the onset of symptoms with 70 percent specificity (103). Besides joint effort by multiple countries to develop vaccines and potential drugs to prevent and treat COVID-19, skin-integrated and skin interfaced sensors, positioned at optimal locations of the body, might address the ongoing and critical need for objective, continuous, and sensitive tools to detect COVID-19 symptoms early in the general population (101, 104). A research study highlighted a practical approach for managing epidemics using digital technologies with a roadmap to a rapid and universal diagnostic method for the population level detection of several respiratory infections in advance of symptoms (102). These anomalies could predict future outbreaks (97) and prevent the spread of infectious diseases (105).

NEXTGEN PUBLIC HEALTH SURVEILLANCE

The COVID-19 pandemic has revealed a need to strengthen our public health surveillance and response systems. With the availability of public data and advances in collection and analysis, there is an opportunity to strengthen existing surveillance systems by harnessing complementary data sources like IoT-based data (31).

Figure 1 describes the NextGen surveillance systems' conceptual framework. The first layer describes the sources of public health data. The second layer represents the data architecture. Once the data integration process is completed, data manipulation and analysis can be possible using statistics, machine learning, and deep learning algorithms. This process will help discover new public health indicators and advance our understanding of existing disease risk factors.

CONCLUSION

Current public health surveillance systems have unique challenges in getting the relevant data at the right time and utilizing those data sources for policy-level decision-making. There is a considerable volume of non-traditional data being self-generated by the public through their ubiquitous use of smart devices. Public health has the potential to utilize the real-time, longitudinal data collected through the Internet of Things (IoT) necessary for health surveillance. Advances in computing are now bringing IoT-based surveillance into the realm of possibility. The advantages of IoT data include high-frequency, high volume, zero effort data collection method, with a potential to have syndromic surveillance.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

AUTHOR CONTRIBUTIONS

KS and PM developed the theoretical framework for the paper. PM supervised KS for the project. KS wrote the first draft of the manuscript with input from all authors. SM and JD helped provide overall direction and planning. All authors contributed to manuscript reading and revision and have approved the submitted version.

FUNDING

This work was supported by Natural Sciences and Engineering Research Council of Canada (RPGIN-2017-05310) and the Ontario Centre of Innovation (33080).

ACKNOWLEDGMENTS

Thanks to all the team members of Ubilab, at the University of Waterloo, for their support.

Trustworthy Intrusion Detection in E-Healthcare Systems

Faiza Akram[1], *Dongsheng Liu*[1], *Peibiao Zhao*[1], *Natalia Kryvinska*[2]*, *Sidra Abbas*[3]* and *Muhammad Rizwan*[4]

[1] Department of Mathematics, School of Science, Nanjing University of Science and Technology, Nanjing, China, [2] Department of Information Systems, Faculty of Management, Comenius University in Bratislava, Bratislava, Slovakia, [3] Department of Computer Science, COMSATS University, Islamabad, Pakistan, [4] Department of Computer Science, Kinnaird College for Women, Lahore, Pakistan

In Internet of Things (IoT)-based network systems (IoT-net), intrusion detection systems (IDS) play a significant role to maintain patient health records (PHR) in e-healthcare. IoT-net is a massive technology with security threats on the network layer, as it is considered the most common source for communication and data storage platforms. The security of data servers in all sectors (mainly healthcare) has become one of the most crucial challenges for researchers. This paper proposes an approach for effective intrusion detection in the e-healthcare environment to maintain PHR in a safe IoT-net using an adaptive neuro-fuzzy inference system (ANFIS). In the proposed security model, the experiments present a security tool that helps to detect malicious network traffic. The practical implementation of the ANFIS model on the MATLAB framework with testing and training results compares the accuracy rate from the previous research in security.

INTRODUCTION

Internet of Things (IoT)-based network systems (IoT-net) are considered as emerging advancements in the field of technology, where cloud network-based servers provide communication, storage, and problem-solving facilities, but these sorts of systems also contain security threats and issues as well (1–4). The network user can access its facility by using an internet source (5). The multiple hardware and software-based environments provide data and information to its end users. Some of the most prominent organizations like Apple, HP, Amazon, IBM, Oracle, Intel, etc., use cloud computing (CC) techniques. CC is based on three-layer models: Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS). Similarly, cloud networks are based on four types: private, public, hybrid, and community (6, 7).

In a cloud networking environment, problems in security and authorization are the key risks. Likewise, there are numerous risks which users and network service providers both face. Mainly, security issues arise from the data storage and networking side (8, 9). Many security enhancement-based algorithms have been proposed to make the IoT-net servers secure. Many cryptographic algorithms like RSA, AES, CRT-RSA, DES, blockchain, machine learning, and artificial intelligence-based code have been proposed to enhance security. Homomorphic encryption algorithms (10–12) help to provide better security to detect non-authorization factors. Many machine learning (13) and artificial intelligence-based security algorithms help to provide better data networking with new classification and risk assessment techniques.

However, many elements remain unsolved and require more improvement and advancement in areas such as cost management, resource utilization, speed prediction, and security, most importantly.

IoT also plays a magnificent role in the healthcare sector concerning data storage, online systems, software, laboratories, pathology, clinic sessions, etc. Medical patient health records (PHR) are an emerging version of IT and smart healthcare records (5). However, here we encounter problems of data security and privacy of PHR (1, 14–18). To overcome the PHR security issue, many researchers have been working on using blockchain and many other artificial intelligence techniques, which allows clinical expertise, patients, laboratories, and the world to be connected.

One of the most effective artificial intelligence techniques is called the artificial neural inference system (ANFIS), which is the combination of an artificial neural network (ANN) and a fuzzy inference system (FIS). ANFIS is mainly used as a computational model for resolving uncertainties, reasoning, and reducing security threats from networks and cloud servers (1). It helps the systems and servers examine the risk of data and information. ANNs work on the principle of mathematical calculation. The ANFIS model is based on if-then rule statements and crisp values, and the final ANFIS surface model uses result accuracy rate. It uses most of its computational time for data classification and estimation.

Problem Statement

In smart e-healthcare systems, networking servers provide a better intermediary platform for data storage, communication, and many other aspects. The end users (doctors, clinical experts, patients, laboratories) get the opportunity to access the PHR and access the cloud servers. It can be any authorized person. It is essential to detect and classify malicious activities and network traffic. The classification of network traffic and attack type detection helps make the system more secure and detect network intrusion.

Motivation

In this research paper, we discuss the existing security risks in IoT-net-based PHR. We classify these issues in managing risk, end-user risk, organizational risk, privacy risk, and many more. Our main agenda is to propose a less risky cloud network for everyone. We represent the list of shortcomings in existing malicious network traffic, and this will benefit the networking service provider and security handler community to comprehend the security issue.

Contribution

In this research, we try to implement the ANFIS model to detect network attacks on database servers. The main agenda is to detect the unauthorized access of users by using an ANFIS-based intrusion detection system. The proposed security algorithm helps to collect malicious activities or information from network traffic. Based on the if-then rule statement and ANFIS-based data classification which can help detect the intrusion attack, the system can determine if the cloud server has been hit by an intruder or not. If there is an attack, identifying the type of attack helps researchers implement precautionary measures to overcome the loss or block the malicious incoming traffic.

Organization

The rest of the research paper is organized as follows: The section literature review discusses the literature review of the previously proposed security approaches. After that, section proposed methodology discusses the proposed work with the working of ANFIS and the proposed security algorithm along with its method. Similarly, section experimental analysis and results discusses the implementation, results, and discussion. Moreover, lastly, section conclusion discusses the conclusion and future work.

LITERATURE REVIEW

According to previous research (1), healthcare-based networking servers require more security and a safe network architecture to provide confidentiality, integrity, privacy, and authentication to its patients, doctors, and management. The author proposed the ANFIS-based data classifier and security provider tool or model for making cloud servers more secure with a higher accuracy rate and smaller error rate. Detection of security attacks and malicious network traffic is considered as the most topical issue for network security (19–23). Therefore, previous research (24) presented an ANFIS-based security framework for classification of attacks and identifying their type.

In another study (25), the research mainly focuses on the interoperability of the cloud server platform and its reliability. The paper uses the hybrid approach of the squirrel search genetic algorithm with the combination of ANFIS to perform better functionality and remove uncertainties of servers by providing a higher accuracy rate. Also, in a previous work (26), an SDN anomaly detection system was proposed to detect malicious behavior and intrusion attacks using the cloud medium. The detection system identified the trusted edge for data or information sharing and communication. Based on multiple parameters, the implementation of the proposed systems showed better performance results. Here **Table 1** represents the ANFIS methodology used for security purposes like in clustering, classification, accuracy, performance evaluation, etc.

In many previous kinds of research, the communication between devices and multiple systems can also cause security threats and need efficient and enhanced network capacities during communication. Hence in a previous research (33), the author used 5G and the multiple-input multiple-output (MIMO) concept to enhance the network capacity and area coverage capacity. Similarly, in another paper (19), the author proposed the ANN technique to detect and identify intrusion attacks in android systems.

In a previous study (34), the author dealt with the security factor of the cloud to improve its performance using the AI technique. The proposed approach helped to overcome the flaw of data breaching and non-authorization access on cloud servers. They utilized different labels to restrict access to specific edge limits to ensure accuracy in decision making. It helped the systems to store a large amount of data securely on cloud servers.

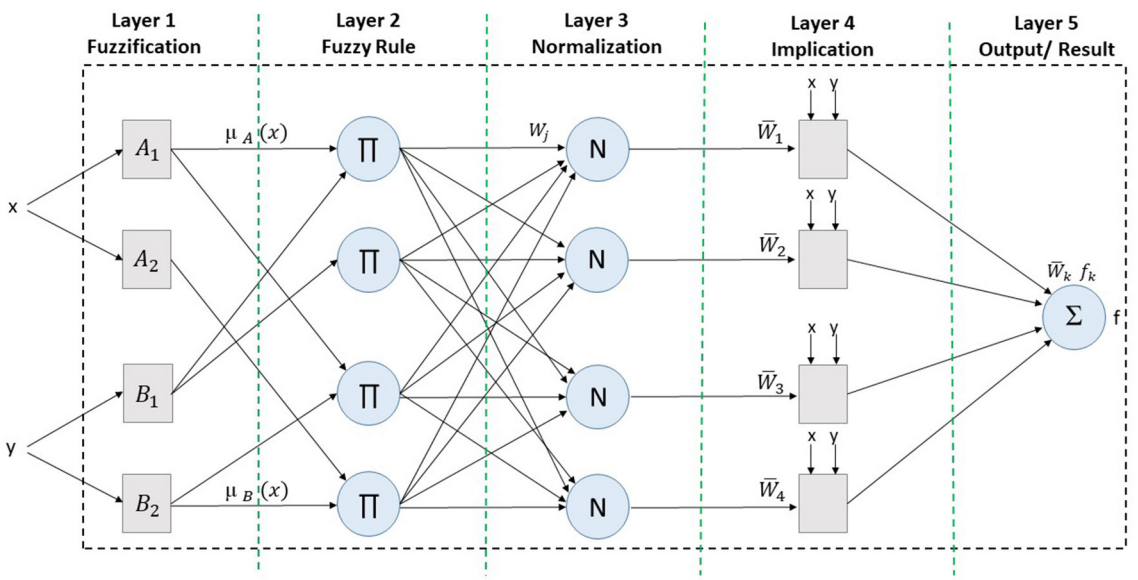

FIGURE 1 | Five layer-based working of the ANFIS architecture.

In an earlier paper (35), the study presented fuzzy-based detection schemes by various machine learning techniques and data mining algorithms to cope with multiple types of malicious attacks or intrusion. This paper first categorized their contribution in two parts, intrusion and detection, and then used fuzzy techniques for classification and identification. Then they

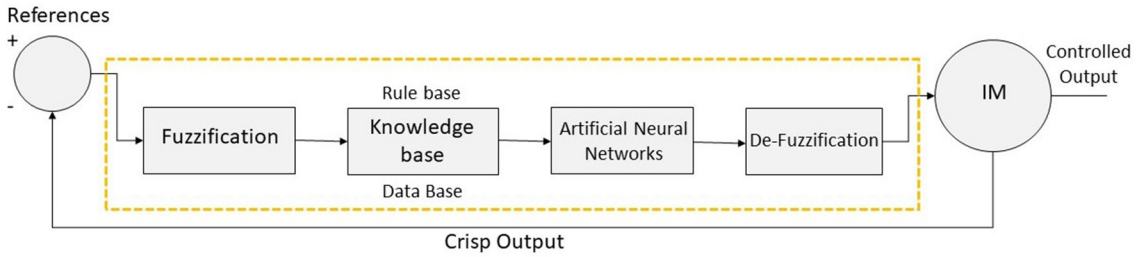

FIGURE 2 | The controller architecture of the ANFIS technique (ANFIS-C).

listed the shortcomings and merits of the ID detection based on fuzzy techniques and algorithms.

In another research paper (36), the author presented a detailed survey on anomaly detection schemes and fuzzy inference systems. This paper mainly focused on combining fuzzy inference systems and machine learning algorithms for the intrusion detection process. It summarized the research with the contributions and shed light on the shortcomings and benefits of FIS. Then, finally, it concluded with future findings and issues in the anomaly detection scheme.

CC is the computing solution that allows multiple end users to connect, share, communicate, and store data or information. Fault tolerance is considered the main concern in data reliability. Therefore, in a previous research (37), detailed analysis was presented to detect the nature of the error and proper implementation of the FIS technique to the response. The process of checkpoints was used to check the intensity of the error.

Table 2 represents the methodology used for cloud security based on previous research work.

In earlier research (48), a comprehensive review discussed CC and IoT in the healthcare sector including smart systems, smart applications, smart software, smart hospitals, and smart record systems. The study presented the IoT-based smart cloud paradigm in the healthcare sector. Similarly, In an earlier work (49), an ANFIS-based healthcare system was proposed to avoid network security risks. The proposed system and already existing ANFIS-based system were compared to evaluate the performance.

Based on previous work, ANFIS is considered an advanced technique for data evaluation, classification, clustering, increased accuracy rate, and detecting various network or systems attacks or any malicious activities on cloud infrastructure to provide a trustful environment to its end users.

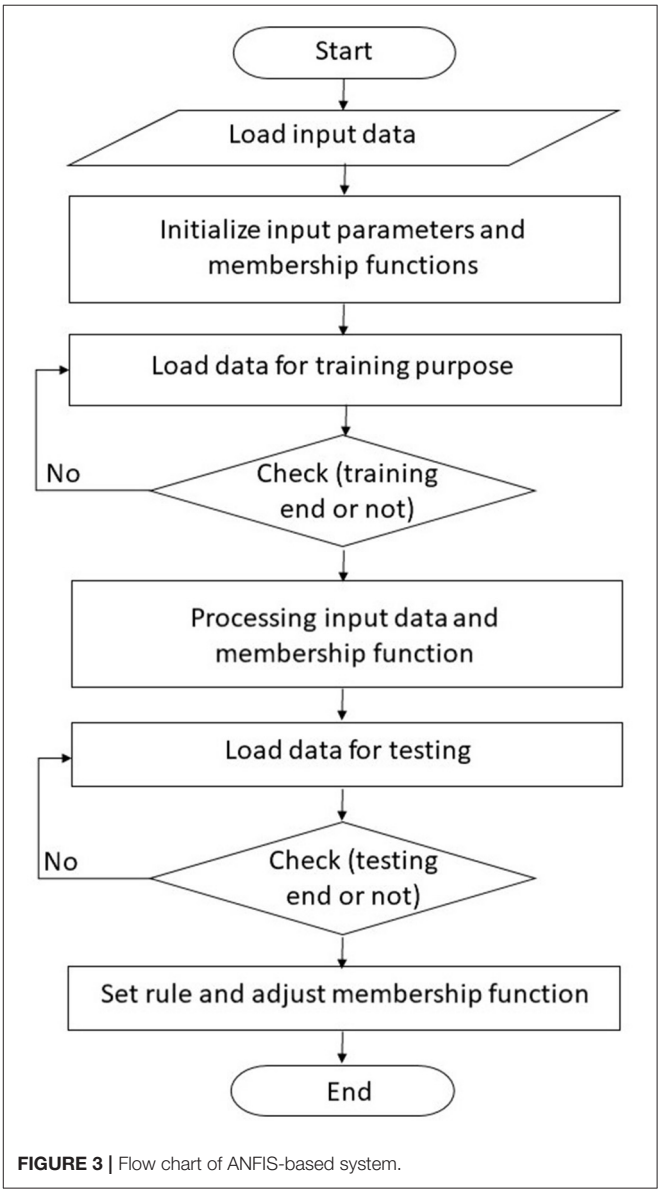

FIGURE 3 | Flow chart of ANFIS-based system.

PROPOSED METHODOLOGY

We propose a tuned version of the ANFIS model to detect intrusion attacks in cloud database servers. We mainly focus on identifying the unauthorized access of end users to systems and diagnosing the type of network attack. The proposed security algorithm will help systems to detect malicious activities or irrelevant information from network traffic. The coming subsection will help understand the ANFIS model's working and the proposed technique's flow chart.

Architecture and Working of ANFIS-Based Systems

To study fuzzy rules-based non-linear systems, the fuzzy inference system (FIS) is considered an efficient methodology. Similarly, artificial neural networks (ANNs) work on neurons and the artificial Intelligence technique. So, an artificial neural fuzzy inference system (ANFIS) is the combination of FIS and ANN, which works on the principle of neural networks and follows the efficiency of FIS. ANFIS uses the hybrid Sugeno-type methodology to specify the input parameters. This method trains the membership function based on input parameters to get the trained dataset. ANFIS is also known for its the parameters which can validate the model. ANFIS is based on a multiple layer architecture, where every layer keeps forwarding the input parameters for continuous working. More detail about the architecture and working of the ANFIS architecture is presented in **Figure 1**.

The architecture of the ANFIS methodology almost resembles that of the Sugeno-type model, as shown in **Figure 1**. The model-based rule sets are as follow:

- If x is A_1 and y is B_1 then f_1 = p_1 x + q_1 y + r_1
- If x is A_2 and y is B_2 then f_2 = p_2 x + q_2 y + r_2

The working of each layer is explained with mathematical equations as listed below:
Layer 1 shows the input parameters and fuzzification, where Ni (N is node) is adaptive to N func (func is function), as represented in Equations 1 and 2.

$$L_1, i = \mu_A i(x), for i = 1, 2 \tag{1}$$

$$L_1, i = \mu_B i - 2(x), for i = 3, 4 \tag{2}$$

Layer 2 shows the fuzzy rule generation phase, where every N computes and sets rules by the multiplication process, as represented in Equation 3.

$$L_2, i = w_i = \mu_A i(x).\mu_B i(y), i = 1, 2 \tag{3}$$

Layer 3 shows the normalization phase, where every neuron is normalized based on the effect of the fuzzy rule sets, as represented in Equation 4.

$$L_3, i = \bar{w} = \frac{w_i}{w_1 + w_2}, i = 1, 2 \tag{4}$$

Layer 4 shows the implication phase, where every input value is set as an input parameter, as represented in Equation 5.

$$L_4, i = \bar{w_i} f_i = \bar{w_i}(p_i x + q_i y + r_i), i = 1, 2 \tag{5}$$

Layer 5 shows the final result or output of the complete process, where the sum of the input values are computed, as represented in Equation 6.

$$L_5, i = \Sigma \bar{w} f_i = \frac{\Sigma w_i f_i}{\Sigma w_i} \tag{6}$$

TABLE 3 | Input/Output parameters and membership functions.

Types of attacks	Ranges and rules
[Input 1] [Normal]	Range: [0 1], MFs: 3 (low, medium, high)
[Input 2] [Probe]	Range: [0 1], MFs: 3 (low, medium, high)
[Input 3] [DoS]	Range: [0 1], MFs: 3 (low, medium, high)
[Input 4] [U2R]	Range: [0 1], MFs: 3 (low, medium, high)
[Input 5] [R2L]	Range: [0 1], MFs: 3 (low, medium, high)
[Output] [Attack_type]	Range: [0 1], MFs: 3 (low, medium, high)

Figure 2 shows the ANFIS-based controller, which helps the systems detect attacks (ANFIS-C). The controller helps to detect the type of attack based on input parameters and membership function. Through the learning process, ANFIS-C adjusts the initial and processed parameters. The least-square method is used here to obtain hybrid propagation. The ANFIS-C alters the initial and processed parameters based on the error rate (here, error rate is calculated with a difference of two output values before processing and after ANFIS-C).

Figure 3 shows the working of the ANFIS-based intelligence system. The initial step involves loading input parameters, and the ANFIS-based classifier evaluates the functions and detects the error rate, intelligence method, and other learning attributes. After that, the training phase defines the initial and processed membership function along with its parameters. Then, after passing from the testing phase, it sets rules and defines membership functions. At last, the ANFIS-based system stores processed parameters and processed attributes.

EXPERIMENTAL ANALYSIS AND RESULTS

The ANFIS model is used to detect the type of attack based on rule viewer, membership function, and surface viewer. For the practical implementation of the ANFIS model, we use the MATLAB framework for experiments and results. We use dataset pf KDDcup 99 for intrusion detection. This dataset consists of 41 features of the network and five network types of intrusions. The network is observed for around 7 weeks to collate more accurate and precise data. We use an ANFIS-based classifier for detection purposes. The basic structure and features of the ANFIS model in PHR network attacks can be examined. In **Table 3** input parameters and membership functions are discussed.

Similarly, **Figure 4** shows the five input parameters (based on attacks type): normal, probe, DoS, U2R, and R2L.

On the basis of input parameters, membership function is defined using the Sugeno-type ANFIS function in **Figure 5**. More than 140 rules are generated to generate the desired output value in the form of attack type. After selecting various combinations of input parameters, various rules are generated to get the results.

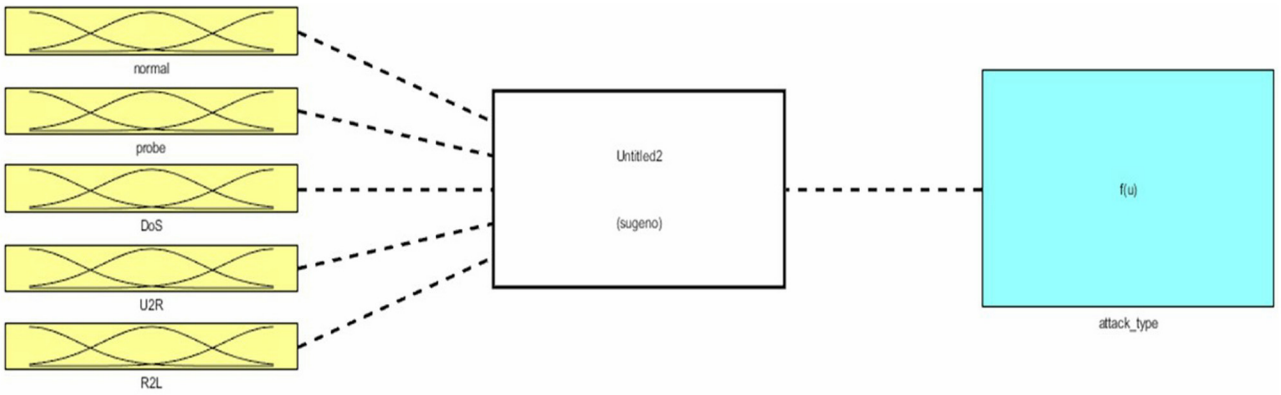

FIGURE 4 | Input parameters.

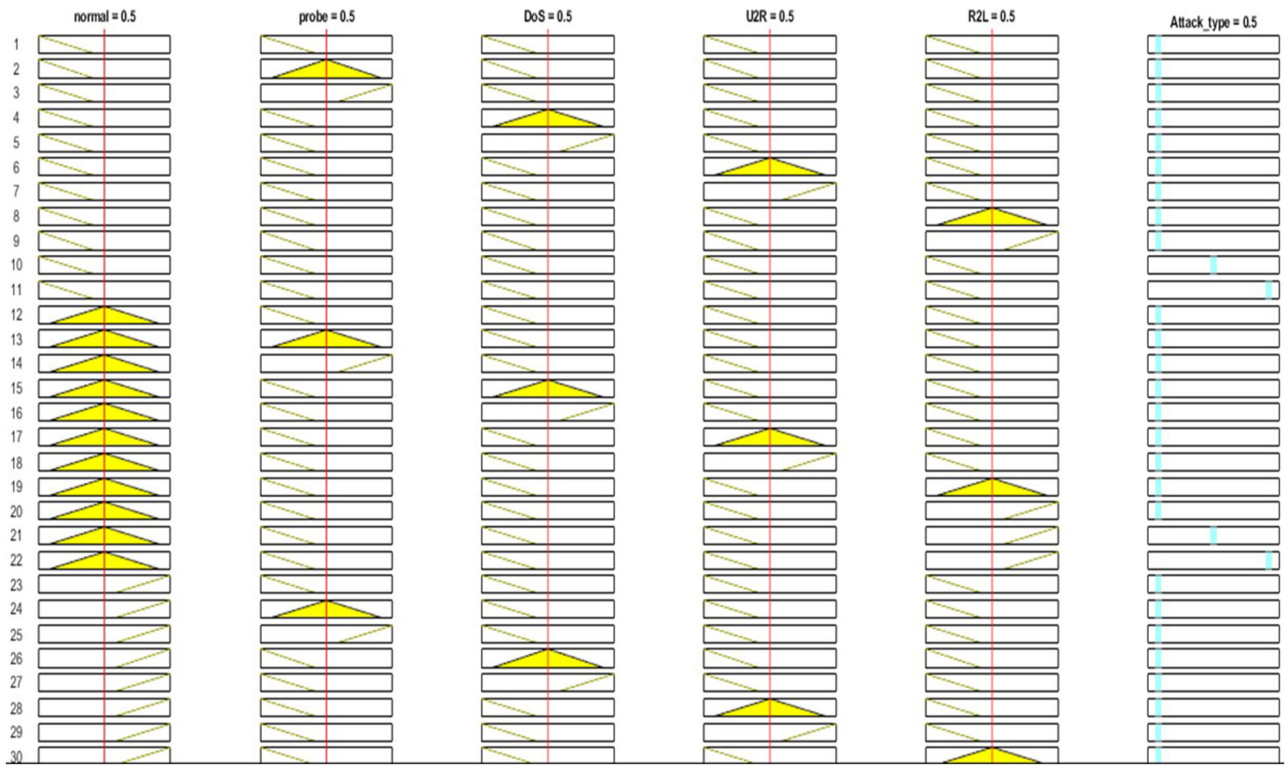

FIGURE 5 | Set of rules based on membership functions.

Figure 6 shows the 3D surface views of all attributes. In section (**Figure 6A**), for attack type the x-axis displays "normal" and the y-axis shows "probe"; then in section (**Figure 6B**), the x-axis presents "probe" and the y-axis shows "normal"; in section (**Figure 6C**), the x-axis shows "U2R" and the y-axis shows "normal"; then in section (**Figure 6D**), the x-axis displays "DoS" and the y-axis presents "normal"; and lastly in section (**Figure 6E**), the x-axis displays "R2L" and the y-axis shows "normal." The surface view shows the comparison of multiple attack type attributes. As the KDD99cup dataset consists of many types of network attacks. In our research, we choose five types of attacks based on their repetition. Moreover, the surface viewer helps predict the accuracy rate in classification and detection based on a rule (which is created by using the membership function).

Similarly, after defining rule sets, the structure of the proposed ANFIS-based model is established, as can be seen in **Figure 7**. In the final structure, after multiple input values, around 140 sets

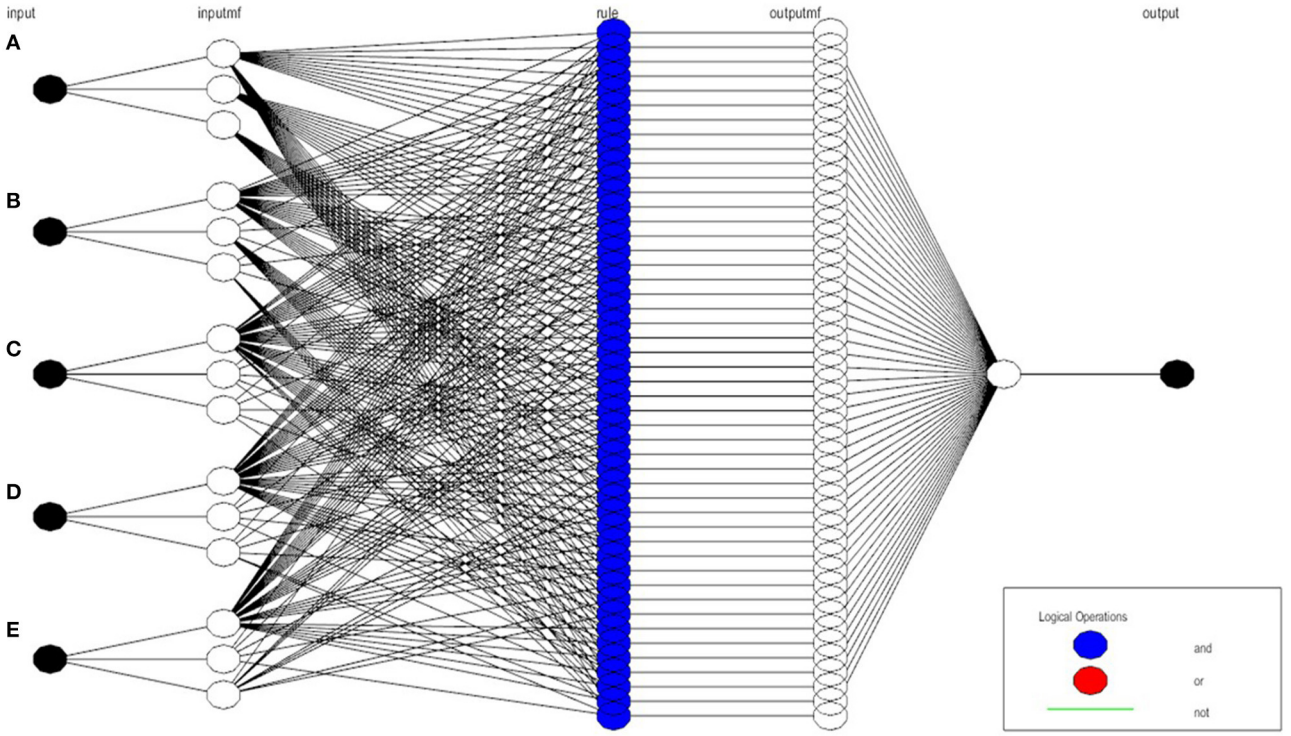

FIGURE 6 | (A–E) Set of rules based on membership functions.

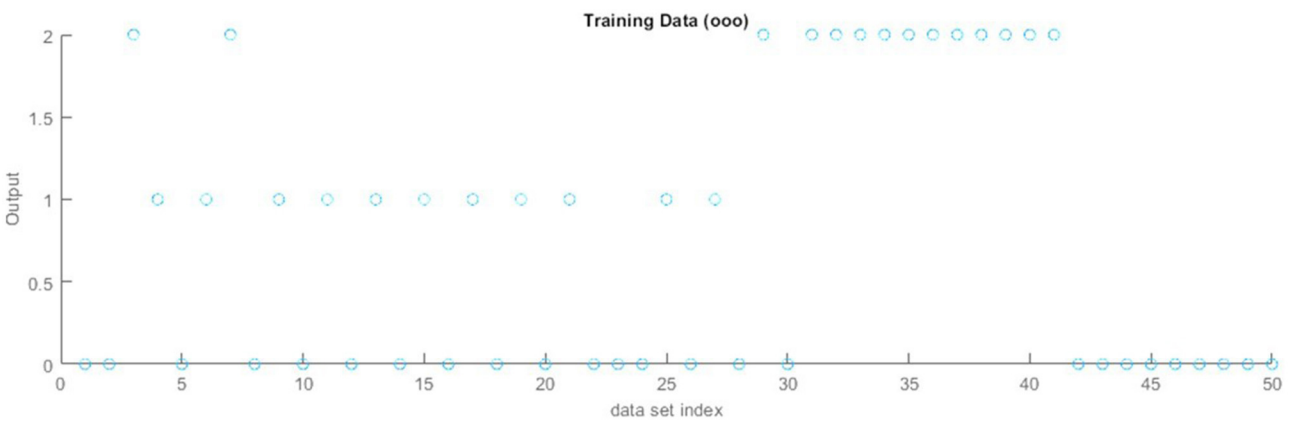

FIGURE 7 | Proposed ANFIS model.

of rules are generated which leads toward the final output value, which indicates the type of intrusion attack.

Figure 8 represents the training results of the KDDcup 99 datasets collected from the Kaggle website for network intrusion detection based on ANFIS. The training model contains five input values and generates a single output. The training model shows the increasing flow of accuracy rate.

Finally, **Table 4** shows the detailed statistical result of the KDDcup 99 datasets. The selected classes for testing and training are normal, probe, DoS, R2L, and U2R.

The final result generated by the ANFIS model is either linear or non-linear. Therefore, the Sugeno-type ANFIS model helps to obtain a single output. The results show that the PHR in the healthcare system require an ANFIS-type framework to detect and prevent network attacks and maintain secrecy and a trustful

R-value	0.6133	0.7336

environment for patients, doctors, laboratories, and all other interlinked sectors.

Comparison of Experimented FIS and ANFIS Model Decision-Making

Table 5 shows the performance comparison of the FIS and ANFIS models for better decision-making in network intrusion detection to make e-healthcare (PHR) more secure. The FIS model has been selected to conduct another experiment to show the comparison of the results of FIS and ANFIS based on performance. The mentioned table helps to evaluate the performance of both models. Other than selecting already proposed solutions, we train the FIS model on the same datasets to obtain results. The computed MSE value for FIS is 0.0183 and 0.0123 for ANFIS, the NMSE value is 0.3185 for FIS and 0.2650 for ANFIS, the MAE value is 0.1170 for FIS and 0.0747 for ANFIS, the error value (for minimum observation) is 0.0110 for FIS and 0.0021 for ANFIS, the error value (for maximum observation) is 0.1279 for FIS and 0.1706 for ANFIS, and then finally the R-value is 0.6133 for FIS and 0.7336 for ANFIS. Based on the performance results and output values, ANFIS is considered a more efficient model for efficient decision-making in e-healthcare systems.

CONCLUSION

Security of network systems in all sectors has become one of the most crucial challenges for researchers. In smart e-healthcare systems, cloud servers provide a better intermediary platform for data storage, communication, and many other aspects. The end users (doctors, clinical experts, patients, laboratories) get the

opportunity to access PHR and access the networking database servers. It can be any authorized person. It is essential to detect and classify malicious activities and network traffic. This research paper proposed ANFIS for effective intrusion detection in healthcare networks to maintain a patient record. The main agenda is to detect the unauthorized access of users by using an ANFIS-based intrusion detection system. The proposed security algorithm helps to collect malicious activities or information from network traffic. Based on the if-then rule statement and ANFIS-based data classification that helps to detect the intrusion attack, it can determine whether the networking database server was hit by an intruder or not. If the system identifies the type of attack, this can help researchers put precautionary measures into place to overcome the loss or block the malicious incoming traffic.

COVID-19 (SARS-CoV-2) was declared as a global pandemic by the World Health Organization (WHO) in February 2020. This led to previously unforeseen measures that aimed to curb its spread, such as the lockdown of cities, districts, and international travel. Various researchers and institutions have focused on multidimensional opportunities and solutions in encountering the COVID-19 pandemic. This study focuses on mental health and sentiment validations caused by the global lockdowns across the countries, resulting in a mental disability among individuals. This paper discusses a technique for identifying the mental state of an individual by sentiment analysis of feelings such as anxiety, depression, and loneliness caused by isolation and pauses to the normal chains of operations in daily life. The research uses a Neural Network (NN) to resolve and extract patterns and validate threshold trained datasets for decision making. This technique was used to validate 2,173 global speech samples, and the resulting accuracy of mental state and sentiments are identified with 93.5% accuracy in classifying the behavioral patterns of patients suffering from COVID-19 and pandemic-influenced depression.

Keywords: sentiment extraction, speech signal processing, COVID-19, mental depression, neural network

INTRODUCTION

The world is at present facing an uncertain time due to the global pandemic caused by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2), also known as COVID-19. The pandemic has forced nations to exercise lockdown as a preventive measure to slow the spread of the virus. The pandemic has resulted in economic failure and disruptions in the supply chain all over the world. There was a race for a vaccine among modern drug and research organizations. The pandemic has caused major adverse effects such as mental depression, isolation, anxiety, and loneliness besides respiratory disorders and aligned symptoms. Depression and other mental health issues have been caused by lockdown and restrictions in travel and work, with a new normal social life now conducted via technological platforms.

The pandemic has bought a sense of maturity and adverse implications concerning psychosocial behaviors and mental health implications such as depression, anxiety, and loneliness. In this research, a systematic evaluation was conducted on the behavior of users based on speech signals, which were recorded using a machine learning technique to extract keywords and classify data using sentimental analysis techniques (1). The research in this article also focuses on identifying the user's mental state via the speech signals recorded over technological platforms used for virtual meetings and other gatherings (2). The research aims to provide schematic evaluation and validation approaches and classify patients based on medical conditions.

LITERATURE SURVEY

The global pandemic situation under COVID-19 has left traces of various adverse effects on people, which are the result of isolation, lockdown, mental health destabilization, and much more. The authors Singh et al. (3) and Naik et al. (4) have discussed the impact caused by COVID-19 and lockdown on the younger generation, focussing on children's behavior and reactions to the new normal. The study shows the overall implications of isolation on children and adolescents. Pfefferbaum and North (5) have discussed the impact and relationship of mental stress caused due to the global pandemic situation, with detailed insights into public health emergencies and the influence of the pandemic on looming health conditions. Furthermore, a discussion on the challenges faced by health care workers (HCW) and their state of mental stress is documented by Spoorthy et al. (6). The HCWs are frontline attributes and hence require assistance in evaluating and validating mental health via the main mode of communication now used, i.e., speech signals through digital media platforms and applications and a similar discussion is highlighted in other studies (7, 8).

Some studies are focused on the terms of technological solutions for the mental distress caused by the pandemic. These solutions have outlined the use of a telemedicine approach for reaching the maximum and remote population of a developing country like India. A study by Ahmed et al. (9) discussed

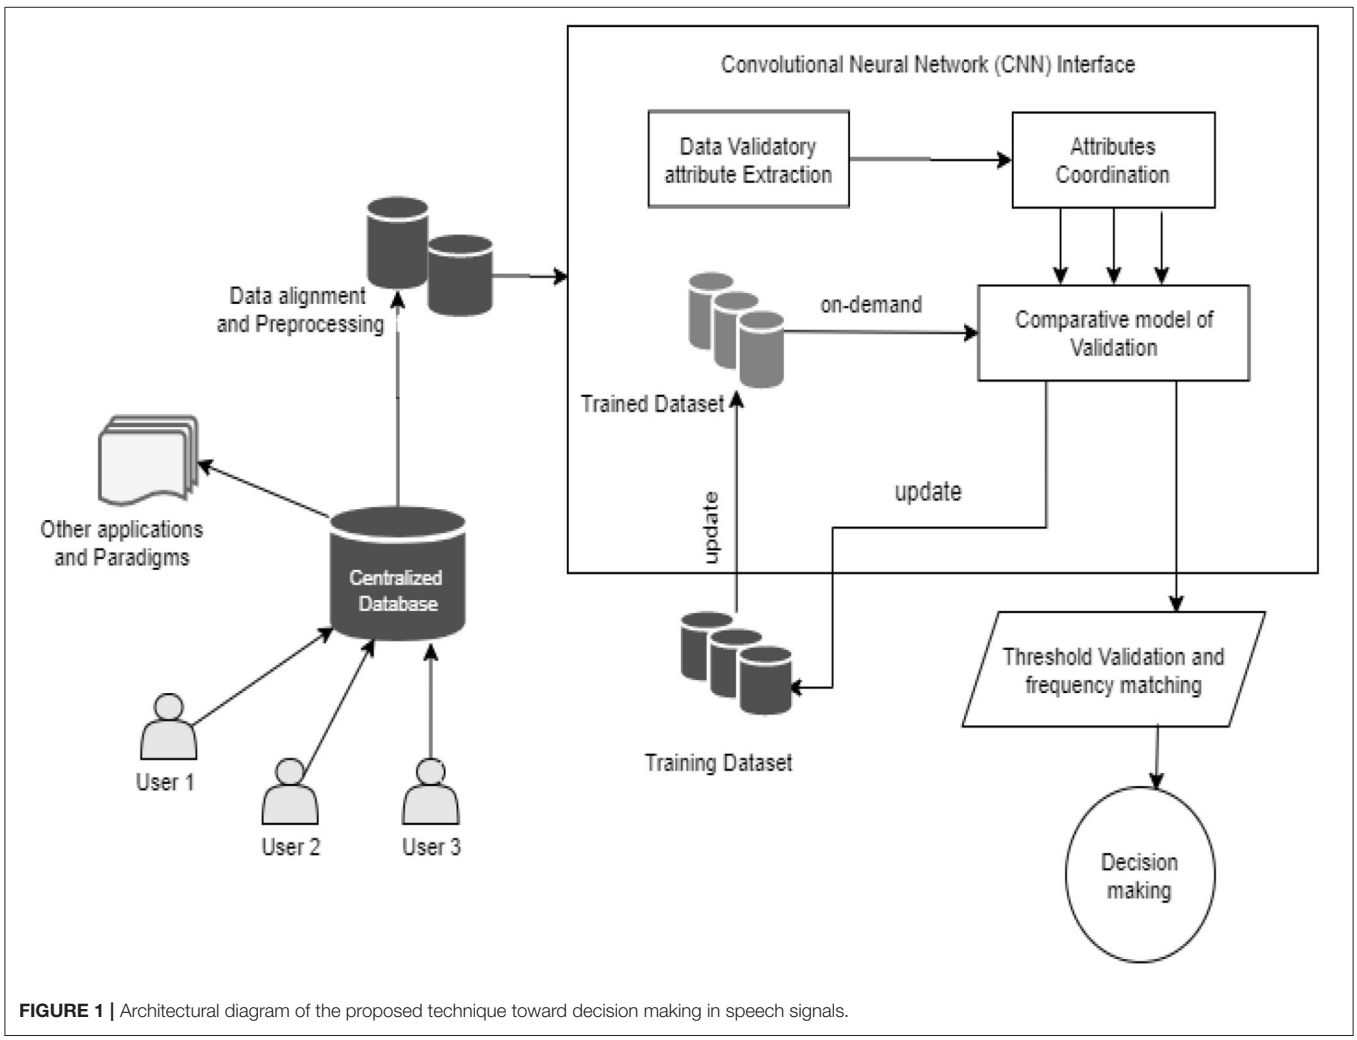

FIGURE 1 | Architectural diagram of the proposed technique toward decision making in speech signals.

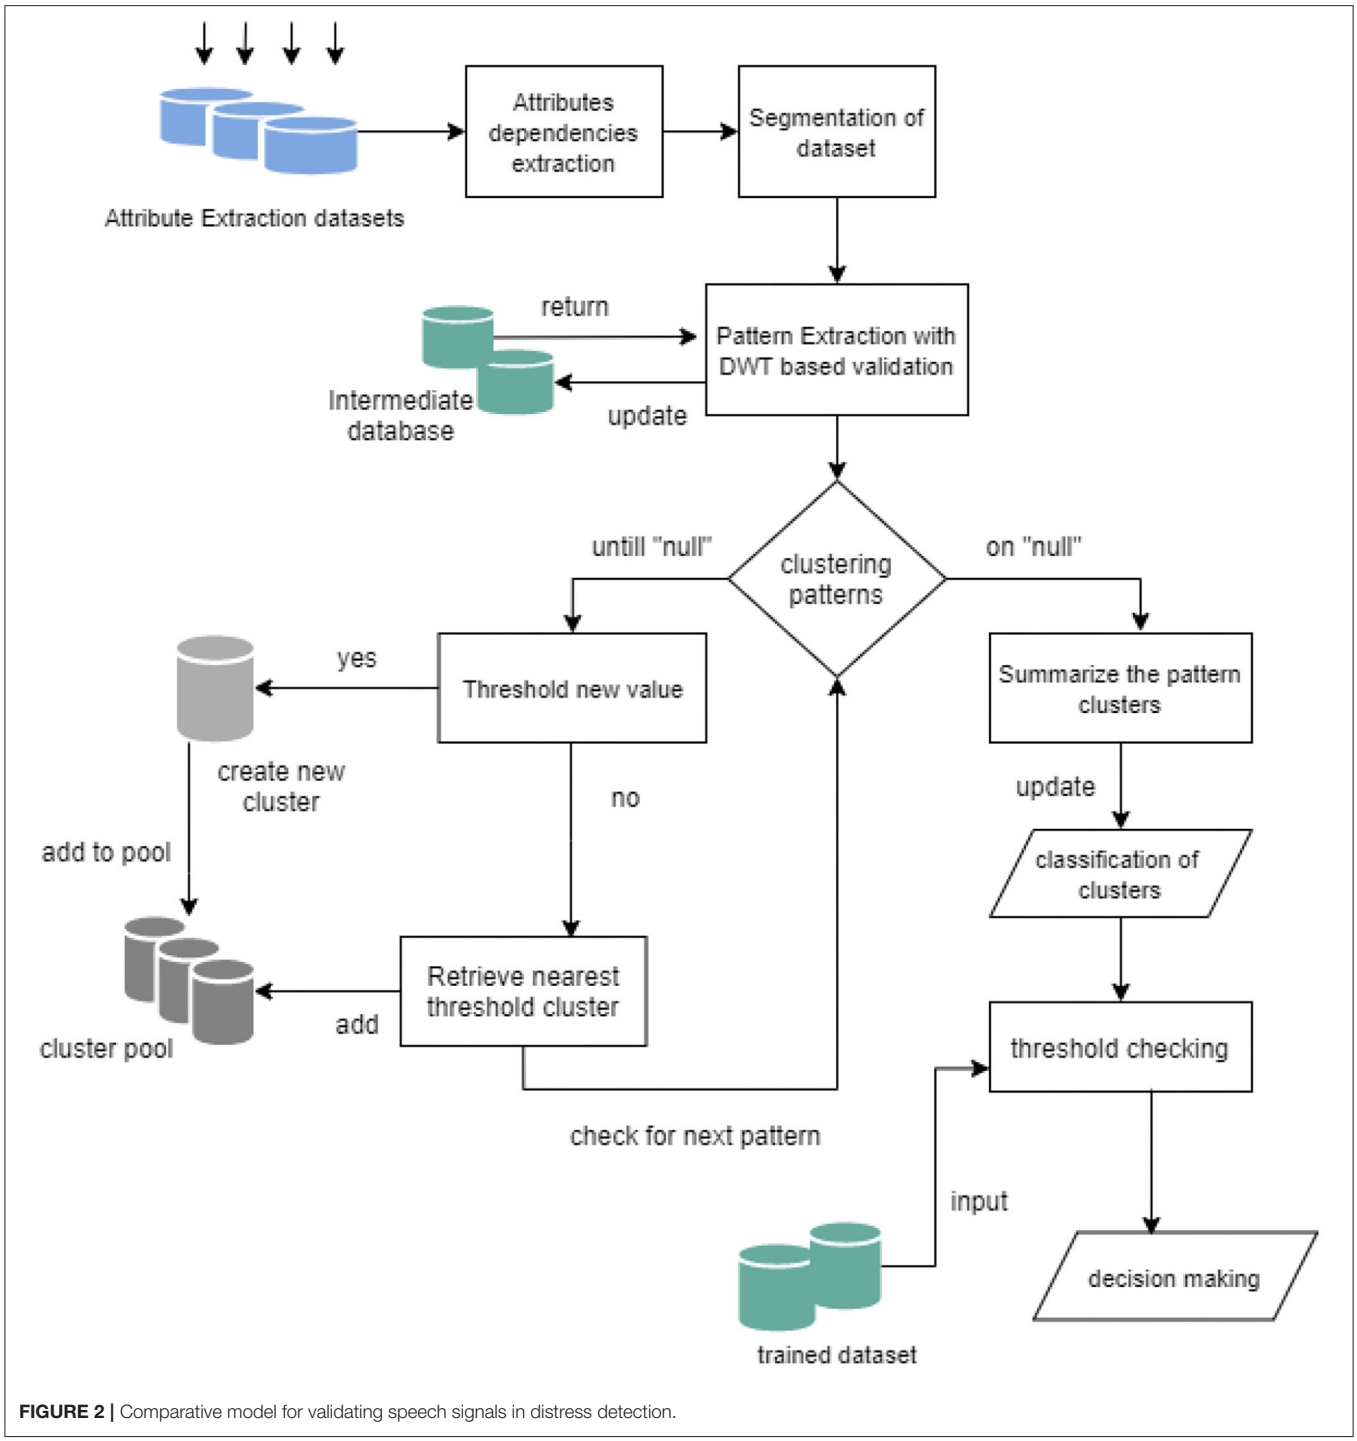

FIGURE 2 | Comparative model for validating speech signals in distress detection.

Multidimensional Optimal Medical Dataset processing under a telemedicine channel. These MooM datasets include a signal processing unit for a standardized approach and can be used for intimated processing in the proposed study, with a supported algorithm from (10). The method of detecting and validating speech signals is also proposed in this article, based on the influence of telemedicine approaches with a numerical clustering validation by (11) and (12).

The latest findings in the survey are recorded with real-time datasets as discussed in (4). This approach aims to validate treatment and handling, focusing on pandemic control and coordination. The prediction and modeling of the pandemic are discussed by Iwendi et al. (13) and Ngabod et al. (14), who propose a technique for classifying pandemic growth in smart cities. Under the process processing state, this dedicated networking model can be utilized, as discussed by Ahmed et al.,

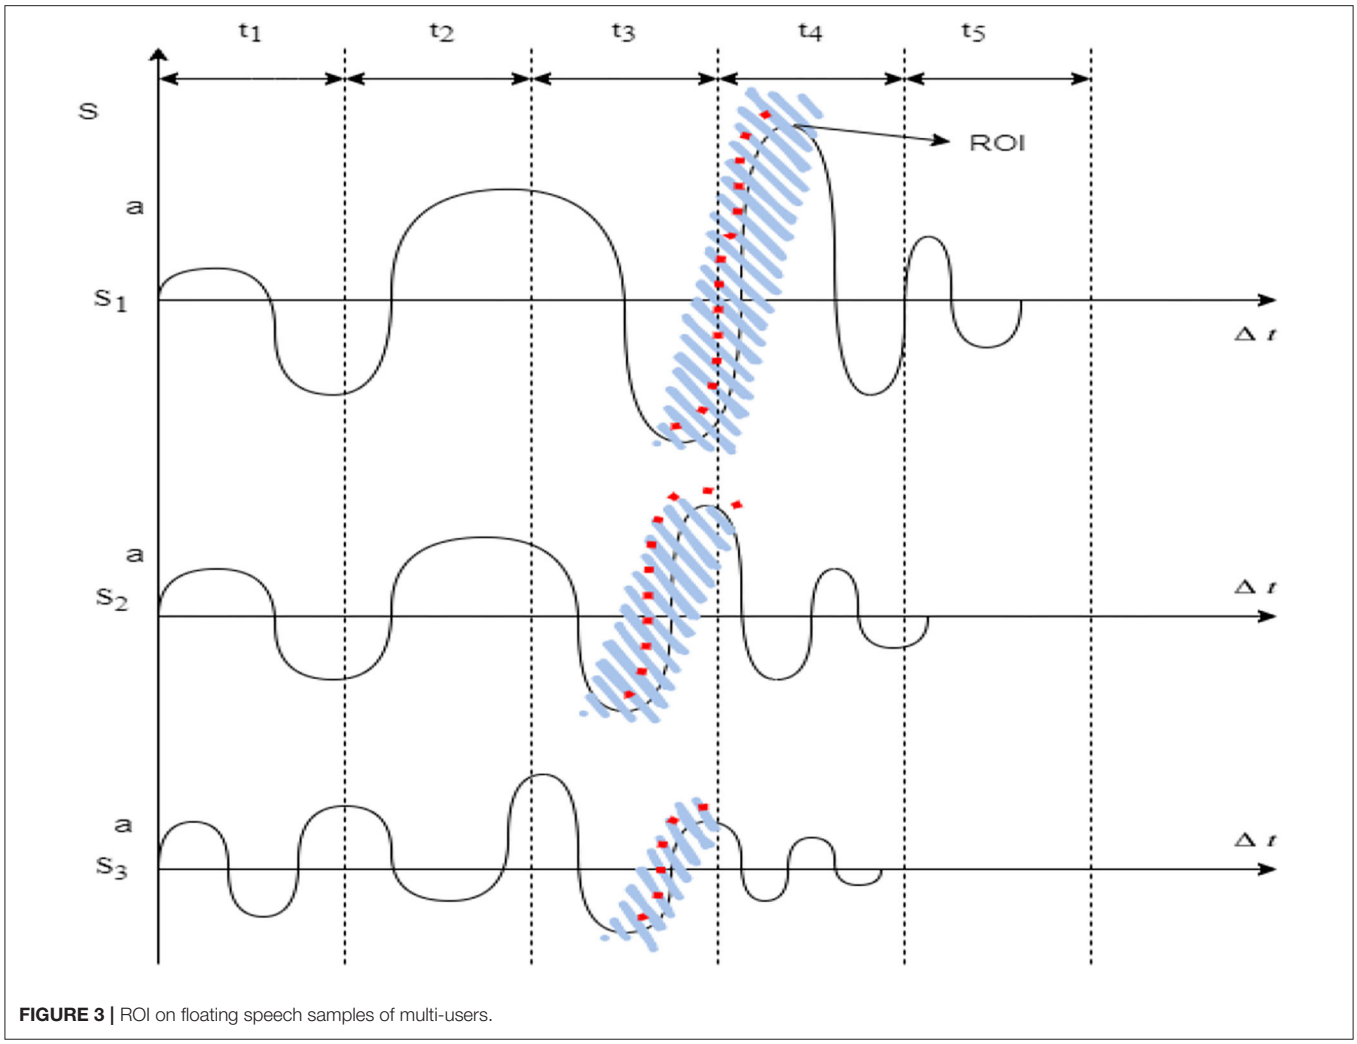

FIGURE 3 | ROI on floating speech samples of multi-users.

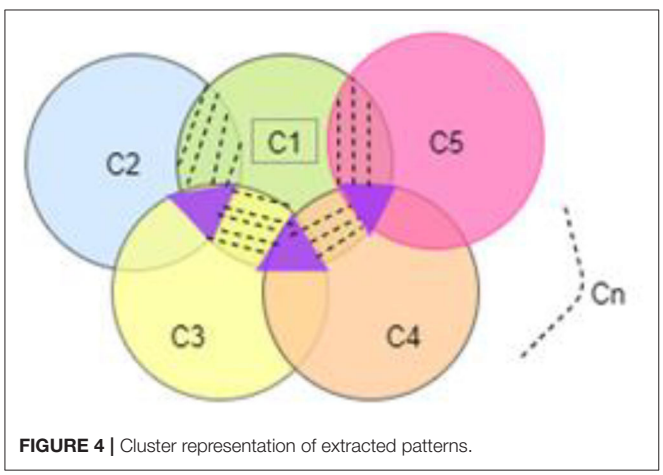

FIGURE 4 | Cluster representation of extracted patterns.

under a dynamic user cluster grouping approach (15–17). These developments have provided a reliable solution for handling pandemic data using text mining and decision support. The classification of Covid-19 studies and surveys are reported and validated by (18, 19).

METHODOLOGY

The proposed methodology aims to focus on the detection and validation of speech signals via a depression and mental disorder identification based on speech signal processing using a neural network (NN). The process is defined using mass datasets from 2,173 speech samples, as discussed in the architecture model in **Figure 1**. The agenda of the proposed technique is to restore a correlation with trained datasets in extracting and evaluating the samples of speech and classifying on demand. These speech signals are interdependent and have a higher order of distinction in recovering and validating the sample of COVID-19 patients' mental stability and sentiments (20).

The processing datasets are computed in a centralized database with user-to-user interface coordination, thereby generating a pool of databases consisting of raw and unprocessed data from the users. The process is initiated with data alignment

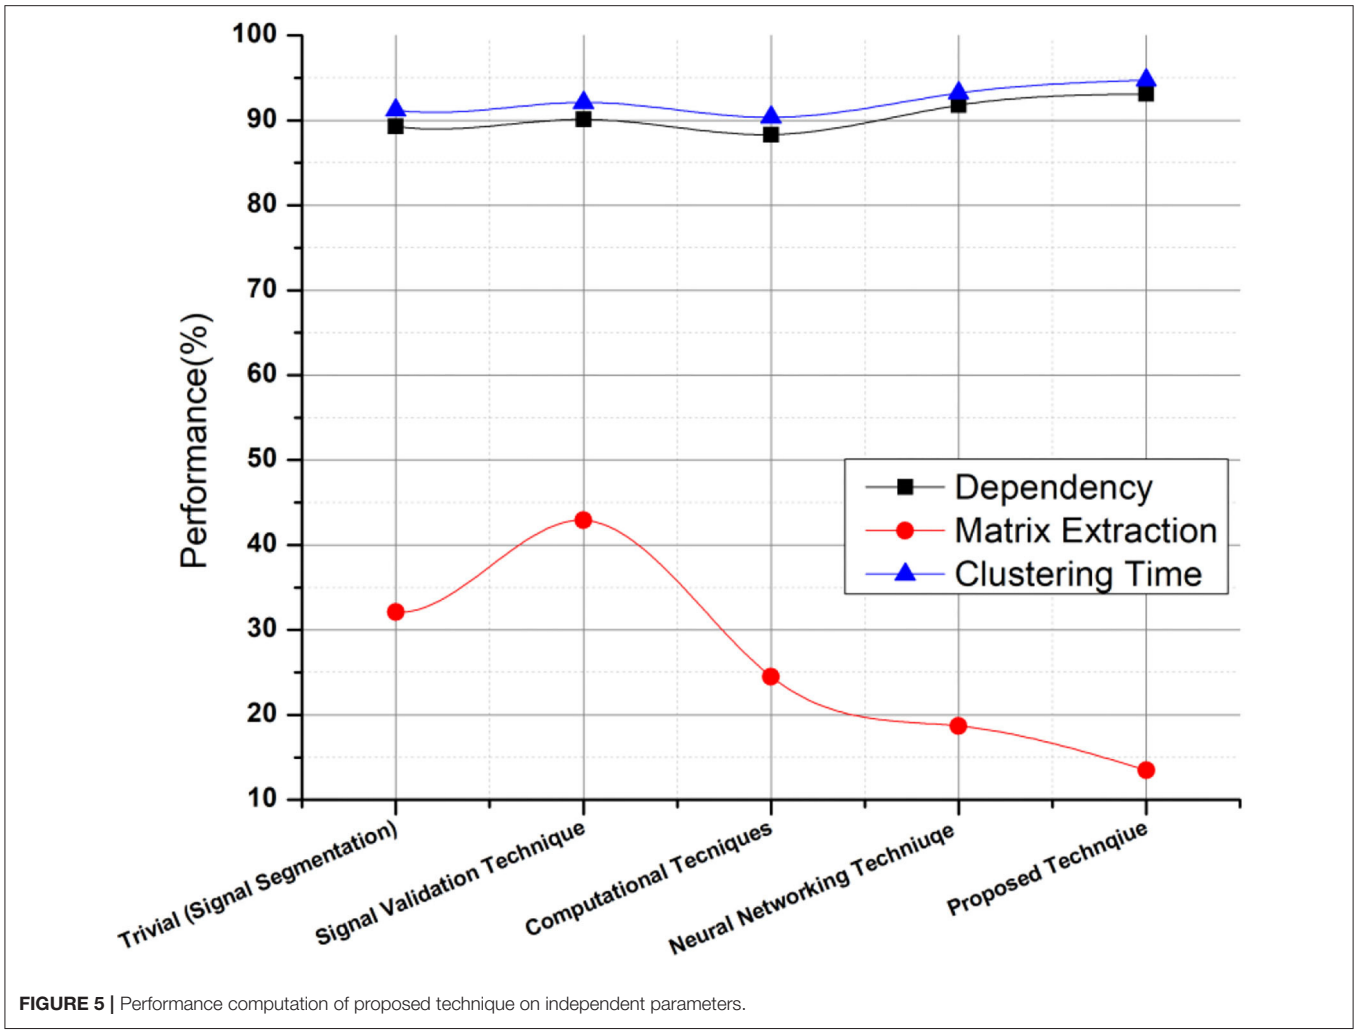

FIGURE 5 | Performance computation of proposed technique on independent parameters.

and pre-processing techniques, as discussed in the mathematical modeling of the proposed technique. The process is designed with a trained database of the speech signals with a heap address of thresholds relating to global attributes such as country, location, gender, age, and professional practice.

The trained datasets provide the threshold process for the extracted attributes of the user input signals. The process is designed with a comparative validation model to assure the process execution, as demonstrated in **Figure 2**. The comparative model evaluates the detailed execution process, such as the pattern extraction and clustering of signal samples in the form of JPEG intermediate files and a dedicated intermediate database, generating a cluster pool for segregation of samples based on ROI as demonstrated in **Figure 3**. This results in a threshold value comparison and thus provides a single decision and classification of the user's mental condition.

MATHEMATICAL REPRESENTATION

The computation of the speech signals and detection of mental stress is achieved under the processed instruction architecture, as demonstrated in **Figure 1**. The process aims to validate the signals into coordination datasets with a synchronization approach of proving learning and pooling clusters of similar patterns, as demonstrated in **Figure 3**. The mathematical approach is discussed in this section.

Attribute Extraction and Dependencies Validation

Consider a dataset *(D)* with a raw calibrated ecosystem of attributes *(A)* where each of attributes $A=\{A_1,A_2,A_3,\ldots\ldots,A_n\}$ such that each attribute (A_i) resembles the paradigm of operation, as in Equation (1).

$$A_i = \int_0^{\infty} \frac{\partial\,(A_i)}{\partial\,(D)} \tag{1}$$

Where, each of the i^{th} attributes, has a correlated paradigm of operation and process extraction. Thus, the extracted attributes (A_e) are as shown in Equation (2).

$$A_e = \int_0^{\infty} \left(\Delta D_z . \sum_{i=0}^{n} \frac{\partial A_i}{\partial D}\right) . \Delta T \tag{2}$$

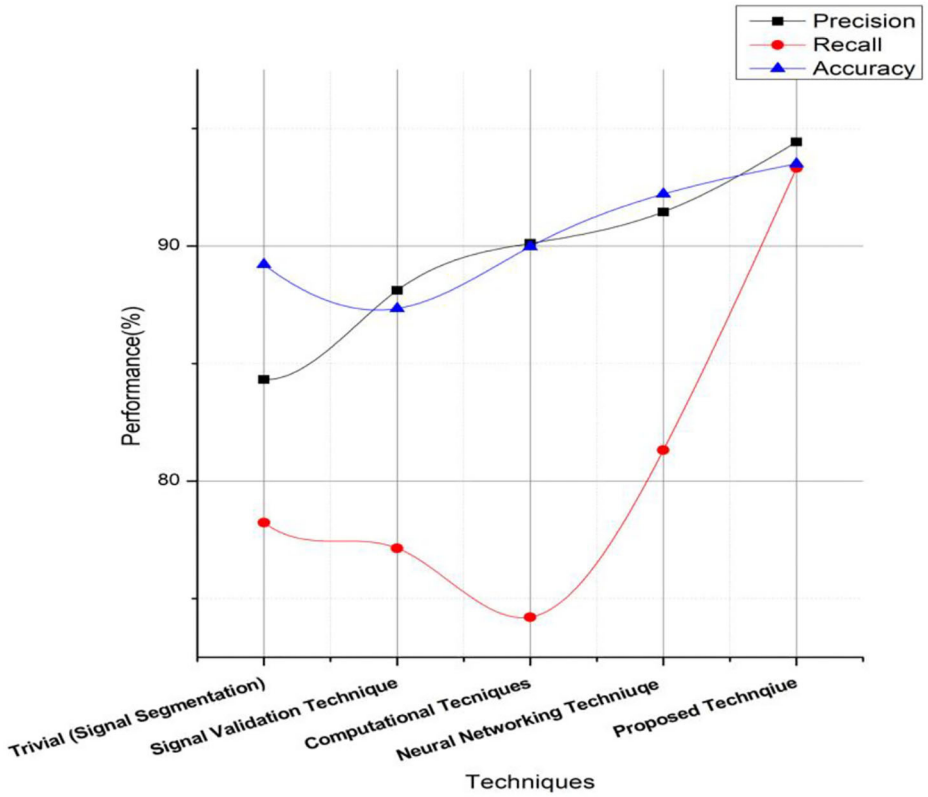

FIGURE 6 | Outcome evaluation of proposed technique.

TABLE 1 | Decision support and evaluation parameters.

Patient relevance (sentiments)	Cluster range	Occurrence difference (Avg. sec)	Pattern differences	Decision accuracy (%)
COVID−19 (positive)	Average	3.211	0.327	97.23
Post COVID−19 (positive)	High	1.432	0.129	94.92
Loneliness	High	1.328	0.091	96.91
Anxiety	Average	2.114	0.181	92.17
Depression	High	0.994	0.021	97.28

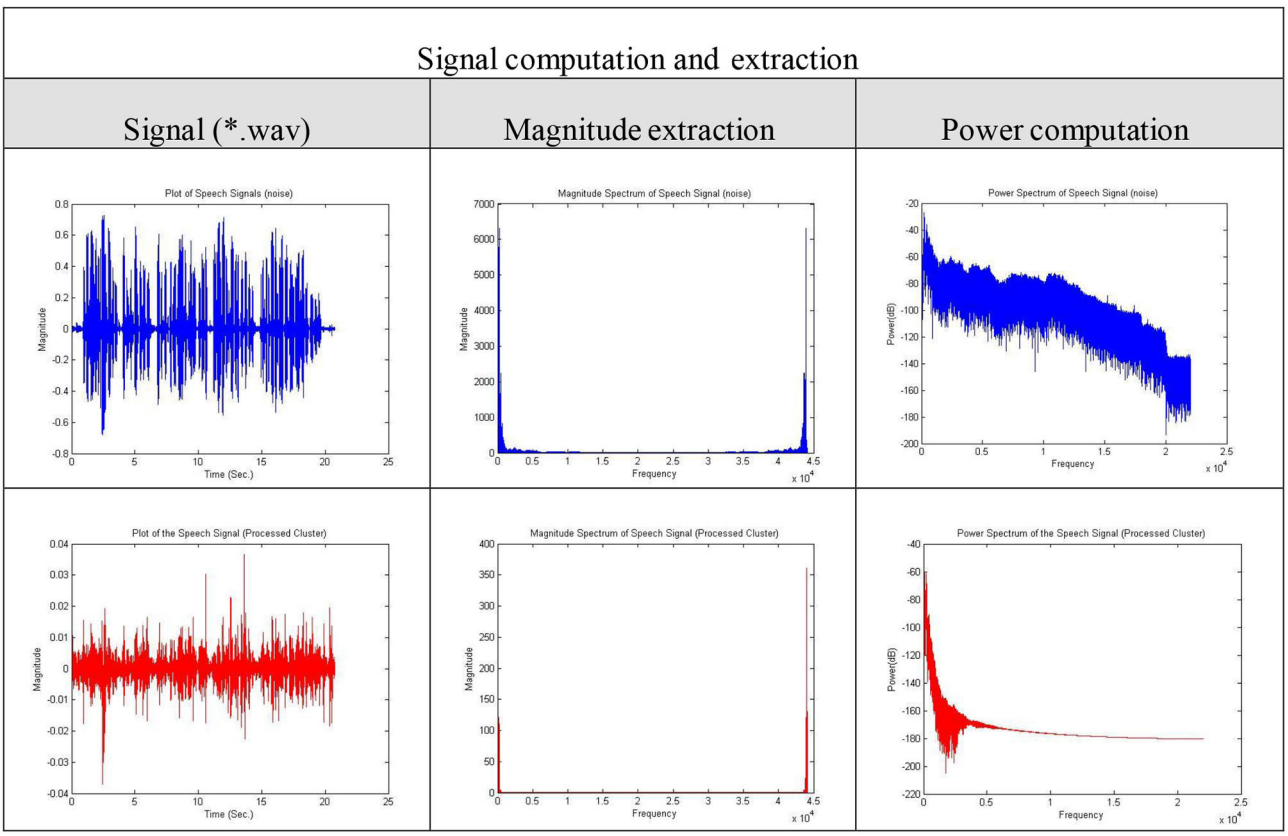
TABLE 3 | Signal processing and analysis appendix.



Where the extracted attribute (A_e) is processed over the raw attributes set, in extracting the most relevant threshold attributes such as the peak frequency of a word or a repeated phrase of a sentence with a dilution of ΔD_z and mapping with ΔT as a threshold paradigm in validating all processing attributes (A_e) in the speech signal.

Segmentation of Samples

Samples are primarily divided into extracted attributes (A_e) sets, such that each of the attribute Region of Interest (ROI) is highlighted and marked in the entire speech signal, as shown in **Figure 3.**

Consider the segmentation (S) of the overall input signal (speech signal) with a highlighted extracted attribute (A_e). On consideration, each attribute in the signal has an occupancy time (Δt) in operating, and thus, a reflective ratio of division is processed based on CNN's evaluation paradigms.

The signal (S) of an independent sample (S_i) tends to occur in ROI in an independent location of the time matrix (Δt). Hence, the segmentation of signal (S) is as shown in Equation (4).

$$S = \frac{2\pi}{\Delta R}\int_0^{\infty}\left[\int_n^i\left(\frac{\Delta S_i}{\Delta t}\right)\right].\frac{\Delta t}{\Delta s} \tag{3}$$

$$\therefore S = \frac{2\pi}{\Delta R.\Delta S}\left(\int_0^{\infty}\left(\frac{\partial S_i}{\partial t}\right).\frac{\partial\,(A_e)}{\partial t}\right).\Delta t \tag{4}$$

Where each signal strength is measured in ΔR with a signal time Δt, for all regional attributes extraction; hence, for segmentation to be processed completely, the schematics of each attribute signal strength (ΔR) is then computed with an exhausted peak of ROI from the signal as shown in **Figure 3**.

Pattern Extraction and Schema Alignment of Datasets

The process of pattern extraction is calibrated with the internally divided segments of datasets. These datasets are processed with a frequency (f) such that the internal segments $(S)= \{S_1,S_2,S_3,\ldots\ldots,S_n\}$ has calibrated frequencies $(f)=\{f_1,f2,f_3,\ldots\ldots,f_n\}$. Thus, the inter-correlated frequencies can be defined and associated as $(S_f)=\{S_{f1},S_{f2},S_{f3},\ldots\ldots,S_{fn}\}$.

The process of pattern with speech signals is internally correlated to the amplitude of the signal (amp). Where it is represented as $f_{amp} =\{f_{amp1},f_{amp2},f_{amp3},\ldots..,f_{ampn}\}$. The amplitude of each frequency feature can be represented and extracted as shown in Equation (5).

$$S_i\,(n) = \int\left\{\sum_{k=0}^{n}\left[\alpha_i\,(k)\,.amp\,(f)\right]\right\} \tag{5}$$

Where each signal pattern (S_n) represents the overall coordination in speech signals, and the '' represents band filters of the speech signal with a coefficient of amplitude and frequency. On extraction of patterns from those correlated in Equation (5), the frequency patterns can be sorted by independent bandwidth as shown in Equation (6).

$$P_i = \frac{2\pi}{\Delta R.\Delta S}\left\{\left(\log\left(G\left(f\right)\right).\int_0^{\infty}\frac{\partial\left(S_i\left(n\right)\right)}{\partial t}\right)^2\right\} \quad (6)$$

$$P_i = \frac{2\pi}{\Delta R.\Delta S}\left\{\left(\log\left(G\left(f_{amp}\right)\right)^2.\int_0^{\infty}\frac{\partial^2\left(S_i\left(n\right)\right)}{\partial t^2}\right)\right\} \quad (7)$$

The 'P_i' on Equation 7 is the pattern of repeated learning from the CNN framework. The internal arrangements can be represented as the frequency (f) under the operation of amplitude, (mode) is represented as f_{amp}, further graded into the Gaussian constant (G). The process in Equation (7) is then concluded, as shown in Equation (8).

$$P_i = \frac{2\pi}{\Delta R.\Delta S}\left\{\left(2log\left(G\left(f_{amp}\right)\right).\int_0^{\infty}\frac{\partial^2\left(\sum_{j=0}^{n}\sum_{k=0}^{n}\alpha_i\left(j\right).amp\left(f_k\right)\right)}{\partial t^2}\right)\right\} \quad (8)$$

$$P_i = \frac{4\pi}{\Delta R.\Delta S}\left\{\left(\log G\left(f_{amp}\right).\int_0^{\infty}\frac{\partial^2\left(\sum_{j=0}^{n}\left\langle\sum_{k=0}^{n}\alpha_i\left(j\right).amp\left(f_k\right)\right\rangle\right)}{\partial t^2}\right)\right\} \quad (9)$$

$$P_i = \frac{4\pi.\log G\left(f_{\text{amp}}\right)}{\Delta R.\Delta S}.\left\{\left(\int_0^{\infty}\frac{\partial^2\left(\sum_{j=0}^{n}\left\{\sum_{k=0}^{n}\left\langle\alpha_i\left(j\right).amp\left(f_k\right)\right\rangle\right\}\right)}{\partial t^2}\right)\right\} \quad (10)$$

Thus, Equation (10) represents the coordinates of the pattern extracted and validated for the pattern with respect to a segment (S_i). Thus, on summarisation, the representation can be as $P = \{P_1,P_2,P_3,\ldots,P_n\}$ co-related to coordination of segment as $S_p = \{S_{p1},S_{p2},S_{p3},\ldots\ldots,S_{pn}\}$, where '$n$' is the last segment of given input signal.

Clustering and Classification of Datasets

Equation (10) retrieves the pattern of individual segments, and thus the coefficient of such segments are summarized and represented in $S_p = \{S_{p1},S_{p2},S_{p3},\ldots\ldots,S_{pn}\}$. Hence the clustering is shown in **Figure 4**.

The cluster (C) is retained from a group of values and its corresponding coefficients for the value re-compensation. The clusters are internally evaluated with the focus of associating.

$$C_i = \int_0^{\infty}\left\{\sum_{i=0}^{n}\left[\sum_{j=i}^{n}\left(\frac{\partial\left(P_i\right)_j}{\partial t}\right).\Delta T_i\right]\right\} \quad (11)$$

Where each cluster (C_i) is validated with a corresponding pattern coefficient and a threshold value (ΔT). The internal Threshold value (ΔT) is validated and evaluated. In summary, the clusters $(C) = \{C_1,C_2,C_3,\ldots..,C_n\}$. These clusters have an association of common patterns, for example, represented as $\{(C_i \cap C_j) \cap C_k\}$, and these associations are subjected to attribute validation, as shown in **Figure 4**.

Threshold Validation and Decision Making

The clusters and classification of speech signals using clusters are validated and approved for processing into decision making. The decision-making approach is termed with a threshold value consultation, i.e., the overall technique extracts the validated pattern coefficient and thereby synchronizes it with a relatively more and likely approach of matching and schema validation. The proposed approach typically validates the decision of signal segmentation using the threshold value toward segregating the dataset of speech signals based on emotions. These emotion-based evaluations are rather computational, and hence a most likely decision is processed.

RESULTS AND DISCUSSIONS

The proposed technique has successfully retrieved the signal attributes and the prediction ratio for evaluation. The input signals from the users via a remote connecting platform are uploaded to a centralized database in a cloud computing ecosystem using AWS-sponsored services. The datasets are processed and validated according to a multidimensional approach.

The variation of predicting the sentiments is based on the information designed and developed via clustering datasets. The prediction ratio is summarized in **Figures 5**, **6**, respectively, with a comparative evaluation from previous systems. **Table 1** shows the parameters related to the mental stress and paradigms to provide decision support. The table highlights the evaluation parameters such as the occurrence delay of a keyword in clustering, as shown in Equation (11). The supported approach thus classifies the pattern of these keyword occurrence sequences for decision making.

The results of data/signal processing and decision-making are shown in **Table 2**. The results show promising outcomes in proving a precision of 90% and higher in various users across the language and location. The results of processing a single sample are included in **Table 3**. The processing signal magnitude and the power spectrum computation demonstrate a higher order of signal clarity in analysis and validation.

CONCLUSION

The technique proposed in the present study uses neural networking terminology to learn and develop a pool of clusters and patterns to provide a systematic and reliable decision to categorize speech signals. The processing system is based on open database processing to validate the mental health conditions of users during the ongoing isolation and lockdowns caused

by the COVID-19 pandemic. The results show a promising outcome with a precision of 90% and higher accuracy across various users. The approach has a projected accuracy of 93.5% under the open validation platform on a computational evaluation. The proposed technique could be included in classifying and categorizing patients' behavior in future, with supervised approaches to keyword extraction and classification in dynamic signals.

The exponential growth of social media users has changed the dynamics of retrieving the potential information from user-generated content and transformed the paradigm of information-retrieval mechanism with the novel developments on the concept of "web of data". In this regard, our proposed Ontology-Based Sentiment Analysis provides two novel approaches: First, the emotion extraction on tweets related to COVID-19 is carried out by a well-formed taxonomy that comprises possible emotional concepts with fine-grained properties and polarized values. Second, the potential entities present in the tweet can be analyzed for semantic associativity. The extraction of emotions can be performed in two cases: (i) words directly associated with the emotional concepts present in the taxonomy and (ii) words indirectly present in the emotional concepts. Though the latter case is very challenging in processing the tweets to find the hidden patterns and extract the meaningful facts associated with it, our proposed work is able to extract and detect almost 81% of true positives and considerably able to detect the false negatives. Finally, the proposed approach's superior performance is witnessed from its comparison with other peer-level approaches.

INTRODUCTION

Emotion Analysis helps us to understand and to retrieve the potential emotional information from any user-generated content. The user-generated content can be text, images, animations, videos, scan images, etc. But the text is predominantly used due to the emergence of social media platforms and other sources as well. Extracting emotions from the text document is a challenging task as it covers a wide range of ambiguities and anomalies that persist over the text content. Emotion Analysis has been categorized into different models, such as the corpus-based model, appraisal-based model, and knowledge-based model. The lexical affinity of a word or a phrase is determined based on the probability of emotion attached to each term and the cognitive factor will be inclusively considered for evaluation. For example, the term, "eager" takes a high probability score against "curious" than "willing." To shun these difficulties, an ontology-based analysis has been used predominantly to disambiguate the terms and to yield a high precision score for the emotional terms.

At first, the term, ontology was inhibited from psychology but it started making its footprint in computer science from the year 1980s. Ontology-based emotion extraction on text documents has been a research focus for many applications and it has gained huge momentum in recent years (1–3). As human beings always use natural language to represent the domain of the specific text document, the ontologies have been using formal language representations to describe the domains of the input document. The use of ontologies has been widely applied in many research areas, such as artificial intelligence, entity extraction, Semantic Web, collaborative software development, and many more (4, 5). Ontologies provide huge benefits, such as conceptualization, reusability, sharing of the resources, and coreferencing the terms. It is indeed a cost-effective process for dealing with text analysis and is very robust for many application areas as mentioned above. Many research works have been implemented with ontologies to remove the ambiguity that persists in the textual content. A structure that provides a formal description of a standard representation of real-world concepts can improve the understanding of these concepts. COVID-19 is the disease caused by SARS-CoV-2, the coronavirus that emerged in December 2019 (6–11). The lack of existing studies allows us to explore this ontology-based emotion extraction on COVID-19 datasets.

The conventional Sentiment Analysis is normally applied to the text to determine whether the given text expresses a positive sentiment or a negative sentiment. Generally, the Sentiment Analysis has been carried out for knowing the feedback or the opinion of the customers about the products they had purchased. In particular, the following two Sentiment Analysis approaches were usually performed to get the sentiment score of the text documents: lexicon-based approach and machine learning-based approach. The first approach segments the text into appropriate morphological lexicons and then extracts the opinion words which are usually expressed either positive or negative. A dedicated dictionary that has been established for opinion words is called a lexicon dictionary and mapping of the opinion words on the lexicon-based approach has been done based on this lexicon dictionary. But in this case, tweets are not considered because of the underlying fact that tweets are within 140/280 characters and normally, words in a tweet are condensed into canonical forms due to their limited length. The machine learning-based approach has now gained huge momentum for many research activities and in that case, a specialized sentiment classifier has been trained for the textual corpus to predict the polarity of the text. Typically, the sentiment classifier has trained the model based on bigram or n-gram textual representation and classifies the text into the respective sentiment scores. The major drawback of this approach is the manual labeling of the training datasets and it has not been worked out well for tweets or any short messages.

The ontology-based approach proposed by Ali et al. (12) indicates that the sentiment score has not been made possible based on the emotional polarity but on the accuracy score obtained from the ontology. The ontology-based model helps to extract the emotions from the tweets based on the factors, such as concepts, the relationship between the concepts, characteristics of individual concepts, and external source document support for disambiguation. In this connection, Semantic Web technologies have been used to construct the ontology for extracting the emotions from the text documents and allow for sharing and reusing of the potential data for various applications. Resource description framework (RDF) is used to identify the resources by Uniform Resource Identifier (URI), and Resource description framework schema (RDFS) helps to organize and formulate the content in the machine-understandable format. The SPARQL query is used to fetch the disambiguous results from the RDFS graph. Therefore, we proposed the novel approach to segment the tweets into appropriate morphological textual representations and to train the classifier to distinguish the polarity of tweets using Semantic Web technologies and natural language processing (NLP) toolkits.

The primary objective of this research work is to quantify the efficient classification of the extracted emotional entities from tweets using the proposed emotional ontology. Following are the outlined objectives of the proposed work:

- The domain entities have been classified with appropriate upper ontology classes and it measures the correctness concerning the metrics given in the Emotion Ontology.
- Selecting and quantifying some of the general domain emotional entities from the tweets that have significant relevance in the upper ontological class of Emotion Ontology.
- Determining the word embedding and taxonomy-based similarity measures for the extracted emotional entities.
- Generating relevant descriptions for those extracted emotional entities and assigning the relevance score based on the results obtained from the SPARQL query.

The rest of the paper is organized as follows: Section Related Works summarizes the existing works based on semantic similarity measures, ontological features, emotion analysis, and sentiment analysis of social media content. Section Proposed Approach for Ontology Creation highlights the important features of Domain Ontology and semantic enrichment of entity categorization. Section Utilization of Emotion Ontology describes the core aspects of designing the semantic-based emotion ontology and taxonomy-based entity classification and disambiguation. Besides, it also explains the importance of ontology modularization for partitioning the large-scale ontologies into some self-contained modules. Section Conclusion delineates the polarity calculation and determines the performance of emotion ontology for the fine-grained measures.

RELATED WORKS

Extracting emotions from the documents is a tedious task as it involves a wide range of subjects, such as psychology, anthropology, society, and biology. In psychology, emotion is defined as the study of different orientations of human beings and the theories of emotions have been represented using cognitive psychology. Even though many cognitive models had been evolved to denote the emotions incurred in the documents, the most widely implemented affective computing models are dimensional (13), categorical, (14), and appraisal (15). Lang (13)

has extensively studied and analyzed the expressions of emotions for effective detection and categorization. He had classified the emotions into three vital categories, namely, subjective emotions, behavioral emotions, and psychophysiological emotions. The subjective emotions were classified based on perceived emotions vented by the user. The behavioral emotions were distinguished by facial, gestural, and speech paralinguistic attributes. The psychophysiological emotions were identified by the heart rate, electroencephalographic results, galvanic skin values, etc.

Later, Lacy (16) had delineated the behavioral models with emotional processes and the methods required to indicate the various stages of emotions are represented by cognitive psychology. They further analyzed the emotional processes very deeply and came out with three critical parameters, to access the behavioral model, such as emotion itself, emotional context, and multimodal behaviors. The study added that time-of-event is a critical factor for representing the emotional context. On the contrary, Baldauf et al. (17) had proposed a novel model in which they assessed the behavioral model in terms of location, time, the person involved, the state of the person at the time of the event, societal activity, and instruments or devices used. These parameters were used for emotional context and augmented the emotional credibility for research analysis.

Later et al. (18) have extended the sentiment analysis of Twitter streams by computational frameworks and analyzed the emotions expressed in Twitter streams by certain questionnaires. The answers pertaining to the questionnaires were later analyzed by the popular probabilistic topic model, latent Dirichlet allocation (LDA) algorithms that effectively disambiguated the ambiguous emotions present in the tweets. Their work highlighted the various factors of emotion discovery shifted among various users' conversations on Twitter.

The emergency of social media has created a huge opportunity for social users to interact and discuss a wide range of topics prevalently happening around the world. These discussions paved the way for analyzing the significant interest of the social media users over the topics and performing sentiment analysis, such as emotion detection and recent opinion mining. According to Ren and Hong (19), emotion analysis had been widely implied in various domains, such as e-mail content, novels, online news content, blogs, dashboards, and other social media content. Researchers, such as Oliveira et al. (20) and Ren et al. (21) have studied the consumers' views on many online products and their purchases and later predict the growth of stock markets. They forecasted the growth of stock markets based on discussions that happen on Twitter and followed the lexical heuristic approach to filter out the basic emotional values presented in the tweets.

The researchers, Baldoni et al. (22) and Dey et al. (23) have implemented the emotion extraction process first by n-ary relations. The complex relations were factorized into some set of binary relations and the potential named entities were extracted from the text. Extracting potential named entities from the text is a complex task and it requires a well-equipped classifier to identify and distinguish the potential entities from the text. So, the classifier has been well trained to suit the needs of the entity extraction and in this case, the learning approach techniques have been used and in particular, the maximum entropy model has been followed for entity extraction. Once the potential named entities have been identified, the complex relationship between the entities has been reconstructed using a simple directed graph. The three significant approaches followed before the emotional analysis processes include (i) rule-based approach, (ii) learning approach (maximum entropy), and (iii) graph-based approach.

Earlier, open information extraction (OIE) has gained huge momentum in extracting the entities and relation sets from the documents. OIE is a full-fledged extraction framework Daniel et al. (24) for both structured and semi-structured documents. OIE enables the extraction process in place of DBpedia and LinkedGeo data for effective entity detection and categorization. Further, it paves way for entity triple formation using the Semantic Web technologies, such as RDF/RDFS and Web Ontology Language (OWL).

Most of the semantic similarity measures attempt to emulate the human ability to evaluate the level of relativeness between the words according to their semantic evidence. According to Madani et al. (25), semantic measures assess the quality of the semantic associations between the words, as indicated by the investigation of semantic proxies (words, senses). For instance, a semantic similarity measure would not think about the two ideas "sloth" and "monkey" to be comparative, regardless of whether the vast majority think sloths to be monkeys. Given that semantic estimates target contrasting things concurring with their significance caught from semantic proof Mozafari et al. (26), it is hard to additionally characterize the thought of semantic measures without characterizing the ideas of meaning and semantics. Likewise, the two ideas, "tea" and "cup" are in this way exceptionally related despite the way that they are not comparable: the idea, "tea" alludes to a drink, and the idea, "cup" alludes to a vessel. In this manner, the two ideas share not many of their constitutive properties. This features a potential understanding of the idea of semantic similarity, which can be comprehended in terms of replacement, i.e., assessing the suggestion to substitute the analyzed components: Tea by Coffee or Tea by Cup. In fact, word-to-word semantic similarity is sometimes assessed not just considering (close) synonymy, or the lexical relations which can be considered as comparable to the ordered connections for words, e.g., hyponymy and hypernym.

Table 1 highlights the performances laid out on semantic similarity measures of different domains.

PROPOSED APPROACH FOR ONTOLOGY CREATION

At first, the proposed approach deals with the creation of Domain Ontology for the bio-medical-related subjects to provide an accurate sentiment score for the opinion words present in the COVID-19 tweets. Here, the use of Semantic Web technologies gains a tremendous prospect to create Domain Ontology for the specific subjects, and further, the opinion words from the subject have been enlisted for the ontology with appropriate properties and literals. The Domain Ontology plays a seminal role in supplementing the feature extraction process to yield the precise sentiment score for the COVID-19-related tweets and

8	Hill et al. (33)		Semantic similarity of pairs of words	999	$\rho = 0.7$

increase the accuracy rate of the results. The proposed system is divided into two crucial phases. (i) Creation of Domain Ontology for the selective subject and (ii) feature extraction of opinion words included in the Domain Ontology. **Figure 1** illustrates the proposed architecture for emotions extracted from the tweets.

Creating the Domain Ontology

Normally, the Domain Ontology can be created either by utilizing the existing off-the-shelf ontologies or developing the ontologies based on the suitable requirements. There were many off-the-shelf ontology resources available for specific domains in the Semantic Web Forums that paved a way for the researchers to utilize these resources to map the properties of the ontology and opinion words (34). Many software solutions have been completely dedicated for knowledge-based entity extraction and deployed further with the extraction of context-specific ontology/structured terminologies, such as the disease ontology (DO), unified medical language system (UMLS), WordNet, Medical Subject Headings (MeSH), Gene Ontology, etc. To support the OWL, the standard RDF grammar has been designed with stipulated functionality (31). These ontological frameworks (28) can be used to define the terms and entities generically. In **Table 2**, we have given the name of the tools used for ontological design, supporting formats, libraries, command-line interface (CLI), and source code library (LIB). As the ontological frameworks support the programming languages, such as JAVA and PYTHON, the semantic similarity measure can be taken into consideration for some pair of concepts (P) or some association between the groups of concepts (G).

Formal Concept Analysis for Ontology Creation

Formal concept analysis (FCA) is a mathematical model that has been mostly applied in knowledge representation and information extraction. The sole objective of FCA is to pave the way for creating the Domain Ontology by a step-by-step approach and by considering all the ambiguities that persist on the properties of the Domain Ontology. With the advent of recent Semantic Web Technologies, the OWL helps to derive the potential objects and their properties and establish the Domain Ontology for accurate knowledge representation.

Basic Elements of FCA in Domain Ontology

The fundamental building block in FCA is the concept that can be derived from two valuable sets: Extension and Intention. The Extension is a set of objects collected for the Domain Ontology in considering the potential opinion words listed for the specific subjects. The set of objects has been chosen based on some grounding rules formulated for creating the ontology. The Intention is a set of attributes for every selected object and each attribute has some inherent properties and literals to represent in the hierarchy of domain levels. Every object that represents the concept has its attributes in the intention and likewise, each attribute linked to the concept of the Domain Ontology can be further shared with all the other objects of the Extension. This mutual connection that exists between the objects and attributes is described through the mathematical representation called Formal Context. A Formal Context is a triple that can be represented as K (O, A, I). Here O is a collection of objects for the Domain Ontology, A is the collection of potential attributes of the objects, and I is a binary correlation that exists between the objects and attributes; $I \subseteq O \times A$, where (o, a) $\in$ I (i.e., "object o has to attribute a").

Method of Ontology Learning

Ontology Learning or ontology acquisition is the inbuilt process of automatically inheriting the concepts and their associated properties from the other ontology resources or datasets (1). This capability has helped the researchers to save time and customize their Domain Ontology as per their requirements. In this study, we have used OntoGen, a semi-automatic ontology editor that reduces the overall deploying time of the ontology, as well as the complexity, which persists over the hierarchy of the ontology. In nutshell, this editor helps resolve the conflict between the ontology editors and domain experts because both do not hold the required ontology-engineering skills. That is, OntoGen is an

interactive editor that can help the domain experts to accept or reject the concepts or objects, or properties of the ontology, based on their requirements, and suggests the appropriate concepts and relations to the ontology. The manual adjustments of assigning instances to the concepts can be done at any level of the ontology hierarchy and thereby reduce the complexity of the overall ontology representation.

Semantics Entailment

The domain ontology has been created *via* FCA and Ontology Learning and it enriched the taxonomy of a set of concepts and its potential attributes. To boast the semantic representation of the concepts, the ontology has now been filled with appropriate synonyms and hyponyms of the corresponding attributes. For instance, the term, "apple" comes under the class, "fruit" as well as "phone"; further, their hierarchy extends above to "vegetables" for "fruit" and "electronics" for "phone." The synonyms and hyponyms can be fetched through the well-formed lexical corpus called WordNet (35, 36). With the assistance of WordNet, we extracted the appropriate synsets for the word and appended the same to the ontology and associated with the appropriate attributes of the object. We have been using the Semantic Web Language for the ontology called OWL which has the following three dedicated categories: OWL DL, OWL Lite, and OWL Full (16). To augment the synsets extracted from WordNet to the Domain Ontology, we preferred to use OWL DL which has the syntax owl: subPropertyOf and owlequivalentProperty. Through these OWL properties, we updated the synonyms and hyponyms, respectively, into the ontology.

Sentiment Analysis on Twitter Streams

After the creation of domain ontology, the next phase of the operation largely relies on performing the Sentiment Analysis of the tweets and distinguishing the polarity of the extracted opinion words from the tweets. The whole process constitutes of filtering the set of tweets from the COVID-19 datasets and then extracts the potential opinion words from the tweets and maps the opinion words in the domain ontology for getting the sentiment score (37, 38). To obtain the sentiment score of the opinion words, we have scaled up three distinct procedures: (i) querying the Domain Ontology for retrieving the correct attributes of the object, (ii) distinguishing the ambiguities that persist over two or more objects, and (iii) disambiguating the objects with necessary attributes and literals.

Step#1: Utilization of the Ontology

The Domain Ontology has been used to extract the appropriate attributes for the opinion words and to fetch equivalent classes for the objects with necessary attribute references. This task can be performed through Jena Fuseki, which is a Java API for handling RDF/s and OWL codes (39). Generally, JENA API is used to filter the results in the form of a triplet which is represented as Subject, Predicate, and Object (SPO). This triplet is used to discriminate the classes of the ambiguous attributes and return the results either in the form of an RDF Graph or as JSON format. Once we obtain this sort of ontology-based hierarchy model for classes and attributes, retrieving the triplet would be easier and this, in turn, results in matching the opinion words in the Domain Ontology.

Step #2: Identify the Ambiguous Entities in the Tweet

In the preprocessing steps of tweet normalization, we removed all the special symbols like @, #, and other uniform resource locators (URLs), and then considered the words which are deemed to be opinion words after verifying them with the opinion-lexical database. The pre-processed tweets are then added to the second phase of the Sentiment Analysis and here we matched the opinion words which are also called entities in the Domain Ontology. The mutual mappings between the opinion words in tweets and their equivalent attributes in the Domain Ontology pose an ambiguity and create a separate list of ambiguous entities for further disambiguation. For logics and inferences possessed in the Ontology, we have used the first-order logics as well as description logics to express the relations given in the Emotion Ontology.

Step #3: Disambiguate the Objects

The ambiguous list of entities is then processed for entity disambiguation which is the crucial task of this research work. The core idea behind the disambiguation process is that the mapping between two objects with dissimilar attributes in the Domain Ontology is identified first and then a comparison of properties and literals of two objects can be measured using semantic similarity-based algorithms i.e., Word2Vec and disambiguate the entities which hold the highest similarity score. The fundamental principle of ontology lies in disambiguation so that the original sense of the attributes can be obtained only at the leaf nodes of the hierarchy and hence the semantic similarity measures, such as Word2Vec have been selected to delve deep into the hidden layers of the neural network to get the precise results for the target words. Algorithm 1 illustrates

Algorithm: 1 Emotional Ontology-Based Entity Extraction and Weight Calculation.

Input: Parse Tweets and Extract Named Entities $NE = (e_1, e_2, \ldots . e_n)$

the Emotional Ontology-Based Entity Extraction and Weight Calculation process.

UTILIZATION OF EMOTION ONTOLOGY

According to Li et al. (40), ontologies are originally stated as a formal, explicit specification of a shared conceptualization. It originally deals with knowledge representation in the hierarchy of concepts ordered in the ontology and it shared the common attributes among other classes in the hierarchy to represent the types, relations, properties, and other interrelation concepts that lie in the ontology. Ontology plays a crucial role in the knowledge extraction process and represents some conventional extraction models, such as keyword-based extraction, bag-of-word models, and other statistical analysis that failed to yield accurate results. Ontologies help share the common attributes and they are made machine-readable. Ontologies play a pivotal role in establishing the mutual connection between class hierarchies and other concepts underlying the objects. Further, the ontologies are very useful for exact labeling and categorizing the mutual relationship that exists between the objects and their properties. The ontologies are defined in the following four forms: (1) an entity that links the object, (2) the relation between the entity, (3) object relationship, and (4) properties that connect the objects. The use of ontology is now gaining momentum and the following are some potential reasons for building the ontology for the given requirements: Examining domain-specific knowledge, distinguishing the domain suppositions, reusing the domain knowledge for diverse applications, converging the domain knowledge and functional designs, and sharing the knowledge with other software bots.

Emotion Ontology Corpus Creation

Eight emotions were selected based on the recommendation given by Ekman (14) and observed that these eight emotions have been widely used in the COVID-19 datasets. We have populated these eight emotions into the Emotion Ontology and represented them as OWL Class (41). A dedicated list of emotional categories of terms has also been chosen based on the psychological models (42) and we structured them in the Emotion Ontology as given in **Figure 2**. Further, 14 subsets of emotions are added as subclasses for the above eight emotions. Besides, the emotions can be further classified into four types: *Basic Emotions* (joy, confusion, anger, disgust, fear, sadness, love, and surprise), *Mid Emotions* (distraction, boredom, acceptance, apprehension, interest, serenity, pensiveness, and annoyance), *Intense Emotions* (ecstasy, amazement, vigilance, grief, admiration, loathing, rage, and terror) and *Complex Emotions* (disproval, love, submission, optimism, awe, contempt, aggressiveness, and remorse). The Emotion Ontology helps to reduce the complexity of the redundant emotion population and also paved the way for detecting the emotions represented in the tweets. Besides, Ontology minimizes the non-emotional terms, which would be very large in Twitter Streams.

The Domain Ontology has been created manually with the help of a psychological-emotional words list and WordNet. But when it comes to the reusability of several classes belonging to different domains, the manual population of ontology would be a hard task. Further, it would lead to duplication of many more properties and their values. Therefore, effective utilization of Semantic Web technologies, such as RDF/RDFS, SPARQL, and OWL would primarily facilitate the mutual connection that exists over other domain ontologies, such as the one given in the Linked Open Data (43). In this proposed approach, Emotion Ontology has been created based on the effective reuse of existing ontologies and with well-formed semantic vocabularies, such as a friend of a friend (FOAF), semantically interlinked online communities (SIOC), Dublin core, etc. The SPARQL query has been generated to map the semantic vocabularies and other domain ontologies appropriately. **Figure 3** illustrates the generation of Emotion Ontology.

Retrieving and Annotating the Twitter Streams

In recent times, machine learning techniques have been used to automatically annotate the text documents and to train the classifiers according to the needs of the ontological requirements and domain hierarchy (2, 4, 29). But the machine learning techniques are not suitable for unstructured documents and they further lead to many serious implications, such as morphological change, lexical error, sense overlap, and ambiguous annotation for entities. Hence, we proposed a novel approach called ontology-based entity extraction and constructed a novel Emotion Ontology. As the Twitter Streams contain diverse information from different sources, the distribution of emotions that persisted on these tweets is deemed essential for extracting more emotions which further helps in tracking the implicit emotions of individual users on Twitter.

To gain a high recall score for the emotion extraction from the tweets, we have also crawled for slang words and out of vocabulary (OOV) words present in the tweet. The slang words and OOV words were disambiguated and we generated the correct term for the slang words using online slang dictionaries,

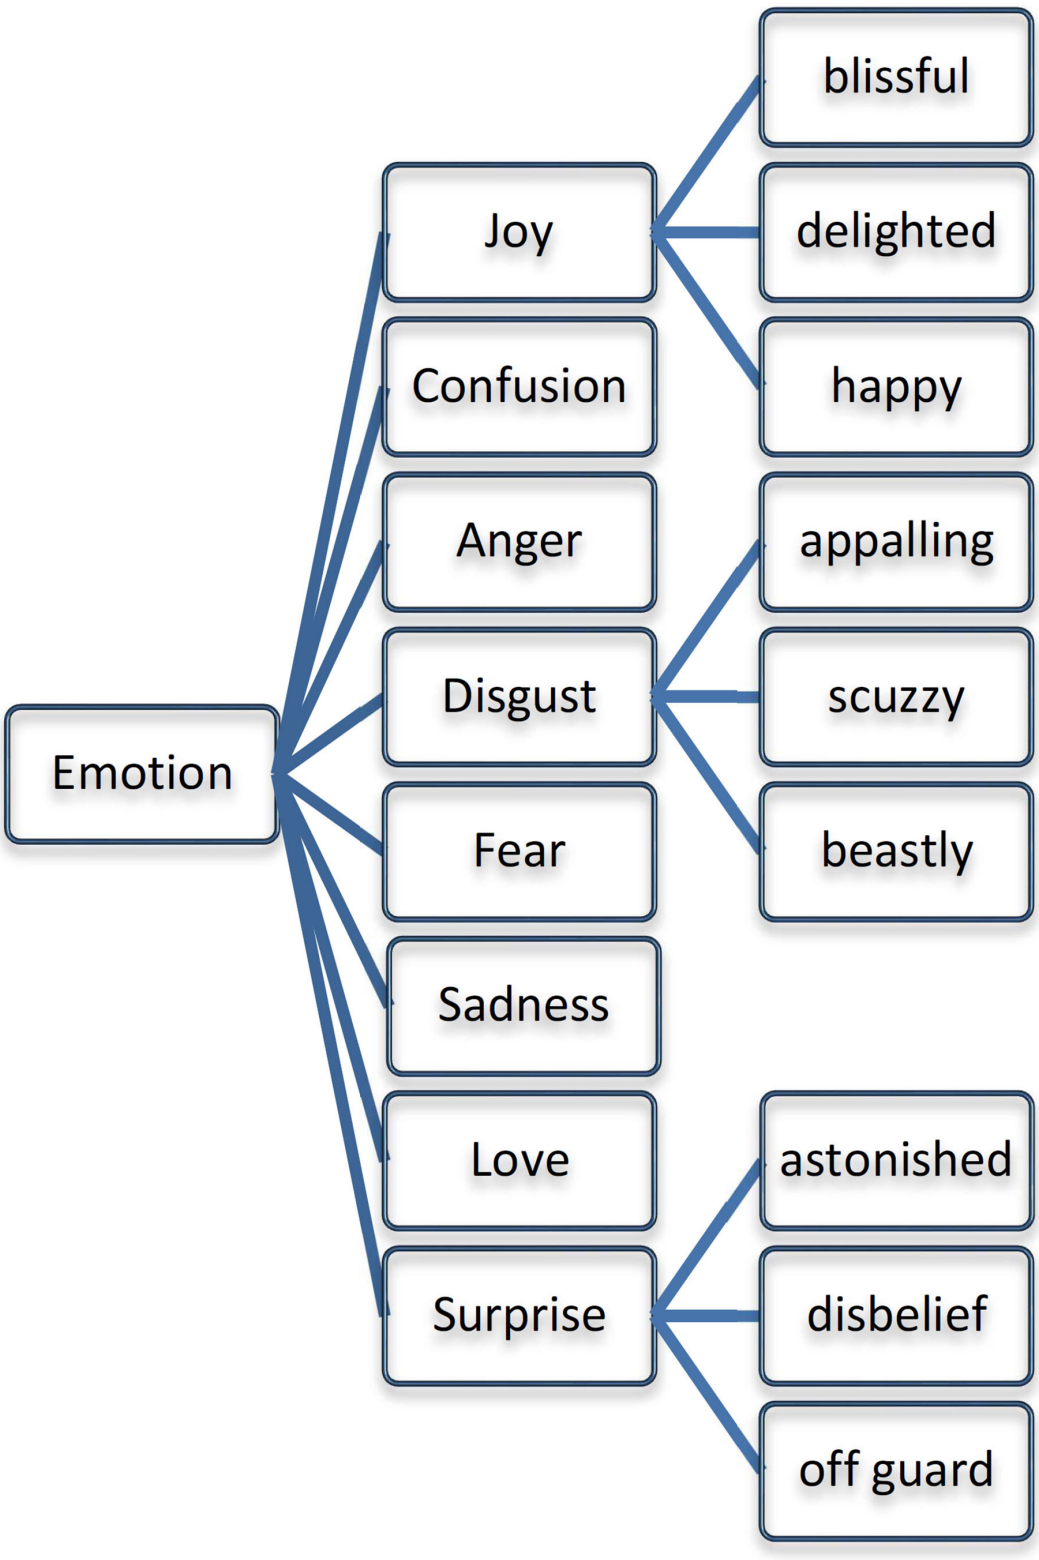

FIGURE 2 | Fundamental emotions list for ontology population.

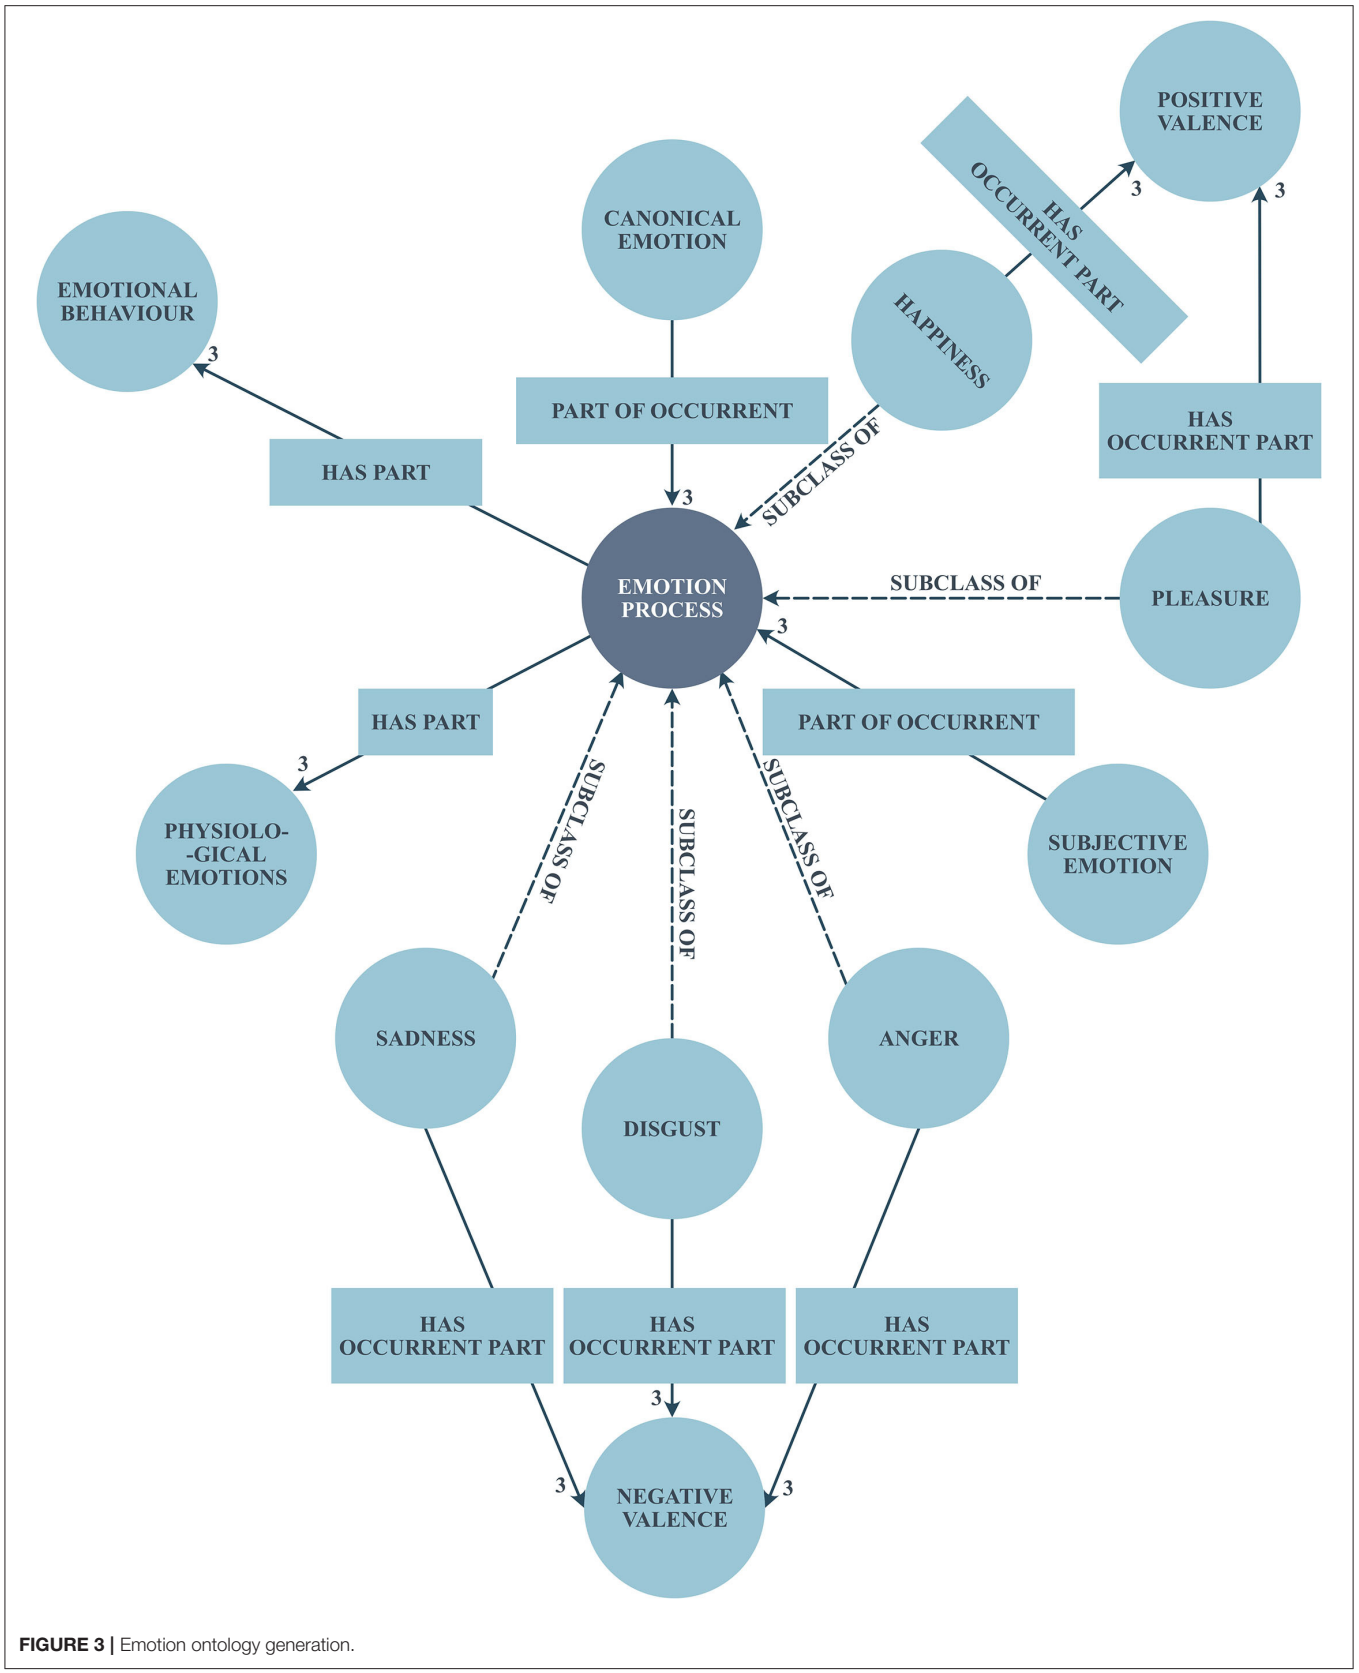

FIGURE 3 | Emotion ontology generation.

such as NoSlang Dictionary, Urban Dictionary, and Translit (44). Further, for every detected slang word, we generated the candidate lists based on the synsets produced from the WordNet Synset. We then used Dictionary.com, Thesaurus.com, and Oxford Dictionary for increasing the probability strength of the words. The intensity of the words resulting from these dictionaries would be considered and populated for our Emotion Ontology.

Emotion Detection in COVID-19 Datasets

Here, we provide a baseline approach that can be followed for automatically annotating the emotions extracted from the COVID-19 tweets[1]. To extract the emotions, we have applied the binary Support Vector Machine (SVM) classifier to effectively identify the eight emotions as proposed by Ekman (14). Each classifier has been trained independently for every emotion which resulted in seven independent binary classifiers and further the merger of these combinations of classifiers would be considered as a single multi-label classifier. Using this single multi-label classifier, the tweets can be annotated even if they possess more than one emotion and return positive if the multi-binary classifier is applied to the tweet. Likewise, it would return negative results if a binary classifier is applied. The result would be neutral for no emotions in the tweet. Each classifier has been following an independent classifier for a different group of features and in particular, the feature used by the binary classifier is a subset of the features deployed in the multi-label classifier (45).

To augment the feature extraction process accurately, we have omitted some of the similarity features which envisioned more on a topic than emotions and rejected the synsets followed by WordNet Affect features in this research. The decision has been taken not to use WordNet Affect for this research as normally the tweet does not possess sufficient synsets to cross-verify over the WordNet Affect. Moreover, WordNet Affect would probably look for possible candidate hypernyms instead of potential resources (i.e., thing, or object, in our case). Another dissimilarity observed on WordNet Affect is that it focused mainly on bigrams and trigrams for normalization instead of phrases. This would not be largely amicable for tweets due to their constraint in length. However, for the effective utilization of feature extraction for the proposed research, we used the topic modeling approach to discover the hidden terms and phrases between the tweets even though the tweet has no entities in common. Here, we have employed the LDA algorithm for topic modeling and it discovers the similarity that exists among the collections of tweets (i.e., the collection of tweets can be considered as a document by the LDA algorithm). For implementing this approach, we have enforced MALLET-based LDA implementation and treated every tweet as its document (46). This approach would project the probabilistic combination of words for every tweet and each topic is generalized into a set of probabilistic combinations of words.

Tweet Polarity Calculation Mechanism

The ultimate objective of this proposed approach is to calculate the polarity of every tweet that we have collected from COVID-19 datasets. In the conventional methods, the sentiment score will be calculated based on the word polarity and the overall strength will be estimated on the grounds of the polarity score obtained from the probability of the positive and negative words. But in this proposed approach, we have modeled a novel approach to get the polarity of words on every tweet by using the SPARQL query that crawls through the emotional ontology to fetch the correct sense for the search word. In our proposed model, we have excluded the pronouns, adjectives, and articles from the tweets and extracted the tokens such as nouns, verbs, objects, and determiners. As the Semantic Web gives a well-defined meaning to the sentences and converts the sentences into appropriate triples, such as SPO, we have followed the same pattern for our proposed approach for the Emotion Ontology building process and extracted the nouns (subjects), verbs (predicates), and objects (objects) that satisfy the Semantic Web triple pattern, respectively. The relation between the entities (either noun or object) can be expressed using the RDF/RDFS. The ontology population can be done either by the tool Protégé or using the Semantic Web language, OWL. For logics and inferences possessed in the ontology, we have used the first-order logics as well as description logics to express the relations given in the Emotion Ontology. Mostly, we have utilized the predicates for relationships between two or more entities and the predicate relationships can be expressed using the OWL predicate type method. For each tweet, we execute the SPARQL query to obtain the disambiguated result. The SPARQL query to fetch the entities embedded with emotions is given below: The Emotion Ontology helps to disambiguate

```
SELECT ?group ?emotion
WHERE
{
?a rdf:type x:EmotionAboutEntityItem;
x:hasEmotion ?emotion;
x:hasEntityItem ?entityItem.
?group x:contains ?entityItem.
}
ORDER BY ASC(?group)
```

the search terms accurately and to return the results precisely. Thereby, the polarity and sentiment score for each term or entity can be obtained and yield an accurate sentiment score for the tweets. Suppose, the search terms used for the execution in the SPARQL query return NIL results, then the context of the token would be considered and an appropriate parameterized SPARQL query will be executed against the Emotion Ontology to fetch the right mix of words for consideration. We then estimated the sentiment score by considering the largest domain value from the list of positive tokens and the smallest values from the other set of negative tokens. Eventually, to determine the polarity of every tweet, the tweet sentiment score is calculated based on the strength score of the tweet, and the strength score of every entity in the tweet is calculated based on the following calculations: (a) positive, if sentiscore is greater than 1, (b) negative if sentiscore is less than or equal to -1 and (c) otherwise neutral.

TABLE 3 | Tweet segmentation and classification for ontology matching.

Segmentation	Precision	Recall	F-Score

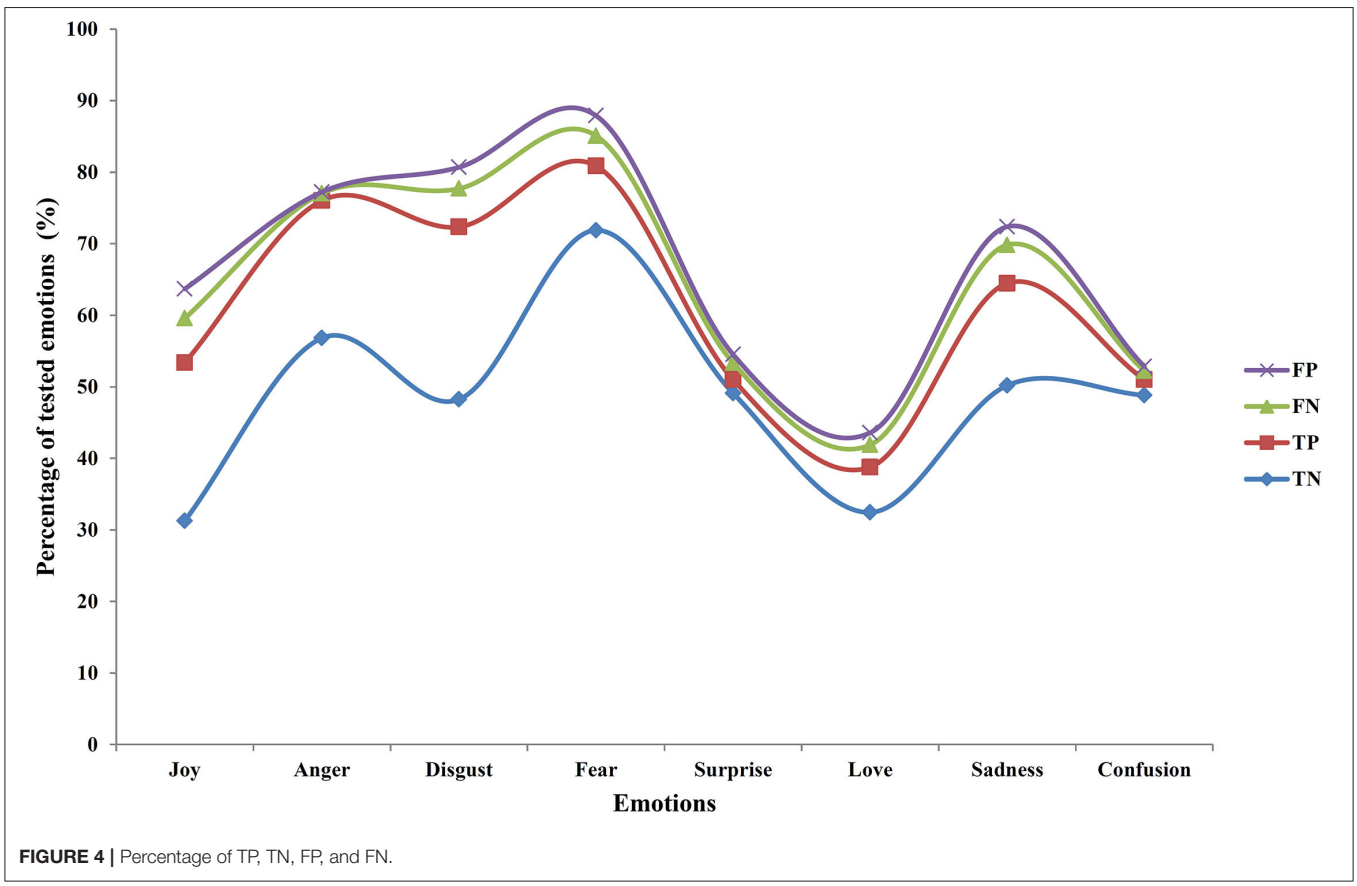

FIGURE 4 | Percentage of TP, TN, FP, and FN.

TABLE 5 | Calculation of the percentage of TN, FP, FN, and TP from the confusion matrix.

	Joy	Anger	Disgust	Fear	Surprise	Love	Sadness	Confusion
TN	31.27	56.81	48.24	71.88	49.11	32.45	50.19	48.82
TP	22.10	19.21	24.11	8.99	1.90	6.33	14.28	2.19
FN	6.21	1.01	5.35	4.22	2.34	3.11	5.36	1.21
FP	4.10	0.19	2.98	2.81	1.16	1.69	2.55	0.61

Further, to assess the absolute performance of our proposed Emotion Ontology, we have considered two implicit functions, such as sklearn.metrics.recall and sklearn.metrics.f1 to calculate the potential values, such as recall and F1 score, respectively. These two metrics were used to handle the multi-label classification (positive, negative, and neutral). Our sheer Emotion

Ontology population using Semantic Web technologies and performance measures selected for sentiment score has enabled the proposed method to avoid manual annotation using any machine learning techniques, and the problem of manual annotation has been resolved. Further, many recent studies have sought the help of machine learning algorithms to manually annotate the entities given in the text or any tweets. The proposed Emotion Ontology can deal with dynamic domain vocabularies that would possess different representations in the text.

Experimental Evaluation of Emotion Ontology Matching

Table 3 shows the performance of our Emotion Ontology and categorizes the accuracy rate based on the different segmentation

TABLE 7 | Comparative analysis with existing models and their limitations.

Reference	Year	Approach	Data sets	One sentence summary	Limitations	F1-score
Our Proposed Model	–	Ontological Framework	COVID-19 Pandemic related Tweets	Right utilization of Ontological Framework coupled with ML algorithms such as SVM and LDA	Can work only with English Text.	0.831
Matla and Badugu (47)	2020	Machine Learning	Tweets	Deployed the Naive Bayes algorithm for classifying the Twitter messages into four emotional categories.	Absences of contextual words in the text.	0.725
Huang et al. (48)	2019	Visual and semantic attention mechanism	Tweets	Deep Multimodal Attentive Fusion for multimodal sentiment analysis of 10 million Tweets.	The fine-granularity relation between image and text pairs is not yet explored.	0.769
Ragheb et al. (49)	2019	Machine Learning	CLEF eRisk-2019 (signs of anorexia) T1 dataset	Categorized the emotions based on Attention based model.	Cannot detect the happy emotions from text.	0.710
Hasan et al. (50)	2019	Hybrid	Tweets	Deployed a supervised learning system for automatically classifying emotion in text stream messages using ANEW lexicon.	Works well only for text messages.	0.778
Almanie et al. (51)	2018	Rule Based	Tweets	Able to extract the prominent 5 emotions in a real time situation.	Low semantic orientation of textual context.	0.719
Badugu and Suhasini. (6)	2017	Rule Based	Tweets	Detected only 4 primary emotions using the Rule Based approach.	This system focused only on English sentences.	0.720

followed for tweet analysis. Recall of the proposed ontology pinpoints the various expression and candidate terms employed over the tweets and reduced the false-positive cases encountered. The tweet segmentation has been carried out for tweets, part-of-speech (POS) tagging, and the likelihood of context rule applied for the analysis.

From the COVID-19 datasets retrieved from Twitter, training was strenuously performed over all the sample tweets, and validation was carried out with the baseline gold standard datasets. The total number of occurrences for each emotion listed was calculated by the number of positive values on the respective emotions and identified from class imbalances over the emotions, such as joy and love. **Table 4** outlines the occurrences of each emotion tested for the COVID-19 dataset.

To measure the accuracy of the proposed system, it has always relied on the precise calculation of the confusion matrix and mostly it is to obtain a low score over false positives (FP). Our proposed work is able to extract and identify almost 81% of true positives (TP) but it has encountered some serious challenges in detecting the false negatives (FN). This result has been vividly depicted in **Table 5** that projects the amount of FP generated against FN. **Figure 4** portrays the percentage of TP, true negatives (TN), FP, and FN.

Eventually, each core emotion that was extracted from the tweets have been analyzed in terms of precision, recall, and f-score, and the details are provided in **Table 6**.

Our proposed model considers every emotion with its associated context returned from the Emotion Ontology, and the sentiment score has been calculated based on the sum, average, and maximum count of emotion score returned by the Emotion Ontology. It has been witnessed in the analysis that our proposed system has extracted the emotional words and their associated context through our proposed Emotional Ontology. **Figure 5** illustrates the receiver operating characteristic curve (ROC) of the emotion classifier for the COVID-19 dataset.

Our proposed model has been compared with some of the benchmarked baseline approaches to highlight the major differences established in terms of F1-score. Some of the limitations that have been witnessed in the existing approaches have been delineated in **Table 7**. Major disadvantages of the existing approaches were mostly due to the lack of contextual information, low semantic orientation between two words, and availability of limited categories to extract the emotions.

CONCLUSION

The proposed Emotion Ontology model has been robust and efficient in extracting the full range of human emotions pertaining to COVID-19-related concepts. The emotions related to COVID-19 have been obtained and several emotional expressions, such as intensifiers, negator, lexical features, interjections, and conjunctions were considered for populating the Emotion Ontology. Semantic Web technologies have been utilized for creating the triples for every tweet, and the ontology construction has been manually done with the use of OWL functions. Compared to other lexicon-based emotion methods and machine learning approaches, the performance of

the proposed system is satisfactory. As the tweets have been considerably informal in nature and have sparse content, in particular, the other lexical-based model and machine learning approaches failed to yield the desired sentiment score and ended up with some satisfactory precision and recall score. Our proposed study is able to extract and detect almost 81% of TP and is able to detect a considerable amount of FN. Since this study mainly focused on dealing with the English language, there is a certain limitation for extracting few emotions that exist in other languages, such as French, Spanish, etc. For future work, we will consider extracting the profound availability of emotional occupancy of resources in other languages and level their accuracy on par with standard metrics defined in the baseline approach.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author/s.

AUTHOR CONTRIBUTIONS

SN and C-YC did the conceptualization and supervised the research. C-YC carried out the funding acquisition. SN investigated the data, performed the methodology, and implemented the software code. KS and C-YC carried out the project administration and validated the results. SN and KS wrote the manuscript. SN, KS, and SM reviewed and edited the manuscript. All authors contributed to the article and approved the submitted version.

FUNDING

This research was partially funded by Intelligent Recognition Industry Service Research Center from the Featured Areas Research Center Program within the framework of the Higher Education Sprout Project by the Ministry of Education (MOE) in Taiwan and Ministry of Science and Technology in Taiwan (Grant No. MOST 109-2221 -E-224-048-MY2).

Background: Bone cement leakage is a common complication of percutaneous vertebroplasty and it could be life-threatening to some extent. The aim of this study was to develop a machine learning model for predicting the risk of cement leakage in patients with osteoporotic vertebral compression fractures undergoing percutaneous vertebroplasty. Furthermore, we developed an online calculator for clinical application.

Methods: This was a retrospective study including 385 patients, who had osteoporotic vertebral compression fracture disease and underwent surgery at the Department of Spine Surgery, Liuzhou People's Hospital from June 2016 to June 2018. Combing the patient's clinical characteristics variables, we applied six machine learning (ML) algorithms to develop the predictive models, including logistic regression (LR), Gradient boosting machine (GBM), Extreme gradient boosting (XGB), Random Forest (RF), Decision Tree (DT) and Multilayer perceptron (MLP), which could predict the risk of bone cement leakage. We tested the results with ten-fold cross-validation, which calculated the Area Under Curve (AUC) of the six models and selected the model with the highest AUC as the excellent performing model to build the web calculator.

Results: The results showed that Injection volume of bone cement, Surgery time and Multiple vertebral fracture were all independent predictors of bone cement leakage by using multivariate logistic regression analysis in the 385 observation subjects. Furthermore, Heatmap revealed the relative proportions of the 15 clinical variables. In bone cement leakage prediction, the AUC of the six ML algorithms ranged from 0.633 to 0.898, while the RF model had an AUC of 0.898 and was used as the best performing ML Web calculator (https://share.streamlit.io/liuwencai0/pvp_leakage/main/pvp_leakage) was developed to estimate the risk of bone cement leakage that each patient undergoing vertebroplasty.

Conclusion: It achieved a good prediction for the occurrence of bone cement leakage with our ML model. The Web calculator concluded based on RF model can help orthopedist to make more individual and rational clinical strategies.

Keywords: percutaneous vertebroplasty, bone cement leakage, machine learning algorithms, prediction model, web calculator

INTRODUCTION

Percutaneous vertebroplasty (PVP) was a minimally invasive technique that uses liquid polymethylmethacrylate bone cement injected into the fractured vertebrae to reduce pain, strengthen the bone and prevent further compression of the vertebral body. PVP has become the mainstay treatment for osteoporotic and malignant vertebral fractures. Leakage of bone cement into the intervertebral disc increases the risk of adjacent vertebral fractures paraplegia due to extravasation of bone cement into the epidural or spinal cord compression associated with the intervertebral foramen (1). Besides, Leakage of bone cement into the paravertebral vein can lead to pulmonary embolism cardiac perforation, cerebral embolism and even death (2). Meanwhile, there are few reports of screening for independent risk factors and risk prediction models for bone cement leakage in patients undergoing orthopaedic percutaneous vertebroplasty.

Algorithmic decision support tools, computer-assisted navigation and surgical robots have served in the clinic (3, 4). Machine learning (ML) has been widely used in healthcare data analysis and some in spinal surgery (5, 6). By the comparison among ML algorithms, a better predictive model can be constructed to predict cement leakage after percutaneous vertebroplasty.

Some studies elaborated that age, bone mineral density (BMD), body mass index (BMI), volume of bone cement injections, and other underlying chronic diseases were risk factors for cement leakage (7). In addition, we added injury-to-operation time, hospitalization-to-operation time, and length of surgery.

Our study aimed to obtain the best ML algorithm, and constructed a big data risk prediction web calculator for postoperative cement leakage in patients undergoing percutaneous vertebroplasty. It ultimately provided a basis for future treatment and prevention strategies related to postoperative complications.

METHODS

Study Population

All data for this study were available from the Department of Spine Surgery, Liuzhou People's Hospital. This study recorded the medical variables of patients hospitalized with or without cement leakage after undergoing percutaneous vertebroplasty, from June 2016 to June 2018. Retrospectively analyzed the basic patient's information, as well as baseline clinical characteristics, surgical details.

Data Collection

To develop the target machine learning model, several variables were obtained, including patient age, height, weight, body mass index, bone mineral density, volume of bone cement injection, length of hospital stay to surgery, length of surgery, history of previous disease, and medication, as well as whether re-fracture occurred after surgery. Various machine learning algorithms such as logistic regression, random forest and other currently popular machine learning models were utilized in this study. Inclusion criteria for inpatient data were as follows: (1) osteoporotic vertebral fracture with moderate or severe low back pain which limited movement as the main complaint; (2) no significant improvement after active conservative treatment; (3) one or more vertebral fractures confirmed by imaging; (4) bone mineral density <2.5 by dual energy X-ray bone densitometry. In addition, exclusion criteria were: (1) fractures with symptoms of spinal nerve compression; (2) pathological vertebral fractures, such as spinal tumors, vertebral hemangiomas, spinal tuberculosis, etc.; and (3) patients with poor physical fitness and intolerance to surgical treatment. This study was approved by the Institutional Review Board of the Liuzhou People's Hospital before data collection and analysis, the IRB approval number is 2020 (KY-E-22-01).

Surgical Strategy

Patients undergo individualized PVP in the prone position with local anesthesia. All PVPs were performed with a unilateral lateral approach through the vertebral arch. The puncture was performed through the vertebral arch under fluoroscopic guidance. The puncture point is located at the intersection of a cephalolateral with a horizontal line 5–15 mm from the arch projection and a lateral vertical line $\sim$ 30 mm from the posterior midline. Under fluoroscopy, a 3.5 mm needle was moved along the root of the arch, the head adjustment and abduction angle of the needle bundle was allowed until the junction of the anterior third of the vertebral body was reached. The spread and distribution of the bone cement was monitored under fluoroscopy while the patient was tested for bilateral lower limb movement. After that, needle was withdrawn, covered with a sterile dressing and secured with pressure. Pre- and post-operative imaging is routinely performed in screened cases to determine the degree of compression of the fractured vertebral body, the height of the vertebral body, the integrity of the posterior wall of the vertebral body, the amount of cement

injected intraoperatively, whether the cement leaks, and whether the vertebral body is re-fractured postoperatively.

Statistical Analyses

Exploring the independent risk factors for PVP, multivariate logistic regression analysis was applied to calculate the odds ratio (OR) with 95% confidence intervals (CI) using a backward stepwise selection method. The value of OR >1 indicates that the variable is a risk factor. $P < 0.05$ was regarded as statistically significant. The predictive ability of ML algorithms has outperformed traditional regression methods in large databases (8). We used six different ML algorithms to analyze our data: logistic regression (LR), Gradient boosting machine (GBM), Extreme gradient boosting (XGB) Random Forest (RF), Decision Tree (DT) and Multilayer perceptron (MLP). After training, the one with the highest average AUC was chosen as the best algorithm. Furthermore, the ML-based model was tuned to avoid overfitting and the accuracy of the algorithm was tested using ten-fold cross-validation method.

In our study, the components and proportions of multiple relevant factors related to PVP were analyzed and visualized by heat map for the collected patient data. Furthermore, the heat map can also be used to identify data of outrageous quality during the actual analysis and assist in quality control.

We first used a multiple regression model as a benchmark for data evaluation and ML (which can handle a large number of input variables, assess the importance of variables when deciding on categories, and detect variable interactions). In the performance comparison of ML algorithms, the more AUC close to one, the better performance these classification model obtained. Based on the best execution model, a web calculator was created in this paper which implemented the prediction of illness for inputting patient data. The calculator allowed the surgeon to assess the risk of possible postoperative cement leakage in patients undergoing percutaneous vertebroplasty.

RESULTS

Demographics Features

The clinical history of 385 patients who underwent PVP was summarized in this study, the number of patients who developed post-operative cement leakage was 81 and the number of patients who did not develop cement leakage was 304 (**Table 1**). Among these observed subjects, the median age was 75.4 years (IQR:68.3, 80.7), the median height of these patients was 155 cm (IQR:149,161), the median weight of the patients was 47kg (IQR:40,58). The median BMD was 4.4 (IQR:3.9,5.0). The *P* values of these indicators were 0.987, 0.2082, 0.948, and 0.1833, respectively. None of them were statistically different. It worth noting that the 205 patients (53.25%) who did not have multiple vertebral fractures ($P < 0.05$). Besides, no cement leakage occurred in 177 patients (58.22%) and cement leakage occurred in 28 patients (34.57%).

In the correlation heat map (**Figure 1**), 15 highly correlated features were chosen as predictors. Weight was absolutely correlated with BMI and to some extent with height. As BMI got a better indicator of obesity, we only considered BMI rather than height or weight.

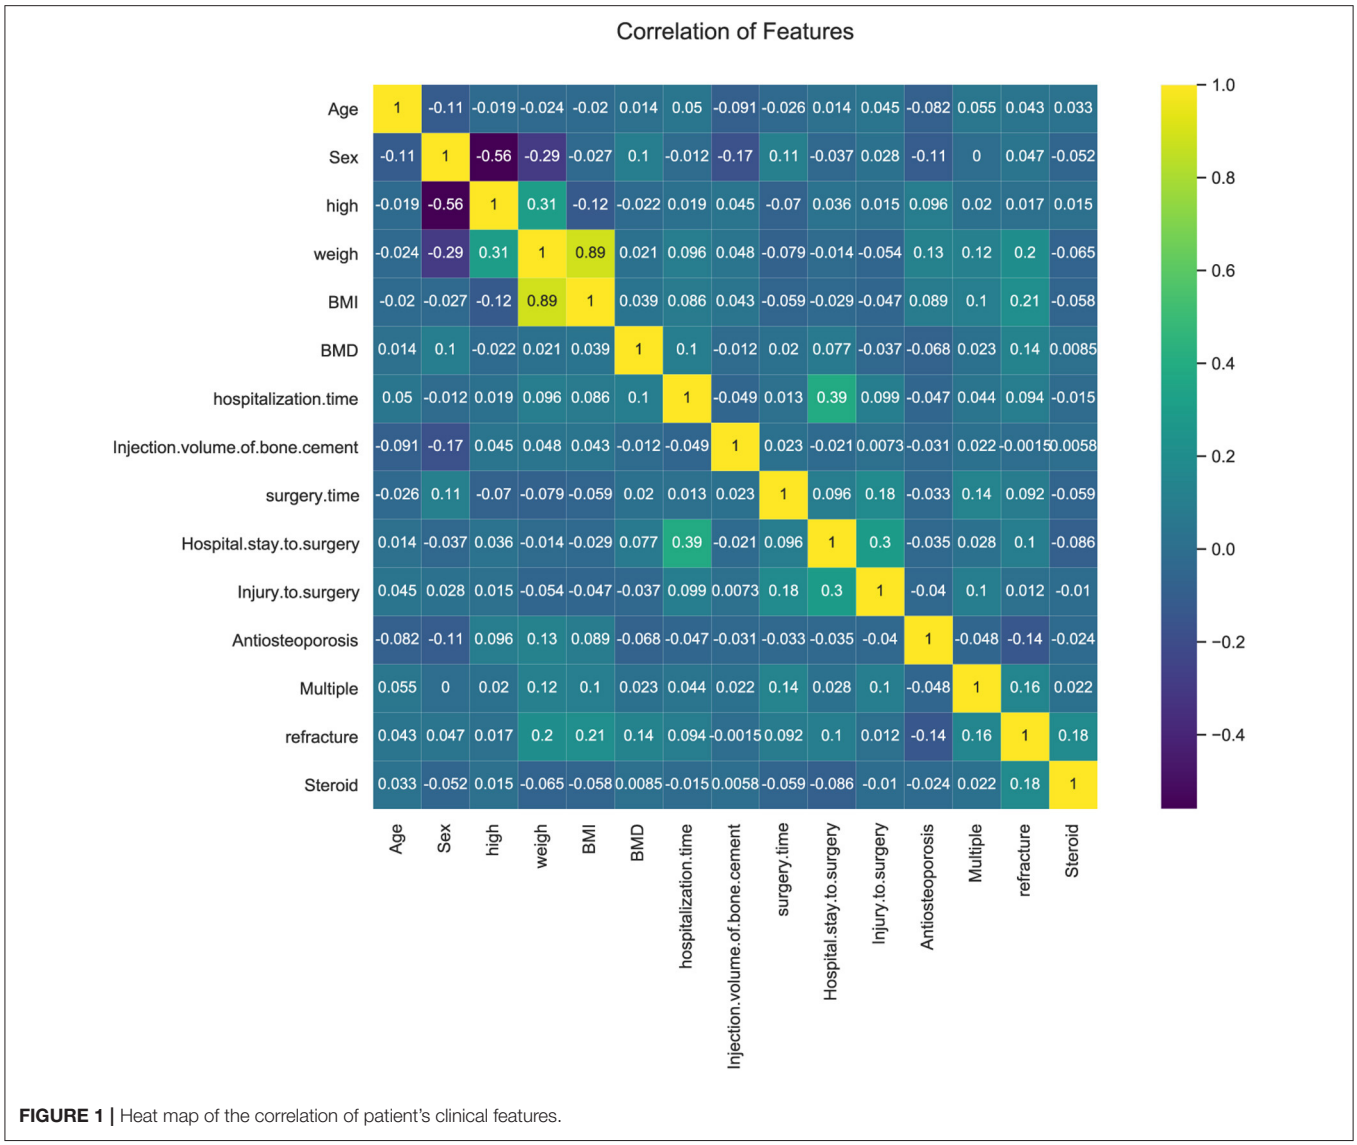

FIGURE 1 | Heat map of the correlation of patient's clinical features.

Univariate and Multivariate Logistic Regression Analyses of Cement Leakage

In terms of univariate analyzing (**Table 2**), age, height, weight, body mass index, bone mineral density, volume of bone cement injected, length of hospital stay, and intraoperative injury didn't have significant difference in occurrence of bone cement leakage in the overall population ($p > 0.05$).

In the multivariate logistic regression analysis, all parameters from the univariate analysis above were included. OR value showed the relative risk of bone cement leakage. The results showed that age (OR 1.002, 95% confidence interval 0.976–1.029), male (OR 0.799, 95% confidence interval 0.421–1.514), body mass index (OR 0.992, 95% confidence interval 0.946–1.040), bone mineral density (OR 1.272, 95% confidence interval 0.878–1.844), and length of hospital stay (OR 1.021, 95% confidence interval 0.973–1.072). Injection volume of bone cement, Surgery time, and Multiple vertebral fracture were all independent predictors for bone cement leakage. Besides, Multiple vertebral fractures (OR 2.638, 95% confidence interval 1.581–4.399), indicating a statistical difference ($P < 0.05$).

Performance of Machine Learning Algorithms

To compare the predictive performance of these six different ML algorithm models, 10-fold cross validation was applied in this study (**Figure 2**). As shown in the figure, the random forest model performed best in predicting bone cement leakage with an average AUC of 0.898. The remaining models were sorted in descending order depending on prediction performance. Therefore, we finally regarded the RF model as the preferred prediction model.

Relative Importance of Variables in Machine Learning Algorithms

The feature importance were different from each other while multiple vertebral fractures and bone density were at first. Intraoperative injury, length of surgery, height, age, body mass index and length of hospital stay were arranged in order of importance. Then, variables such as steroid hormone use, length of hospital stay to surgery, volume of bone cement injection, body weight, anti-osteoporosis medication, and gender had bad performance in predicting the contribution of bone cement leakage and were ranked in descending order (**Figure 3**). Particularly, re-fracture had no effect on bone cement leakage.

Web-Based Calculator

In this study, a web-based online calculator based on random forest model was developed. By entering variables that characterize the clinical profile of patients about to undergo percutaneous vertebroplasty, clinicians were able to predict the risk of cement leakage of their patients (https://share.streamlit.io/liuwencai0/pvp_leakage/main/pvp_leakage) (**Figure 4**).

DISCUSSION

Our research work used clinical data from patients to produce a risk calculator for bone cement leakage using ML algorithm, which using multiple variables to predict the risk oucomes of patients. The model was established based on a range of predictions and tested for accuracy and reasonableness through 10-fold cross validation. This artificial intelligence-based strategy can be exploited by clinicians to help them select more rational treatment responses (9).

ML contributes to the paradigm shift inherent in healthcare, where computers learn from patient data without being explicitly programmed to do the task (10, 11). It has the advantage of being highly capable, objective and repeatable in processing large data sets, reliable data (12, 13). It also has the potential to improve the quality of early diagnosis, identify disease progression and can increase the likelihood of predicting specific patient outcomes in orthopaedics, such as outcome scores, risk of complications and survival of implants (14). These benefits can facilitate the sharing of decision-making information between clinicians and patients and promote the effective planning and rational use of healthcare services (15, 16). In addition, the model can be retrained over time in order to improve predictive accuracy (17).

Percutaneous cement augmentation has become a common treatment for osteoporotic fractures of the thoracolumbar spine. Bone cement filling is an essential component that reconstructs the strength and biomechanics of the fractured vertebra and prevents re-fracture (18, 19). The incidence of bone cement leakage ranges from 5 to 87% (20, 21) and pulmonary embolism or spinal injury due to bone cement leakage is rarely reported (22, 23). Bone mineral density was an important indicator of bone strength and was the most effective predictor of fracture risk (24). Guo et al., found that the volume of injected bone cement was an independent risk factor for cement leakage (25), so we added this variable to our model algorithm.

In this study, we compared multiple machine learning algorithms for predicting the risk of bone cement leakage in patients undergoing percutaneous vertebroplasty. The comparison of ML algorithms revealed that the random forest performed best. To better utilize the model, we further built a web calculator estimating the probability of bone cement leakage in patients.

It was important to note that preoperative variables including age, body mass index and bone mineral density were significant predictors that can be used to assess the risk of cement leakage and thus help clinicians to choose the best treatment and know the prognosis of the patient. However, these factors in previous studies were based on preoperative information and were deficient to achieve reliable predictions. In addition, few studies have assessed the predictive value of intraoperative factors. Therefore, we established the key variable of intraoperative cement injection volume, which not only ensures that correct intraoperative

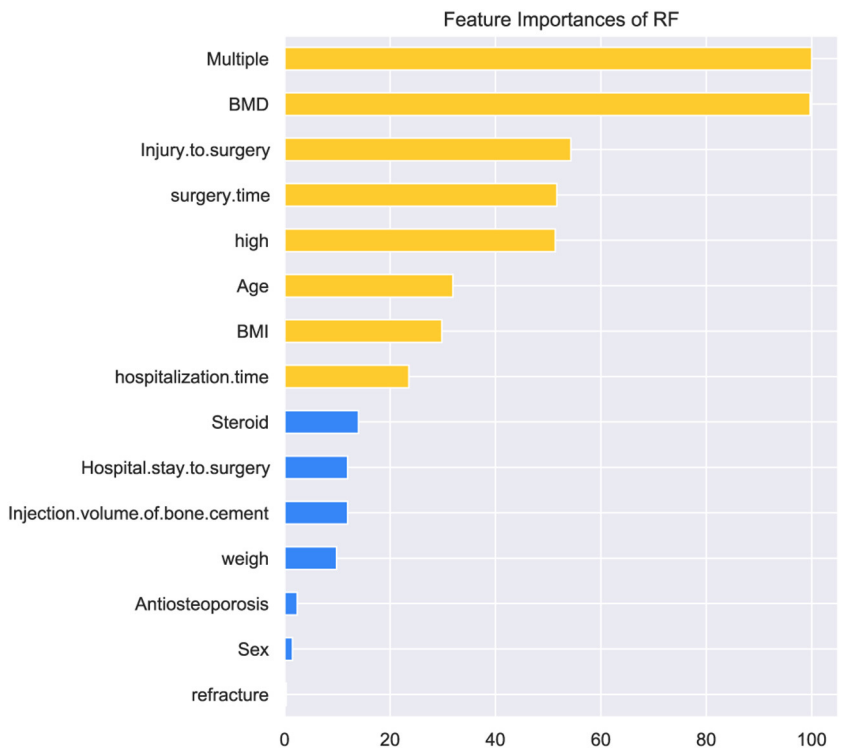

FIGURE 3 | Patient clinical feature importance of Random Forest.

manipulation and restoration of vertebral strength can be safely performed, but also helps us to predict the extent of cement leakage.

This study aimed to use a dataset consisting of 385 patients to help us select the best machine learning prediction. Our work had several advantages. First, few studies have used

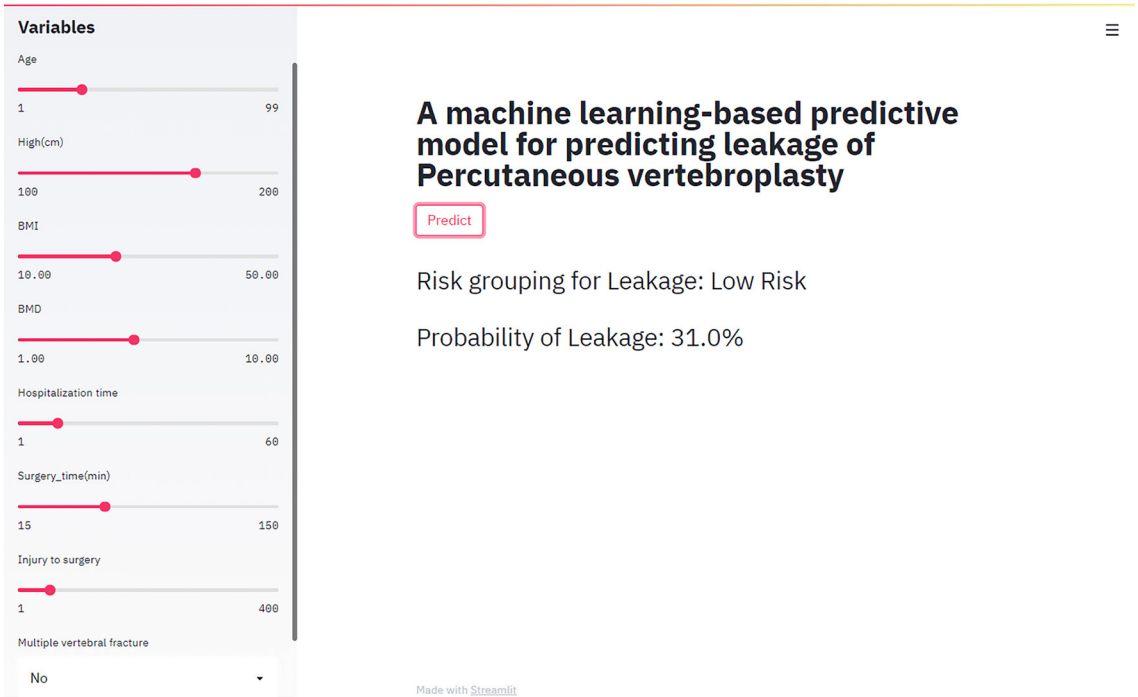

FIGURE 4 | The web-based calculator for predicting bone cement leakage in patients with percutaneous vertebroplasty.

machine learning methods to assess the risk of bone cement leakage during percutaneous vertebroplasty. Besides there were few studies in the existing literature that have applied ML algorithms to orthopaedic surgical complications. As far as we know, this study was the first to use ML algorithms to develop a web calculator that allows orthopaedic surgeons to use clinical data for real-time risk assessment of surgical complications. Last but not least, by comparison, our model shows superior predictive power and based on this we have built an online risk assessment program that allows orthopaedic surgeons to calculate risk variables and provide individualized surgical treatment to patients.

However, there are some limitations in this study. Firstly, the nature of retrospective studies can lead to subjective bias and selection bias. Secondly, ML algorithm model we developed was limited to one hospital. This may limit its use in other regions, which requires more use for further validation. Thirdly, the predictive performance was not good enough.

In machine learning, supervised learning identified the relationship between input data (e.g., patient clinical characteristics) and output data (e.g., bone cement leakage), which can help us predict outcomes. This has done through regression or classification. In classification tasks, the analysis was usually implemented by using logistic regression or decision trees. There were several studies on the latter shown that patient's age, associated comorbidities, functional status, etc. could lead the patient not being discharged as planned (26, 27). Furthermore, as more data being obtained, models can be retrained over time to improve prediction accuracy. Of course, clinicians always have the final decision when it comes to interpretation based on their domain expertise.

In conclusion, in this article we found that the random forest algorithm had good performance while applied as a tool for predicting bone cement leakage after orthopaedic surgery, Meanwhile, it was reasonably accurate and simple to use. Using this web-based calculator we could effectively prevent complications after percutaneous vertebroplasty and assist doctors in their surgical decisions. It is hoped that in the near future this web calculator will be able to cover a wide range of clinical variables, even at the molecular and cellular level, so that it can be used more accurately to assist a wider population.

Mishra S, Tripathy HK, Kumar Thakkar H, Garg D, Kotecha K and Pandya S (2021) An Explainable Intelligence Driven Query Prioritization Using Balanced Decision Tree Approach for Multi-Level Psychological Disorders Assessment. Front. Public Health 9:795007. doi: 10.3389/fpubh.2021.795007

Human emotions affect psychological health to a great level. Positive emotions relate to health improvement; whereas negative emotions may aggravate psychological disorders such as anxiety, stress, and depression. Although there exist several computational methods to predict psychological disorders, most of them provide a black-box view of uncertainty. This research involves developing a novel predictive model for multi class psychological risk recognition with an accurate explainable interface. Standard questionnaires are utilized as data set and a new approach called a Q-Prioritization is employed to drop insignificant questions from the data set. Moreover, a novel balanced decision tree method based on repetitive oversampling is applied for the training and testing of the model. Predictive nature along with its contributing factors are interpreted with three techniques such as permuted feature importance, contrastive explanation, and counterfactual method, which together form a reasoning engine. The prediction outcome generated an impressive performance with an aggregated accuracy of 98.25%. The mean precision, recall, and F-score metric recorded were 0.98, 0.977, and 0.979, respectively. Also, it was noted that without applying Q-Prioritization, the accuracy significantly drops to 90.25%. The error rate observed with our model was only 0.026. The proposed multi-level psychological disorder predictive model can successfully serve as an assistive deployment for medical experts in the effective treatment of mental health.

Keywords: psychological risks, explainable intelligence, decision tree, oversampling, predictive learning

1. INTRODUCTION

According to the observation of WHO, a healthy mind with physical well-being is possessed by a healthy individual (1). Also, it has been noted that various mental risks are gradually prevailing the society as a whole. In this fast-paced world with constant changes in the style of living, various kinds of psychological disorders are emerging in modern society. Mental

health concerns including anxiety, stress, and depression are common in people's life. Both personal and professional instabilities contribute to the occurrence of these disorders. Also, it is noted that such psychological concerns exhibit many overlapping symptoms. As an instance, individuals experience loneliness in all the three mentioned disorders (2). These health risks are vital parameters of psychological well-being and must be given proper attention at right time in order to prevent any potential negative impact on individuals (3). Usually, experts take the help of questionnaires and interactive sessions to assess these mental risks issues. As per their observation, psychologically affected patients reserve their sentiments within themselves and are reluctant to share them with family, friends, or even medical professionals. Common symptoms observed in an anxious person include nervous feeling, frequent irritation, insomnia accompanied by fatigue, panic tendency, fast breathing, rapid pulse rate, and concentration issues (4). Similarly being regularly upset, unable to relax, less energetic, having chronic headaches, and overreacting to situations are some primary symptoms noted in stress disorder (5). Similarly, depression exhibits some vital factors like lack of focus, memory fluctuations, poor decision making, lack of zeal in recreation, feeling of helplessness and restlessness, weight loss, and suicidal mindset (6). Thus, as it is discussed, many common overlapping symptoms are observed in these three psychological risks like pain in the chest, insomnia, fatigue, pulse rate rise, and lack of concentration. The presence of multiple overlapping symptoms makes effective categorization of these disorders a concern. The gradual rise in these psychological risks has led clinical researchers to focus their explorations in this domain. Accurate assessment, categorization, and treatment of anxiety, stress, and depression disorders are also a challenging task for machines (7). So a suitable learning model is needed for reliable assessment and diagnosis (8). Magnificent success in data analytics has led to numerous applications of artificial intelligence. Continuous rise in these techniques leads to developing intelligent models with self-ability to perceive, learn, and take a decision on its own (9). But the efficiency and robustness of these autonomous models are restricted by their incapability to interpret their outcomes and decisive functionalities to users. The real concern is on relying on decisions that lack proper justification, thereby unable to provide a detailed explanation of certain system behaviors (10). These predictive models provide a black-box view which is tough to explain. However, with the rapid rise in deploying these self-learning models in various application domains, the need for transparency and interpretability is highly required from all stakeholders in data analytics (11). Especially in critical health related applications it requires an extensive explanation of any decision to medical experts rather than a simple projection of output for diagnosis. Thus, in recent times with the modern adoption of complex learning models in the healthcare field, more attention is to develop human interpretability enabled frameworks that can enhance its implementation capability. Thus, a new approach called explainable intelligence needs to be adopted that are modeled to use predictive learning methods that perform the following functionalities.

- Generate explainable frameworks maintaining a high level of accuracy.
- Enabling end users to trust and understand the underlying functional characteristics.
- Ensuring impartial decision making.
- Determining all relevant factors which are essential for the prediction of an outcome.

Predictive models with such explainable intelligence capability can readily provide explanation toward any outcome, weighs pros and cons of a model and, thereby suggest on the future behavior of the developed model. These interpretability based frameworks can be integrated with system interfacing to transform a predictive decision into an upgraded reasoning prototype with relevant explanation to users.

The purpose of implementing explainable intelligent techniques is to appropriately explain the interpretation of predictive decisions obtained. Both the machine learning unit and the explainable intelligent unit are supplied with data and through the use of an explainable unit, precise explanations combined with prediction decisions are generated. These explanations can assist healthcare professionals to verify the decision of the predictive unit. Furthermore, it can be utilized with medical reports to provide in-depth reasoning and recommendations. A sample illustration of a predictive model supported by explainable intelligence is shown in **Figure 1**. Explainable intelligence is characterized by some vital elements which distinguish it from other conventional learning models. These critical elements concerned with an explainable intelligent model are discussed in this study.

- **Trust** is denoted by the certainty of a predictive model to perform during any troubleshooting.
- **Causality** is determined by the easiness to find associations such that there exists a strong logical link among variables.
- **Transferable** is governed by the interpretation of internal links occurring in a model which helps the user in reusing information to solve different problems.
- **Informative** property is based on the need for enormous information to reason predictive outcomes of a model, thereby avoiding local minima.
- **Fairness** symbolizes clarity of visualized results and the ethical ability to identify factors that affect a specific outcome.
- **Accessible** represents a feature allowing users to involve in the procedure of enhancing and building a predictive framework. Interactive is the capability of a learning model to share data and interact with the end user for effective interpretation.
- **Privacy** explores the functionality to interpret the internal links of a learning model by another third party to compromise the security aspects of the information.

2. PROBLEM STATEMENT

Psychological disorder risks such as anxiety, stress, and depression are quite common in modern society. There exist several prediction models that use different algorithms to detect

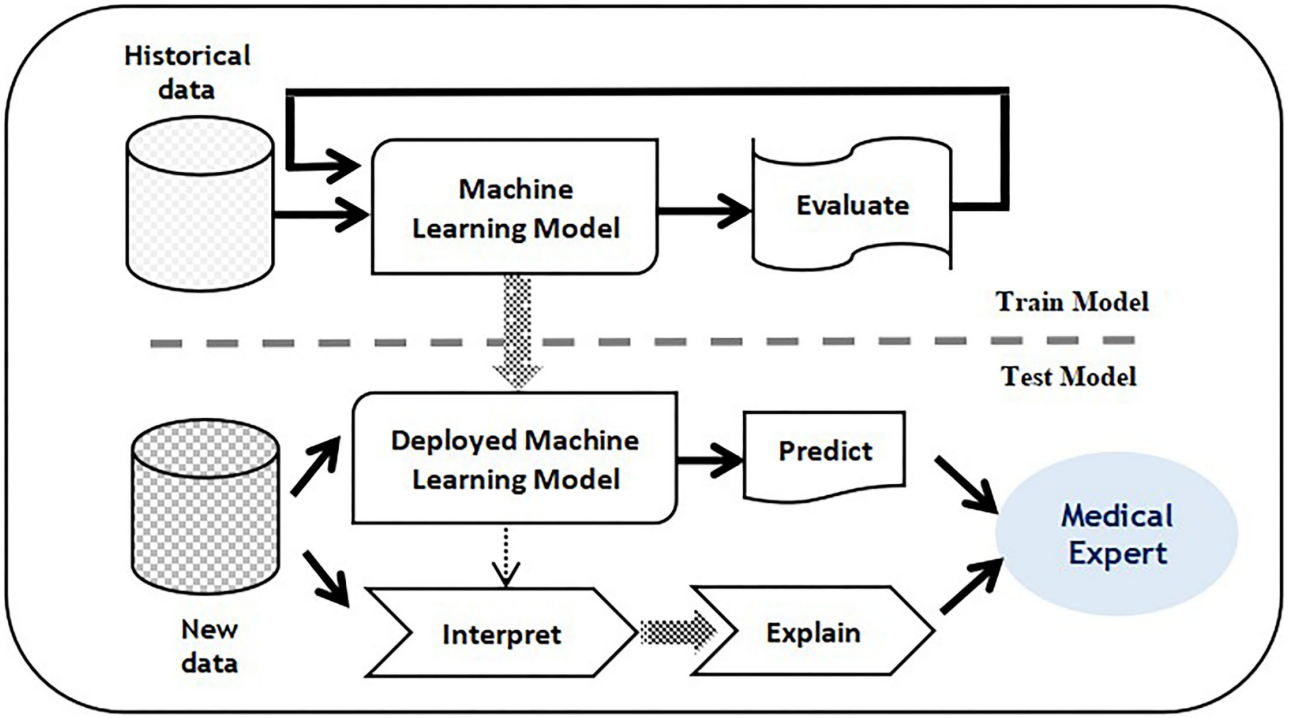

FIGURE 1 | Training and testing phase with proposed Balanced decision tree approach.

the presence of these mental health issues at an early stage. Unfortunately, these standard machine learning techniques present a black box view whose predictive nature cannot be easily interpreted by medical experts. With the rise of computationally intelligent models in the critical healthcare sector, effective reasoning and transparent functionalities are very essential since a contradictory predictive result may affect the mental stability of a patient. Therefore, a trade-off must be addressed between the prediction and transparent capability for critical use cases that almost benefit more reliably and implements a robust system to assist medical experts to find it easy to backtrack a certain psychological risk recognition. Thus, the high predictive ability should be well supported by an explainable interface to be more productive. In this study, we present an explainable intelligence-enabled psychological disorders predictive model comprising a transparent and reliable intelligent model to detect acute mental disorders from accumulated online questionnaires through interactive sessions with patients.

3. RELATED WORKS

Various academicians and researchers throughout the world have undertaken numerous quality oriented works related to healthcare prediction (12, 13) across different domains (14, 15) using recent technologies. Researchers have also analyzed psychological health disorders using many predictive learning models. Different datasets are used for this purpose. Evaluation of several existing models are also done to figure out the best performing models. But no model is singled out to deliver the optimum performance. Based on varying use cases, scenarios, dataset composition, training algorithm employed, and other miscellaneous factors, the performance fluctuates. Some high profile works which are significantly suited for the domain are discussed in this section. Dooshima et al. (16) have utilized learning models using several characteristic features such as biological, geographical, mental risks, and environment based variables to predict psychological disorders in patients. Many health professionals verified the authenticity of the model along with these metrics. Srividya et al. (17) framed a questionnaire to retrieve data of various features which was later used to detect mental risks in people. Among machine learning algorithms used in the study, nearest neighbor and random forest gave identical and good results. Dabek and Caban (7) applied an artificial neural network model for forecasting mental health ambiguities which include anxiousness and depression tendency. The study also stressed the impact of injuries and concussions on the health of sportspersons. A detailed analysis concerning various predictive models such as support vector machine, neural network, and k-nearest neighbor was undertaken for psychological patients by Alonso et al. (18). The review concluded that using information mining methods on depression and dementia-like disorders can yield fruitful outcomes and can enhance the life style of patients (19). Sau and Bhakta (20) applied several data analytics algorithms such as regression, boosting, and Naive Bayes to classify patients affected with mental disorders. In this study, around 500 data samples were collected through interviews,

and it was observed that boosting algorithm gave an optimal precision and accuracy value of 84.1 and 82.6%, respectively. A joint modeling architecture was developed by Saha et al. (21) where many linguistic variables on online sites were selected to classify psychological issues of virtual communities. The model performed better than other task learners, and the result explored the presence of sentiments beyond depression in the majority of online patients. Reece et al. (22) discussed the prediction parameters of depression and stress among the Twitter community where stress level was gauged through Hidden Markov Model (HMM). It was noted that around 24% and 32% of people were diagnosed with stress and depression tendency, respectively. Braithwaite et al. (23) used a decision tree model to determine patients with suicidal mindsets. About 135 tweets of different candidates were aggregated from Amazon Mechanical Turk and an accuracy rate of 92% was recorded. Du et al. (24) fetched Twitter samples with psychiatric stress units to tag suicidal tweets. Among all learning methods used, it was noted that convolution neural network performed the best among others including support vector machine and extra trees giving a 78% precision value in identifying online tweets with a suicide mindset. Al Hanai et al. (25) proposed a text-audio framework to detect depression where long short-term memory neural network was utilized to classify patients suffering from depression. The context-free method generated optimal results for multi-modal audio analysis. Ramiandrisoa et al. (26) predicted depression during early phases using social media data. CLEF eRisk tool was used to collect data. After an extensive evaluation, it was inferred that integration of information retrieval and machine learning produced the best outcome. Big data analytics was applied by Hou et al. (27) to forecast frustration and depression tendencies on basis of the reading pattern of users. Variables of Chinese textual data were retrieved to build a meta classification model. Naive Bayes gave the best performance among all. Leightley et al. (28) detected traumatic-related stress risks in ex-serviceman militants with supervised intelligent classifiers using various metrics such as gender, job state, and alcohol usage among others. It was observed that a good sensitivity rate was obtained for many classifiers except for the false negatives outcome. Young et al. (29) scanned facial expressions and body language of patients to detect mood variation and anxiety risks. The cross-validation method was used to generate a better precision rate and was alter validated by statistical algorithms. Mary et al. (30) conducted an experimental validation of stress, anxiety, and depression assessment with multiple machine intelligence methods using the DASS 21 dataset. Logistic regression gave the best performance with an accuracy of 90.33% on both stress and depression while 92% on anxiety risks. A detailed survey with around 6,000 candidates was done by Kessler et al. (31) to assess the degree of depression through the information mining approach and traditional methods. It was discovered that machine learners outperformed the traditional approach in detecting depression accurately. De Beurs et al. (32) presented an expert system with intervention mapping to help enhance user involvement in activities. The work discussed various patient specific design strategies for mental medicare using limited resources. Peng et al. (33) used kernel of support vector machine with some other learning classifiers to categorize depression patients on virtual community-based Twitter data. An accuracy rate of 83.46% was noted with kernel-based method. Anupriya et al. (34) analyzed various degrees of stress, depression, and anxiety risks using machine learning methods through DASS 2 questionnaires. Small dataset size was the major limitation of this study. Hatton et al. (35) assessed persistent depression in senior citizens through the gradient boosting method. In this study, PHQ-9 questionnaire was used for data collection purposes. Many such relevant existing research works are summarized in **Table 1**. Moreover, in Ray et al. (47), assessment of autistic disorder using machine learning approach is described. In Tripathy et al. (48), application and evaluation of classification model to detect autistic spectrum disorders in children are described. In Ray et al. (49), a review on Facial Expression Based Behavioral Analysis Using Computational Technique for Autistic Disorder Patients is described. In Mishra and Mohanty (50), an integration of machine learning and IoT for assisting medical experts in brain tumor diagnosis is described.

All these discussed work models provide good prediction and classification of psychological health risks. Various machine learning and attribute optimization methods are applied for precise analysis of such mental health concerns in humans. The majority of works used standard questionnaires based data set gathered through interactive face-to-face sessions. Also, the existing models have experimented on patients with varying age groups. Though all of these above mentioned works generate good performance, still they suffer from certain constraints. Problems related to the small sample size are a challenge for several deployed models. Another problem is the fact that data samples collected from interviews or manual queries based analysis restricts users from freely responding to any queries. As earlier observed, an individual having anxiety, stress, or depression symptoms are quite reserved within themselves rather than interacting with family, friends, or clinical staffs. They usually share their mind through anonymous platforms. But most importantly the biggest challenge lies in the fact that most of these predictive intelligent models simply provide black-box predictions without any reliable justified explanations of those mental health risk predictions. As a result, it creates ambiguities, and appropriate interpretations of a certain risk prediction can not be reasoned out. Thus, large sized dataset collected from online platforms are more desirable, and an explanatory interface is the need of the hour to properly interpret the psychological health prediction outcomes.

4. PROPOSED METHODOLOGY

The prime focus of the research is on recognizing physiological disorders such as anxiety, stress, and depression implementing an explainable intelligence based predictive model. Psychological disorder data samples in the form of responses of questionnaires are collected from the desired participants through Google forms and are stored for analysis. The proposed framework can be viewed to comprise certain interlinked functional phases which are discussed in this section.

TABLE 1 | Relevant works on psychological risk analysis using predictive analytics.

References	Reviewed risks	Approach	Inference
Bauer et al. (36)	Bipolar disorder	Paper-based survey	47% elderly people utilized internet and 87% youths exhibit bipolar disorder.
Dhaka and Johari (37)	Mental disorder	Genetic algorithm and MongoDB tool	Storage and processing massive mental risks data on MongoDB database.
Kumar and Bala (38)	Depression	Sentimental analysis and save data on Hadoop	Preprocessing online social media perspective on specific business products.
Furnham (39)	Personality disorder	Hogan "dark side" measure (HDS) concept of dependent personality disorder (DPD)	Most personality risk factors are highly linked to a type of cooperative personality.
Bleidorn and Hopwood (40)	Personality assessment	Prediction models and K-fold validation	Focused on aspects such as organized adaptability and arguments to improve verification of predictive techniques.
Sarraf and Tofighi (41)	Alzheimer's risk	Convolutional neural network	Mental health instances were successfully categorized with 96.86% accuracy rate.
Fiscon et al. (42)	Brain disorders	Decision tree and EEG signals	Decision tree outperforms others in precise risk detection with 90% accuracy and 87% specificity with use of cross validation method.
Chatterjee et al. (4)	Anxiety analysis	Regression and bayesian classifiers	Used a probabilistic technique to validate patients with anxiety levels. It concluded that Bayesian Network showed the best accuracy of 73.33%.
Omurca and Ekinci (43)	Traumatic stress risks	Neural networks and social media optimization	A hybrid system to classify PTSD individuals and allowed feature selection methods to find vital metrics of patients' risks. The accuracy differed between 74 and 79%.
Dabek and Caban (7)	Mental risks	Neural network	Analyzed 89,840 samples and recorded a classification accuracy of a range (73%-95%).
Katsis et al. (44)	Anxiety disorders	Integrated meta classifiers	Proposed a hybrid model with mental health signals for assessing anxiety risks. Accuracy of 77.33, 80.83, and 78.5% was the output with neural network, radial networks, and SVM, respectively.
Saxe et al. (45)	Stress risks	SVM and Lasso regression	Optimal AUC value noted was 79 and 78% with SVM and RF, respectively.
Karstoft et al. (46)	Stress and depression	Hybrid method Feature selection and SVM	Target Information Equivalence Algorithm optimized detection of PTSD when used with support vector machine. The mean AUC was 0.75.

1. Transform-Encode Phase.
2. Segregate-Label Phase.
3. Q-Prioritization Phase.
4. Train-Test Phase.
5. Prediction Interpret Phase.
6. Validate Phase.

The sequential six phases are required for a comprehensive psychological assessment. The Transform-Encode Phase is employed as the data samples are gathered in the form of the google form, the raw and unprocessed data need to be presented in a suitable template that can be easily interpreted. The Segregate-Label Phase is employed to partition the attributes of the data set into three distinct sets of physiological disorders such as anxiety, depression, and stress. After the data samples are pre-processed and labeled, it is followed by the Q-Prioritization phase which is responsible for dropping out less significant queries or attributes from the data set. Once the irrelevant attributes in the data set are eliminated, Train-Test Phase is used to learn through examples using an appropriate machine intelligence algorithm. The Prediction Interpret Phase provides a suitable explanation of the prediction outcomes.

4.1. Transform-Encode Phase

The retrieved data samples are gathered in the form of google responses from users. These raw unprocessed data need to be presented in a suitable template that can be easily interpreted. Thus, the collected responses are mapped onto a two-dimensional tabular structure by allowing it to be saved in a csv (comma separated values) file in a new editable excel sheet. If an online survey is followed then the Typeform tool can be applied to fetch the responses in the .csv file directly. If any other ways to fetch data in the spreadsheet is used then excel can be used in saving it as a .csv file. The collected data samples can be loaded and their attributes are summarized in the python platform with appropriate libraries in store. It is important to detect any missing values in the data as it affects the processing. Any data entries which are out of their predefined range are tagged as missing values. These values are counted, identified, and are accordingly replaced with the data value which is most common for that specific column. It is followed by the encoding of data where based on severity level, the responses are assigned numerical values in the range of 1 to 4. Finally, the rate point is determined on a [0,3] scale by subtracting 1 from the encoded value (51, 52).

4.2. Segregate-Label Phase

In this phase, the attributes of the dataset are partitioned into three distinct sets of physiological disorders which include anxiety, depression, and stress based on its belonging value defined at prior. Five severity levels of these disorders are considered and domain range for every level is set at prior corresponding to individual sets of anxiety, depression, and stress disorders. Normal (N), Mild (M), Moderate (MD), Severe (S), and Extremely Severe (ES) are the detected levels

1	2	1	0	0	0	3	3	1	3	0	2	3	3	22	S
3	1	2	0	0	1	0	1	2	2	2	1	1	2	18	MD

for the research work undertaken. The Weight Score (WS) for all disorder sets is calculated by summing up every data rate points for individual set of disorders taking into consideration of all column cell values and is given in Equation (1).

$$W_S = \sum RP^i \tag{1}$$

In this study, RP_i denotes the rate points of an individual set of mental disorders. "ES" label for anxiety, stress, and depression risks was assigned a WS of 20+, 33+, and 28+, respectively. "S" severity levels for these three classes were allotted a WS range of 15–19, 26–33, and 21–27, respectively. Similarly "MD" labeled instances were adjusted WS range of 10–14, 19–25, and 14–20, respectively. The WS values for the "M" class for all the risks were 8–9, 15–18, and 10–13, respectively. The WS values less than the above range are considered to be the "N" class.

A sample data-sheet illustrating the query set corresponding to anxiety, stress, and depression risks is represented in **Table 2**. It shows the computation of WS for all tuples and based on which the severity class label is assigned.

4.3. Q-Prioritization Phase

After the data samples are pre-processed and labeled, it is followed by the Q-Prioritization phase which is responsible for dropping out less significant queries or attributes from the dataset. It is to note that, the pre-processed question set is the input while a reduced and optimized question set is the output of the Q-prioritization phase. Sometimes it is observed that all attributes in the samples do not equally contribute to the processing and prediction process. The presence of these less relevant attributes affects the overall performance of the predictive model in the context of latency delay or accuracy of prediction. Thus, detecting and eliminating these less relevant features is a vital task. In this phase, a novel attribute relevance method is adopted before the model is subjected to training and testing using classifiers. The WS computed in the predecessor phase is analyzed and a relevant threshold (Rth) for every physiological disorder set is determined by Equation (2) as follows.

$$R_{th} = \frac{Normal_{max(PD)}}{Count_{col} \times Rate_{max}} \tag{2}$$

A R_{th} for every physiological disorder set is determined in Equation (2). In this study, $Normal_{max(PD)}$ represents the maximum value corresponding to the N level of any disorder set. The $Count_{col}$ denotes the number of attribute columns present in the questionnaire data set, and $Rate_{max}$ represents the optimum scaled rate point considered. Based on the equation, the R_{th} for every attribute column of the respective disorder set is computed.

The computed R_{th} value for anxiety, stress, and depression is 0.5, 1.0, and 0.2, respectively. Cumulative summation of all rate points which are grouped by individual column name is found out and a simple mean average for every column is determined. Furthermore, the priority of attribute columns is calculated on the basis of the ranking of their mean value in descending order which is calculated in terms of priority relevance (P^{rel}) as shown in Equation (3):

$$P^{rel} = \sum_{i=1}^{S} \frac{R_i}{S} \tag{3}$$

In this study P^{rel} is the priority relevance value to be computed. R_i denotes the rate point for every data sample for a specific disorder set, and "S" is the total samples of data collected. Based on the computation of P^{rel} obtained, those attributes are considered to be relevant and are retained. The overall pseudo code of this procedure is depicted in **Algorithm 1**.

Algorithm 1: Pseudocode for Q-prioritization phase.

Input: W_s
Output: Relevant prioritized queries.
Scan all labeled W_s determined in "Segregate-weight score phase" ;
Compute relevant threshold R_{th} for each *PD* subset: $R_{th} = \frac{Normal_{max(PD)}}{Count_{col} \times Rate_{max}}$;
foreach *disorder set D* **do** Add all rate points R_i grouped by column. ;
Find mean μ_i for each column. ;
Designate μ_i as P^{rel} ;
Rank all P^{rel} in ascending order priority: $P^{rel} = \sum_{i=1}^{S} \frac{R_i}{S}$;
if $P^{rel} \leq R_{th}$ **then**
  corresponding attribute column is irrelevant. ;
end
if $P^{rel} \geq R_{th}$ **then**
  corresponding column is relevant. ;
end
Relevant prioritized queries are retained. ;

4.4. Train-Test Phase

Once the irrelevant attributes in the dataset are eliminated, it is all set to learn through examples using an appropriate machine intelligence algorithm. After the model is adequately trained, it can be used to predict outcomes based on new data samples. In our research, an improved adaptation of the decision tree algorithm is deployed as the machine learning method. The decision tree is a widely used supervised approach to solve classification problems. It can be viewed as a hierarchical structure with internal nodes mapped onto attributes, branches denoting rules, and leaf nodes are the decision outputs. The decision node and leaf node are the two nodes of a decision tree. Decision nodes are responsible to take decisions while the outcome of decisions is denoted by leaf nodes. Based on the attributes of a dataset, decisions are made.

Algorithm 2: Decision tree building from training instances of data partition *P*.

Input: Data Partition *P*, Attribute_set, Attribute_select_method.
Output: Decision Tree.
Create node *s* ;
if *tuple* $\in$ *P with same label* **then**
  return *s* as leaf node with label *p*. ;
end
if *Attribute_set* == *NULL* **then**
  return *P* as a leaf node with major class in *s*. ;
end
Apply *Attribute_select_method*(*P*, *Attribute_set*) to check best split criteria. ;
Label node *s* with split_criteria. ;
if *split_attribute is discrete AND multi-way split permit* **then**
  Attribute_set = *Attribute_set* − *split_attribute* ;
  foreach *result I in split_criteria* **do** Let *P_i* be the tuple set in *P* satisfying result *i*. ;
  if P_i *is NULL* **then**
    A leaf attached to major class in *P* to node *S*. ;
  end
  else
    Attach node returned by *Build_Decision_tree*(P_i, *Attribute_set*)*tonodeS*. ;
  end
end
return *S*. ;

$$Gain(I, F) = Ent(I) - \sum_{s \in values(F)} \frac{|I_s|}{|I|} \times Ent(I_s) \tag{4}$$

A decision tree works with the purpose of predicting the label of a data sample initialized from the root node of the tree. Values of the root node are compared to the data variable and on basis of comparison follow the branch and move to the subsequent node. The process further compares the feature against all sub-nodes and proceeds. The same procedure is continued till the leaf node is reached. **Algorithm 2** relates its overall pseudocode.

One of the major concerns in a decision tree implementation is to choose the best attribute during the split. A suitable attribute selection measure solves the purpose. Information gain is a statistic based method for the selection of suitable attributes for testing at every node. It is a measure of entropy changes after attribute driven data segmentation which computes the information that an attribute gives regarding a class. Based on its value, the node is split, and accordingly, the decision tree is built. Gain (I; F) of an attribute A, that concerns a set of samples S is highlighted in Equation (4).

Where values (F) is the set of all possible values for attribute F, and Is is the subset of I for which the attribute F has value s.

Algorithm 3: Pseudocode for Information gain

Input: Instances, Attr, EntropyofSet
Output: Information Gain: $Gain(I, F)$

$Gain(I, F) = Ent(I)$;
for $Value \in Attr_Values(Instances, Attr)$ **do**
  $sub = subset(Instances, Attr, Value)$;
  $Gain(I, F) = Gain(I, F) - \frac{(count \in sub)}{number_of_samples} \times Ent(sub)$;
end
return $Gain(I, F)$;

The pseudocode for information gain is shown in **Algorithm 3**. Entropy in information theory is a metric that exhibits the purity of a random dataset. When the target feature accepts m distinct values, then its entropy I corresponding to m-wise categorization is denoted by Equation 5.

$$Ent(I) = \sum_{n=1}^{m} -P_i \times log_2 P_n \tag{5}$$

where "Ent" represents the entropy and pi denotes the probability of I which belongs to a class i.e., the logarithm of base 2 refers to the entropy of encoded size determined in bits.

4.4.1. Proposed Balanced Decision Tree Method

It is observed that the majority of predictive learning techniques generate optimistic classification performance which is misleading at times due to the uneven distribution of data samples in classes. It is due to the fact that many computational algorithms are built to function on classification samples with identical observations in every class. Data sampling can be used to deal with this issue a sit constitutes a set of methods to map an unbalanced data set onto more evenly distributed classes. The decision tree is biased toward the majority class, and as a result, the mis-classification rate of the minor class is more. In this study, sampling process can be fruitful in tackling this uneven data distribution. One such type called oversampling process replicates existing samples from minor classes and augment those to the train set. Here, training samples are randomly chosen with replacement such that a more balanced data set can be created. A balanced decision tree model differs from a simple decision tree in that it incorporates the oversampling technique to create an even distribution of data samples in both major and minor classes. The performance of a balanced decision tree is much better than the simple decision tree.

The improved decision tree presented in this study utilizes the oversampling method to generate a more efficient model. The physiological disorder data set is pre-processed and less relevant attributes are removed using the attribute relevance phase. The entire dataset is then partitioned into anxiety, stress, and depression sets on the basis of the predefined attribute set. The data instances are mapped onto the five disorder levels using simple if-then rules. Based on the cumulative rate point of a specific row, that instance falls in its corresponding disorder level. The labeling step is followed by oversampling where the minority class is identified in the training samples and random replicas of its instances are created. The sampling rate "S" chosen is 0.1. A decision tree algorithm is applied to the resultant oversampled dataset, and the accuracy rate is computed. The initial accuracy before the first iteration is assumed to be zero (Aold = 0). If the recent computed accuracy is found to be more than the predecessor value then the latest value is stored, thereby incrementing the sampling rate by 0.1. Again the data is oversampled with S = 0.1 to find the new accuracy. The process is repeated as long as the new accuracy Anew for a round is less than its previous value. At that point, the algorithm stops and generates the maximum accuracy value obtained throughout the process and is restored. After the training of the decision tree is done, the new test data is subjected to the model to predict the level of physiological disorder in the patient.

Thus, the developed model successfully detects the presence of any mental risk disorder, and if any inconsistencies are found then it predicts the level of disorder that the patient has probably developed corresponding to each set of a physiological disorder (anxiety, stress, and depression). Since the oversampling process is repeated multiple times in learning of decision tree to form a more evenly balanced data set, it is referred to as Balanced Decision Tree model which is illustrated in **Figure 2**.

4.5. Prediction Interpret Phase

An important observation that should be addressed is the set of attributes that have more impact on prediction outcomes. Most predictive models focus simply on the prediction performance rather than providing a suitable explanation for it. This creates an ambiguous scenario where factors that contributes to a certain prediction can not be determined. This creates a concern, especially when dealing with the real time critical healthcare domain. In our research analysis of detecting psychological health risk severity, an appropriate interpretation of predictive results is necessary from the medical experts and the patient's perspective. Thus, a predict interpret phase is augmented in our proposed model to facilitate the explainable intelligence functionality. This explainable intelligence capability is operated through a reasoning engine. The main aim of this reasoning engine is to allot a scoring value to all attributes on basis of their individual usefulness and relevance to a certain prediction. This module helps in providing a detailed insight in to the dataset. The scoring level of attributes can identify their relevance ranking which can be further used by medical experts to reason a particular mental health risk prediction. Our model implements a novel reasoning engine that consists of permuted feature importance, contrastive explanation, and counterfactuals methods for empowering the explainable intelligence functionality. The permutation feature importance explores the relationship between a specific attribute and the target label where a reduction in score indicates the dependency of that attribute on the developed model. The contrastive explanation method (CEM) aims to provide local interpretations to an abstract black box system that discusses

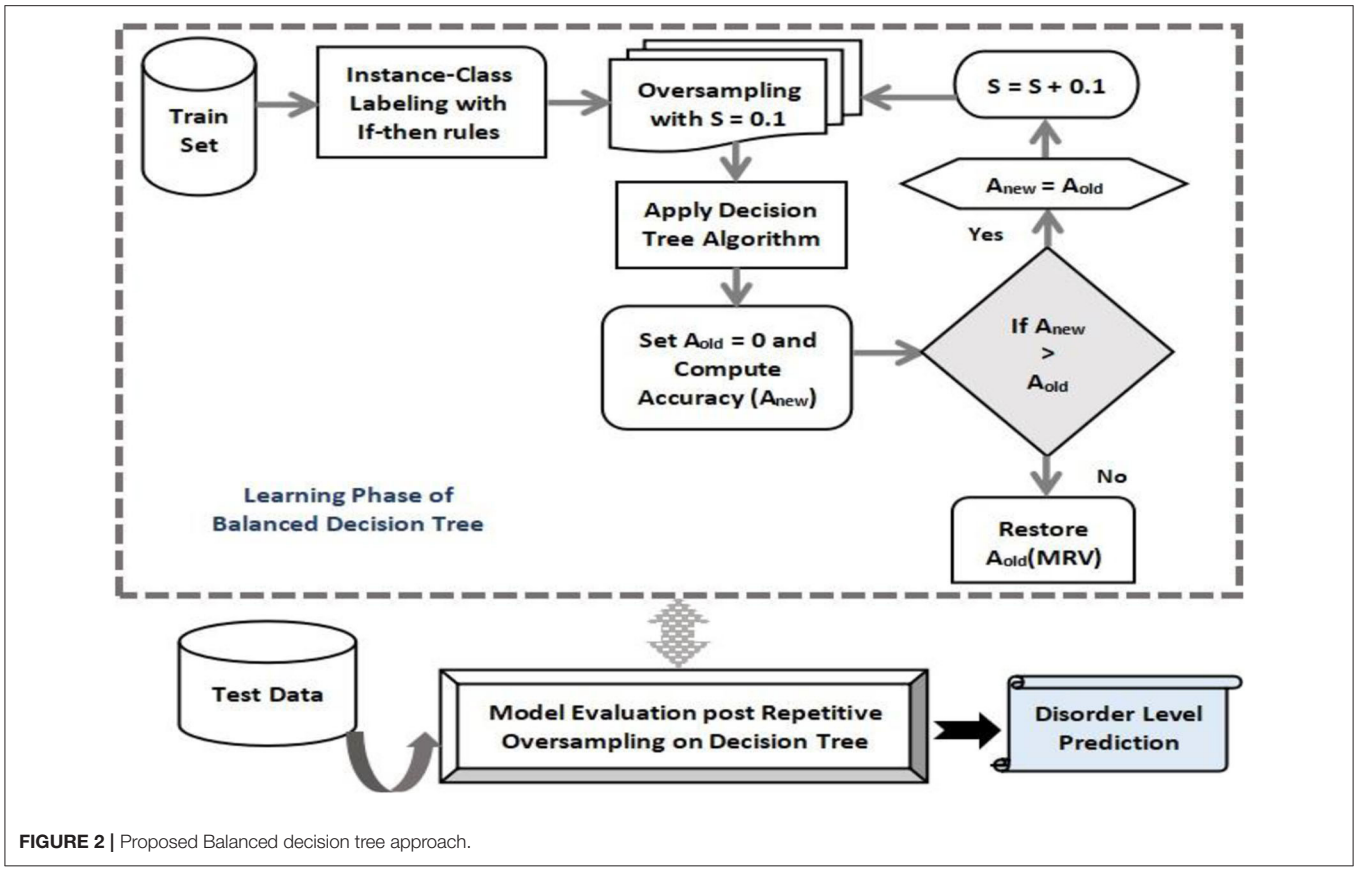

FIGURE 2 | Proposed Balanced decision tree approach.

explanation for classification by detecting less relevant features. A counterfactual interpretation of a prediction defines the variation in features that alters the prediction to a predetermined outcome.

4.5.1. Permuted Feature Importance Method

Permuted feature importance is an approach to calculate the relative significance scores of attributes and is independent of the model used. It acts as a non-local interpretation approach providing an in-depth idea of the nature of a predictive learner. Attributes are ranked on basis of the significance of every attribute on the trained learning algorithm predictive decision. Feature permutation importance computes the prediction ability of an attribute for a black box determinator by exploring the increase in prediction error if an attribute is absent. It begins with the calculation of base error on a trained predictive model. For each attribute, random shuffling of the corresponding column of trained data is performed, and the predicted error of the varied samples is computed. Then the feature importance is determined and stored as the difference between the base score and the varied sampled score. These steps are repeated multiple times to determine the average as it reduces the impact of random shuffling. Subsequently, on basis of the mean relevance of attributes on the score of the model, their ranking is done. Attributes with high score relevance on shuffling are labeled as more significant compared to attributes with less impact on the score of the model. Its pseudocode is shown in **Algorithm 4**.

Algorithm 4: Pseudocode for permuted feature importance method.

Input: Predicted model P, Dataset S
Output: Gain
Computer accuracy score c of the model P on dataset S. ;
for *each attribute column* $n \in S$ **do**
  for *each iteration* $m \in M$ **do**
    Randomly suffle n ;
    Generate referenced dataset $S_{m,n}$;
    Compute $c_{m,n}$ on dataset $S_{m,n}$;
  end
end
Computer importance $P - score$ for attribute A_n:
$P - score = c - \frac{1}{M} \sum_{m=1}^{M} c_{m,n}$;
Sort attributes in descending order of $P - score$;

Permutation feature selection can be used *via* the permutation_importance() function that takes a fit model, a dataset (train or test dataset is fine), and a scoring function P-score. The relative attribute importance can be illustrated in a bar chart where the x-axis shows the importance value and the y-axis denotes the attributes in significance order. A long bar is an indicator for an attribute with more relevance.

4.5.2. Contrastive Explanation Method

Contrastive explanation method is another explainable method that derives local interpretations of a black box architecture. Technically it may be defined as "An input m is categorized into class n since attributes ai,…aj are available and since attributes ax,…ay are unavailable." This approach suits more for tabular sample data which explains a classification model by giving details on relevant attributes or pertinent positives (PP) as well as irrelevant attributes or pertinent negatives (PN). It is a process that reasons out what may be minimally present and which variables may be essentially absent from the samples so that the original predicted class can be maintained. The two interpretation sides can be denoted as follows:

Pertinent Positives: An explanation to the PP figures out the attributes that are vital for model to predict the same output class as the predicted class. So from our research context, it consists of the crucial queries of the psychological risk data that impact most on the prediction outcome. The above result in **Figure 3** highlights the prediction of mental risk severity level is the same when PP is applied. The generated CEM values near 0 since those are the least values present to predict specific risk levels and these queries are to be essentially present to obtain the same original level as the severity level predicted S.

Pertinent Negatives: Explanation to PN computes the attributes which are to be adequately unavailable, form a sample, thereby retaining the original output level.

It can be seen from **Figure 4** that some of the CEM values in the array such as Q1, Q3, and Q5 are different from the original values, and these values alter the prediction class from "MD" to "S." Hence, we may conclude that variation in these attribute queries may essentially be absent in order to restore the original predicted class since they can flip the class label. Using CEM, we can improve the accuracy of the predictive model by analyzing the misclassified samples and subsequently processing those through CEM explanations.

4.5.3. Counterfactuals Method

Counterfactuals method provides a somehow "what-if" explanations based on prototypes where an instance represent the whole sample set of a class. Technically, it can be said that if M and N are independent and dependent variables, respectively, then counterfactual depicts the impact on N as a result of minor variation in M. Thus, it notifies the variation to be performed on M so as to alter the output from N to N. It is fast and gives quite accurate results by interpreting results with the use of prototypes of the target class. In context to our research analysis, a counterfactual sample denotes the vital modification in input query set of a testing sample which change the prediction to a predetermined outcome. A counterfactual sample Sxy should possess some basic characteristics which are outlined in this study.

1. The prediction over S_{xy} should be enclosed in a predetermined output label.
2. Variation β of the initial sample S_0 over $S_{xy} = S_0 + \beta$ needs to be sparse.
3. The counterfactual S_{xy} should be near to the general counterfactual class sample sharing.
4. The counterfactual S_{xy} should be computed fast to be applied in real time use cases.

These features can be approved by including a loss function in the form denoted by Equation 6 as:

$$Loss = xL_{Pred} + \beta L_1 + L_2 \tag{6}$$

Where xL_{pred} denotes the instance variation for predicting another class label than the original class. $\beta L_1 + L_2$ acts as the regularizer that defines sparsity by considering the net difference between counterfactual and alternate samples. In this study, as shown in **Figure 5**, samples of mentally disordered person with anxiety were collected and diagnosed. After diagnosis and an evaluation prototype was created to detect variations in various attributes to analyse risk possibilities. The observation highlights certain modifications to alter the outcome. The query Q1 (being upset) should be decreased by 0.76532 to avoid getting "S" risk level. Q12 (being nervous) should be under control by 0.182345 units. Similarly, as noted in Q29(–2.5674) and Q35(–0.5573), the patient should calm down more and be more tolerant to prevent being in "S" level of risk.

4.5.4. Validate Phase

Usually among all psychological health response data instances used as input, few among them may be misclassified to incorrect class in a predictive model. Thus, the performance of the proposed explainable intelligence enabled predictive model needs to be validated to figure out its effectiveness. Both training and testing of the model require validation using different metrics. Various performance parameters are involved in demonstrating its efficiency in detecting correct outcomes. Accuracy is a vital parameter that indicates the total mental health disorder instances that were correctly predicted among all the instances which were used as input to the predictive model. It is depicted in Equation 7 as:

$$Accuracy = \frac{TP + TN}{FP + FN} \tag{7}$$

Precision denotes the number of accurate mental health risk instances predicted which in reality maps to be positive. It is a fruitful indicator where false positives is a concern than false negatives. It is shown in Equation 8 as:

$$Precision = \frac{TP}{TP + FP} \tag{8}$$

The recall represents the actual positive risk instances that accurately predict the model, and it is a very helpful indicator where false negative exceeds false positives. It is represented in Equation 9 as:

$$Recall = \frac{TP}{TP + FN} \tag{9}$$

In reality, if the precision is increased then the recall value decreases and vice-versa. To capture both metrics simultaneously, another measure called F-score is used to present a combined concept of both. It denotes the harmonic average of

```
mode = ' PP'
lm = load_model(' stress.s5' )
cm = CEM(lr, mode, shape, kappa=kappa, beta=beta,
attr_range=attr_range, max_iterations=max_iterations,
c_init=c_init, c_steps=c_steps, learning_rate_init=lr_init,
clip=clip)
cm.fit(x_train, no_info_type=' median' )
interpret = cm.explain(X, verbose=False)
print(' Original sample: {}' .format(explanation.X))
print(' Prediction label: {}' .format([explanation.X_pred]))
print(' Pertinent positive: {}' .format(explanation.PP))
print(' Predicted label: {}' .format([explanation.PP_pred]))

.....................................................

Original sample: {{-1.0202; -1.342; -0.166; -0.785; -1.918}}
Prediction label: { 'S' }
Pertinent positive: {{-4.639e-09; -3.227e-03; -3.571e-05; -5.128e-4;
-4.952e-06}}
Predicted label: { 'S' }
```

FIGURE 3 | Pertinent positive sample example.

both recall and precision. The F-Score metric is denoted in the Equation 10 as:

$$F - Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{10}$$

Mean square error (MSE) is another relevant metric that accepts the mean value of the square of the difference of the original and the predictive values which are represented by Equation 11 as:

$$MSE = \frac{1}{M}\sum_{i=1}^{M}(Z_i - \bar{Z}_i)^2 \tag{11}$$

Where M represents the data points count, Z_i is the observed value, and $\bar{Z}_i$ is the predicted value.

Thus, as it is observed, all the phases of the proposed explainable intelligence model are interrelated such that the output of one phase acts as the input for the other. The overall working model is summarized in **Figure 6**. The psychological health risk data DASS 42 is retrieved online. The dataset is in the form of 42 questionnaires along with its responses. The original data samples are mapped onto an excel sheet for analysis. It undergoes appropriate pre-processing tasks like handling missing values and any inconsistencies in the dataset. The data is then encoded in the range of [1–4] based on the response of patients and scaled up to [0–3] for uniformity and ease of analysis. The dataset is grouped by predefined queries to partition into three subsets on the basis of psychological health disorders. Anxiety, stress, and depression are the identified subsets. The WS of all rows is determined, and accordingly, the risk severity level is labeled. The least priority queries are identified using the attribute mean rate point method and are eliminated from the dataset in Q-Prioritization phase. Then the resultant data is trained with a novel, newly proposed balanced decision tree technique which involves repeated oversampling. Once the model is trained, it can predict the appropriate disorder severity level for anxiety, stress, and depression risks with new unseen psychological data of new patients. The prediction outcome is further analyzed and interpreted using the reasoning engine which is comprised of three constituents. The first component called permuted feature importance method ranks all queries in priority order

```
n = 1
M = m_test[n].reshape((1,) + n_test[n].shape)
mode = ' PN'
shape = (1,) + n_train.shape[1:]
attr_range = (n_train.min(axis=0).reshape(shape)-.1,
n_train.max(axis=0).reshape(shape)+.1)
lm = load_model(' stress.s5' )
cm = CEM(lr, mode, shape, kappa=kappa, beta=beta,
attr_range=attr_range, max_iterations=max_iterations,
c_init=c_init, c_steps=c_steps, learning_rate_init=lr_init,
clip=clip)
cm.fit(x_train, no_info_type=' median' )
interpret = cm.explain(X, stress=False)
print(' Attribute names: {}' .format(attr_names))
print(' Original sample: {}' .format(explanation.M))
print(' Prediction label: {}' .format([explanation.M_pred]))

print(' Predicted label: {}' .format([explanation.PN_pred]))

.....................................................

Attribute names: {Q1, Q12, Q22, Q29, Q35}
Original sample: {{-1.0202; -1.342; -0.166; -0.785; -1.918}}
Prediction label: { 'MD' }
Pertinent negative: {{-1.365; -1.342; -0.131; -0.785; -1.425}}
Predicted label: { 'S' }
```

FIGURE 4 | Pertinent negative sample example.

to identify the most relevant queries which contributed to prediction. The contrastive explanation approach further helps in recognizing the queries which should be present and similar queries that should be absent for the prediction of the severity risk level. Based on this, an interpreted tabular feedback is generated for reference of medical experts. The counterfactuals method is the third reasoning method that defines the required variations required in input queries in order to flip the generated severity class label. Thus, this reasoning engine forms the most vital part of the model a sit empowers the predictive model with an explainable intelligence capability.

```
Y = y_test[target].reshape((1,) + x_test[target].shape)
count = CounterFactualProto(nn, shape, use_ID3=True,

5. IMPLEMENTATION RESULTS AND ANALYSIS

The proposed explainable intelligence based mental health risk detection model is tested with the newly built balanced decision tree technique to predict the severity level of anxiety, stress, and depression health risks in patients. Before real time deployment, it is validated with different performance parameters to explore its efficiency in detecting psychological disorders.

5.1. Training Data Evaluation Performance

The psychological health disorder dataset used for performance evaluation is the standard DASS 42 questionnaires. As many as 13,000 responses of patients forms the dataset. With the help of the performance parameters indicated in the previous section, the

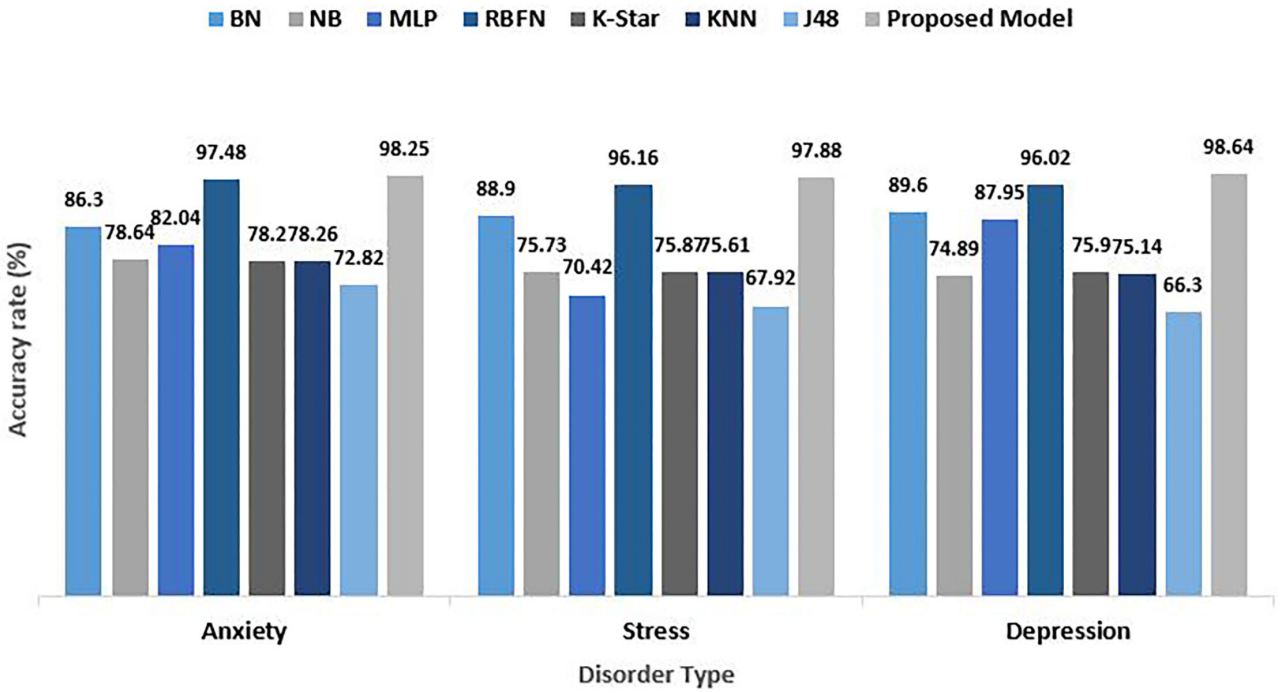

FIGURE 7 | Comparative analysis of accuracy rate for psychological risks.

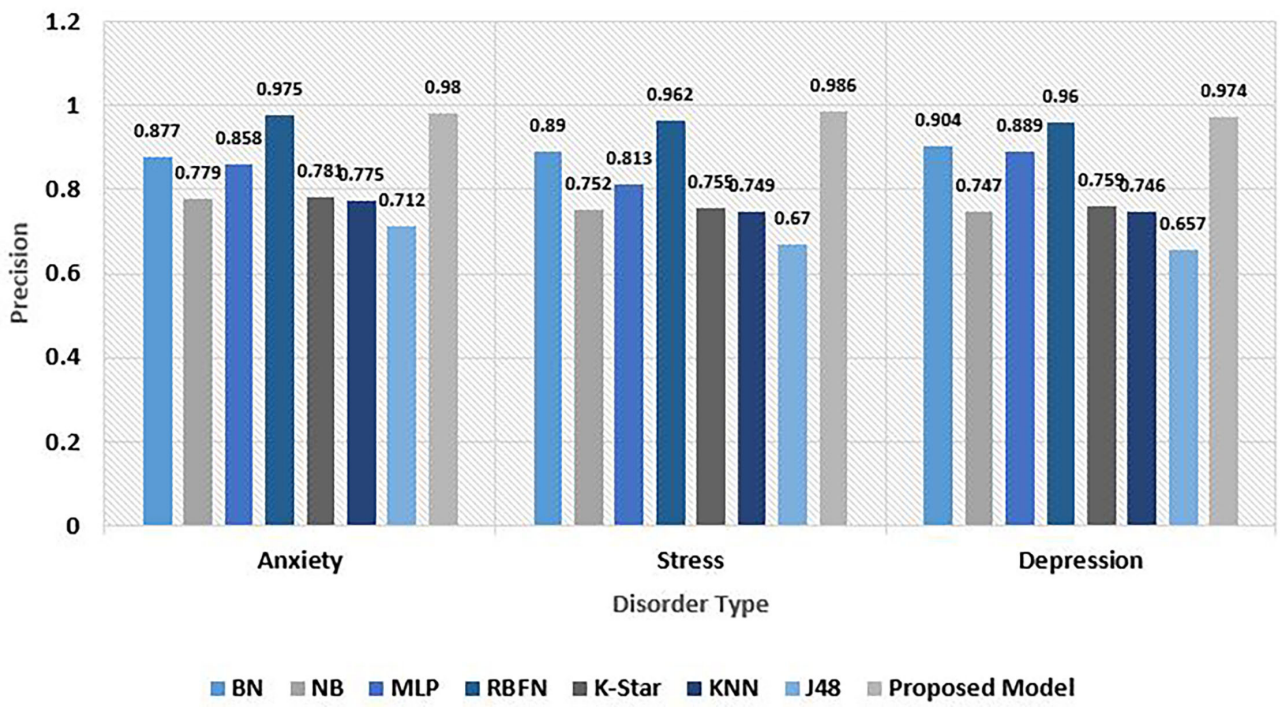

FIGURE 8 | Comparative analysis of precision for psychological risks.

performance is determined. The dataset is experimentally trained using many predictive models such as Naive Bayes, RBFN, KNN, J48, and neural network apart from the proposed model. Accuracy is the most important evaluation parameter which denotes the proportion of accurate predictions to the cumulative observations. Accuracy is a very relevant metric in an evenly

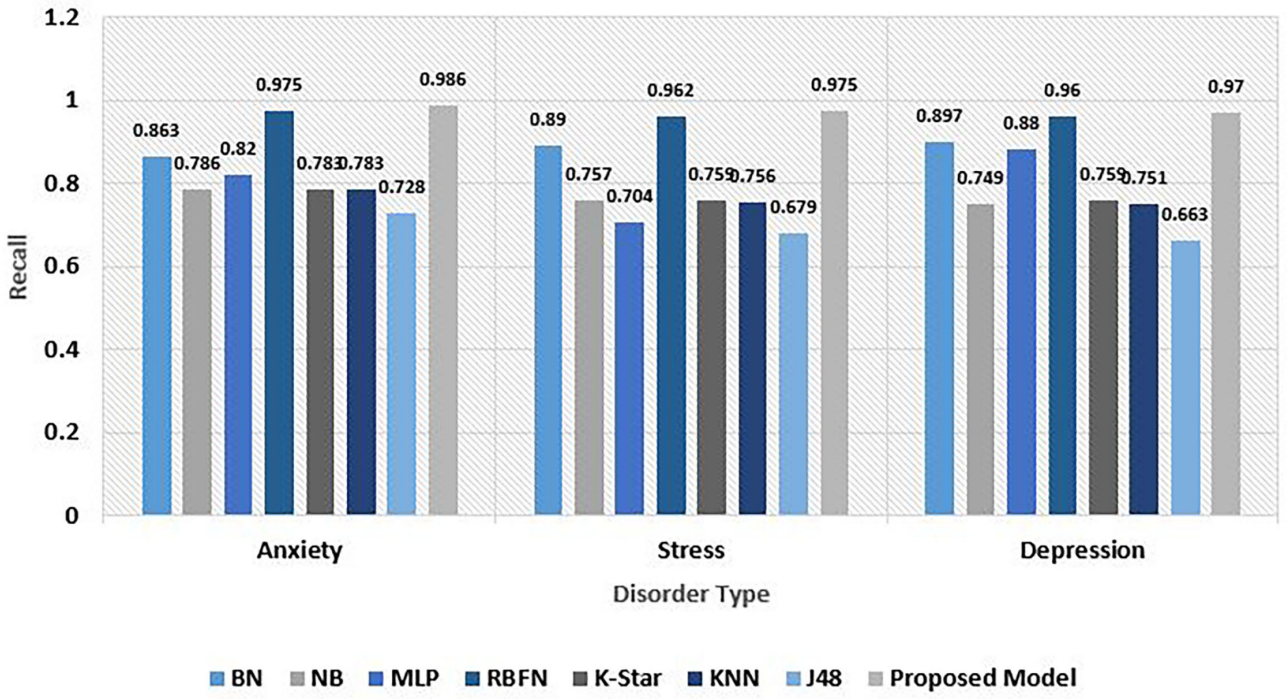

FIGURE 9 | Comparative analysis of Recall for psychological risks.

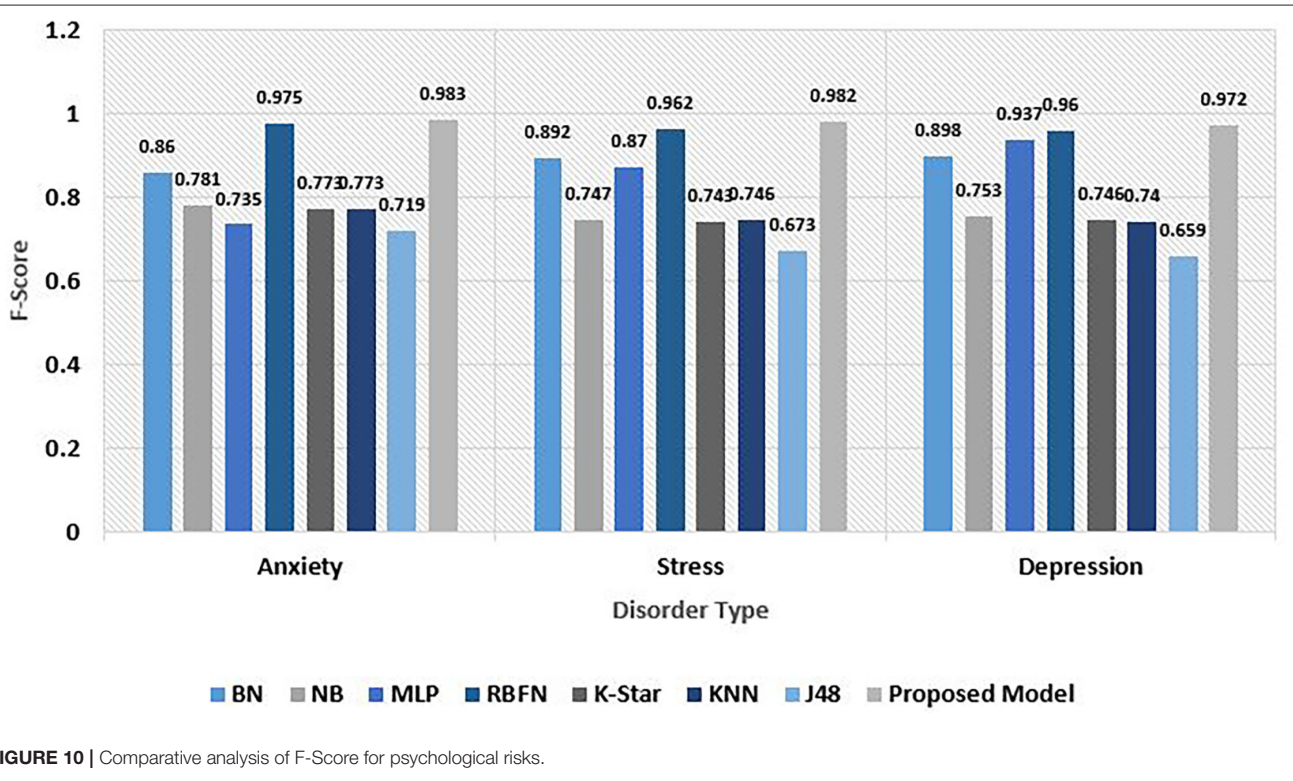

FIGURE 10 | Comparative analysis of F-Score for psychological risks.

balanced data samples. It is observed that among all existing techniques, the RBFN model provided an impressive accuracy on all three datasets while the accuracy of J48 was relatively discouraging. But our proposed explainable intelligence model outperformed others recording an accuracy rate of 98.25%, 97.88%, and 98.64% on anxiety, stress, and depression set,

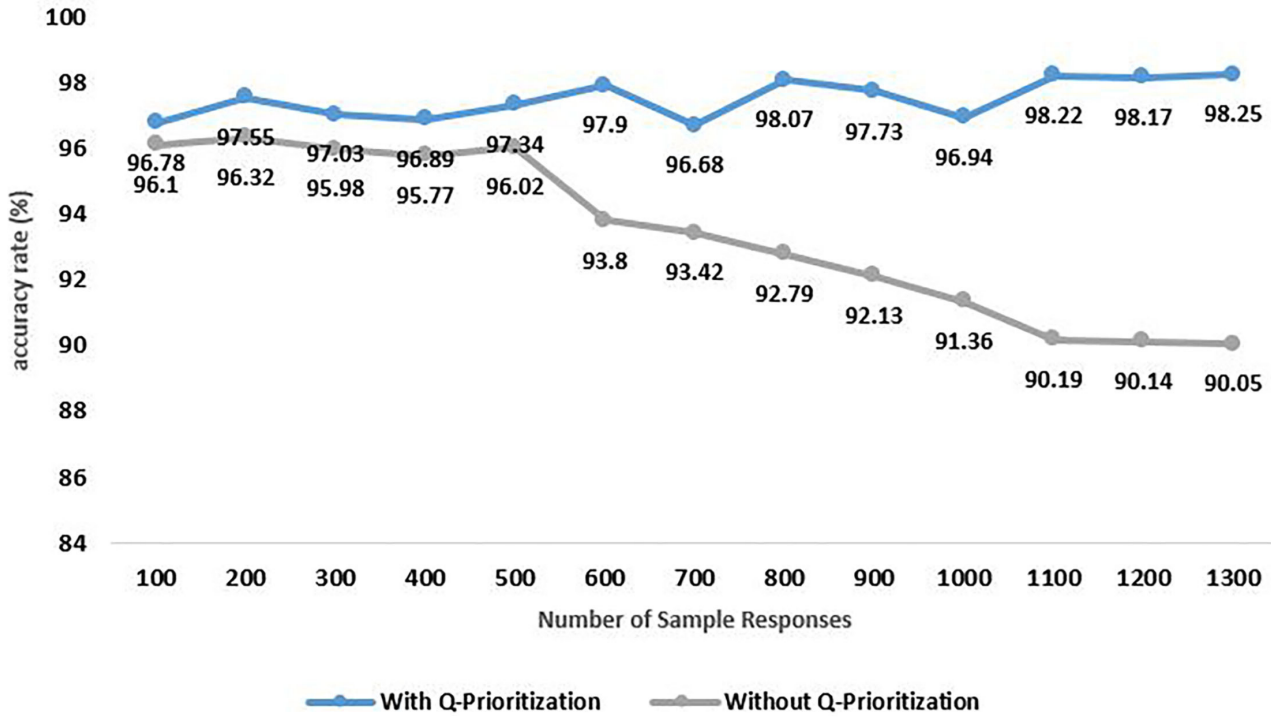

FIGURE 11 | Accuracy rate analysis of psychological risks in context to Q-Prioritization phase.

TABLE 3 | Performance metrics comparison using different datasets.

	DASS 42	DASS 21	
Accuracy	0.982	98.16	Anxiety
Precision	0.98	0.976	
Recall	0.986	0.982	
F-Score	0.983	0.978	
Accuracy	97.88%	97.69%	Stress
Precision	0.986	0.98	
Recall	0.975	0.968	
F-Score	0.982	0.975	
Accuracy	98.64%	98.42%	Depression
Precision	0.974	0.958	
Recall	0.97	0.962	
F-Score	0.972	0.96	

TABLE 4 | Queries associated with anxiety risk.

Query	Description
Q2	I was aware of dryness of my mouth.
Q4	I experienced breathing difficulty such as rapid breathing and breathlessness.
Q7	I had a feeling of shakiness such as legs going to give away.
Q9	I found myself in situations that made me so anxious I was most relieved when they ended.
Q15	I had a feeling of faintness.
Q19	I perspired noticeably in the absence of high temperatures of physical exertion.
Q20	I felt scared without any good reason.
Q23	I had difficulty in swallowing.
Q25	I was aware of the action of my heart in the absence of physical exertion.
Q28	I felt I was close to panic.
Q30	I feared that I would be thrown by some trivial but unfamiliar task.
Q36	I felt terrified.
Q40	I was worried about situation in which I might panic and make a fool of myself.
Q41	I experienced trembling in the hands.

respectively, as shown in **Figure 7**. The aggregated accuracy computed was 98.25%.

Precision represents the proportion of accurate positive prediction observations to the cumulative positive prediction based observations. Precision evaluates the accurately categorized samples against those samples classified to be positive. The model performed exceptionally well in terms of

TABLE 5 | Queries associated with stress risk.

Query	Description
Q1	I found myself getting upset by quite trivial things.
Q6	I tended to over-react to situations.
Q8	I found it difficult to relax.
Q11	I found myself getting upset rather easily.
Q12	I felt that I was using a lot of nervous energy.
Q14	I found myself getting impatient when I was delayed in any way.
Q18	I felt that I was rather touchy.
Q22	I had it hard to wind down.
Q27	I found that I was very irritable.
Q29	I found it hard to calm down after something upset me.
Q32	I found it difficult to tolerate interruptions to what I was doing.
Q33	I was in a state of nervous tension.
Q35	I was intolerant of anything that kept me from getting on with what I was doing.
Q39	I found myself getting agitated.

TABLE 6 | Queries associated with depression risk.

Query	Description
Q3	I could not seem to experience any positive feeling at all.
Q5	I just could not seem to get going.
Q10	I found that I had nothing to look forward to.
Q13	I feel sad and depressed.
Q16	I felt that I had lost interest in just about everything.
Q17	I felt I was not worth much as a person.
Q21	I felt that I was not worthwhile.
Q24	I could not seem to get any enjoyment out of the things I did.
Q26	I felt down-hearted and blue.
Q31	I was unable to become enthusiastic about anything.
Q34	I felt I was pretty worthless.
Q37	I could see nothing in the future to be hopeful about.
Q38	I felt that life was meaningless.
Q42	I found it difficult to work up the initiative to do things.

precision metrics on all three risks. A value of 0.98 was observed with anxiety data, 0.986 on stress data, and 0.974 on depression data. Thus, a simple mean value of 0.98 precision was noted leaving behind the RBFN model which has a 0.968 precision value. J48 performed relatively poor in comparison with others. **Figure 8** depicts the precision score analysis of the proposed explainable model with others.

Recall metric helps in the quantification of accurate positive predictions among all positive predictions performed. While precision gives an idea of accurate positive predictions, recall gives a measure of missed out positive predictions. For imbalanced learning, recall is typically used to measure the coverage of the minority class. The explainable driven predictive model outperforms all other existing models in terms of recall value on all disorder data. While an excellent value of 0.986 is the result with anxiety data, on stress and depression set, the recall metric evaluates to be 0.975 and 0.97, respectively. The aggregated recall observed was 0.977. The recall analysis is depicted in **Figure 9**.

F-score is a means to integrate both recall and precision metrics, thereby capturing both features. Once both of the metrics are computed for our multi-level classification, an F-score can be utilized to combine both generating a harmonic average value. F-score considers both false negatives and false positives. The F-score value recorded on the anxiety, stress, and depression risk set was 0.983, 0.982, and 0.972. The average mean F-score value generated was 0.979. Among other models, the RBFN algorithm recorded a very good value while J48 gave a comparatively inferior outcome. The overall F-score analysis was observed in **Figure 10**.

The impact of the Q-Prioritization phase on the performance was also explored and the outcomes are illustrated in **Figure 11**. The observation was quite clear. Right from the initial data size of 100 instances, the accuracy of the explainable model using Q-Prioritization phase, 96.78% was more than that of the model deployed without it, 96.1%. As we can see that the accuracy shows a significant drop once the dataset size exceeds 500 instances. The difference in accuracy increases with the rise in the size of data and toward the end of simulation with 1,300 samples. The final accuracy without the Q-Prioritization phase is found to be 90.05%.

The experimental evaluation was also undertaken with DASS 21 data set that constitutes 21 queries being mapped onto anxiety, stress, and depression risk. The same performance indicators were used for the evaluation. We obtained 98.09, 0.971, 0.97, and 0.972% as the mean accuracy, precision, recall, and F-score value obtained with DASS 21 sample set. This shows the consistent performance of our proposed model with heterogeneous data sets. The outcome summary is outlined in **Table 3**. There is variation in values because two different data sets (DASS 42 and DASS 21) are used for the evaluation of the proposed research on mental risk disorders. Both these data sets comprise dissimilar questions. Also, distinct questions are associated with both data sets so based on the feature importance of individual questions, the values for accuracy and other parameters are different.

5.2. Real Time Prediction Outcome

The experimental evaluation was undertaken in a real time environment. Our proposed model was validated with volunteers. DASS-42 is the standard dataset used for the purpose. The dataset constitutes a series of 42 distinct queries being asked to patients affected with psychological disorder risks. The queries were equally clustered into anxiety, stress, and depression which forms the three predefined sets as discussed earlier. So every risk set comprises 14 non-overlapping queries. **Tables 4–6** displays the 14 queries each chosen for anxiety, stress, and depression disorder set.

Figure 12 depicts the google form prepared for our research hypothesis. This form comprises a total of 42 distinct questionnaires which are mandatory to be filled up by users. This acts as a self-testing interface for the users in an attempt to test themselves of the presence of any psychological health risks and is called psychology parser. The user needs to enter his name and ID before appearing in the test.

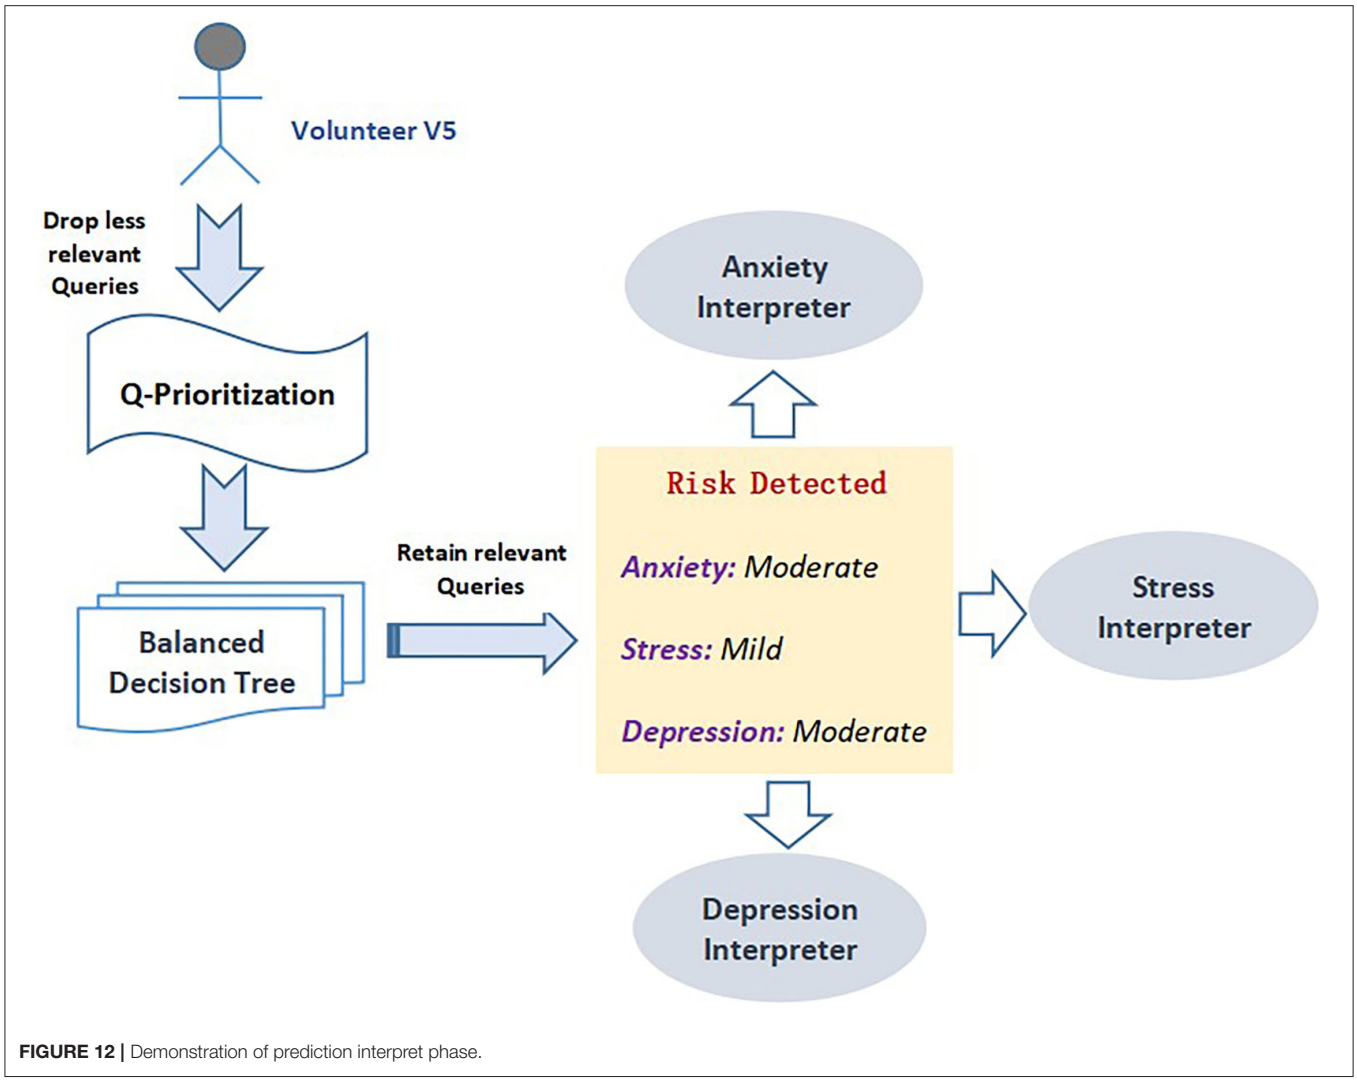

FIGURE 12 | Demonstration of prediction interpret phase.

The outcome demonstration for one specific day is discussed in this section where the test data of 10 volunteers are accumulated and their responses are mapped onto an excel sheet in a .csv file. It is followed by the important Q-Prioritization phase which is responsible for identifying less relevant queries from all sets and eliminating them using the mean Rate Point method. **Table 7** demonstrates this process. It starts with the original query set segregated into 14 queries in each disorder set including anxiety, stress, and depression. The individual queries are assigned their scaled-up value (0–3) based on the response of patients. The priority relevance value (Prel) for all queries (attributes) corresponding to individual disorder sets are determined using the mean rate point method.

This is followed by the ranking of the queries based on the P^{rel} value obtained. Accordingly, the least priority query that fails to satisfy the R_{th} is eliminated from the resultant data set. As it is observed in **Table 10**, query "Q9" was found to be less relevant in the anxiety set. Similarly, queries "Q18" and "Q5" in stress and depression set, respectively, were detected to be at less priority compared to others. Thus, these least priority queries were dropped from the data set after the Q-Prioritized phase. The least priority queries are marked in bold in **Table 8**.

The psychological parser is definitely technically feasible. It is a kind of google form software created at the back-end of model development in which all questions related to the research task is included and randomly shuffled. Patients are required to fill up the parser and then the risks of anxiety, stress, and depression are auto-computed. So it is completely software enabled with no complex hardware involved.

Once the data set undergoes the Q-Prioritized phase, it is pre-processed and is ready for prediction. Test data sample of any particular volunteer is subjected to the proposed Balanced Decision Tree algorithm model for detection of psychological disorder risks.

Figure 13 highlights the test data of volunteer "V5" as the input to the Q-Prioritization phase to find the priority based relevant query set. This query set is applied to the proposed balanced decision tree model. The prediction outcome I presented was in the form of an interface. If any risk is detected

then it will display the information based on the severity level. As it is observed that "V5" is detected with psychological risks in all three sets. An "MD" level of risk is recognized for both anxiety and depression disorder while an "M" risk level is detected with stress set. The predicted risk disorders are supported and regulated by a well-built interpreted engine. The interpreter engine explains the predicted outcome corresponding to all three disorders. Permuted feature importance method, CEM method, and Counterfactual method are the three different explanatory approaches implemented in this module for a comprehensive interpretation of predicted result class for each mental disorder set. Prediction interpretations for each set are presented in context to the detected outcome of volunteer "V5."

5.3. Anxiety Interpreter

Anxiety interpreter acts as an reasoning interface that facilitates an effective explanation of the prediction outcome on the anxiety dataset which is depicted through the three significant methods discussed above. **Figure 14** shows the anxiety interpreter.

TABLE 8 | Irrelevant queries detection and elimination in Q-Prioritization phase.

Anxiety														
Q2	Q4	Q7	Q9	Q15	Q19	Q20	Q23	Q25	Q28	Q30	Q36	Q40	Q41	Pre-Q-Prioritized
Q9	Q40	Q41	Q23	Q15	Q19	Q28	Q7	Q36	Q25	Q20	Q4	Q30	Q2	Post-Q-Prioritized
Stress														
Q1	Q6	Q8	Q11	Q12	Q14	Q18	Q22	Q27	Q29	Q32	Q33	Q35	Q39	Pre-Q-Prioritized

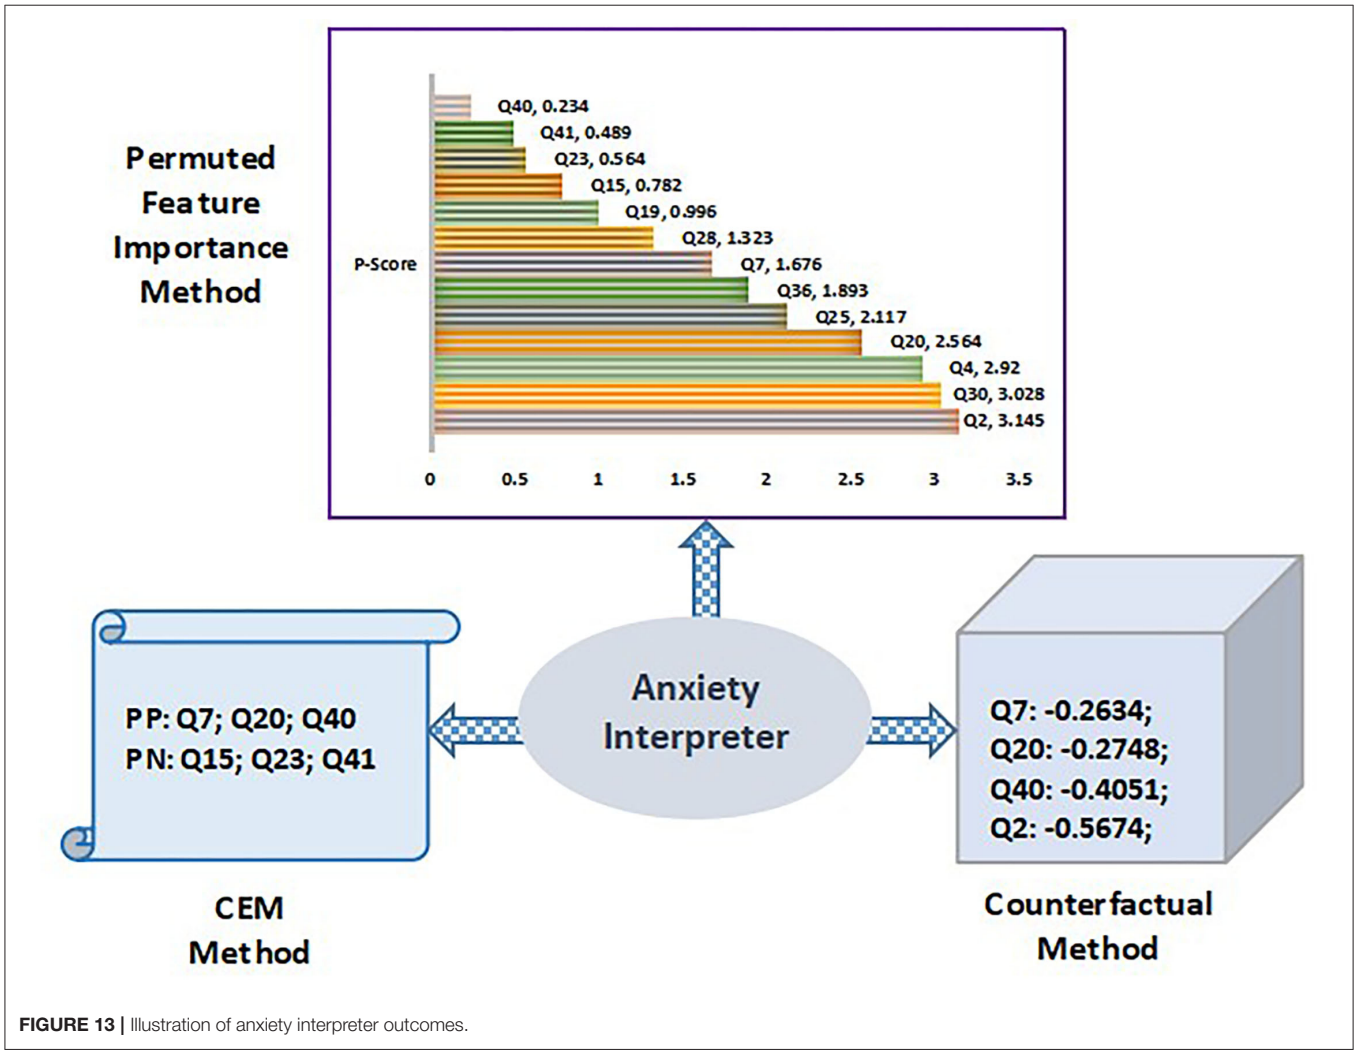

FIGURE 13 | Illustration of anxiety interpreter outcomes.

In context to permuted feature importance method, the P-score value determines the importance of attributes. Q-score value changes with every iteration based on the individual position of attributes. Therefore, *P*-score also updates with every iteration. The value of *P*-score depends on the number of iterations and the accuracy value of all attributes in every round of execution. **Figure 8** shows the ordered ranking of different queries based on their individual the P-score value for the volunteer "V5." It is observed that "Q2" exhibit the highest importance score of 3.145 while "Q40" is the least important attribute with a score of 0.234. It shows the top ranked query attributes that impact the prediction decision making. CEM method is another approach to provide a suitable explanation for the prediction. It denotes the minimal queries to be present for the prediction of a specific class (PP) while simultaneously it also notifies the queries that should be absent during the prediction

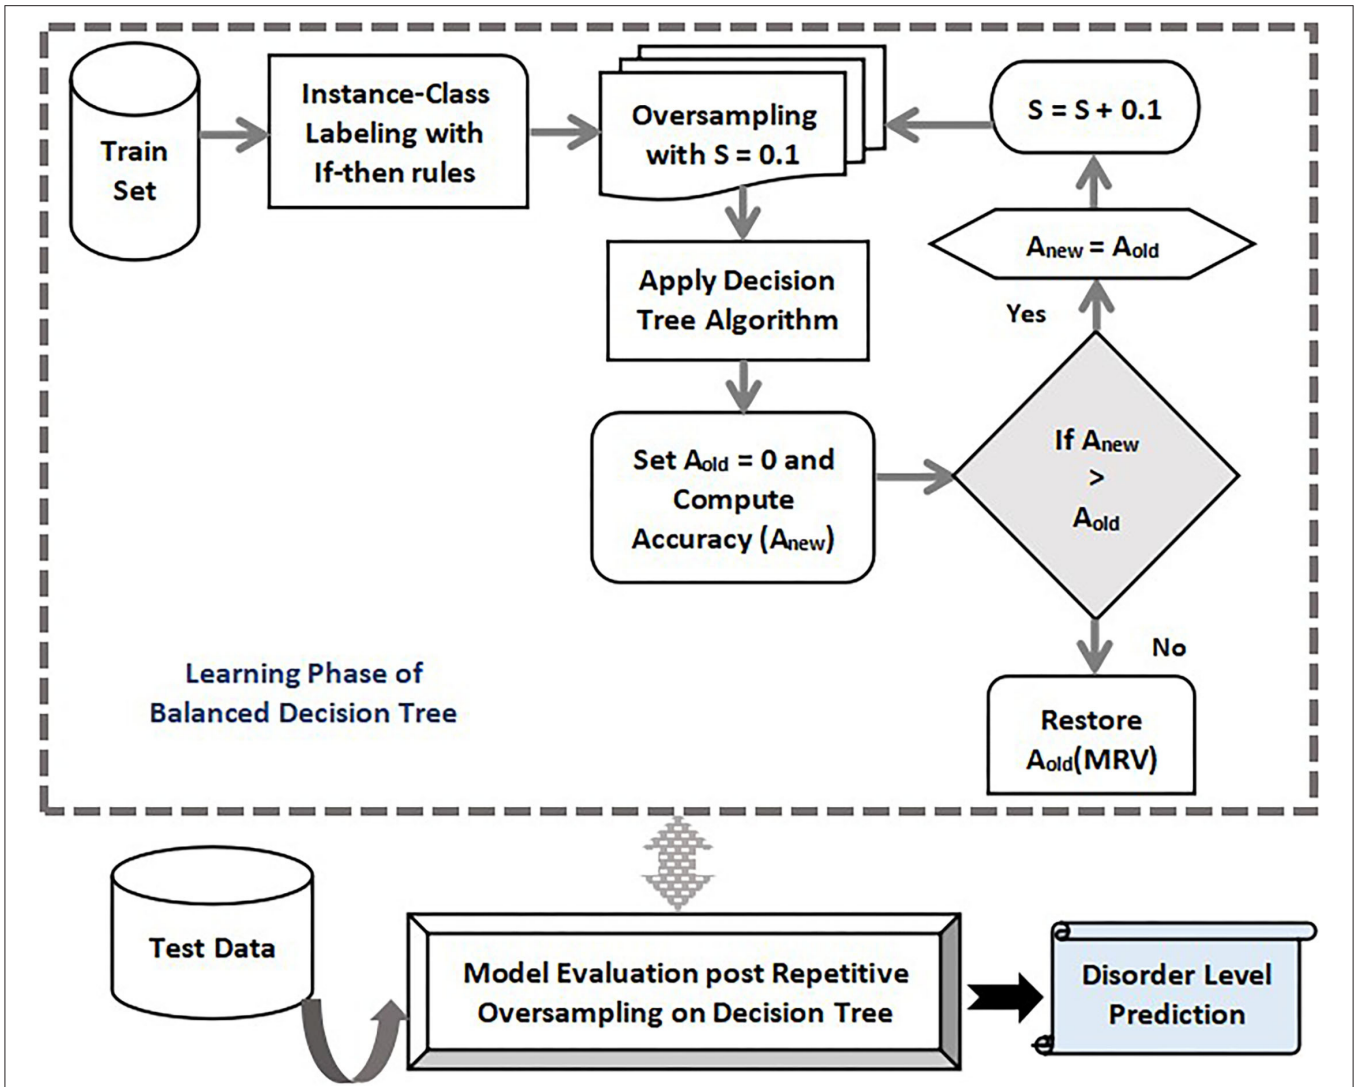

FIGURE 14 | Training and testing phase with proposed balanced decision tree approach.

(PN).The inference of the CEM method is presented in tabular form in **Table 11**. It clearly indicates the scenario where queries Q7, Q20, and Q40 are the PP while Q15, Q23, and Q41 are regarded as PN. Based on the inference, relevant feedback is generated to the user for guidance as shown in **Table 9**.

The counterfactual method is the third interpreter approach used for effective explanation for prediction. As it can be seen that the original prediction for anxiety was "MD." So to downgrade the prediction to "M," the queries Q7, Q20, Q40, and Q2 represent the counterfactuals generated that are listed below. The negative values of the queries denote that the corresponding metric should be reduced. Thus, to reduce the anxiety risk to a mild level, "V5" should control the feeling of panic and constant shakiness. Furthermore, symptoms such as dryness in the mouth and calmness will assist in dealing with anxiety related issues.

Original predicted label: "MD"; Counterfactual prediction: "M"; Q7: –0.2634; Q20: –0.2748; Q40: –0.4051; Q2: –0.5674.

5.4. Stress Interpreter

Stress interpreter forms the second platform to provide an appropriate interpretation of the prediction outcome on the stress dataset. The explanation is shown through the same methods as highlighted above. Stress interpreter and its decision outcomes are highlighted in **Figure 15**.

According to the CEM method, the essential attribute queries (PP) recorded were Q1, Q22, Q29, and Q33 while the non-essential queries needed to be absent (PN) were Q6, Q12, Q14, and Q27. The stress feedback is shown in **Table 10** where the relevant feedback is provided to the user based on the generated "PP" and "PN" values.

The query importance is further validated with the counterfactual method to determine the attributes of the stress set that need to be regulated. The counterfactual results showed that "M" was the actual predicted class level, but it can be further regulated to "N" if certain attributes are properly taken care of. The attributes of impact detected were Q1, Q29,

TABLE 9 | Feedback to anxiety interpreter with CEM method.

Volunteer ID	Queries	PP	PN	Feedback (anxiety)
V5	Q2; Q15; Q23; Q30; Q41	Q7; Q20; Q28; Q40	Q15; Q23; Q41	V5 is detected "Moderate" anxiety risk due to shakiness feeling, scared and panic. However, if he would have experienced faintness, difficulty in swallowing and trembling in hands then the risk would be upgraded to "Severe."

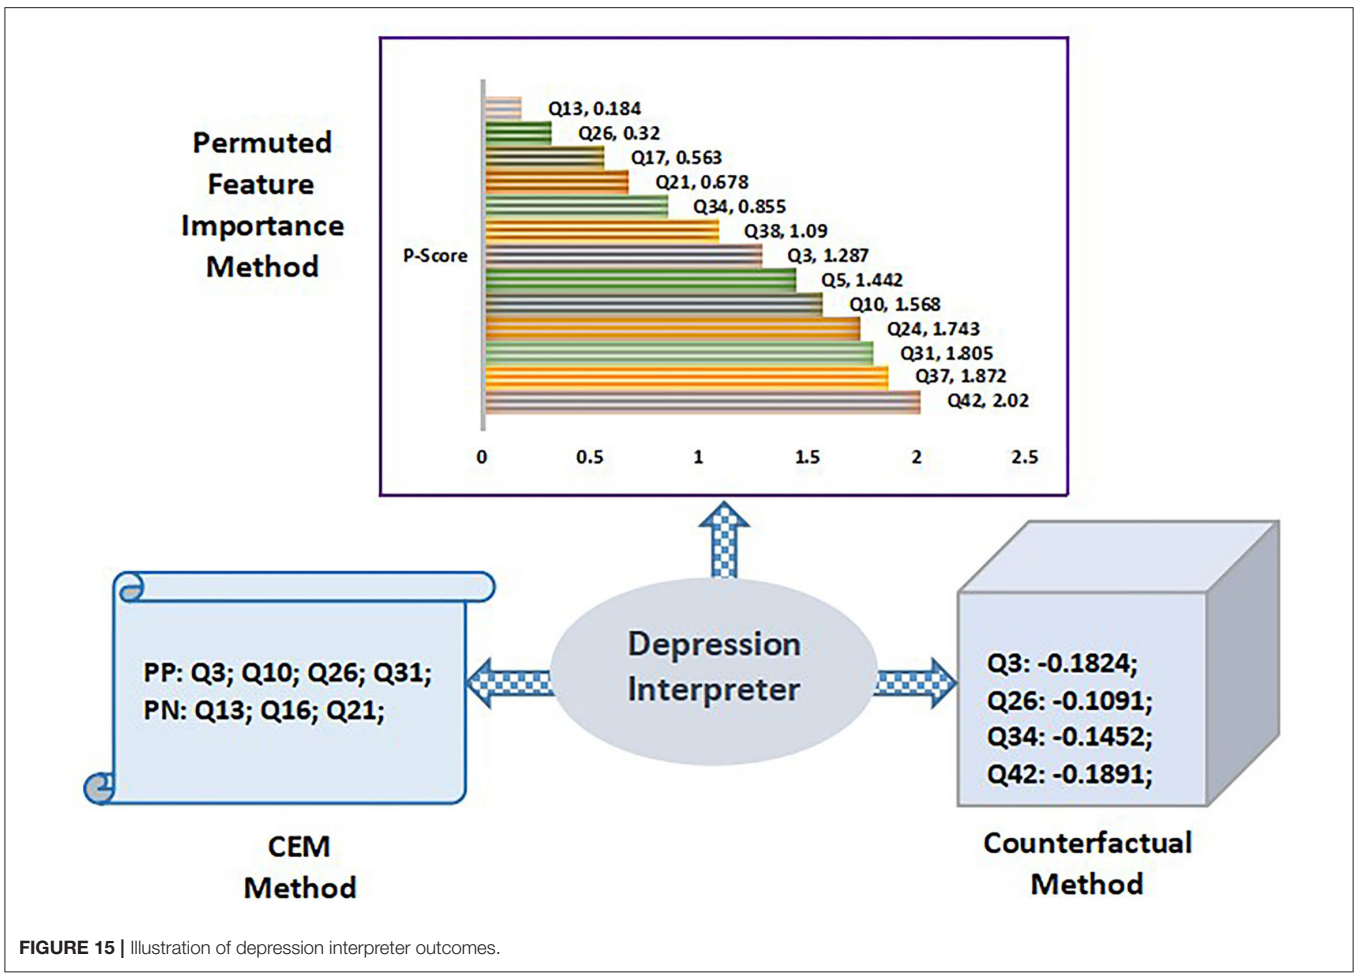

FIGURE 15 | Illustration of depression interpreter outcomes.

TABLE 10 | Feedback to stress interpreter with CEM method.

Volunteer ID	Queries	PP	PN	Feedback (stress)
V5	Q1; Q6; Q11; Q12; Q22 Q27; Q32; Q33; Q39	Q8; Q1; Q14; Q22; Q29; Q35; Q33	Q6, Q12; Q14; Q27	V5 is detected with "Mild" stress risk due to being easily upset, unable to rest and maintain calm with excess tension. Moreover, if he tends to over-react more, get nervous and impatient with frequent irritation then he would develop "Moderate" risk.

TABLE 11 | Feedback to depression interpreter with CEM method.

Volunteer ID	Queries	PP	PN	Feedback (stress)
V5	Q3; Q10; Q16; Q17; Q24 Q26; Q34; Q37; Q42	Q13; Q3; Q21; Q12; Q31; Q26; Q38; Q31	Q13; Q16; Q31	V5 is detected with "Moderate" depression risk due to high negative feeling, lack of objective in life, down-hearted and worthless mindset. However, if he continues to remain sad continuously with no zeal and worth in life feeling then the risk may be uplifted to "Severe."

Q32, and Q33 as listed in **Figure 2**. So as per the counterfactual outcome, volunteer "V5" should avoid being frequently upset for silly reasons and should maintain calm. Furthermore, the usage of sensors and smart gadgets will enable remote monitoring of patients. Original predicted label: "M" Counterfactual prediction: "N" Q1: –0.2284; Q29: –0.1941; Q32: –0.3382; Q33: –0.1674.

5.5. Depression Interpreter

The user interface used in our work to provide an effective explanation for depression prediction is referred to as depression interpreter.

It also utilizes the same three approaches to provide a suitable explanation for prediction. Through permuted feature importance method, the priority ranking of all queries is obtained by their P-score value. The highest P-score of 2.02 is noted for query "Q42" while the least score of 0.184 is recorded for "Q13." So it can be said that "Q42" is the most relevant query that had an impact on the prediction of depression in volunteer "V5." The critical queries required for accurate prediction and queries that should be absent are computed using the CEM approach. It is noted that Q3, Q10, Q26, and Q31 are absolutely required for prediction of the same class level "MD" while queries "Q13," "Q16," and "Q21" should not impact the prediction process. On basis of the CEM method outcome, the feedback table is auto-generated as shown in **Table 11**.

The query importance in depression risk prediction is evaluated with the counterfactual method to determine the queries that require attention. The counterfactual results showed that "MD" was the original predicted depression level which may be upgraded to "M" if four attributes are effectively controlled. These detected attributes were Q3, Q26, Q34, and Q42 as listed in **Table 5**. Hence, a volunteer "V5" should be more positive rather than being down-hearted. A volunteer should be kept busy to avoid anxiety related issues.

Q3: –0.1824; Q26: –0.1091; Q34: –0.1452; Q42: –0.1891;

The performance of the proposed model can be further enhanced in terms of speed and accuracy by taking image based datasets and using deep neural networks. Also, the entire system can be made smart by integrating sensors and actuators so that remote monitoring of patients can be possible. In the future, the model can be further upgraded to include more detailed questionnaires that capture the emotions of patients more accurately. Also, more mental risks types can be embedded in the research work to make the model more generic and broad.

6. CONCLUSION

Psychological health plays a crucial role in the well-being of a person. Any disturbance related to mental disorders may pose serious concerns in the future. Anxiety, stress, and depression contribute to the majority of psychological risks. Thus, it is important to recognize these health concerns and address them at the earliest. Many predictive learning based models are already being developed to predict these mental disorders. But most of these models simply predict the occurrence of such risks without providing any concrete explanation and reasoning. So reliability on these black-box models is questionable. So a more transparent and robust approach should be deployed such that the predictions of a model can be accurately visualized and interpreted. Thus, in our research, an explainable intelligence enabled predictive model is developed to not only accurately detect multiple severity levels of psychological health risks in an individual but also generate a transparent explanation of the contributing factors of a certain prediction. The model used a standard online questionnaire dataset to accumulate responses from online users. The data samples were filtered using a new method called Q-Prioritization through which the least priority queries in the dataset were dropped out. The query optimized dataset was trained with a new repetitive oversampled variant of the decision tree called the balanced decision tree method. After the successful learning phase, it was able to predict psychological issues such as anxiety, stress, and depression on a new test sample. Furthermore, a reasoning engine is used to visualize and interpret the prediction made by the model so as to determine the main contributing symptoms and less essential factors for a certain prediction of mental risks severity level. Permuted feature importance, contrastive explanation, and counterfactuals methods are utilized as constituents of the reasoning engine to empower the model with explainable intelligence. The deployed model gave very impressive results. The mean accuracy of prediction was 98.25% while the mean precision, recall, and F-score metric noted were 0.98, 0.977, and 0.979, respectively. It was observed that without applying Q-Prioritization, the mean accuracy significantly got reduced to 90.25%. The MSE generated with our model was a least of 0.026. Through the reasoning engine, the prediction outcome was more clear and transparent. Risk factors primarily responsible for a certain severity disorder level detection were quite evident and relatable. Based on the outcome, medical experts can suggest suitable recommendations to patients. Thus, the proposed multi-level psychological disorder predictive model driven by explainable intelligence can benefit medical professionals in the accurate diagnosis of patients concerned with psychological health risks. In the future, the model can be further upgraded to include more detailed questionnaires that capture the emotions of patients more accurately. Also, more mental risk types can be embedded in the research work to make the model more generic and broad.

Front. Public Health 9:818439. doi: 10.3389/fpubh.2021.818439

Background: This study aimed to develop and validate a nomogram for predicting mortality in patients with thoracic fractures without neurological compromise and hospitalized in the intensive care unit.

Methods: A total of 298 patients from the Medical Information Mart for Intensive Care III (MIMIC-III) database were included in the study, and 35 clinical indicators were collected within 24 h of patient admission. Risk factors were identified using the least absolute shrinkage and selection operator (LASSO) regression. A multivariate logistic regression model was established, and a nomogram was constructed. Internal validation was performed by the 1,000 bootstrap samples; a receiver operating curve (ROC) was plotted, and the area under the curve (AUC), sensitivity, and specificity were calculated. In addition, the calibration of our model was evaluated by the calibration curve and Hosmer-Lemeshow goodness-of-fit test (HL test). A decision curve analysis (DCA) was performed, and the nomogram was compared with scoring systems commonly used during clinical practice to assess the net clinical benefit.

Results: Indicators included in the nomogram were age, OASIS score, SAPS II score, respiratory rate, partial thromboplastin time (PTT), cardiac arrhythmias, and fluid-electrolyte disorders. The results showed that our model yielded satisfied diagnostic performance with an AUC value of 0.902 and 0.883 using the training set and on internal validation. The calibration curve and the Hosmer-Lemeshow goodness-of-fit (HL). The HL tests exhibited satisfactory concordance between predicted and actual outcomes ($P = 0.648$). The DCA showed a superior net clinical benefit of our model over previously reported scoring systems.

Conclusion: In summary, we explored the incidence of mortality during the ICU stay of thoracic fracture patients without neurological compromise and developed a prediction

model that facilitates clinical decision making. However, external validation will be needed in the future.

Keywords: intensive care units, nomogram, spinal fractures, prediction model, mortality

BACKGROUND

A spinal fracture is a dislocation or fracture of the vertebrae with an annual incidence of 26 per 100 000 (1), accounting for ∼23.3% of all trauma patients (2). The most prevalent spinal fractures occur at the level of the lumber spine, followed by the thoracic spine (3). Motor vehicle accidents (MVC) and falls from heights are the most common causes of spinal fracture; the annual incidence of spinal fracture has increased, with the reported increase in motor vehicle crashes (4). In China, the incidence rate of spinal fractures in 2007 was twice that in 2001 (3).

Numerous studies have investigated the long-term prognosis of spinal fractures using data from large patient populations in recent years. In patients with thoracolumbar fractures exhibiting mild symptoms, the visual analog scale (VAS) scores and the Roland Morris Disability Questionnaire demonstrated poor results and a poor outcome in 6% of patients 10 years after non-operative treatment (5). Furthermore, for patients exhibiting more severe symptoms requiring surgery, only 50% reportedly return to their original jobs postoperatively (6).

Meanwhile, long-term mortality associated with spinal fractures is significantly increased in post-traumatic patients compared to those with no history of trauma (7), especially in osteoporotic patients (8, 9). It has also been shown that old age and male gender increase the long-term mortality risk after thoracolumbar fracture (10). Interestingly, studies have shown that trauma patients in the ICU have high mortality rates, as high as 31% (11). Notwithstanding that substantial progress has been made in trauma advanced life support over the years, the mortality rates are still high (12). Patients with concomitant spinal cord injury are more likely than those without neurological damage to present with multiorgan injury and die from secondary infection (13). Most importantly, many patients experience death prior to hospitalization due to severe spinal cord injuries (14). To the best of our knowledge, the prognosis of acute severe spine fracture patients in ICU has been largely unexplored, and current research hot spots still focus on osteoporosis, bone cement, biomechanical analysis, and so on. Meanwhile, the interest of intensivists in trauma patients has mostly focused on rib fractures and pelvic fractures (15–17). Due to the lack of adequate attention to such patients, a large number of high-risk patients are not identified in time for admission, which often leads to poor prognosis and even higher mortality. Little is currently known about the risk factors of poor prognosis in ICU patients with thoracic spine fractures, which has resulted in high mortality rates. Accordingly, we selected this specific patient population for our study.

It is essential to develop a prediction model based on routine clinical and laboratory parameters to ensure that it can be easily implemented during clinical practice. It has been established that nomograms can provide evidence-based and personalized risk estimates and contribute to clinical management and prognosis evaluation (18–21). This study aimed to develop a prediction model to predict mortality during the ICU stay of thoracic fracture patients without neurological compromise based on the Medical Information Mart for Intensive Care III (MIMIC-III) (22) clinical database.

MATERIALS AND METHODS

Data Source

Our data were derived from the MIMIC-III database, a database established and open source by the Massachusetts Institute of Technology (MA, USA) containing information on more than 58,000 patients that attended the Beth Israel Deaconess Medical Center. We completed a web course offered by the National Institutes of Health (NIH) and were granted access to the MIMIC-III database (certification number: 42442549). The data were extracted from the MIMIC-III database using structure query language (SQL) with pgAdmin4 PostgreSQL 9.6.

Study Population

Structured Query Language (SQL) with PostgreSQL (version 9.6 University of California, Berkeley) was used to extract information associated with each patient's unique HADM_ID from the MIMIC-III database. Through International Classification of Diseases 9th Edition (ICD-9) code = 8,052, we obtaining 381 patient. For patients with multiple admissions, we retained information only on the patient's first admission to the ICU. Patients with missing data >20% for laboratory tests ($n = 5$) and ital signs ($n = 1$) were excluded. Finally, 298 patients were included in the study (**Figure 1**).

Clinical Variables and Definition

Using the patient's HADM_ID and ICUSTAY_ID as described above, we extracted the following data: demographics, vital signs, laboratory tests, comorbidities, and scoring systems. Among these, demographics included age and gender; vital signs included heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP), mean blood pressure (MBP), respiratory rate (RR), temperature, SpO_2, bicarbonate; laboratory tests included blood urea nitrogen (BUN), chloride, creatinine, glucose, hemoglobin, potassium, platelet, partial thromboplastin time (PTT), prothrombin time (PT), sodium, white blood cell (WBC), red blood cell (RBC); comorbidities included congestive heart failure, cardiac arrhythmias, liver disease, coagulopathy, fluid-electrolyte disorders, hypertension, renal failure, obesity, chronic pulmonary; scoring systems include scoring systems included simplified acute physiology score II

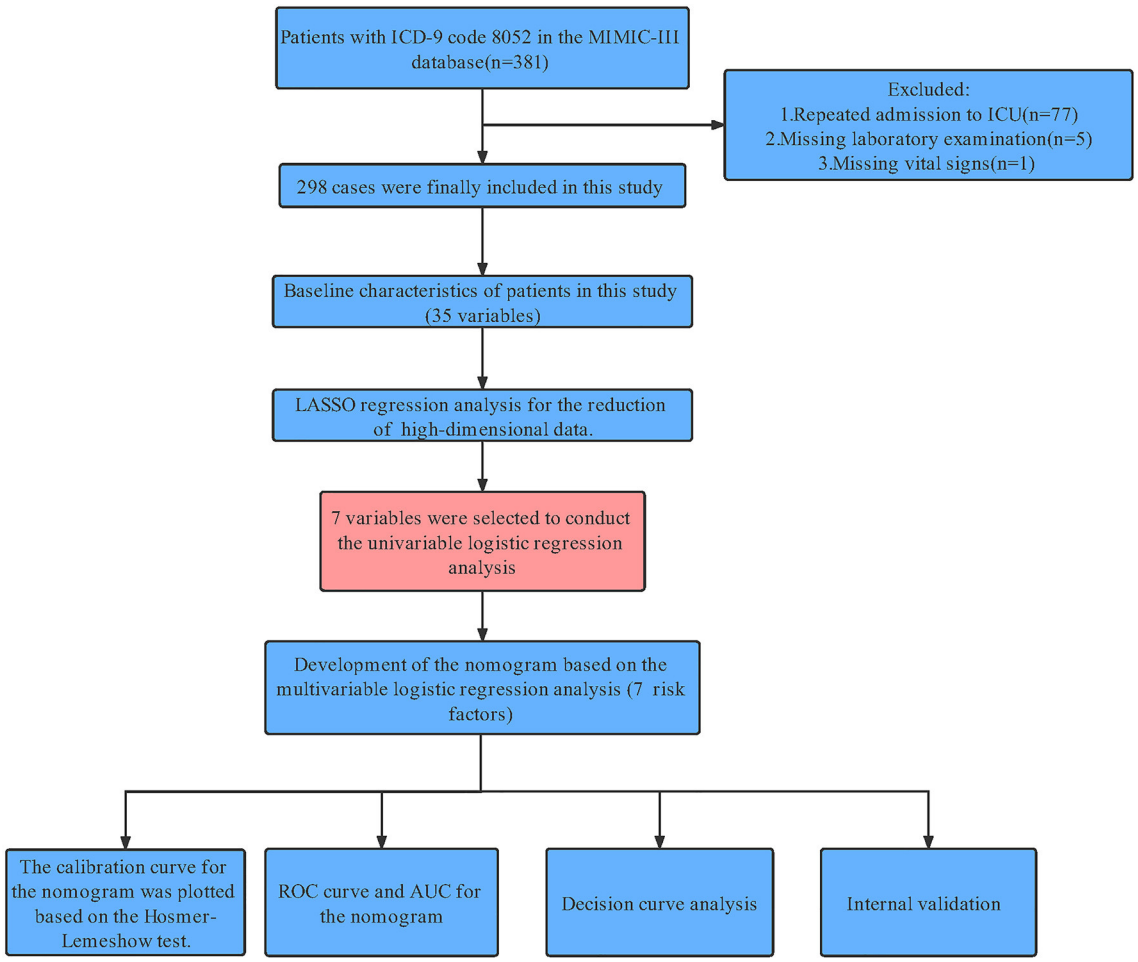

FIGURE 1 | Workflow of the study. MIMIC-III, Medical Information Mart for Intensive Care III; ICU, intensive care unit; LASSO, least absolute shrinkage and selection operator; AUC, area under the curve; HL test, Hosmer-Lemeshow goodness-of-fit test; DCA, decision curve analysis.

(SAPS II), sequential organ failure as severity (sofa) score, oxford acute severity of illness score (OASIS), and the Glasgow coma scale (GCS). Indicators with >20% missing data were removed, such as height, weight, calcium; A deletion was also made for some complications that were not present in all patients, such as peptic ulcer, lymphoma, metastatic cancer. All the variables mentioned above were collected within 24 h of patients' admission.

Statistical Analysis

We used the median and interquartile range to express continuous variables, while Wilcoxon's rank-sum test was selected for comparison between two groups; The categorical variables were expressed as frequency and proportion. Chi-square tests or Fisher's exact test was chosen for inter-group comparison according to the situation. We selected the bootstrap method for internal validation based on the number of patients, in accordance with the transparent reporting of a multivariable prediction model for individual prognosis or diagnosis (TRIPOD) guidelines (23). We used the neighbor interpolation method in the MICE R package (24) to fill in missing data. Then, the least absolute shrinkage and selection operator (LASSO) expression was used for screening predictors of mortality (25). For the cross-validation results, we selected lambda = min to determine the final candidate variables (26, 27). The multivariate logistic regression model was established using these variables, and multicollinearity was evaluated by variable inflation factors (VIF). The area under the receiver operating curve (AUC), sensitivity and specificity were used to evaluate the model's performance. The Youden index determined the best cutoff point. Finally, the nomogram was plotted using the R package "regplot." The calibration C index (bootstrap resampling 1,000 times) (28), the calibration curve (relationship between observation probability and prediction probability), Hosmer-Lemeshow goodness of fit test (HL test), and brier score were used to evaluate the degree of consistency between observed and predicted outcomes. Decision curve analysis (DCA) was used to assess the net clinical benefit (29). All statistical analyses were completed using R language (version 3.6.3); a $p < 0.05$ was statistically significant.

TABLE 1 | Baseline characteristics of in-hospital death and survival groups.

Variable	Total (n = 298)	Survival (n = 270)	Death (n = 28)	P-value

RESULTS

Patient Characteristics

Two hundred and ninety eight patients were finally included in the study, with an average age of 53.5 years. 34.6% (n = 103) were female, with a mortality rate of 13.6% while male patients accounted for 65.4% (n = 195), with a mortality rate of 7.2%. **Table 1** compares the differences in characteristics between the in-hospital death group and the survival group. Compared with the survival group, patients in the death group were older, had lower body temperature and blood pressure, faster respiratory rate, and lower bicarbonate. Meanwhile, lower hemoglobin and platelet counts were observed in the death group, while PT and PTT values were relatively higher, indicating poor coagulation function. The OASIS, SOFA, and SAPS II scores were significantly higher, with a higher prevalence of cardiac arrhythmias, coagulopathy, and fluid-electrolyte disorders.

Characteristics Selection and Development of a Nomogram

Out of 35 variables, seven remained in the lasso logistic regression model based on the binomial deviance minimum criteria (ratio 5:1) (**Figure 2**). The final seven variables included in the multivariate logistic regression, were: age (OR: 1.02; 95% CI 0.99–1.06), OASIS score (OR: 1.08; 95%CI 1.00–1.17), SAPS II score

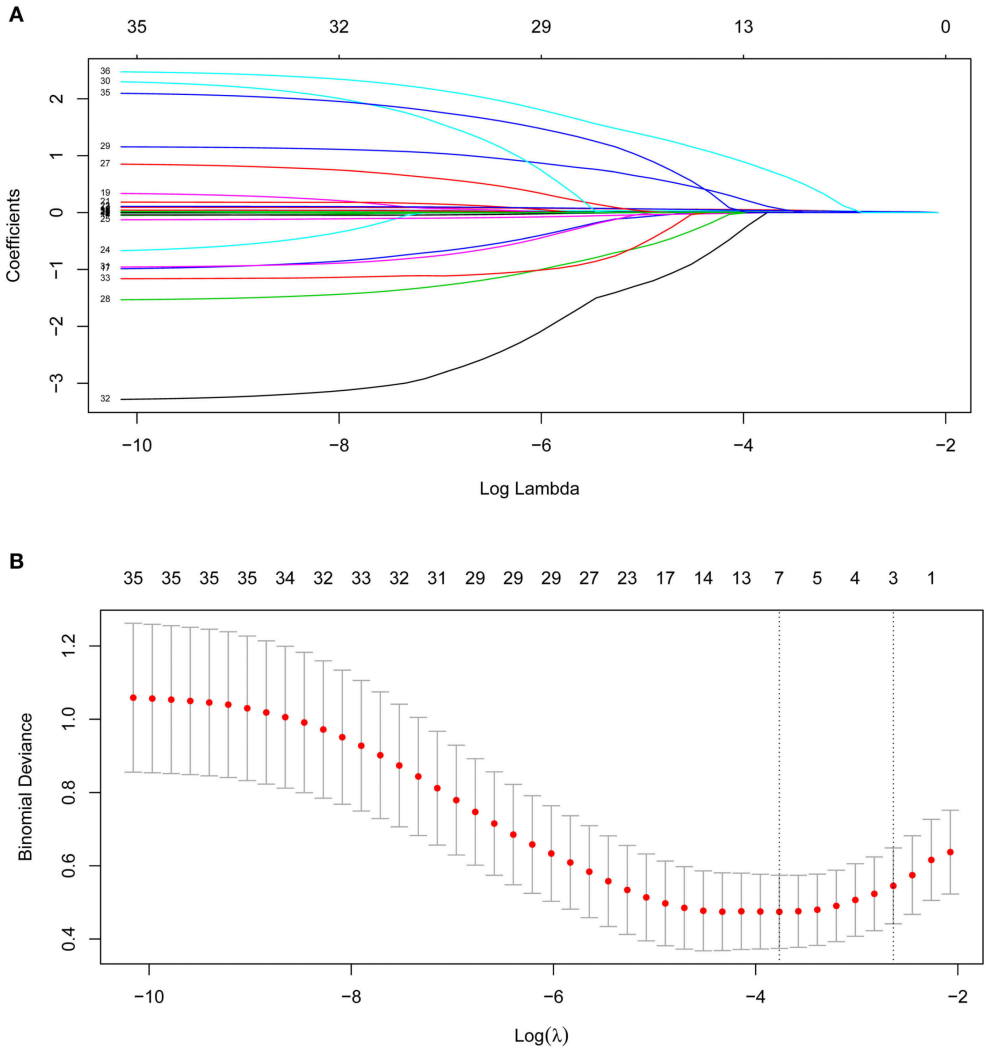

FIGURE 2 | Clinical variables were selected using the lasso logistic regression model. **(A)** Tuning parameter (λ) selection using LASSO penalized logistic regression with 10-fold cross-validation. **(B)** LASSO coefficient profiles of the radiomic features.

(OR: 1.03; 95% CI 0.98–1.08), RR (OR: 1.07; 95% CI 0.94–1.20), PTT (OR: 1.08; 95%CI 1.03–1.13), cardiac arrhythmia (OR: 1.44; 95%CI 0.43–4.62), and fluid-electrolyte disorders (OR: 4.40; 95% CI 1.62–12.54) (**Table 2**). Based on this model, we constructed a nomogram to predict mortality in ICU patients with thoracic spine fractures without neurological injuries (**Figure 3**).

Apparent Performance of the Nomogram and Web Calculator

Our model yielded an AUC value of 0.902 (95% CI 0.849–0.959), with a C-index of 0.883 after 1,000 bootstrap resampling internal validations. According to the Youden index, the optimal cutoff value was 18.45%, with a sensitivity and specificity of 0.870 and 0.786, respectively (**Figure 4**). Meanwhile, the calibration curve showed a good fit during internal validation (**Figure 5**), while the HL test showed that our predicted and observed values were close ($P = 0.648$); The Brier score was 0.0543 and 0.0623 after bootstrap correction. The ROC values of the scoring systems SAPS II and OASIS incorporated into the regression were 0.856 and 0.837, respectively, suggesting that our model exhibited better predictive performance than scoring systems commonly used clinically. To facilitate clinical use, we constructed a web calculator (https://ouyyjlueducn.shinyapps.io/dynnomapp/) based on the model.

Clinical Practice

DCA of the nomogram was performed (**Figure 6**). The blue curve in the figure represents that all the patients received intervention, the straight purple line represents that none patients receive the intervention, and the red curve represents the clinical benefit of our model. For our model, when the predicted probability threshold was set to 0.065%, the net clinical benefit was 9.39%. Our results showed that our model had a superior net clinical benefit than the OASIS and SAPS II scoring systems.

DISCUSSION

Fractures have become a major public health problem in most countries (30), especially spine fractures, which account for approximately 46% of spinal injuries in severe trauma (31, 32). In this regard, patients that sustain spine fractures have the poorest functional prognosis and potential to return to work (33). Although many studies have discussed the long-term prognosis of spinal fractures, to the best of our knowledge, this is the first study to investigate the mortality risk of spinal fracture patients without neurological impairment. The injury severity score (ISS) has previously been used to guide the risk stratification of trauma patients; however, some studies have pointed out that this scoring system was not reliable (34) since it did not consider the characteristics of patients with spinal trauma. We summarized the related works in **Table 3**. Previous methods of classifying spinal trauma have been most relevant in guiding surgical treatment (35), and commonly include the Trauma and Injury Severity Score (ISS) and the New Trauma and Injury Severity Score (NISS). However, none of these assessment methods take into account the individual spinal trauma patient, and our work fills a gap in the risk stratification of patients with severe spinal trauma. After internal validation of the model, we found that the predictions of the model were in good agreement with the actual results. More interestingly, the constructed model had better discrimination and net clinical benefit compared to the previously used OASIS and SAPSII systems. Also, based on the reviewers' comments, we have done more work. To facilitate clinical use, we constructed a web calculator (https://ouyyjlueducn.shinyapps.io/dynnomapp/) based on the model. In summary, we provide an easy-to-use model for this group of patients, which can identify high-risk patients early, take appropriate interventions early, and reduce poor prognosis and in-hospital mortality.

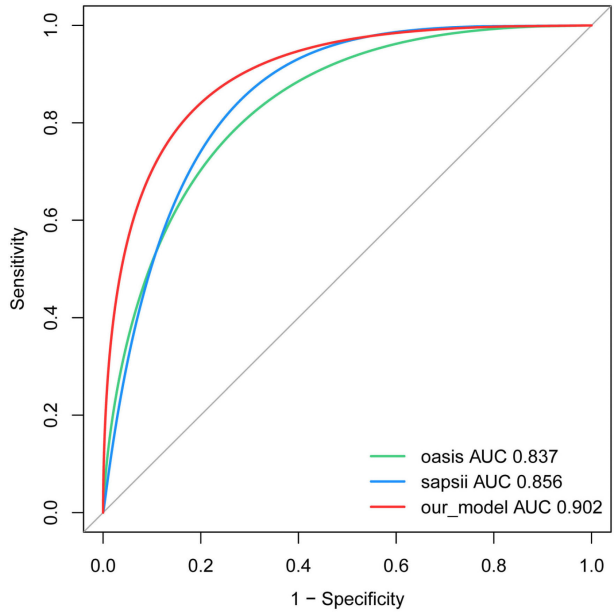

FIGURE 4 | Receiver operating characteristic curve of the nomogram. AUC, area under curve; OASIS, oxford acute severity of illness score; SAPS II, simplified acute physiology score II.

With the rapid development of computer technology in recent years, the combination of machine learning technology and medical practice has become a major trend (19–21, 26, 27). Along with the continuous innovation of convolutional algorithms, from LeNet by Lecun et al. (36) to ResNet by He et al. (37), computer-aided decision making through imaging has become a hot topic in medical research, such as prediction of BMI by facial image features to predict BMI (38) and fundus images to predict diabetic retinopathy (39). In addition, the prevalence of electronic medical records and the establishment of large medical databases have also provided the basis for research on clinical problems, and the combination with machine learning has shown remarkable performance in predicting the occurrence and prognosis of diseases (40, 41). Unfortunately, however, there is still a lack of research in the current field for our patient population. It is therefore necessary to develop an easy-to-use and reliable tool to inform clinical practice. In the present study, we established a nomogram consisting of seven predictors: age, OASIS score, SAPS II score, RR, PTT, cardiac arrhythmias, fluid-electrolyte disorders. Multiple indicators used during the validation process, including AUC, calibration curve, HL test and DCA, indicated that our nomogram yielded satisfactory prediction results.

As seen in **Table 1**, significant differences in coagulation markers PT, PTT, and coagulopathy were found between the death and the survival groups, especially PTT, which was an important predictor of mortality. Trauma-induced coagulopathy (TIC) has been reported to play an important role in trauma healing (42), and an increasing body of evidence suggests that uncontrolled hemorrhage is a preventable cause of death in the early stages after injury (43–45), which has been reported to be as high as 40–80% (46). The incidence rate of TIC often correlates with the severity of tissue injury (47) since tissue injury releases a large number of damage-associated molecular patterns (DAMPs), which promote multiple inflammatory pathways and thereby affect coagulation (42). Endothelial dysfunction has been reported to participate in TIC (48), and plasma samples from severely injured patients on admission exhibited increased levels of syndecan-1, which correlated with increased activated protein C (APC), prolonged PTT, and elevated epinephrine levels (49). Furthermore, platelet defects and dysfunction are also important contributors to TIC (50). In our study, even though the platelet count in the deceased group was still within the normal range, a significant decrease was observed (**Table 2**), suggesting an association between a relatively low platelet count and increased mortality, consistent with previous studies (51, 52). Similarly, a prospective study demonstrated that 91% of patients with severe injuries had platelet dysfunction despite normal platelet counts (53).

The most common arrhythmia in patients with chest trauma or surgery is atrial fibrillation, often associated with longer ICU stay and higher mortality (54). On the one hand, most patients with pre-existing atrial fibrillation receive anticoagulant therapy. When combined with previously described coagulation dysfunction, fatal bleeding can result from small traumas (55). On the other hand, patients with new-onset atrial fibrillation have higher in-hospital mortality than patients with previous atrial fibrillation (56) reportedly. The mortality among patients with arrhythmia in our study group was 23.3% ($n = 10/43$), much higher than that of patients without arrhythmia. Moreover, a significant difference in the number of patients with arrhythmia was found between the survival and death groups ($P < 0.01$).

It is widely acknowledged that the onset of arrhythmias is highly correlated with electrolyte disturbances (54). Many studies have demonstrated that electrolyte disturbances and vertebral fractures are associated with higher mortality, while elderly patients with fractures are more likely to have hyponatremia (57–59). Interestingly, in our study, albeit patients in the deceased group were much older than those in the survival group, no significant difference in sodium levels was found between the two groups. However, our study also confirmed higher mortality in patients who develop fluid-electrolyte disorders, emphasizing the need for early and effective fluid management in this subset of patients (60).

An analysis of nationwide patients with vertebral fractures in Japan revealed that advanced age is a significant risk factor for complications (OR 1.38) (61). We consistently found that advanced age patients were more likely to experience in-hospital death, which may be associated with sarcopenia (62), poor nutritional status (63), and development of fluid-electrolyte disorders, as mentioned earlier. However, we found that gender was not a relevant factor for in-hospital death in our study, which was inconsistent with the literature. This discrepancy could be accounted for by the fact that the subjects of our research were ICU patients, which were critically ill, while gender had more influence in long-term prognosis (10).

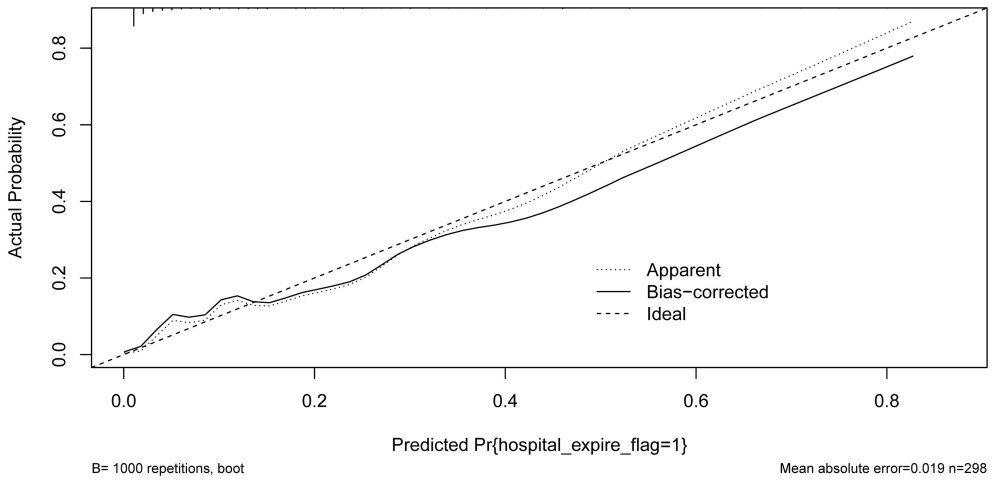

FIGURE 5 | Calibration curves of the predicted nomogram. The dashed line represents the original performance, and the solid dashed line represents the performance during internal validation by bootstrapping (B = 1,000 repetitions). Results of the Hosmer-Lemeshow test demonstrate that the P-value was 0.648.

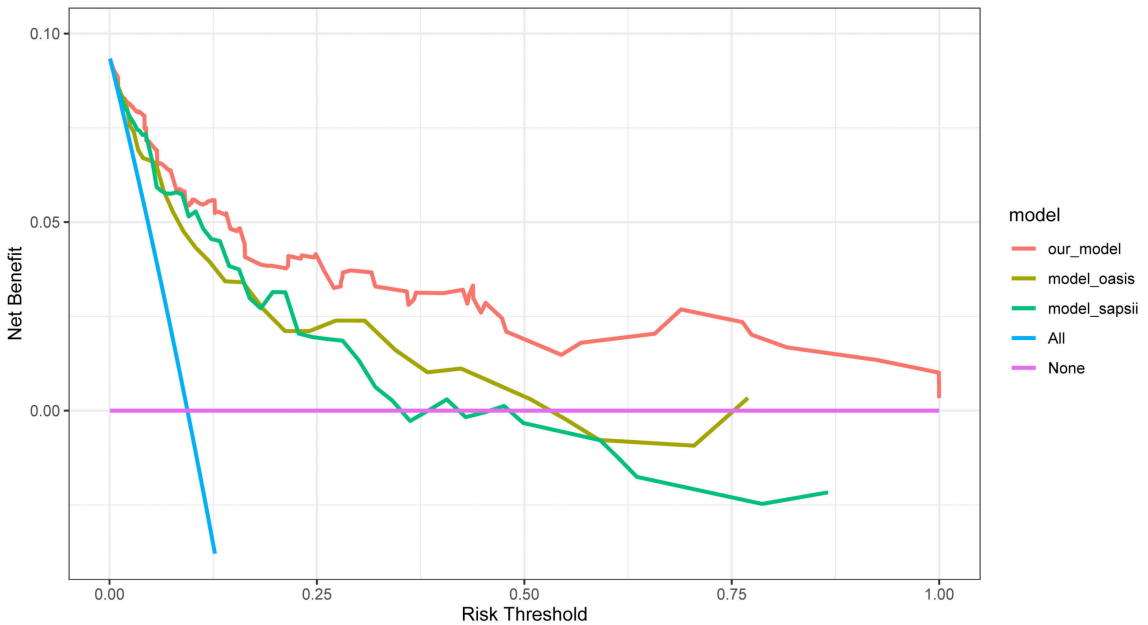

FIGURE 6 | DCA for our model, OASIS and SAPS II. The y-axis measures the net benefit. DCA, decision curve analysis; OASIS, oxford acute severity of illness score; SAPS II, simplified acute physiology score II.

Due to its simplicity and ease of observation, the respiratory rate is one of the indicators traditionally used for the early identification of high-risk patients after trauma (64). A respiratory rate >20 was an important indicator in new evaluation criteria for trauma patients (65). Consistently, we found that tachypneic patients with a respiratory rate within 24 h of admission are more likely to experience in-hospital mortality and require early intervention. Two severity scoring systems, SAPS II and OASIS were also included in the prediction model of this study. At present, much controversy surrounds the predictive accuracy of these two scoring systems in orthopedic trauma patients (66, 67). In our present study, both scoring systems were integrated into our nomogram. The ROC plots showed that our model outperformed these two scoring systems in discrimination (**Figure 3**). At the same time, DCA exhibited greater net clinical benefit than these two scoring systems (**Figure 5**).

There are still limitations that need to be considered. First, these data were from a public database spanning 2007–2014. Therefore, the model needs external validation from different medical Institutions. Second, because missing data is >20% in the dataset, there is a lack of some important clinical parameters. Finally, although nomogram is already widely used

in clinical practice to aid medical decision making, we want to further simplify the work and expand the scenarios in which it can be used. Therefore, in the future we hope to package predictive tools into applications for mobile devices, wearables, or personal computers.

CONCLUSION

Our study found that age, OASIS score, SAPS II score, RR, PTT, cardiac arrhythmias, and fluid-electrolyte disorders are predictors of mortality during the ICU stay of thoracic fracture patients without neurological compromise. A multiple logistic regression model and a nomogram were developed and validated. During clinical practice, this nomogram could help physicians screen high-risk patients, make optimal use of resources, and decrease the occurrence of death in this patient population.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors, without undue reservation.

AUTHOR CONTRIBUTIONS

HW collected the data, analyzed the data, and drafted the manuscript. TF, YO, MK, JZ, and RD conceived of the study, participated in its design and coordination, and helped to draft the manuscript. YQ was responsible for the whole project, reviewed the manuscript, designed the study, and supervised the study. All authors contributed to the article and approved the submitted version.

FUNDING

This work was supported by Norman Bethune Program of Jilin University (JJKH20201101KJ).

Over the last decade, the field of bioinformatics has been increasing rapidly. Robust bioinformatics tools are going to play a vital role in future progress. Scientists working in the field of bioinformatics conduct a large number of researches to extract knowledge from the biological data available. Several bioinformatics issues have evolved as a result of the creation of massive amounts of unbalanced data. The classification of precursor microRNA (pre miRNA) from the imbalanced RNA genome data is one such problem. The examinations proved that pre miRNAs (precursor microRNAs) could serve as oncogene or tumor suppressors in various cancer types. This paper introduces a Hybrid Deep Neural Network framework (H-DNN) for the classification of pre miRNA in imbalanced data. The proposed H-DNN framework is an integration of Deep Artificial Neural Networks (Deep ANN) and Deep Decision Tree Classifiers. The Deep ANN in the proposed H-DNN helps to extract the meaningful features and the Deep Decision Tree Classifier helps to classify the pre miRNA accurately. Experimentation of H-DNN was done with genomes of animals, plants, humans, and Arabidopsis with an imbalance ratio up to 1:5000 and virus with a ratio of 1:400. Experimental results showed an accuracy of more than 99% in all the cases and the time complexity of the proposed H-DNN is also very less when compared with the other existing approaches.

INTRODUCTION

The problem of imbalanced data has often been recognized as a significant challenge in Machine and Deep Learning. The ML classifiers tend to get influenced by the majority classes when it comes to imbalanced data. This results in a poor classification of the minority classes. Whenever the class sizes are significantly different, the classification methods perform much better in the larger class, achieving accurate results, whereas the minority class seems to have a very poor recall. The classification of one class being considerably neglected in comparison to another is still one of the most difficult problems to solve in the creation of new classification models today. Bioinformatics is one of the major streams that provide a large number of highly imbalanced data. These enormous

datasets require a great solution that can handle such problems and are appropriate for such imbalance ratios. One of the major data imbalance problems in bioinformatics is the identification of the precursor micro RNAs (pre-miRNA) from the genome. The miRNA is a special type of non-coding RNA. They have a length of 21 nucleotides and they play a key role in the posttranscriptional regulation of gene expression. The miRNA is a minute, endogenous RNA having a hairpin-like structure. Numerous key biological processes, such as disease genesis and progression, are regulated by miRNAs. They can act as an oncogene or tumor suppressor in a variety of cancers assisting in prognosis prediction, therapeutic assessment, and disease diagnosis (1). A promising therapy for breast cancer is delivered by the latest miRNA-based drugs (2).

The genome data consists of hundreds of thousands of sequences out of which there will be only a few miRNAs. Moreover, there are several other similar RNAs which makes it even more difficult to differentiate them. Further, the minority class usually contains a small number of high-variability instances, making it more challenging for a classifier the generalization of the new dataset. So, to find them in the highly imbalanced genome data and classify them is a great challenge and hence there is a need to find an optimal solution for identifying them with a simple procedure. Although the computational methods have been necessary tools in miRNA gene finding and functional studies (3). The Machine Learning (ML) techniques have made it possible to classify them to a good extent (4). Machine Learning and Deep Learning (DL) have taken control over every field and are providing adequate solutions for every complex problem. There are few algorithms proposed for which the True Positive Rate (TPR) is very less and complexity is more. For the genome datasets, there are many negative samples and very few positive samples of miRNA sequences. Generally, this type of problem is related to Imbalanced data. To handle such Imbalanced data there are a few solutions out of which Sampling is the most famous and efficient way. There are two variants of sampling: Oversampling and Undersampling. Oversampling is the technique in which the fewer samples in the dataset will be upscale (in other words upscaling the minorities) to make the data to be balanced. In this technique, many dummies for fewer samples are generated. When the dataset is with a smaller number of samples (both positive and negative) this technique will help to build a model with an adequate number of samples. Under Sampling is the technique in which the greater number of samples in the dataset will be downscaled (in other words downscaling the majorities) to make the data to be balanced. In this technique, the Selection method or Random sample method is chosen. In general, when the dataset is very large, the model will take a huge time to execute, this technique will help us to overcome this issue. In one of the proposed models (5), they chose an Imbalance Ratio (IR) up to 1:2000 (meaning one positive sample and 2,000 negative samples), and different ratios like 1:1, 1:100, 1:500, 1:1000, 1:1500, 1:2000. To improve the model and follow the consistency, different IRs like 1:2500, 1:3000, 1:3500, 1:4000, 1:4500, 1:5000 have been added. A model was proposed where, in addition to the Animal and Plant dataset, the Human and Arabidopsis dataset with IR up to 1:5000 and virus dataset with IR up to 1:400 was considered to enhance the performance (6).

The existing systems like Multi-layer perceptron (MLP), Support Vector Machine (SVM), Deep Self-Organizing Map (DeepSOM), Deep Elastic SOM(DeSOM), Deep Elastic Ensemble SOM (DeeSOM), Deep Belief Neural Network (DeepBN) can solve this problem to some extent only. The Deep Architectures which work without SMOTE (Synthetic Minority Oversampling Technique) (7) take more time and accuracy is also poor, the other systems stated above also produce low accuracy if the class imbalance ratio is gradually increased. Most of the existing works so far have not considered multiclass pre-miRNA classification having an imbalanced dataset, even if they have discussed their performance is not up to the mark and hence end up having low accuracy. The accuracy of the existing work also goes down as the imbalance ratio is increased as it is given in the real-time scenarios. So, to address the problems like high run time and low accuracy faced in these existing systems, we propose a Hybrid Deep Neural Network (H-DNN) architecture, which is implemented by integrating the Deep Artificial Neural Networks (ANN) with a Deep Decision Tree classifier (Deep DT). Deep ANN is capable of optimizing a wide range of coefficients. As a result, Deep ANN can tolerate a much larger variation than traditional models. With enough training, Deep ANN will be prepared for any circumstance. It is a type of machine learning technology with a large memory capacity since it is capable of remembering every call. On imbalanced data, DT usually performs effectively. They operate by understanding a hierarchy of if/else scenarios, which forces them to address both majorities as well as minority classes. The main contributions of the proposed work can be listed as follows:

- Preprocessing of multiclass genome dataset and selection of features using Select-K-Best and Recursive Feature Elimination.
- Building proposed H-DNN framework by integrating Deep Artificial Neural Network and Deep Decision Tree for classification of miRNA from a multiclass genome dataset.
- Apply the H-DNN architecture with different imbalance ratios of multiclass genome dataset consisting of Animal, Plant, Arabidopsis, Human, and Virus genomes.

The rest of the paper is organized as follows: Section Related Work discusses the related work. Section Proposed Work discusses the proposed H-DNN architecture and its components. Section Experimental Work details the experiments and presents the results of H-DNN and section Results and Discussions summarizes the proposed approach and its future enhancements.

RELATED WORK

Due to the imbalanced class distributions in the data, handling such class imbalance problems and drawing a large amount of interest toward it, has become the major issue. To deal with these class imbalance problems many ensemble methods are proposed but most of them focus on the two-class imbalance problems, leaving many issues unsolved in the multiclass imbalance

problems. To solve those multi-class problems efficiently an algorithm called AdaBoost.NC was proposed. It produced better results when compared with other popular ensemble Techniques (8). As the availability is expanding in all kinds of fields it becomes difficult to perform analysis and progress from raw data to decision-making processes. Even though new data engineering techniques are showing great success in solving real-world problems, learning from imbalanced data has emerged as a new challenge. To enable efficient learning from imbalanced data it is required to have new approaches, understandings, algorithms, principles, and tools, because of its complex characteristics (9, 10). Class imbalances make supervised learning problems difficult because some classes have more examples than others. The existing methods have completely focused on binary-class cases. A dynamic sampling method for Multilayer Perceptron (MLP) was proposed to solve the multi-class imbalance problems. To train the MLP, DyS dynamically selects informative data. This Dynamic sampling technique has performed well when compared with other techniques (11). There are several other preprocessing techniques for the data, classification algorithms, and evaluating the model involved in modeling methods (12). The important regulators of gene expression are MicroRNAs (miRNAs). The genetic loss of the tumor suppressor miRNAs or Amplification and the overexpression of one's 'oncomiRs' is related to human cancer and is enough to cause tumorigenesis in mouse models. Besides, the depletion of global miRNA by genetics and in the components of miRNA biogenesis machinery epigenetic alterations is oncogenic. All these together with novel miRNA regulatory pathways and factors show how important miRNA dysregulation is in cancer (13). Even after identifying hundreds of miRNAs in different species, a lot of others remain unknown. So, in understanding miRNA-mediated posttranscriptional regulation mechanisms the discovery of new miRNA genes is an important step. The biological approaches in identifying miRNA genes might be limited. So, to overcome those limitations in the biological approaches sophisticated computational approaches are followed to identify the possible miRNA (14). Some of the work deals with the miRNAs in terms of diagnosing dreadful diseases in the medical field. Several web-based bioinformatics tools were proposed for the analysis of miRNA such as expression, detection, etc. with an easy-to-use model that doesn't require any previous knowledge of utilization (15). A Support Vector Machine (SVM) based approach was proposed to classify the real and pseudo miRNA. It achieved an accuracy of up to 90% (16). The model was exclusively for the human dataset but the remaining datasets could also be used. In this work, then genomic information was not required. Later, software that classified the RNA of mammals, nematodes, and also urochordates was proposed. A new methodology was proposed based on Support Vector Machine (SVM) and named

Proposed HDNN Methodology	Artificial Neural Network embedded with Decision Tree	Various metrics were used for evaluation for different imbalance ratios. The results yielded F1 Score of more than 0.50 (0.50–0.93) for Animal, more than 0.58 (0.58–0.95) for Plant, more than 0.60 (0.60–0.94) for Human, more than 0.50 (0.50–0.95) for Arabidopsis and more than 0.50 (0.50–0.94) for Virus.	Animal, Plant, Human, Arabidopsis, and Virus.

as Microprocessor SVM, which predicted with 50% accuracy (17). To improve the accuracy of this model, the model was trained with another classifier and ensemble both to get better results than acquire 90% in total. Another work dealt with the miRNA sequences of the mouse and human using the SVM approach (18). The model worked with around 377 mouse data and 475 human data and with the candidates, the dataset had 3,441 humans and 3,476 mouse samples in total. The classification was done according to the structure of the miRNAs, the model names, and the mirCoS. One of the works also dealt with the use of ab initio Prediction model clustered microRNA identification (19).

An application for the classification of pre-miRNAs was proposed which dealt with the classification of the mammalian miRNAs such as Human, Rat, and Mouse (20). This approach analyzed the genome properly using the model named ab initio which gives an accuracy of up to 60% when they undergo cross-validation. To analyze the structure of miRNA, a tool named MiRFinder was proposed which was built with the SVM model (21). The structure of the miRNA is a hairpin-like structure, the prediction mainly focused on the structure and later the features were used to predict the miRNA. This tool was mainly used for the genome-wide search of the miRNAs. The dataset which has 697 real miRNA and 5,428 pseudos from different sources was collected and experimented with. The tool gained sensitivity up to 93%. Another model named miRenSVM was proposed that gave good results for the data in miRBase 13.0 animal and other species (22). For animal data in miRBase 13.0, it gave 100% sensitivity. A novel RNA effective classification methodology namely microPred was proposed which classified the types of miRNA using the Machine Learning approach (23). It used a classifier namely microPred, which also could handle the data imbalance issue as well as new feature extraction relevant biologically. It achieved a specificity of 97.28% and a sensitivity of 90.02%. The model gave the prediction rate of 92.71% for humans and 94.24% for the virus. Another new model was developed that used a method named YamiPred, which is an ensemble of Genetic Algorithms (GA) and Support Vector Machine (SVM) for the prediction of miRNAs (24). The model mainly used a human dataset to predict the human miRNAs. The model appeared to be robust and efficient with different performance characteristics. **Table 1** illustrates the comparison of various state-of-the-art methodologies used for the classification of miRNA.

PROPOSED WORK

In this section, we discuss the proposed Hybrid Deep Neural Network approach for the classification of miRNA from genome data. Different genome datasets have been considered in our proposed work such as Animal, Plant, Human, Arabidopsis, and Virus datasets. First, the dataset is preprocessed and all

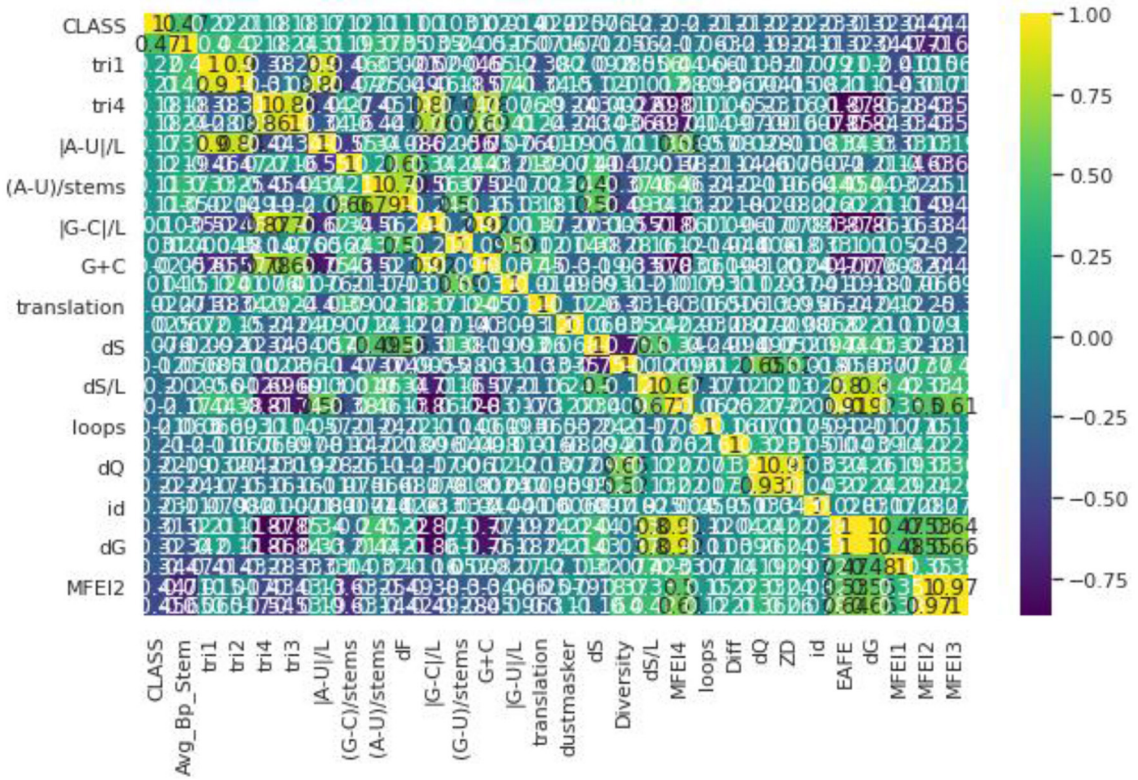

FIGURE 1 | Correlation matrix.

the important features are selected and extracted and the non-useful features are omitted. For feature selection and extraction feature selection Algorithms like Select-K-Best and Recursive Feature Elimination are used. After preprocessing the dataset, the proposed H-DNN algorithm is implemented. The proposed H-DNN framework is the integration of Deep ANN with the Deep DT. Then the implemented model has experimented with the different genome datasets (31).

Preprocessing

Pre-processing refers to Feature Selection or Feature Extraction. Different Feature Selection algorithms have been applied with the dataset (32). To have a clear idea of feature selection, the dataset has to be analyzed first. Different genome datasets have been considered in our proposed work such as Animal, Plant, Human, Arabidopsis, and Virus datasets. Even though these datasets have a different number of samples in each, they have the same number of features (33). The dataset used here has a total of 30 features in which one is a serial number, hence we omit that attribute. The remaining 29 features are taken into consideration and passed to the Feature Selection Algorithms (34). **Figure 1** illustrates the correlation matrix plotted for all the features and a heat map is produced out of that as shown. The correlation matrix helps us to characterize and sum up the data for our understanding. Correlation, here, helps us to compute the association between two variables by testing the effectiveness of their linear relationship. After estimating the correlation matrix, the Feature selection Algorithms like Select-K-Best and Recursive Feature Elimination are used. In the Select-K-Best algorithm, the features are assigned with particular scores. The Selection is generally made based on the scores which are greater than the mean of all the scores in this Feature Selection (35). In the Recursive Feature Elimination, the rank is assigned to each feature and the ranks may be the same for more than one feature. The feature selection is made based on the ranks that are assigned. Generally, the selection is done based on the first few ranks like 10, 12, etc., based on several features (36). The Recursive Feature Elimination with Cross-Validation is used. This gives scores between 0 and 1. The 0, being the least important and one is the most important feature to build any model. This algorithm is applied to the dataset and the results state that all the features are nearer to the one (37). Hence, all the features are important. This proves that there is no need for removal or elimination of any feature from the data so all 29 features are used to build the proposed model (38).

Proposed H-DNN Architecture

In this section, we discuss our proposed work. We have developed a Hybrid Deep Neural Network (H-DNN) wherein we have integrated Deep Artificial Neural Network and Deep Decision Tree (DT) classification technique for classifying the miRNAs in the genome data. The integration of feature extraction using machine learning techniques and feature analysis and classification using Deep Neural Network has provided better results. The experimental results have been carried out using Animal, Plant, Human, Arabidopsis and, Virus genome datasets. The results are then analyzed and compared for the model using Deep ANN and Deep DT. Deep ANN here helps in analyzing the features by optimizing a wide range of coefficients. As a result, Deep ANN can tolerate a much larger variation than traditional models. Deep ANN gets well prepared for any circumstance with sufficient training. It is a type of machine learning technology with a large memory capacity since it is capable of remembering every call. DT usually performs effectively in case of imbalanced data by understanding a hierarchy of making decisions for different scenarios, which forces them to address both majorities as well as minority classes.

The structure of ANN consists of a neuron, a propagation function, and a bias. Consider a neuron k having an input $I_k(t)$ received from the previously connected neurons. The neuron will have an activation function $a_k(t)$, an optional threshold θ_k, an activation function f for computing new activation for time $t+1$ as given in Equation 1, and a function f_{out} for computing the activation output which is formulated as given in Equation 2.

$$a_k(t+1) = f(a_k(t), p_k(t), \theta_k) \quad (1)$$

$$O_k = f_{out}(a_k(t)) \quad (2)$$

The input, $I_m(t)$ to the neuron m from the output of k, is computed using the propagation function defined as given by Equation 3. After adding the bias, w_{0m}, we formulate the input as given in Equation 4.

$$I_m(t) = \sum_k O_k(t) w_{km} \quad (3)$$

$$I_m(t) = \sum_k O_k(t) w_{km} + w_{0m} \quad (4)$$

Artificial Neural Networks (ANNs) have several different coefficients, which the ANNs can optimize. So, when compared with the traditional models, ANNs can handle much more

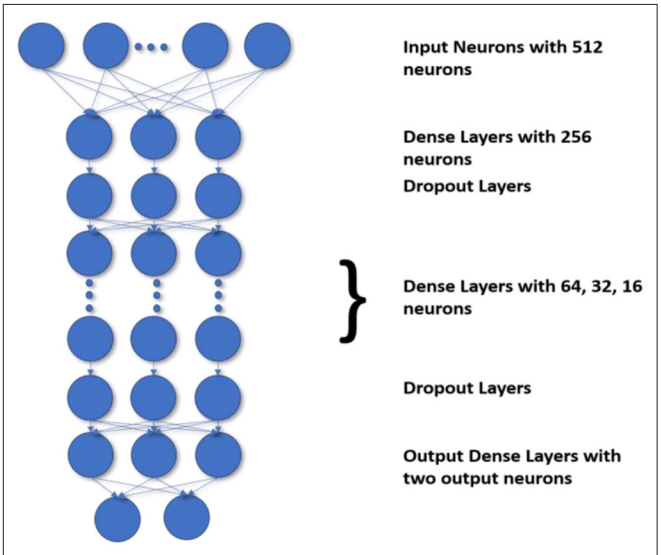

FIGURE 2 | Structure of ANN in each node of Decision Tree in the proposed framework.

variability (39). This makes ANN a stronger model when it comes to memorization (40). A decision tree is a supervised learning Algorithm. Both regression and classification problems can be solved using Decision Trees. In the tree representation, each leaf node represents a class label and the internal node of the tree represents the attributes. Decision trees include three main units that are node, branch, and leaf. The node is the decision. The branch is the potential decision, and the leaf is the potential outcome of each decision. The DT illustrates the long-term consequences of certain decisions. The trade-offs and probabilities can also be expressed using decision trees. In a decision tree, after every level, we have a split taking place which in turn results in the next level. Therefore, the major challenge in Decision trees is to identify the attribute for the root node in each level. This is called attribute selection. There are various popular attribute selection measures in decision trees we have used Gini Index for attribute selection in our framework. Gini index can be formulated as shown in Equation 5.

$$Gini\ Index\ =\ 1 - \sum_{j} p_j^2 \tag{5}$$

here p_j denoted probability for class j. Gini index is used here as a cost function for the split evaluation in feature selection. When compared with other algorithms, the decision tree needs less effort for data preparation during preprocessing. It does not require scaling of data or normalization of the data. In addition to this transparency and ease of use makes the decision tree a better model to handle large amounts of data.

The most challenging task is to handle the imbalanced data. The current state-of-the-art methods do not define the decision process take more time and accuracy is also poor. Generally, the state-of-the-art frameworks produce low accuracy if the class imbalance ratio is gradually increased. Before DNN, decision trees were the standard method used to improve accuracy and performance. Though as compared to DNN the accuracy gained by using a decision tree for classification are less the DT preserves the interpretability. So to preserve the DT's interpretability and match the DNN's performance, we use the H-DNN architecture wherein we integrate the Decision Tree and the ANN. The H-DNN model consists of a DT wherein each node of the DT will have an ANN model. The DT is used to make the classification of miRNA in an H-DNN, maintaining high-level interpretability. Every node in a decision tree, on the other hand, is a neural network that makes low-level decisions. First, a hierarchy for DT is constructed and then the sample is passed through the ANN, which is a fully connected neural network, in each decision node. Then the model computes the analysis by executing the final fully connected layer as a series of integrated decision rules. The final prediction is a culmination of these decisions. The ANN structure proposed in this paper deals with a dense layer as input layer with 512 nodes and ReLu activation function followed by another dense layer with 256 nodes and a dropout layer, then three more dense layers with 64, 32, 16 nodes respectively with ReLu activation function and a dropout layer and finally one dense layer with two nodes as output layer. This ANN structure, as illustrated in **Figure 2**, is embedded into each node of the decision tree for making the decision rules. In the fully connected layer of each node of the decision tree, the inner product of the matrix-vector is calculated and an inner product that constitutes the maximum value is chosen for the class decision rule as shown in Equation 6.

$$= [y_1\ y_2 \vdots y_n\ ] \rightarrow argmax(y) \tag{6}$$

Algorithm 1 illustrates the H-DNN algorithm that uses the Deep Decision Tree having Artificial Neural Network embedded in each root node. The ANN framework in the proposed model has a single input layer, a few hidden layers, and a single output layer. In the final layer of the hidden layer, the decision rule for splitting the tree has been incorporated using Gini Index. Line 1 and 2 in **Algorithm 1** initialize the tree and the minimum criteria to be considered for making the decision rule. The Deep ANN is embedded into each node of the Deep DT as illustrated from lines 3 to 10. For a given input node and input, line 4 and 5 illustrates the implementation of the first layer, i.e., the input layer of the Deep ANN. Using the output of the input layer the hidden layer is calculated using lines 6 and 7. In line 8 the Gini Index is calculated to determine the decision rule for splitting the node or tree further. Using the output of the hidden layers the output layer is constructed in lines 9 and 10. In line 11 the Backpropagation algorithm is called to adjust the weight according to the errors. In lines 12 to 15, the decision rule has been implemented. Once the decision rule is applied the nodes are split accordingly as shown in line 16. This process is then implemented for each node until all the nodes are processed and no further nodes can be split.

Algorithm 2 illustrates the implementation of the backpropagation algorithm used for generalizing the Neural Network (NN) by fine-tuning the weights based on the previous iteration's error rate. After applying the forward propagation, the backpropagation algorithm is called to fine-tune the NN. From lines 1 to 6 in **Algorithm 2** all the required parameters are initialized. From lines 7 to 13 the backpropagation process is applied to the neural network.

The proposed architecture can be divided into four modules as illustrated in **Figure 3**. Module one is the Imbalanced genome dataset which has the collection of Plant, Animal, Human, Arabidopsis, and Virus genome data. This data is preprocessed in module two wherein the feature variables are correlated to find the relationship between the features. In this module, the required features are extracted using the Select-K-Best Method and Recursive Feature Elimination Method, and the rest of the unwanted attributes are discarded. After the feature selection and extraction, the preprocessed data is passed to the third module. The third module is the proposed H-DNN architecture. The H-DNN architecture is the integration of the Decision Tree and the ANN framework. The ANN framework used here helps to avoid overfitting and thereby increasing the performance. The Decision tree helps to make a decision and examine the benefits and cons of each final option. Every node in a decision tree, on the other hand, is a neural network that makes low-level decisions. The inputs of each node of the Decision Tree are passed to ANN for making the decision and analyzing the probability values of the class. The final evaluation of the model is done in the fourth Module, the Model Evaluation module, using Accuracy, Specificity, Precision, and F1-score as the evaluation metrics.

EXPERIMENTAL RESULTS

Experimental Work

In this section, the dataset and the experimental results will be explained in detail by each dataset (41). In the Animal dataset, there are 7,053 positive and 218,154 negative samples and in total there are 225,207 animal sequences. One lakh seventeen thousands one hundred and one plant sequences are taken in which 2,154 positive and 114,929 negative samples are present. One thousand four hundred six positives and 81,228 negatives

1:5000	44	218,154	23	114,929	16	81,228	6	28,359

TABLE 3 | The number of positive and negative samples for different IRs for virus.

IR	Virus	
	No. of positives	No. of negatives
1:1	237	237
1:50	17	839
1:100	8	839
1:200	4	839
1:300	3	839
1:400	2	839

and in total 82,634 human samples are given in this dataset. In Arabidopsis 231 positive samples and 28,359 negative samples in total, and there are 28,590 sequences. The virus samples are very few so it has only 1,076 in a total of which 237 are positive and 839 are negative samples (26). This is treated as a separate one and the maximum IR is only 1:400 (27). For the Animal, Plant, Human, and Arabidopsis datasets, the number of positive and negative samples for different IRs are tabulated in **Table 2**. For the virus, the number of positive and negative samples for different IRs is listed in **Table 3**. The initial target is to find the specificity and other metrics till IR up to 1:2000. Later, to improve the model it was extended to 1:5000. For the classification, here two Algorithms are used. They are ANN and Decision Tree Classifiers (10, 25, 28, 39, 40, 42–44).

RESULTS AND DISCUSSIONS

As discussed in section Proposed Work the ANN has been integrated with the DT in our proposed work and the results are represented graphically. Graphs are plotted for clear visualization of the results. As explained in the previous sections, the model is improvised by using different datasets like Animals, Plants, Humans, Arabidopsis, and Viruses genomes. The work is extended in terms of the Imbalance Ratios also it is extended up to 1:5000. The model gives some predictions even for the 1:5000 ratio also, this can be visualized individually. **Figure 4** illustrates the graphical representation of experimental results done using the proposed H-DNN framework on Animal, Plant, Human, Arabidopsis and, Virus genome datasets. The x-axis in the graph indicates the IR and the y-axis in the graph plotted illustrates the metric values. The result analysis of the proposed H-DNN Algorithm was done based on the evaluation metrics: Accuracy (Acc), Specificity (SP), Sensitivity (SE), F1-score (F1), and Precision (Prec).

First, the ANN and Decision Tree Classifier results were analyzed individually. Then their results were compared with the proposed H-DNN framework. The Experimental analysis was done by implementing the state-of-the-art ANN and DT separately and then by implementing the proposed H-DNN approach using the above-said dataset. The dataset was trained batch-wise. **Table 4** illustrates the result comparison of the proposed H-DNN Algorithm with the ANN and the DT algorithms for the Animal dataset. **Table 5** illustrates the result comparison of the proposed H-DNN Algorithm with the ANN and the DT algorithms for the Plant dataset.

Table 6 illustrates the Experimental results for the Human dataset. **Table 7** illustrates the Experimental results for the Arabidopsis datasets. **Table 8** illustrates the Experimental results for the Virus datasets.

By analyzing the results, we observed that the ANN gives better results and gives a good True Positive Ratio (TPR) with 2 epochs and up to IR 1:2000. If the model is trained further for more epochs, then we are getting an over-fitted model. The time required is also in milliseconds which is very optimal whereas the existing system takes hours to train one epoch. Furthermore, when the model needs to be trained with IR up to 1:5000 Decision Tree Classifier gives better results with good TPR. But when we integrate both the DT and

the ANN we get a better result for almost all the IRs up to 1:5000 as compared to the performance gained by DT and ANN separately.

CONCLUSION

The production of imbalanced data in large quantities in Bioinformatics provides a great scope for work in the AI world. These kinds of problems require modern solutions for which many questions will arise that have to be justified and have to satisfy all the complex conditions too. One such problem is the classification of these miRNA sequences which are very few in genome data and are similar to other RNA structures. The miRNA seems to help detect and diagnose cancer disease. Hence classifying this miRNA is a big challenge that has to be faced. So, a novel solution is required with minimal complexity that provides better results in terms of the TPR, time, and accurate classification of miRNA from the imbalanced genome dataset. In this paper, we have proposed a Hybrid Neural Network model in which we have integrated Deep ANN and Deep Decision Tree

Classifiers. The Deep ANN gives better results when compared with the existing result and good TPR with 2 epochs and up to IR 1:2000. Furthermore, when the model needs to be trained with IR up to 1:5000, Deep Decision Tree Classifier gives better results with good TPR than ANN. When we integrate both Deep ANN and Deep DT we get better performance as compared to both taken individually. In our future work, we would like to further extend by increasing the IR and reducing the time of convergence. We would also like to check the performance of the proposed model on other large genome datasets. The main aim is that the model should not follow any sort of sampling techniques and predict the miRNAs with good TPR.

Cervical malignant growth is the fourth most typical reason for disease demise in women around the globe. Cervical cancer growth is related to human papillomavirus (HPV) contamination. Early screening made cervical cancer a preventable disease that results in minimizing the global burden of cervical cancer. In developing countries, women do not approach sufficient screening programs because of the costly procedures to undergo examination regularly, scarce awareness, and lack of access to the medical center. In this manner, the expectation of the individual patient's risk becomes very high. There are many risk factors relevant to malignant cervical formation. This paper proposes an approach named *CervDetect* that uses machine learning algorithms to evaluate the risk elements of malignant cervical formation. *CervDetect* uses Pearson correlation between input variables as well as with the output variable to pre-process the data. *CervDetect* uses the random forest (RF) feature selection technique to select significant features. Finally, *CervDetect* uses a hybrid approach by combining RF and shallow neural networks to detect Cervical Cancer. Results show that *CervDetect* accurately predicts cervical cancer, outperforms the state-of-the-art studies, and achieved an accuracy of 93.6%, mean squared error (MSE) error of 0.07111, false-positive rate (FPR) of 6.4%, and false-negative rate (FNR) of 100%.

1. INTRODUCTION

Machine learning (ML) and deep learning (DL) are being utilized for brain tumor detection, cervical cancer detection, breast cancer detection, COVID detection, physical activity recognition, thermal sensation detection, and cognitive health assessment of dementia individuals (1–3, 3–10). Advancements in Health Care Industry makes it more effective than traditional diagnosing techniques (11–14). According to medical reports published by Global cancer statistics (15) every year, 493,000 cervical malignancy patients have been added, among which 15% are female malignancy patients. This disease is mainly found in developing countries (16) with an 83% death ratio. Prominent in African countries (17) e.g., Uganda, which ranks fourteenth among the highest incidence of cervical malignancies with 65% of confirmed cases (18).

Human papillomavirus (HPV) contamination is mainly caused by cervical malignancy. HPV contamination is sexually transmitted. Sexual behavior associated with age at first sexual contact and the sexual activity of the accomplice is linked to the increased risk of HPV acquisition. Throughout this case, the cervical malignancy is profoundly preventable through accessible screening and detection than other different sorts of malignancy, and it is critical to actualizing

risk expectations. The malignant cervical formation is a malignant tumor. Cervical tissue cells expand and replicate abnormally without regulated cell division and death cause. If the tumor becomes malignant, the cell travels to other areas of the body, such that certain sections become subsequently infected and, in most serious situations, may be avoided through early identification (19). Deaths due to cervical malignancies can be reduced if effective screening strategies are implemented (20). With the fast advancement of present-day clinical innovation and computer technological innovation, various screening and diagnostic strategies depend on computer-aided (CAD) architectures.

A procedure of retrieving applicable information from information sources is known as data mining (21, 22). Real-world information comprises grimy information, for example, inaccurate and incomplete. Along these lines, cleaning and changing crude information to permit a reliable analytic delivery can accurately reflect the outcome (23, 24). It is implemented on the dataset. The cervical cancer dataset acquired for examination contains redundancy, missing values, and noise. Mining methods are considered one of the greatest challenges and significant fields of study in medicine due to the growing importance of health issues (25). The data mining framework can advance the cervical cancer screening process with the help of the knowledge it extracts (26). Across the medical sector, these techniques are helpful not just in finding similarities and correlations between such symptoms but also in predicting diseases. By applying several data mining techniques, continuous research and medical treatment can be immediately recommended, resulting in life-saving, especially for cervical cancer. The first step is pre-processing 80% of information, which plays a vital role as a round of all data mining operations (27).

The random forest (RF) is used to identify essential features in our research that improve the training dataset's quality. RF constructs a forest of tree classifications in which each tree grows on a bootstrap sample data, and the characteristics of every other tree node are selected from a random subset of all characteristics. The final level of the entity is measured by voting across all trees in the forest. Several significant benefits to an RF method makes it the perfect methodology for studying particular biological data in pharmacogenomics research findings. Next, it can accommodate a wide range of both qualitative and quantitative input vectors. Second, it tests the attribute's importance in estimating the type, thereby providing a benchmark for selecting features. Third, RF generates an accurate classifier for unbiased internal generalized analysis during the forest growth process. Finally, RF is relatively stable in the face of etiological variability, and a reasonably low amount of missed data (28).

This article makes the following contributions:

- *CervDetect* implements ML algorithms on the medical data to gain a deeper understanding and to evaluate the risk elements of malignant cervical formation.
- Utilizes Pearson correlation between input variables and the output variable to pre-process the data.
- *CervDetect* uses the RF feature selection technique to select significant features.
- Proposes a Hybrid approach by combining RF and shallow neural network to detect cervical cancer.
- Effectively enhance the detection rate in comparison with state-of-the-art studies.

The rest of the part is arranged as follows. Section 2 presents the literature review. Section 3 presents the dataset and preliminaries. Section 4 presents the proposed methodology. Section 5 examines the result and discussion. Finally, section 6 presents the conclusion and future work.

2. LITERATURE REVIEW

In earlier studies, various methodologies based on traditional ML approaches, including k-nearest neighbors (KNN) and K-means clustering and RF, have been utilized for cervical cancer diagnosis (29–31). In 2017, WEN WU1 and HAO developed a clinical decision support network for malignant formation, using a knowledge-based method in conjunction with a rough collection of hypotheses hereditary genetic algorithms calculations in a soft computing model (32). Parallelism, self-learning, and sensitivity to internal failure are artificial neural network (ANN) characteristics. The suggested paradigm takes advantage of these characteristics. Although the information processing capabilities of the rough set theory, and the robust, parallel, and vigorous search are characteristics of the GA's. It still faces high computation problems.

Ashok, Dr. P. Aruna (33) discussed various methods of ML, including support vector machines (SVM), gray level concurrence matrix (GLCM), KNN, convolutional neural networks (CNN), spatial fuzzy cluster algorithms, RF, C5.0, and hierarchical cluster algorithm for feature extraction, segmentation, cell classification, and evaluated in typical parameters, such as dataset volume, disadvantages, and precision. Although it is only best suited for small datasets. Chih-Jen Tseng and Chi-Jie Lu (34) have used image processing, data extraction, and ML techniques to diagnose cervical cancer. The combination of texture and shape features is extracted from each image. Optimal properties are chosen to select reciprocal information, sequential forward selection, and random section selection. Images of cervical cancer are classified using the SVM. Various selection methods are contrasted to determine the proper mechanism suitable for the diagnosis of cervical cancer. The problem faced by SVM is that there is no probabilistic explanation for classification, which leads to very rigid classifications.

In 2006, Reif et al. (35) described RF efficacy in various model genetic and proteomic datasets. RF progress fails to classify related traits based on genetic data and proteomics datasets. Experimental findings indicate that using several data sources is useful where the disease definition is uncertain, and the corresponding data basis for the phenotypic outcome is unknown. This study's findings indicate that RF is exceptional for detecting high-dimensional data vector characteristics with minimal main effects and low heritability, but the problem faced by RF chooses only one attribute at each tree split during construction, strictly epistatic. In 2016, Vidya and Nasira (36) worked on predicting the normal cervix. The cancer cervix is

evaluated using practical data mining algorithms. Geetha and Thangamani (37) addressed the imbalanced distribution of data and risk factors for cervical cancer diagnosis.

Anuraga et al. (38) attempted to explore the conditions that affect cancer patients' survival in Makassar, Indonesia. The specimens included in this research contained as many as 38 cancer sufferers. They use the RF to identify tree merger data by combining sample data training. The main problem faced by this technique is that it only achieves 50% of accuracy. The Bandyopadhyay and Nasipuri (39) focused on K-Means clustering to segmentation pre-processed images, and Herlev analysis is carried out. IOU segmentation outcomes, verified ground truth values, and shape attributes are extracted from the segmented nucleus. The identification of the nucleus on the grounds of the shape features is carried out with the RF Classifier's aid, and the contrast is rendered with the other classifiers.

In 2020, Alyafeai and Ghouti (40) build a completely integrated cervical cancer identification and cervical cancer screening pipeline from cervical images. The current pipeline comprises two deep neural network-learning models for automated cervical identification and diagnosis of cervical tumors. The first test detects the cervix area 1,000 times faster than the state-of-the-art data-driven simulations, thus obtaining a detection precision of 0.68 in terms of union intersection (IoU) estimation. Self-extracted characteristics are used in the second model to identify cervical tumors. Such features are trained using two lightweight models focused on co-evolutionary neural networks (CNNs). William et al. (41) performed to reduce the probability of mistake by automating the diagnostic process for cervical cancer from Pap-drug photos. Local adaptive histogram equalization was used for image enhancement.

Brats data (24) is used to localize brain tumors in FLAIR scans of MRI. Bilateral flipping is applied to remove noise, while the Gabor filter bank creates text-ton map images. A superpixel is generated by segmenting out an image superpixel is generated by segmenting-level features include at each superpixel histogram level of texton-map is calculated, and the first-order intensity features are calculated as well. Their major contribution is that they made low-level features significant for the localization of brain tumors at the region level approach by integrating features from texton-map images. The prediction of three classes, namely tumor, non-tumor, and background, was made by giving these extracted features later to the classifier. A cross-validation technique leave-one-out (LOOCV) for the tumor area localization is applied to outperform the existing solution and achieve a dice score of 88%.

In 2021, Wang et al. (42) worked to solve challenges regarding physical security and over-centralized server problems in wireless medical sensor networks (WMSN). Physically unclonable function (PUF) and cutting-edge blockchain technology are combined to propose a reliable and authentic protocol for WSMN. In addition, to deal with biometric information, fuzzy extractor method has been used. For the evaluation of their proposed method, two schemes are used. Their work outperforms the existing studies by achieving higher accuracy through minimizing computation and communication costs. Similarly, Xiong et al. (43) provided a design of blockchain-based ECDSA with fault-tolerant batch verification protocol for blockchain-enabled IoMT. In 2021, Khamparia et al. (1) combined a convolutional network with a variational encoder for data classification. The dimensionality of images data can be reduced by using a variational encoder with a softmax layer with the kernel size of 2x2 and 3x3. Their architecture outperforms the current ML models. Chen et al. (11) developed Cyto Brain that facilitates in subsequent clinical diagnosis, an artificial intelligence (AI) based system. CytoBrain consists of three main modules: (1) to extract only cell images in a whole slide image efficiently, cervical cell segmentation module has been designed. (2) for the cell classification, vgg 16 is used, and a classifier module is designed; Moreover, the last one is the human-aided diagnosis module which can automatically diagnose cervical cancer based on the classification results of cells on a whole slide image.

3. DATASET AND PRELIMINARIES

The dataset[1] used has been released in The University of California's database at Irvine (UCI). The collection contained existing patient history, practices, and procedures and demographic statistics for 858 instances with 32 features per scenario. The dataset contains several missed features since others are incomplete instances, which were chosen not to tackle any privacy concerns, as privacy and security are the common issues in healthcare record frameworks (44–48). **Table 1** displays the dataset characteristics and the missed value for each function.

4. PROPOSED METHODS

Figure 1 illustrates the flow of our work in a block diagram consisting of pre-processing and classification of cervical cancer. The proposed approach consists of pre-processing and classification of cancer using ML algorithms and deep learning algorithms.

Algorithm 1 shows the working of *CervDetect*. Random samples have been collected from the input cervical cancer risk factor dataset. For each collected sample, a decision tree has been made to make a prediction. Counting has been done for each final score, and the features are ranked according to their importance. Selected features are input to the shallow neural network where x_i(i=1, 2, ... n) are the number of input features, w_{21} and w_{22} are the weights and B1 is constant. y stores the features convolved with a randomly initialized filter matrix. V store results of applying a linear transformation on y. O_1 stores the output generates after applying a sigmoid function on y, and e calculates the change in error concerning weights. Infeed backward change error to the weights has been calculated with the help of the chain rule, and the weights are updated.

4.1. Data Pre-processing

The dataset regarding cervical cancer has many missed values. A missing value can imply a variety of differences. Records with

Algorithm 1 *CervDetect* Algorithm

Input: Cervical cancer risk factor dataset.

Begin with the collection of random samples from a dataset.
First, this algorithm must generate a decision tree for each sample.
The prediction will come from the decision tree.
Counting will be carried out in this stage for each final score.
Ultimately, pick the most elected outcome of the prediction as to the outcome of the prediction.
Output: Rank features with according to their importance.
Input: selected features input to shallow neural network x_i(i=1, 2, 3, 4…n)
Initialization is the first step after the configuration of the neural network
Initiate all weights w_{21}, w_{22} with a random number from the usual distribution, i.e. N (0, 1).
Put all of the bias nodes B1 = B2 = 1.0.
Feedforward
for $I \in l$ **do**
  each of x input have weights w21, w22 …
  y=$w_{21}\ x_1$, $w_2 2\ x_2$, …,$w_m\ x_i$,
  v= sigmoid(y)
  $o_1 = y_{v1}\ w_{21}$
  $o_v = o_1$
  e=$\frac{1}{n}\sum_{i=1}^{2}$ (y_i-ovi)^2
end for
Feed backward
for $i \in k < l$ **do**
  Partial derivative of the e to the weight adjusted w_i^{k+1} w_{ik}-Δ /(φw_{k^i})
  weight update e_i=e_i Δ+w_i^{k+1}
end for

missed values could be included, omitted, or the mean of the variable can be replaced for missing numerical characteristics or with the most frequent value in the case of categorical features. The technique of eliminating the amount of data with missing rows of values decreased from 858 to 737 when applied. We aim to scale the number of features but not the number of input vectors used in the dataset. The following steps are included to pre-process data and make it suitable input for the classifier.

1. Nan: To see relations between variables to treat Nan. Nevertheless, according to the data, the scale of more than 100 Nan values may impact results. We fill features with a median value of less than 100 Nan values in them with median values.
2. Hormonal contraception: There are so many Nan values during the data diagnosis information. Because of this, we cannot calculate the impact of this information, and must eliminate them. Instead, using the Pearson correlation, we will decide which attribute influences hormonal contraceptives. We fill Nan values with correlated attributes according to the resultant heat map. If the patient is older than the mean sample or the amount of pregnancy is less than the mean, the patient may take hormonal contraceptives. Nan values in HC (years) fill with median values using HC attributes.
3. IUD: Using the Pearson correlation, we can decide which attribute is the "IUD" influencer. Age and amount of maternity factors have an impact on the IUD feature. This indicates that 80% of patients taking IUD are older than the average age. 70% of patients who do not take IUD have fewer births than the mean amount of pregnancies. We can fill in the remaining Nan IUD feature values. With the IUD (years) rule, we can fill the -1 values with the IUD rule. If the patient takes IUD, then the UID (years) will be non-zero, so we need to adjust it to mean values.
4. STDs: condylomatosis and STDs: vulvo-perineal condylomatosis has the "STD" effect. We never consider "STD (number)" and "STDs: number of diagnoses" as they are the same attributes as "STDs." Based on our analysis of STDs,

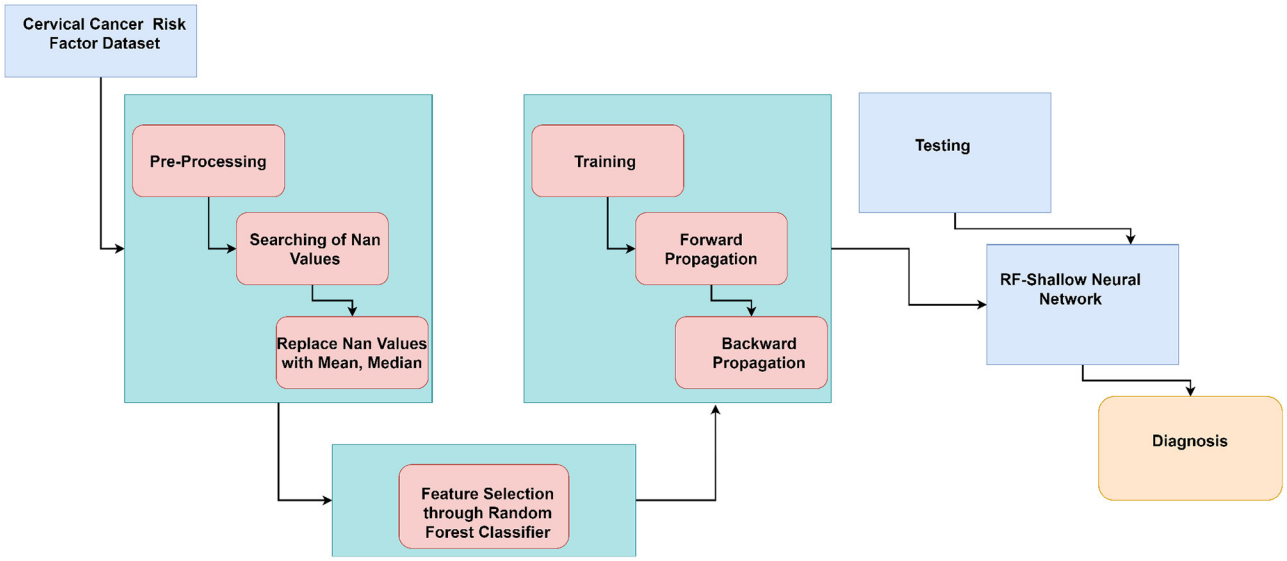

FIGURE 1 | Block diagram of proposed work flow.

we can conveniently fill the Nan values of 1 or zero, and if the individual has either of the STDs, then, the STDs should be 1, the other one will be 0.

5. STD diseases: According to information, 73% of non-smoking patients have STD. We do not have Nan values 75% of patients who do not take IUD are even STDs. Even STDs (number) are the same attribute as STDs. The median case is not helpful because we use mean values for replacement. As per the heat map and our domain awareness, all STD diseases rely on the STDs function and STD (number). We fill Nan values using median for specific values since all STDs rely on certain STDs, and we cannot be assured of a person's disease.
6. AIDS: The correlation function does not give us any hints. However, we recognize that AIDS is also a condition of STDs. So, we fill in the Nan values.
7. STDs-Hepatitis B: This aspect is the result of the STDs-HIV factor. Here we have one patient with a disease, and this importance is negligible compared to the population. The value of Nan is filled with 0.
8. STDs-HPV: The positive values of HPV are not enough. Zero values cannot be determined by using significant attributes, and we filled the value of Nan with 0.
9. STDs-time after the first diagnosis and STDs-time after the last diagnosis: When the patient's STDs are negative, the first and last diagnoses cannot be positive. This assumption fills the Nan values in these attributes. **Figure 2** illustrates the Pearson correlation between attributes in the cervical cancer risk factor dataset after handling missing values.

4.2. Random Forest

The RF model utilizes a sequence of decision trees, where each tree in the forest has been trained using a bootstrap sample of data items, so each tree splitting attribute is picked from a random subset of features. The categorization of patterns shall be based on the collective vote of all trees in the forest. Attribute importance is measured as the decreases in the node's impurity, weighted by the likelihood of approaching the node. The likelihood of the node can be determined by the number of instances that enter the node, separated by the total number of instances. The greater the value, the more important the characteristic is. In Scikit-learn Decision tree, approximates the value of the nodes using Gini significance, considering just two child nodes (binary tree):

$$nodei_{j=} Weight_j C_j - W_{l(j)} C_{l(j)} - W_{r(j)} C_{r(j)} \quad (1)$$

In Equation (1), $nodei_j$= Importance of j node; $Weight_j$= Weighted samples that reach at node j; C_j = Impurity of jth node; l(j)= From left split child node on jth node; r(j)= From right split child node on jth node. Each feature importance calculated at decision tree is given by Equation (2):

$$featureimportancei_i = \frac{\sum j\, n_{i(j)}}{\sum kn_{ik}} \quad (2)$$

Where, $\sum$j= splitting of a feature I at node j; $n_{i,j}$= node j importance; $\sum$k= all nodes. In Equation (3), normalizing these values between 0 and 1 is done by taking the sum of all feature's importance values and then dividing them.

$$normalizedfi_i = \frac{fi_{i(feature\ importance)}}{\sum j\, fi_j(all\ features\ )} \quad (3)$$

In Equation (4) at the RF stage, the final feature of importance is the sum, including all trees. Estimating an attribute's significance at each tree is calculated and divided by the overall tree species.

$$Random\ forestfi_i \frac{\sum j\ normalizedfi_{ij}}{T} \quad (4)$$

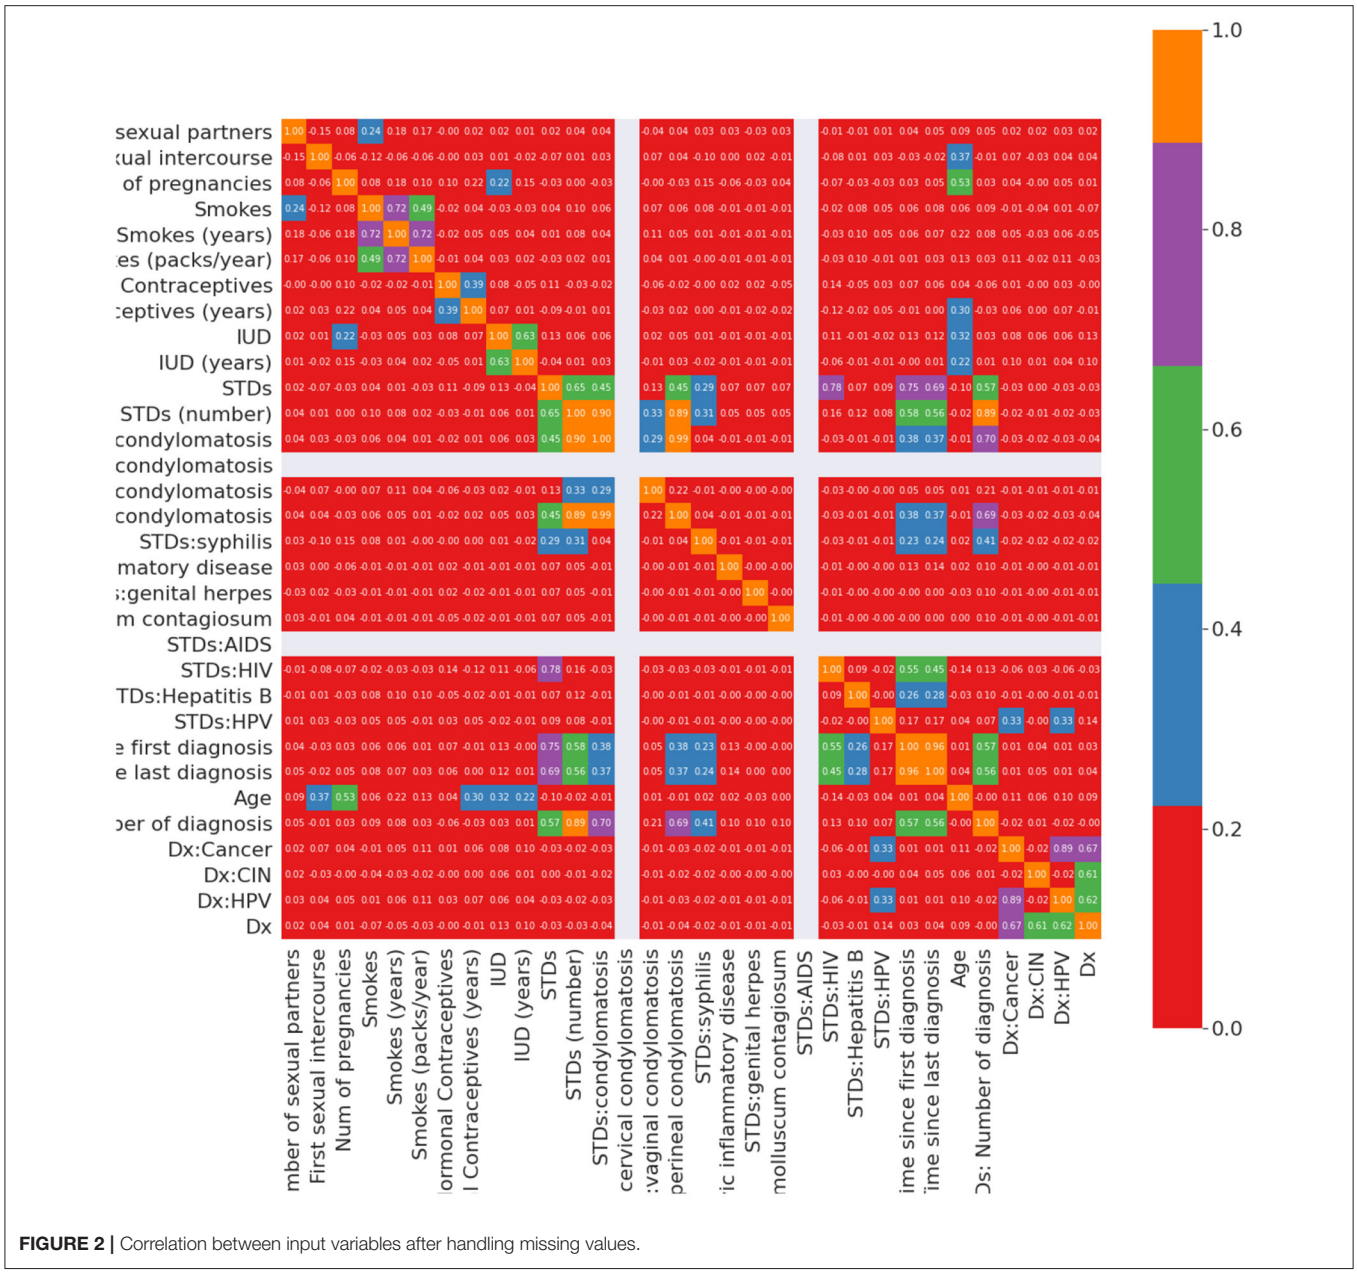

FIGURE 2 | Correlation between input variables after handling missing values.

Normalized $fi_{i,j}$ is the normalized feature importance for I feature at jth tree, and T is the total number of trees in the forest. **Figure 3** illustrates the feature importance graph that improves the quality of the training dataset.

4.3. Artificial Neural Networks

Artificial neural network models are influenced by the human brain structure, which interconnects many biological neurons that are important for maintaining coherent communication. The ANN architecture is computer-based and consists of a variety of simple parallel processing units (49). It is a common statistical technique that can analyze exact relationships between variables. There are several parallel layers in the ANN models, and each layer consists of several neurons. Input, hidden, and output layers are three different types of layers. No calculations are conducted on the input layer. Only feature variables are input. The hidden layer is the key part of the ANN and includes different neurons commonly detected by checking and error. The linear and non-linear functions for the hidden layer neurons are required. The first stage is where the hidden layer neurons receive the input variables compounded by the corresponding correlations (weights), and the second cycle is followed by a non-linear induction system, usually a sigmoid. A fully connected ANN consists of neurons. The neurons are split into layers composed of one input layer, one output layer, and numerous hidden layers with the contribution of each layer in the next

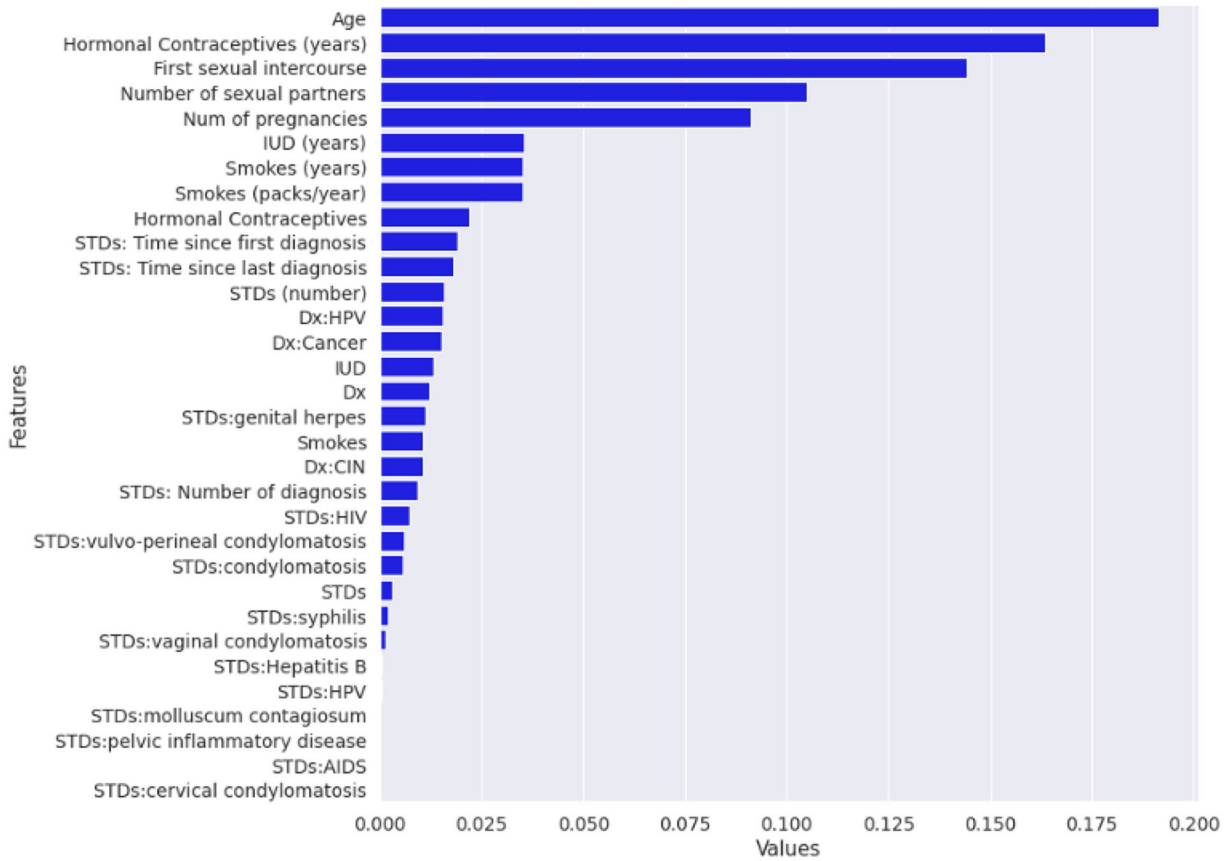

FIGURE 3 | Graph plotted after applying random forest (RF) algorithm for feature importance.

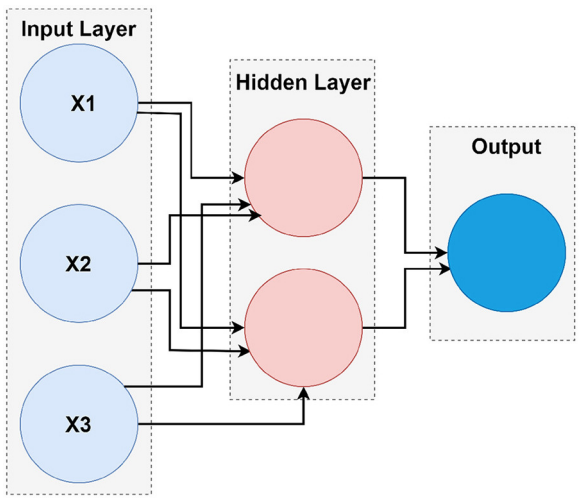

FIGURE 4 | The architecture of shallow neural network.

layer as an input in our research, and we concentrate on neural networks with only one layer of hidden data, hidden neurons, and a single output.

4.4. Shallow Neural Network Architecture

Different types of neural networks, both shallow and deep, have been built. The terms "shallow" and "deep" refer to the neural network with a minimum number of layers typically known to have a common hidden layer. Deep neural nets are used by neural networks that contain several deep layers. These types of networks execute various tasks, and the fundamental framework of shallow networks enables them to do so. Almost all shallow networks had an input layer, a single hidden layer, and an output layer. The number of hidden nodes in the layer is the only different hyper-parameter. Networks use online learning instead of batch learning, which uses simple backpropagation and gradient descent. Besides, a scaled conjugate gradient descent (SCG) backpropagation algorithm was used in shallow networks. **Figure 4** is the fundamental model for shallow neural networks.

The neurons are the atomic component of the neural network. For input data, the output is defined as well as the output is passed to the next layer as an input vector. A neuron may be thought of as a fusion of different segments:

1. The first section calculates the output Y, using input parameters and weights.
2. The second section executes the activation on Y to give the final performance of neuron A.

The hidden layer consists of several neurons, which each executes below mentioned 5 and 6 equations. Those two neurons found in the hidden layer of the external neural network are evaluated as follows:

$$Y_1^{[1]} = w_1^{[1]}Tz + b_1^{[1]}, a_1^{[1]} = \sigma\left(y_1^{[1]}\right) \quad (5)$$

$$Y_2^{[1]} = w_2^{[1]}Tz + b_2^{[1]}, a_2^{[1]} = \sigma\left(y_2^{[1]}\right) \quad (6)$$

Where the superscript number [i] is the number of the layer, and the subscription number j is the number of the neurons in a particular layer. Y is an input vector made up of three components.

W_i represents the weights connected to each input variable, and bi represents the bias factor connected to each line, hidden line, and output layer. Z[i]j is just the intermediate output associated with the j neurons found in the ith layer. A[i]j is the final output associated with the neuron j in the ith layer.

TABLE 2 | Confusion matrix of *CervDetect*.

Predicted class /Actual class	Biopsy	Normal
Biopsy	TP	FN
Normal	FP	TN

TABLE 3 | Selected optimal features.

Serial no	Important features according to their rank
1	"Age"
2	"Hormonal Contraceptives (years)"
3	"First sexual intercourse"
4	"Num of pregnancies"
5	"IUD (years)"
6	"Smokes (years)"
7	"Smokes (packs/year)"
8	"Hormonal Contraceptives"
9	"STDs: Time since first diagnosis"
10	"STDs: Time since last diagnosis"

Sigma is a function of activation that squashes the input value into the range of (0,1). Mathematically, this is described as in Equation (7):

$$\sigma = \frac{1}{1 + e^{-yi}} \quad (7)$$

Equation (8) represents all Z intermediate outputs in a single multiplication matrix.

$$Z^1 = X^{[1]T}X + b^1 \quad (8)$$

$$A_1^{[1]} = \sigma(Z^1) \quad (9)$$

The above Equation (9) represents all activation A in a single multiplication matrix.

To calculate the output for an input vector y, the following steps are performed as mentioned in below (10), (11), (12), and (13) equations. These steps can also be called feed-forward propagation.

$$Z^1 = W^{[1]T}Y + b^1 \quad (10)$$

$$A_1^{[1]} = \sigma(Z^1) \quad (11)$$

$$Z^2 = W^{[2]T}A^1 + b^2 \quad (12)$$

$$Z^{final} = A^{[2]} = \sigma(Z^2) \quad (13)$$

Where the Equation (10) measures the Z (18) intermediate output of the first hidden layer. The Equation (11) is used to measure the final production A (18) of the first hidden layer. The Equation (12) calculates the Z intermediate value of a processing layer Z. The Equation (13) calculates the end product A of the

TABLE 4 | Accuracy table.

serial no	Performance measures	Performance%
1	Accuracy	93.6%
2	TPR	100%
3	FPR	100%

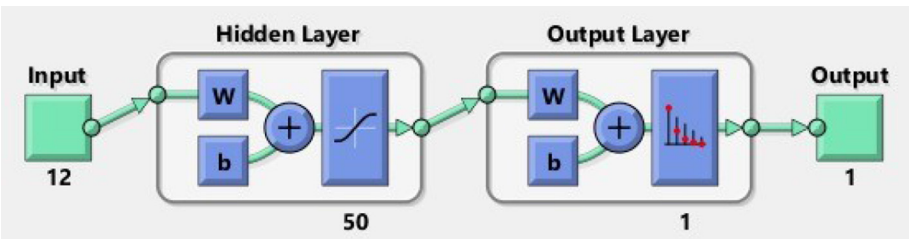

FIGURE 5 | Shallow neural network.

output layer, which is now the result of the whole neural network. When the results are obtained from each neuron's hidden layer, they are transferred to the next layer, where each neuron in the output layer finalizes the values.

$$Y_1^{[2]} = w_1^{[2]} out\,(y_1) + w_2^{[2]} out\,(y_2) + .. + w_{14}^{[2]} out(y_{14}) + b_2^{[2]} \quad (14)$$

$$a_1^{[2]} = \sigma\left(Y_1^{[2]}\right) \quad (15)$$

$$Y_{15}^{[2]} = w_{30}^{[2]} out\,(y_1) + w_{31}^{[2]} out\,(y_2) + .. + w_{43}^{[2]} out(y_{15}) + b_2^{[2]} \quad (16)$$

$$a_{50}^{[2]} = \sigma\left(Y_{50}^{[2]}\right) \quad (17)$$

Equations (14– 17) are used to determined the error after the results are obtained for each neuron in the output layer. When this is the critical error, it will avoid back-propagating to change the previous weights to get the minimal error in the feed-forward process.

5. RESULTS AND DISCUSSION

In our work, the most significant performance measure for cervical cancer diagnosis accuracy is used to calculate the RF-shallow neural network's performance. The true positive (TP) is identical to those rejected, representing the number of cancer patients marked as Biopsy. False-positive (FP) is the inverse to deny wrongly and represents normal patients as cancer patients. The true negative (TN) is equal to those correctly identified, representing the number of normal patients identified as normal. False-negative (FN) is equal to any incorrectly identified, representing the number of cancer patients identified as normal patients. **Table 2** shows the confusion matrix.

Accuracy: the proportion of the number of patient records correctly categorized against the overall number of patient records in the dataset as shown in Equation (18).

$$AC = \frac{TP + TN}{Tp + TN + FP + FN} \quad (18)$$

True positive ratio (TPR): it is identical to detection rate (DR). TPR indicates the proportion of the number of patient records

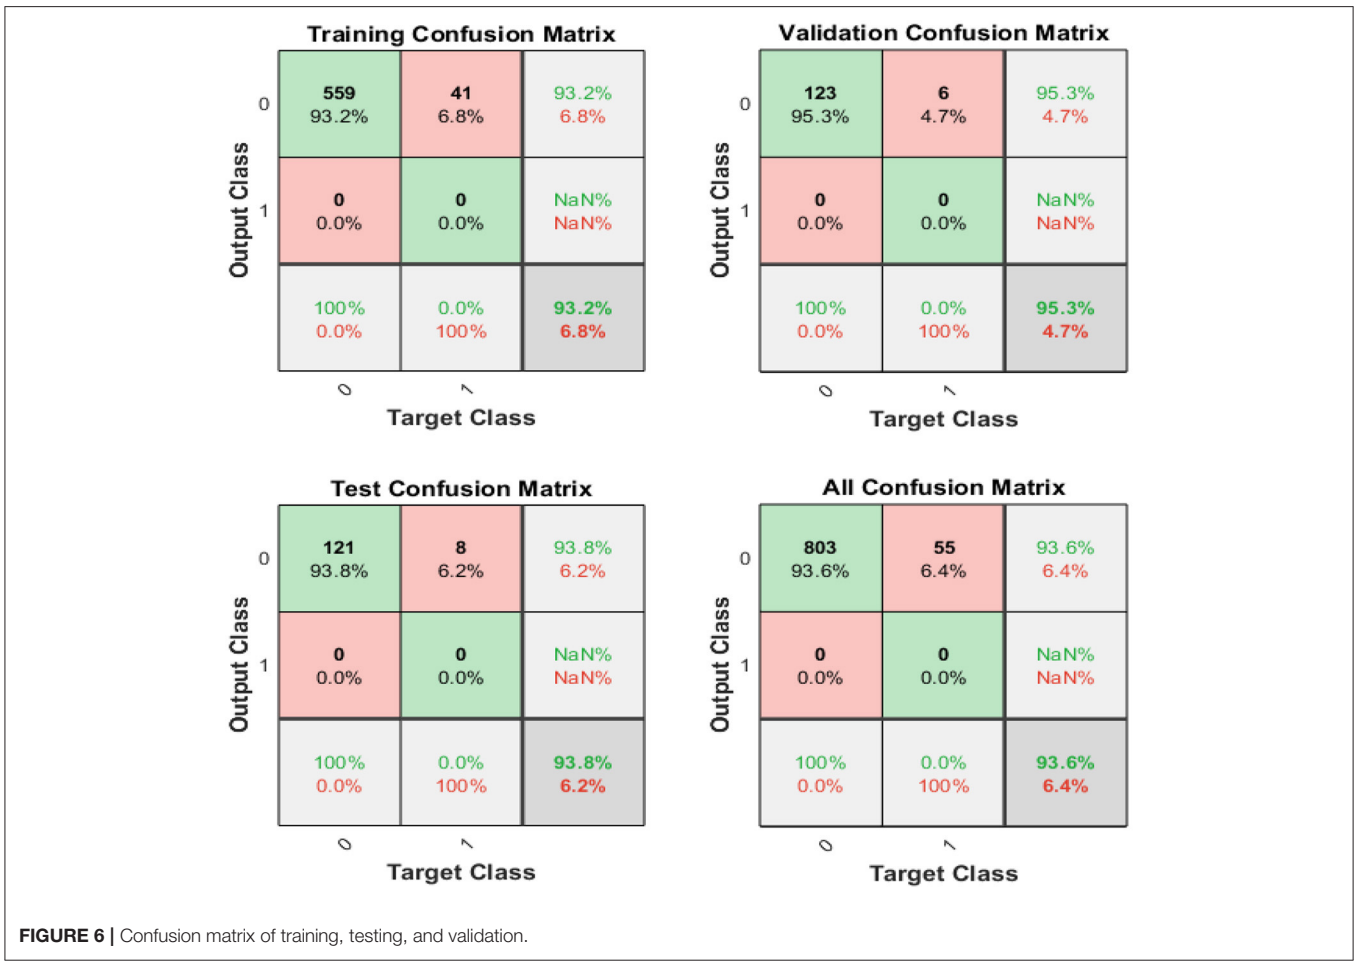

FIGURE 6 | Confusion matrix of training, testing, and validation.

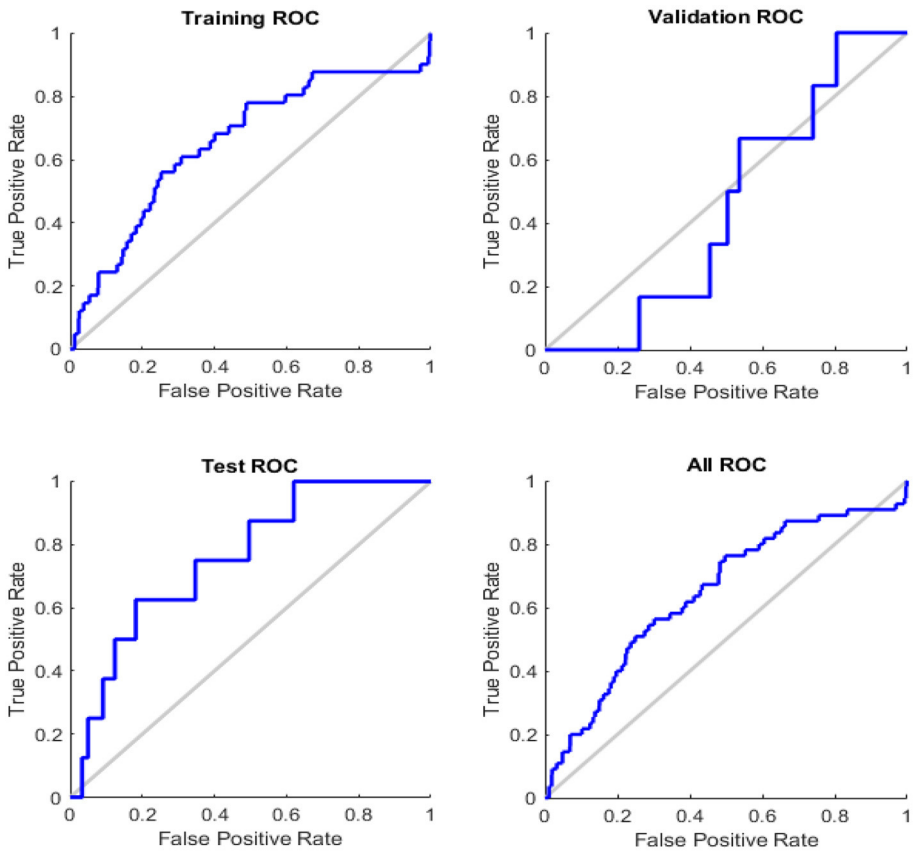

FIGURE 7 | Roc curve of testing, training, and validation.

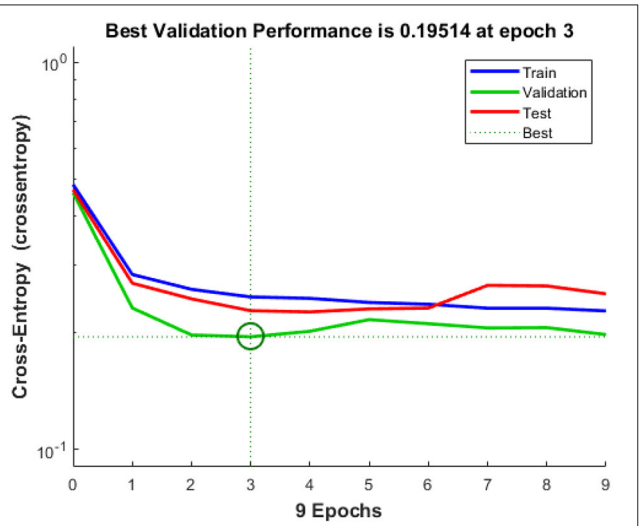

FIGURE 8 | Cross entropy.

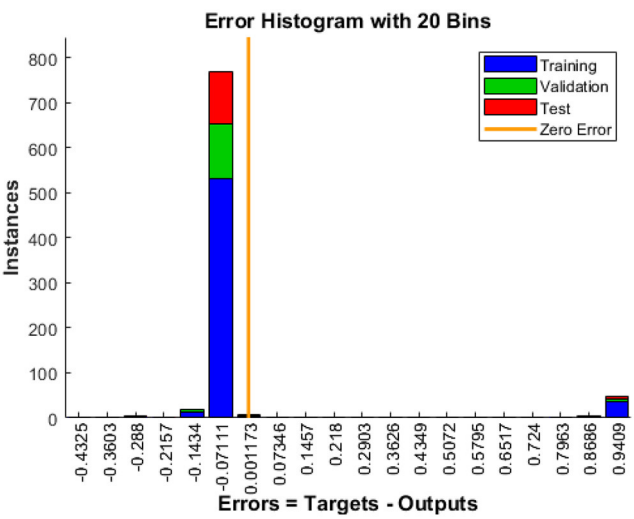

FIGURE 9 | Error histogram.

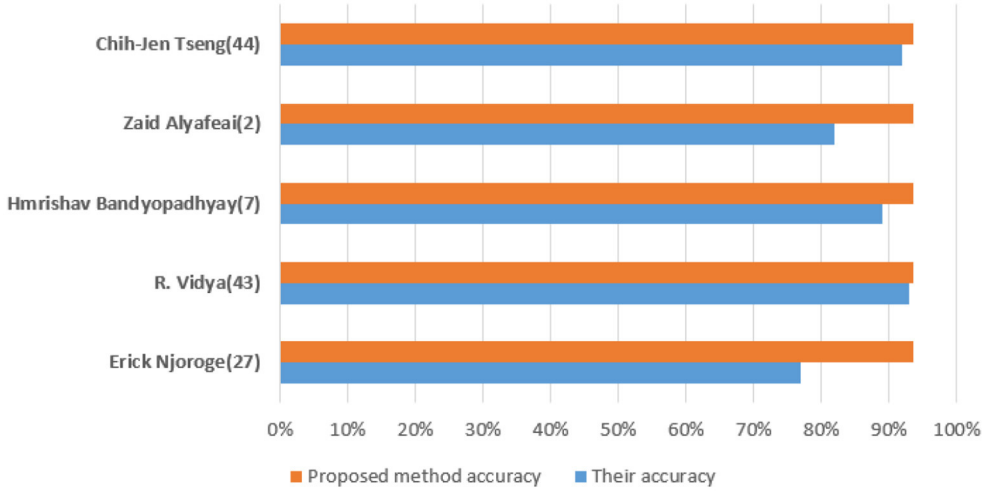

FIGURE 10 | Comparative analysis with existing works.

correctly identified over the overall patient records, as shown in Equation (19).

$$TPR = \frac{TP}{TP + FN} \tag{19}$$

False positive ratio (FPR): the ratio of the numbers of incorrectly declined records divided by the cumulative amount of total record as shown in Equation (20)

$$FPR = \frac{FP}{FP + TN} \tag{20}$$

In this study, we have proposed a new method called RF-shallow neural network to diagnose cervical cancer as the effect of the wrong diagnosis in cervical cancer or vice versa is high. Data mining provides tools and techniques to derive important data from a huge dataset by analysis. Throughout this study, ML models (RF and shallow neural network) were used for cervical cancer diagnostics to demonstrate the importance of building the model with data cleaning, the replacement of null values, and the implementation of a feature selection procedure to achieve a better accuracy prediction for an optimal function subset. This methodology used ML methodologies for cervical cancer data to assess the efficacy of classifier models by considering all medical records. Dataset missing records are filled by replacing missing values in rows with their mean and median by finding the Pearson correlation between variables. The RF's implementation as a feature selection technique and the shallow neural network training by an optimum subset of features was chosen based on the variables' value. In addition to the one target attribute biopsy for cervical cancer diagnosis, the following attributes in **Table 3** have been defined as more important features among the cervical cancer risk factors dataset.

A shallow neural network consists of one input layer, one layer of hidden neurons, and a single output layer, as shown in **Figure 5**. Neural pattern recognition uses the scaled conjugate gradient algorithm. The value of one class, "0," is treated as a negative test for a cervical cancer patient, and the value of another class, "1," is considered a positive measure for a cervical cancer patient and recommended for biopsy.

A total of 12 optimum features input space has been created after their importance and ranking. We took 70% of the data from 859 records for training, 15% for validation, and 15% for testing. To obtain the results, we used 50 hidden neurons and 1 epoch. **Table 4** shows the findings we obtained from ANN using scaled conjugate gradient using minimized cross-entropy, correct true positive rate, false-positive rate, and accuracy.

Figure 6 displays the confusion matrixes for validation, testing, and training, and the three pieces of information merged. The network findings are promising because we can conclude with many correct responses in green squares and a minimal number of wrong responses in red squares. The lower squares indicate the actual precision.

Figure 7 illustrates the receiver operating feature (ROC) curve. The colored lines in each axis represent the curves of a ROC. The ROC curve is a graphical representation of a true positive (sensitivity) vs. the false positive (1-specificity) in which the threshold has been changed. The optimal search has shown points in the upper left corner with 93% accuracy.

There have been several lines, train, validation, testing, and best in this study, as shown in **Figure 8**. In general, the ideal (dotted) line is that the other will lie on or above this (dotted) line, and we can conclude that the training has been carried out effectively. If all of the 3 (training, validation, and testing) lines cross or travel past the ideal (dotted) path, this implies that convergence has been completed. If this is not the case, retrain the network.

When the model is tested for more than 129 tests, the histogram displayed in **Figure 9** shows the error that occurs during the test process. The distribution of the error size of the histogram shows how well the neural network matches the

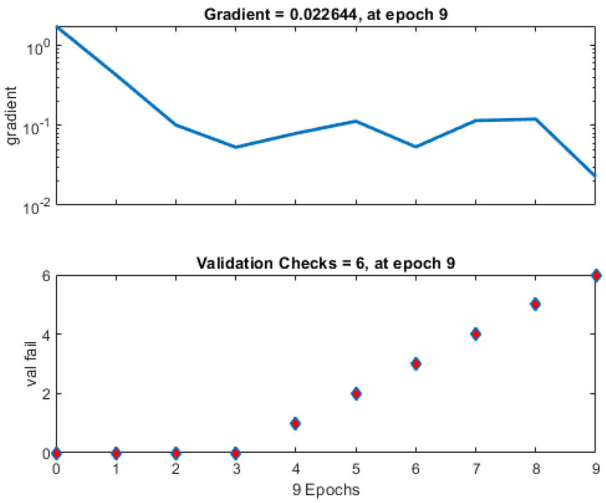

FIGURE 11 | Training state of neural network for cervical cancer diagnosis.

results. It indicates errors that the solution to mean squared error (MSE) in our scenario is good. More than 500 events are utilized for training purposes. Approximately, 129 are used for validation, and the remaining 129 is used to check which indicates an error of 0.07111.

Figure 10 shows a training state that represents the actual progress/state of the training at a given period when the training is in progress. In our situation, 6 validation errors are stated, i.e., unless 6 validation tests are performed, then training will end. Validation test error implies that the dataset has specific issues; a training algorithm cannot recognize certain instances. This indicates that due to dataset issues, validation test errors may be produced. In our case, 6 validity tests are included. As shown in **Figure 11**, modified *CervDetect* achieved 93.6% that outperforms the existing work.

6. CONCLUSION AND FUTURE WORK

This study provides a risk factor for cervical cancer. The cure percentage, the number of female cases recovered from cancer may be improved by recognizing risk factors for cervical cancer. Data mining techniques in the medical industry have an immense capacity to develop diagnostic and prognosis indicator applications that can aid in the proper initial treatment of life-threatening diseases. With various data mining techniques, it is important to enhance the standard of care in hospitals and maximize patients' recovery rates. The outcomes of the data reduction also continued to increase the efficiency of the methods. Generally, the less critical features used in the classification process, the stronger the external neural network's efficiency. In this article, we present *CervDetect*, a hybrid approach that combines RF and shallow neural network to understand the risk elements of malignant cervical formation by deploying machine learning algorithms on medical data. *CervDetect* utilizes Pearson correlation between input variables and the output variable to pre-process the data. The RF feature selection technique is used to select significant features. *CervDetect* effectively enhances the detection rate in comparison with state-of-the-art studies. Results show that the proposed approach achieved an accuracy of 93.6%, MSE error of 0.07111, FPR of 6.4%, and FNR of 100%. For future work, applying a sequential model to this dataset, such as a recursive deep neural network, can be useful for diagnosis. Due to the severity of the disease, cervical cancer is chosen as a starting point. The same work delineated here could be extended to other gynecological cancer predictions and other disease entities. Thus, the provided approach *CervDetect* showed optimal performance accuracy with the optimum features dataset.

Since its emergence in December 2019, there have been numerous posts and news regarding the COVID-19 pandemic in social media, traditional print, and electronic media. These sources have information from both trusted and non-trusted medical sources. Furthermore, the news from these media are spread rapidly. Spreading a piece of deceptive information may lead to anxiety, unwanted exposure to medical remedies, tricks for digital marketing, and may lead to deadly factors. Therefore, a model for detecting fake news from the news pool is essential. In this work, the dataset which is a fusion of news related to COVID-19 that has been sourced from data from several social media and news sources is used for classification. In the first step, preprocessing is performed on the dataset to remove unwanted text, then tokenization is carried out to extract the tokens from the raw text data collected from various sources. Later, feature selection is performed to avoid the computational overhead incurred in processing all the features in the dataset. The linguistic and sentiment features are extracted for further processing. Finally, several state-of-the-art machine learning algorithms are trained to classify the COVID-19-related dataset. These algorithms are then evaluated using various metrics. The results show that the random forest classifier outperforms the other classifiers with an accuracy of 88.50%.

1. INTRODUCTION

Reports about the novel coronavirus' (COVID-19) origin in Wuhan city in Hubei province, China came into the limelight in December 2019. Since then, the virus has spread in several provinces in China, and gradually to the majority of countries across the globe. Millions of people have been affected globally by this virus leading to the deaths of hundreds of thousands of people across the globe especially in countries like Italy, Spain, the United States, India, Brazil, and Russia as of June 2020 (1–3). This led the World Health Organization to declare COVID-19 as a pandemic in March 2020 (4, 5). It is estimated that on average, each person infected by COVID-19 infects around 2.5 persons if everyone goes on with their normal lives. Thus, the initial person infected may lead to 406 further infections per month. Hence, many nations have implemented lockdowns and social distancing to reduce the spread of COVID-19 (6).

Social media is flooded with millions of posts about COVID-19. Even though some of the information in social media is genuine and informative, most of the information spread in social media about COVID-19 is potentially rumor. Several doctored videos and photos about origin,

spread of the virus, vaccines, and deaths caused by COVID-19 are being shared over social media. It is estimated that around 30–35% of the news, videos, and photos spread on social media platforms are fake. This fake news travels faster than the virus itself creating widespread panic (7).

According to the International Fact Checking Network's (IFCN) study between January and April 2020, the fake news spread on social media can be categorized as follows: content about symptoms, causes, and cures, government documents, spread of the virus, misrepresentation of videos and photos, comments of politicians, and conspiracies that blame particular groups, countries, or communities for the spread of the virus. The fake news spread on social media has led to economic crisis in some countries. For instance, in some countries people stopped consuming non-vegetarian food as fake news was spread that animals and birds could be infected with COVID-19 and consuming non-vegetarian food may spread the virus in people. This had a severe impact on the sales of non-vegetarian food in some countries affecting the livelihood of many people (8). **Figure 1** depicts the application of machine learning (ML) algorithms (9, 10) to detect fake news spread on social media.

In view of the serious impacts of the spreading of fake news which affects the privacy and security (11, 12) of users, the need of the hour is to design a successful mechanism to detect/predict fake news. In this work, an attempt is made to classify the fake news regarding COVID-19. The dataset used in this work is a fusion of fake and real news collected from several social media platforms and websites (13). This dataset is then subjected to preprocessing to remove some irrelevant text such as URL punctuations and noisy data, etc. Then, the resultant text is split into several small words using tokenization. Then, the most important features are extracted from these tokens. These features are then trained by state-of-the-art ML algorithms to classify whether the COVID-19-related news is fake or real.

The main contributions of the current work are as follows:

- Classification of a novel COVID-19 fake news dataset collected from several social media platforms.
- Generating 39 linguistic and sentiment (14–16) features from text.
- Extracting the most important features from the COVID dataset to improve the accuracy of the ML algorithms.
- An accuracy of 88.50% is achieved by the random forest classifier.

The rest of the paper is organized as follows: In section 2, related works on COVID-19 fake news are discussed. ML algorithms used in this work to classify the fake news dataset are discussed in section 3. The proposed architecture is presented in section 4. The experiment results are presented along with the discussion in section 5. Finally the paper is concluded in section 6.

2. LITERATURE SURVEY

Artificial intelligence (AI) has made a significant contribution to different aspects of the COVID-19 outbreak. A survey on various applications of AI for fighting COVID was presented in Nguyen (17). Specifically, deep learning algorithms play a vital role in empowering AI in most of the applications with larger datasets with different types of data. Some of the applications are computer-generated for predicting infected people from a large gathering through a high-resolution image. The most prominent application is in text mining assisted with natural language processing (NLP) for extracting semantically related information from numerous texts in multilingual news data collected from various social networking platforms. The details obtained from these models such as susceptible infected recovered (SIR) models can be injected into deep learning models for the prediction of COVID-19 trends of transmission and can avoid future pandemic or epidemic diseases (18). Furthermore, a mapping study on various AI models with big data for detecting fake news on social media was carried out in Meneses Silva et al. (19). They suggested that the long short term memory model provides better results than other algorithms but incurs more processing power.

Although social media is the platform that spreads news faster with low cost than any other media among all age groups, it is progressively more dangerous in spreading fake news. Many research projects were conducted on detecting fake news from social media. A two-step model for detecting fake news from the real story in social media using artificially intelligent algorithms was designed (20). Three real datasets were considered for the study. The dataset with unstructured data was preprocessed to obtain meaningful data and was represented using vectors. In turn, the results were generated for 23 supervised learning algorithms and compared based on four evaluation metrics. On the other hand, a biostatistical analysis of the COVID-19 pandemic was carried out in Bandyopadhyay and Dutta (21) using the KNN classifier. They collected data based on certain information from the news topics in social media through multi-document summarization. This summarization method extracted the information based on the lexical information of the topic and social patterns. The KNN classifier predicted fake news with an accuracy of 80%.

Furthermore, the study in Groza (22) investigated the spread of deceptive information on social media through COVID Ontology. The reasoning in the natural language is converted into description logic for perceiving inconsistencies among different medical sources. The authors argue for an ontology-based approach for detecting fake news related to the coronavirus. The proposed model explores how well description logics (DLs) understand contradictions in figuring out whether they are true or false. The authors pay particular attention to translating the natural language into DL using the FRED translator, after which, justification is performed to test the performance of the prediction using the racer method. The proposed ontology model reveals misconceptions that circulate in digital news and shows accurate facts. However, potential research can be expanded by program evaluation and provides a verbal remedy for any conflict that exists.

Fake news or false information about this COVID-19 pandemic are very prominent and should be detected to avoid unwanted chaos. A FakeCovid dataset from a multilingual news article was generated, and a classifier was designed to detect the fake news from the dataset generated (23). BERT, the ML-based

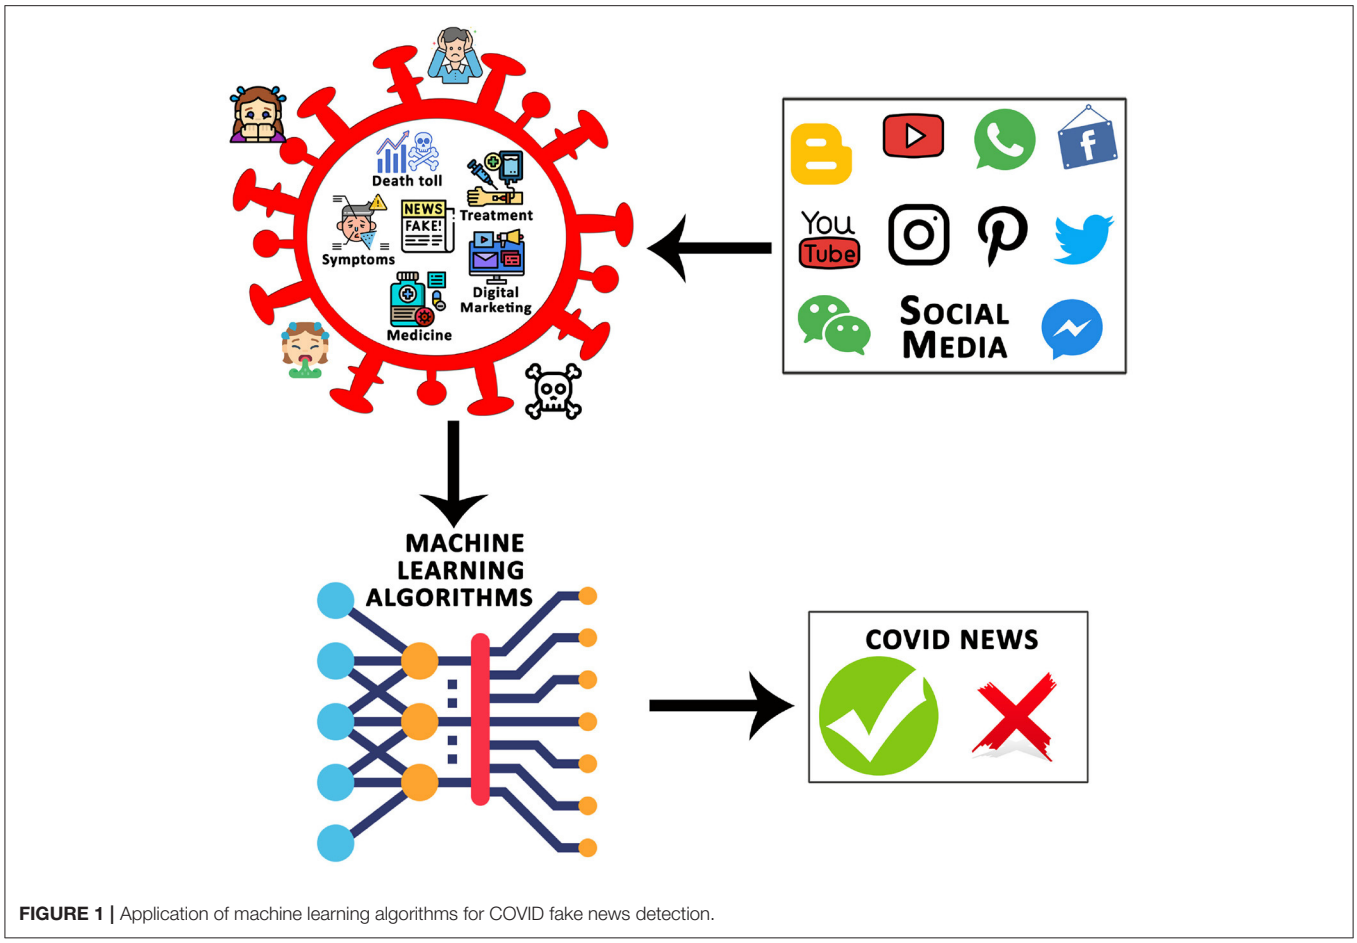

FIGURE 1 | Application of machine learning algorithms for COVID fake news detection.

classifier model, performed better on the dataset generated with an F1 score of 0.76 at the initial stage of COVID 19. The model does not have a polyglot, so they annotated categories manually for three languages.

The study in Daley (24) used ML algorithms for the automatic classification of fake news on COVID-19. The features considered for evaluation included the count of motion words and relativity words, prepositions in the headlines of the news website, tone expressed, and word count. Also, any news media would concentrate on the increased count of these parameters to convince the customers on the fake news outlets. They attained 79% accuracy on 5-fold cross-validation using a decision tree classifier, which outperformed other algorithms in the scikit-learn API. An automated framework for detecting COVID-19 cases from X-ray images of the raw chest was proposed in Ozturk et al. (25). They used a deep neural network, namely the DarkCovidNet model (used for real-time object detection) with 17 convolution layers, each with different filters. The average age of the positive COVID patients in the dataset was 55. The model was used for binary (COVID or not) and multiclass classification (COVID or pneumonia or not) with an accuracy of 98 and 87%, respectively. The performance of the system was assessed with radiologists only, and the robustness of the system can be tested with large datasets.

Therefore, it is evident from the survey that very few attempts were carried out for detecting the fake news in COVID. Although various deep learning techniques were employed for detection, the datasets taken for analysis are very small. It is mandatory to have a strong model to detect false information on COVID-19 to avoid unwanted chaos in different aspects of COVID-19.

3. PROPOSED ARCHITECTURE

In this section, the proposed work is discussed in detail.

The steps involved in the proposed work are shown in **Figure 2** and are summarized as follows:

- The dataset used in this study is collected from various websites and social media cites.
- Data preprocessing is performed on the dataset by removing URLs, punctuation marks, and empty columns.
- After text preprocessing, tokenization is performed to convert the larger text into words or small lines.
- In the next step, extracting the features from text is performed.
- The features extracted are then passed on to the state-of-the-art ML learning algorithms to train the model.
- Various evaluation metrics are used to evaluate the performance of the ML algorithms.

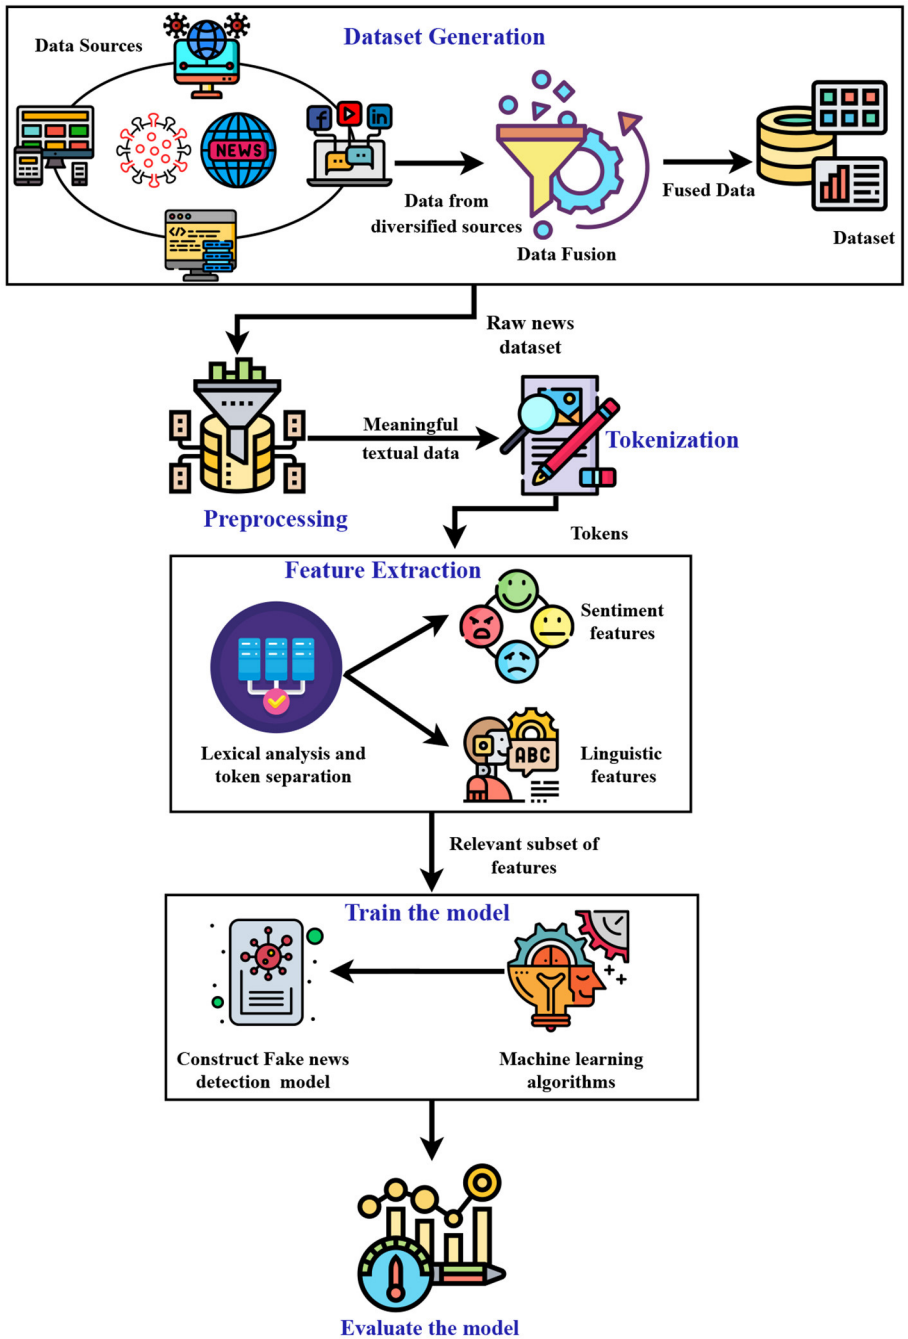

FIGURE 2 | Proposed architecture.

The rest of this section discusses various steps involved in the proposed work.

3.1. Dataset Description

The dataset used in this work is a fusion of several fake and real news articles about COVID-19 which are collected across several platforms such as Facebook, Twitter, The New York Times, Harvard Health Publishing, WHO, etc. The dataset has 1,164 instances out of which 586 instances are true and the remaining 578 are fake news (26).

3.2. Preprocessing and Tokenization

The dataset considered for this work is clean. However, some unnecessary symbols which have an impact on the final classification of the news are to be removed from the dataset. To remove the unnecessary symbols, such as

punctuation marks, URLs are removed from the dataset as part of preprocessing.

Tokenization is the process of splitting text into a set of tokens. The fake news dataset is tokenized to convert the long sentences into small words/tokens.

3.3. Feature Extraction

The major contribution of this work is the extraction of important features from the COVID-19 fake news dataset. Feature extraction plays a very important role in text processing as it reduces the dimension of feature space by considering only the important features (27–29). To extract the features, the named-entity recognition (NER) approach is used in our work. The NER is a popular approach for feature extraction that can classify unstructured text based on location, person names, quantities, etc. (30).

In this study, 39 features are created from the COVID-19-related fake news dataset. The extracted features are represented in **Table 1**.

3.4. Training of the Dataset Using ML Algorithms

In the next step, the extracted features are trained using several state-of-the-art ML algorithms. The ML algorithms used in this work are linear SVC, logistic regression, SGD classifier, random forest classifier, bagging classifier, AdaBoost classifier, decision tree classifier, and K-nearest neighbors classifier (KNN) (31). These algorithms are explained briefly in the rest of this section.

3.4.1. Random Forest Algorithm

The random forest classifier is one of the supervised ML algorithms used for classification and regression purposes (32). The random forest method constructs decision trees from datasets and creates a forest made of trees. Then it collects the prediction value from each decision tree and computes the optimal solution with the help of voting. It is used as an ensemble method and helps to avoid overfitting (33). The following steps are implemented in the random forest classifier:

1. Random data samples are selected from the available dataset.
2. A decision tree is constructed for each data sample selected, and a prediction value is obtained from each decision tree. The Gini coefficient method is applied for node splitting as follows:

$$Gini(D) = 1 - \sum_{i=1}^{n} P_i^2 \quad (1)$$

   where D is the sample dataset and P_i is the probability of decision class that can appear in D
3. A voting method is applied on the prediction values obtained from each decision tee.
4. A final prediction result is chosen from the prediction value with more votes.

3.4.2. AdaBoost Classifier

The AdaBoost classifier (34) is an ensemble boosting classification method which combines several weak classifiers to build a strong classifier. The weak classifier performs the

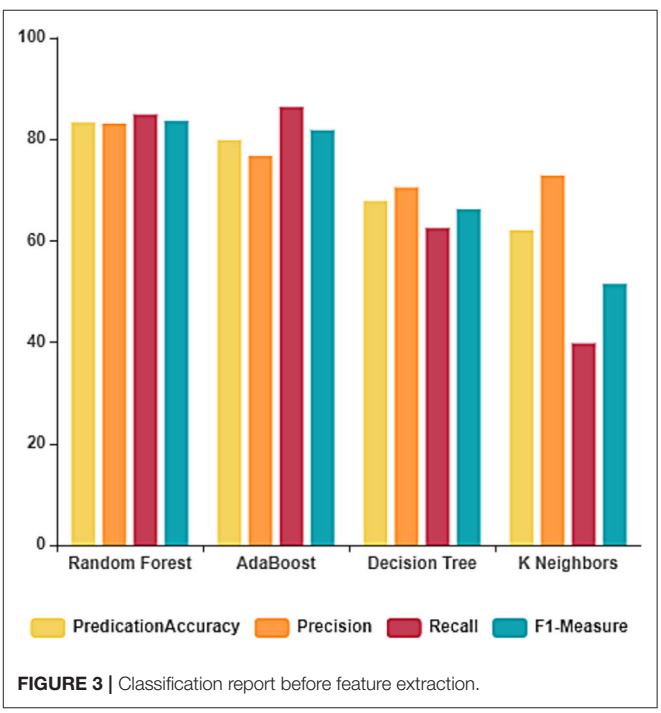

FIGURE 3 | Classification report before feature extraction.

TABLE 2 | Performance of the ML algorithms before feature extraction.

Algorithm	Predication accuracy	Precision	Recall	F1-measure	Predication time (S)	Training time (S)
Random forest classifier	83.33	83.14	84.90	83.61	0.065862	0.383069
AdaBoost classifier	79.88	76.76	86.36	81.82	0.056415	0.347593
Decision tree classifier	67.81	70.51	62.50	66.26	0.003247	0.091995
K-nearest neighbor classifier	62.06	72.91	39.77	51.47	0.084975	0.001555

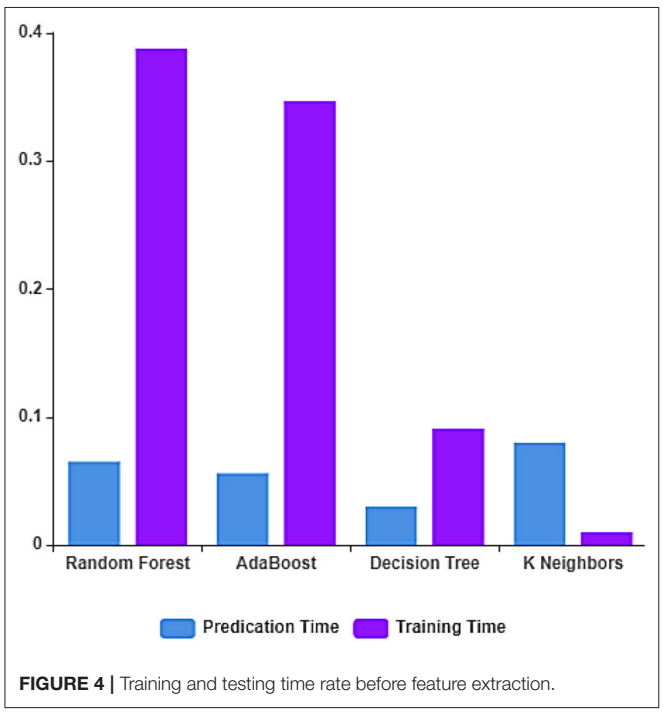

FIGURE 4 | Training and testing time rate before feature extraction.

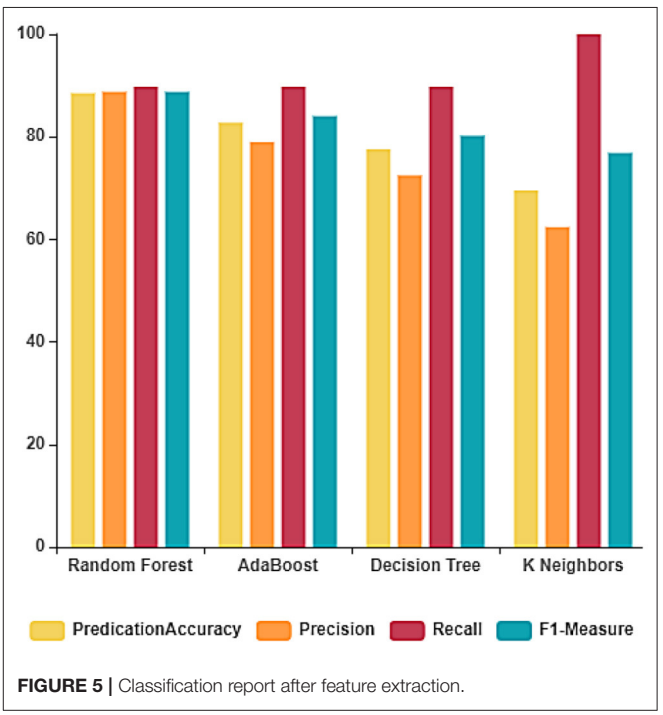

FIGURE 5 | Classification report after feature extraction.

classification of one dimension of the input vector. The number of weak classifiers are increased during the training process to obtain more accuracy. The classifier applies minimum error to compute the weight of the newly added weak classifier. Then it updates the weights of each training dataset and sends the value to the recently added weak classifier. The selection of weak classifiers is very important for this algorithm. The result of the strong classifier $S(f)$ is represented in the equation given below (35):

$$S(f) = sign\left\{\sum_{t-1}^{T} \beta_t h_t(f)\right\} \quad (2)$$

where f denotes the input feature vector, T denotes the number of input vectors, $h_t(f)$ denotes weak classifiers, and β_t denotes the weights of weak classifiers.

3.4.3. Decision Tree Classifier

The decision tree classifier is one of the more popular ML algorithms applied for classification and prediction problems on supervised data. It classifies the trained dataset into trees and rules. It defines methods for the classification of categorical data characterized by their factors. It works better on classification problems where extensive data are involved, and is therefore used in many data mining applications. The first step in the decision tree classifier is to find the attribute to split the tree. Entropy measure is used to identify the best attribute as the root of the decision tree. The entropy measure is used to calculate the update in homogeneity that results from the split on every attribute. Entropy D of the dataset is defined as follows:

$$Entropy(D) = \sum_{i=1}^{n} -p_i log_2(p_i) \quad (3)$$

Where D is the data partition, n defines the number of decision classes, and p_i defines the proportion of the records that comes under the decision class i. Information gain is used for this calculation. This is defined as the difference between the entropy of the dataset calculated before the split (D1) and the entropy calculated from the partitioned split (D2). The formula to calculate the information gain is given as follows:

$$InformationGain(G) = Entropy(D_i) - Entropy(D_2) \quad (4)$$

The attribute with maximum information gain is selected to build the tree with a root node. A decision tree is constructed recursively using the obtained data partition until there are no attributes left. And decision rules can be defined from the constructed decision tree.

3.4.4. K-Nearest Neighbor Classifier

The K-nearest neighbor (KNN) (36) classifier is one of the popularly used supervised learning algorithms for classification and regression. It is a non-parametric and lazy algorithm in which the method is defined from the dataset. Also it does not require a training dataset for the development of the classification model. K is the number of nearest neighbors and it is the deciding factor. The classifier is based on the estimation of the nearest neighbor. It works on the calculation of a similarity value defined by the distance measure. The training step stores all the instances and their corresponding class labels. The test phase for a new instance 's' is calculated using the following steps:

1. Calculate the distance between the instance 's' in the test data and every instance in the training dataset 'd' using the Euclidean distance formula given as follows:

$$\sqrt{\sum_{i=1}^{n}(x_i - y_i)^2)} \tag{5}$$

   where n is the total number of instances in the dataset, x_i represents instances in the training dataset, and y_i are instances in the test dataset 'd'.
2. Arrange the distances in ascending order and select the first 'k' instances.
3. Find the most frequent decision class in the calculated 'k' nearest neighbors.

4. EXPERIMENT RESULTS

The experiments on the COVID-19 fake news dataset are carried out in Google Colab, an open source cloud-based graphical processing unit (GPU)-based platform offered by Google Inc. The programming language used to implement the ML algorithms is Python 3.7.

A total of 70% of the COVID-19 fake news dataset is used for training the ML algorithms and the other 30% of the dataset is used for validating and testing the ML algorithms. The performance of the ML algorithms is evaluated on several metrics like accuracy, precision, recall, F1-measure, prediction time, and training time.

The rest of this section discusses the results obtained by the ML algorithms on the COVID-19 fake news dataset before and after the feature extraction.

4.1. COVID-19 Fake News Experiment Results Before Feature Extraction

The performance of the ML algorithms on the COVID-19 fake news dataset before the feature extraction is depicted in **Figure 3** and **Table 2**. From the table, it is evident that the random forest classifier achieves better prediction accuracy, precision, recall, and F1-measure with 83.33, 83.14, 84.90, and 83.61%, respectively. The random forest classifier trains the dataset in the least time when compared to other ML algorithms. The training and testing time of the ML algorithms on the dataset considered before feature extraction is depicted in **Figure 4**.

4.2. COVID-19 Fake News Experiment Results After Feature Extraction

The performance of the ML algorithms on the COVID-19 fake news dataset after the feature extraction is depicted in **Figure 5** and **Table 3**. From these results, it is evident that the random

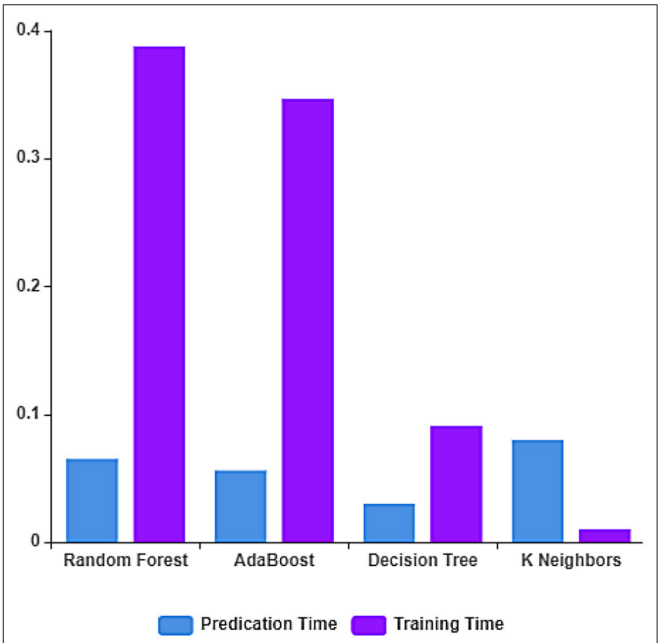

FIGURE 6 | Training and Testing time rate after feature extraction.

TABLE 3 | Performance of the ML algorithms after feature extraction.

Algorithm	Predication accuracy	Precision	Recall	F1-measure	Predication time (S)	Training time (S)
Random forest classifier	88.50	87.77	89.77	88.76	0.004685	0.011387
AdaBoost classifier	82.75	79.00	89.77	84.04	0.004750	0.053603
Decision tree classifier	77.58	72.47	89.77	80.20	0.002851	0.081209
K-nearest neighbor classifier	69.54	62.41	100	76.85	0.003293	0.008997

forest classifier outperforms the other classifiers in terms of accuracy and precision with 88.50 and 87.77%, respectively. Whereas, linear SVC achieved better recall and F1-measure with 89.77 and 88.76%, respectively.

The training and prediction time of the ML algorithms on the dataset considered after feature extraction is depicted in **Figure 6**. From the figure, it can be observed that the decision tree classifier has the least prediction time and the linear SVC classifier has the least training time.

5. DISCUSSION

From the results section, it is clear that the performance of the machine learning algorithms improves after they are trained with extracted features from the COVID-19 fake news dataset. Since the size of the dataset is approximately 1,100 records, ML algorithms are chosen for classification rather than deep neural network-based algorithms.

The raw fake news dataset has several words that have no affect on the classification results. When the ML algorithms are trained by the raw dataset without feature extraction, there is a very high chance that the performance of the ML algorithms will be affected by some of the frequent words in the text that have no effect on the classification results. Hence, in this work, we employed NER to extract features from the fake news dataset. The extracted features are then fed to the ML algorithms for training. The comparison between the results of the ML algorithms before and after the feature extraction prove that the performance of the ML algorithms increase after feature extraction.

6. CONCLUSION

In this work, a sophisticated model that extracts important features from a COVID-19 fake news dataset is presented that improves the performance of ML algorithms. Social media applications are the most significant source to spread any kind of information. So in his work, the dataset related to COVID-19 which was the fusion of several diversified social media platforms and news websites is used for evaluating the performance of the proposed model. A data preprocessing step is applied on the dataset to remove several unnecessary symbols like tags and URLs from the dataset. Later on, to enhance the performance of the machine learning algorithms, the relevant subset of features categorized into linguistic and sentiment features are extracted using the NER approach. The extracted features are trained using several state-of-the-art ML algorithms, namely the random forest classifier, AdaBoost classifier, decision tree classifier, and KNN classifier. The performance of the ML algorithms is analyzed before and after the feature extraction. Random forest provides better accuracy at 83.33% without feature extraction, whereas KNN trains the dataset faster than others. Of several ML algorithms, the random forest classifier with feature extraction outperforms the others with an accuracy of 88.50%, precision of 87.77%, recall of 89.77%, and F1 score of 88.76%. The experiment results prove the importance of feature extraction in fake news detection.

Further in future, audio clips, images, and video clips can be considered for generating fake news data as they are the most attractive way to spread fake information. Deep learning algorithms and natural language processing for the semantical understanding of linguistic features can be further analyzed on a dataset containing text, images, audio, and video.

DATA AVAILABILITY STATEMENT

Analysis of Tracheobronchial Diverticula Based on Semantic Segmentation of CT Images *via* the Dual-Channel Attention Network

Maoyi Zhang[1], *Changqing Ding*[2]* *and Shuli Guo*[1]

[1] School of Control Science and Engineering, Beijing Institute of Technology, Beijing, China, [2] Department of Imaging, Fengxian People's Hospital, Xuzhou, China

Tracheobronchial diverticula (TD) is a common cystic lesion that can be easily neglected; hence accurate and rapid identification is critical for later diagnosis. There is a strong need to automate this diagnostic process because traditional manual observations are time-consuming and laborious. However, most studies have only focused on the case report or listed the relationship between the disease and other physiological indicators, but a few have adopted advanced technologies such as deep learning for automated identification and diagnosis. To fill this gap, this study interpreted TD recognition as semantic segmentation and proposed a novel attention-based network for TD semantic segmentation. Since the area of TD lesion is small and similar to surrounding organs, we designed the atrous spatial pyramid pooling (ASPP) and attention mechanisms, which can efficiently complete the segmentation of TD with robust results. The proposed attention model can selectively gather features from different branches according to the amount of information they contain. Besides, to the best of our knowledge, no public research data is available yet. For efficient network training, we constructed a data set containing 218 TD and related ground truth (GT). We evaluated different models based on the proposed data set, among which the highest MIOU can reach 0.92. The experiments show that our model can outperform state-of-the-art methods, indicating that the deep learning method has great potential for TD recognition.

INTRODUCTION

Background

Tracheobronchial diverticula (TD), or paratracheal air cystic (PTAC), is defined as a congenital or acquired air cyst located in a lateral wall of trachea (1). Specifically, it is a cystic lesion involving primarily the outpouching of the trachea and main bronchial lumen and is located mainly on small round air cysts lesion beside the superior mediastinal trachea.

Tracheobronchial diverticula, mostly discovered in the chest CT by accident, is usually asymptomatic. Chronic cough, dyspnea, stridor or recurrent tracheitis, dysphagia, dysphasia, odynophagia, neck pain, hoarseness, suffocation, and hemoptysis caused by TD are less frequent. In rare cases, TD may lead to the chronic infection of the tracheobronchus. Only when the relationship

between TD and symptoms is confirmed can the symptomatic treatment of antibiotics, mucus solubilizers, and physical therapies be used. The endoscope check includes electrolumes and laser or electroconding endoscopes. Inspections including detachable and longitudinal frame suction and biopsy, thoracoscope, braking, and longitudinal isolation are only needed in rare cases. Before the advent of the CT, due to insufficient understanding of this disease, the lack of specificity of the clinical symptoms, and the restrictions of imaging methods such as chest portions, only severe symptoms could be diagnosed. Thanks to the wide application of multislice spiral CT and the advancement of computer technology, the detection rates of the tracheal and bronchial diverticulums are greatly improved. The coronary and sagittal images are useful in showing the relationship between the tracheal cavity and TD.

Tracheobronchial diverticula is mainly identified by the following lesions: apical lung hernia, trachea laceration, paramediastinal emphysema, esophageal diverticulum, paratracheal air cyst, pneumomediastinum, subcutaneous cervical emphysema, mediastinal emphysema, cervical subcutaneous emphysema, and cervical tracheal duplication. CT should be taken as the main diagnostic tool. The whole picture of the diverticulum and its communication with trachea and bronchi can be observed through thin-section CT and its 3D reconstruction; so we should give full play to spiral CT's advantages in diagnosing tracheal diverticulum, and avoid unnecessary invasive inspection. Bronchoscopy is another tool for diagnosis, but with it, some patients suffering from tracheal occlusion can be misdiagnosed as narrow neck TD or fibrous connection. Unfortunately, not all physicians have sufficient understandings in this regard, as a large number of missed diagnoses still occur in many hospitals worldwide. In addition, since the lesion area of TD is small it poses great challenges to diagnosis. Therefore, designing an efficient and accurate automated method to detect TD can significantly reduce the workload and the missed diagnosis or misdiagnosis rates, ultimately enhancing the diagnostic effectiveness. Once the method is widely applied to hospitals, large sets of diagnostic data obtained can be utilized to explore the potential causes further, and to determine the prevalence rate, morphology (i.e., quantity, size), and clinical features of TD. For a clearer illustration, **Figure 1** shows the scenarios of TD's application.

Related Work

The related work is divided into four parts: tracheobronchial diverticula, machine learning, deep learning, and cloud technology.

Research Status of TD

Few cases of TD have been reported since the first description by Rokitansky in 1838 (2). With the increasingly wide application of CT as a high-performance and non-destructive testing method in the medical field, especially as the main screening method for early lung cancer, the detection rate of PTAC has increased significantly by about 4–8.1% (3–5), which is 1% higher than previously reported postmortem prevalence (0.3% in children) (6). Pace et al. suggested that this disease was associated with the congenital defect or abnormal development of the posterior tracheal membrane, or possibly with acquired chronic obstructive pulmonary disease (7). Ahmet et al. used chest multidetector computed tomography (MDCT) to determine the prevalence of paratracheal air cysts and their correlation with different lung diseases, and finally proved that air cysts are associated with chronic obstructive pulmonary disease (3).

Unlike traditional medical segmentation, the lesion area of TD is relatively small in both real conditions and CT image. In the medical field, most researchers only reported related cases and gave prescriptions but did not design an automatic method for detection.

Research Status of Machine Learning

In the field of machine learning, Deepa et al. (8) used Ridge Adaline Stochastic Gradient Descent Classifier for the early prognosis of diabetes, with higher accuracy than other algorithms. Dhanamjayulu et al. (9) adopted machine learning algorithms to identify malnutrition from facial images. Ghazal et al. reviewed the machine learning in smart healthcare (10) and an improved SVM method for diagnosing Hepatitis C (11). Shah et al. (12) proposed two gender-based risk classification and age-based risk classification methods to identify cardiovascular diseases (CVD). The accuracy of the model can reach 98%, which improved the identification efficiency. In addition, the progress of machine learning in the direction of medical data mining (13) is also gratifying.

Research Status of Deep Learning

In recent years, deep learning (14) has shown a booming trend of development, in which many networks for medical segmentation of small and medium targets have emerged. For example, U-net (15) is specially developed for medical image segmentation. Its U-shaped structure is an asymmetrical structure of up- and downsampling, whose feature mapping can be connected through the intermediate jump connection, thus enriching the extracted semantic information. Shrivastava et al. (16) presented a learning mechanism method for cognitive maps, which has been successfully applied to identify problems in targets. Jégou et al. (17) restored the complete input resolution by adding an up-sampling path, and extended DenseNets to FCN to reduce the impact of large computation and parameters, resulting from high-resolution characteristic patterns multiplied by a large number of input filters. However, these networks have difficulties in the segmentation of small and medium targets.

In view of this, researchers combined the detection and segmentation tasks to produce a series of networks. Mask RCNN (18) is the most advanced instance segmentation technology, with which, the pixel-level labels in each prediction box can be predicted, and multitask segmentation can be completed. However, its pooling layer using "ROI-align" reduces the resolution of input features, resulting in a loss of spatial detail of the image. In addition, it will increase computer overheads and network parameters. BlitzNet (19) used a full convolutional network to detect and segment the target and promoted model learning through weight sharing between the two tasks. But the model did not show the advantages of segmenting tasks. Based

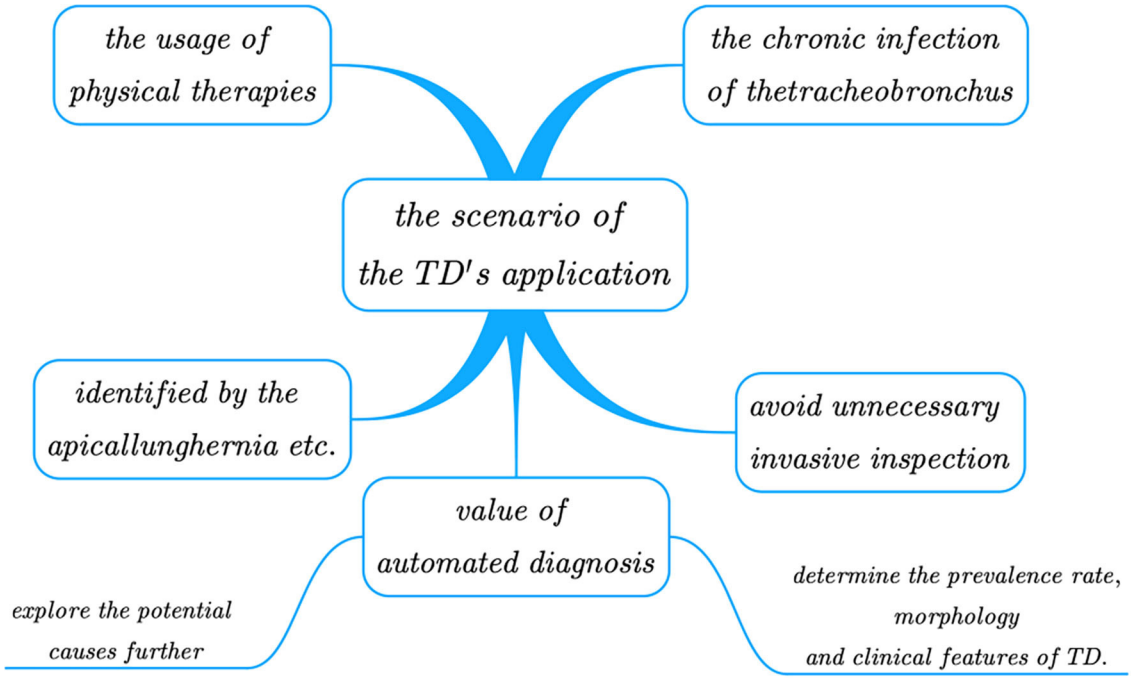

FIGURE 1 | The scenarios of the TD's application.

on the network mentioned above, Zhang et al. (20) introduced an ROI convolution directly in the location network area. This convolution module operates on all ROI during calculation, and it is applied to acetabulum segmentation from ultrasonic images. In addition, it helps solve the segmentation problem of small targets by experimentally demonstrating the introduction of localization units. Bak et al. (21) used the deep learning model to analyze the LDCT images of 131 patients, and calculated related indicators such as the emphysema index and mean lung density. Deep learning and statistical methods were also combined to detect emphysema quantitatively. Jin et al. (22) proposed a two-stage deep learning structure to improve the accuracy of emphysema quantification. Srinivasu et al. (23) proposed an algorithm based on probabilistic deep Q network for real-time robotic surgery, showing excellent performance in terms of the learning rate. Lin et al. (24) developed a deep learning model for COVID-19 identification and compared the CT images of TD and the coronavirus. Deep learning methods are also widely used in face recognition (25), breast cancer detection (26), and cervical cancer classification (27).

Research Status of Cloud Technology

With the development of cloud technology and blockchain technology, Ghayvat et al. (28) combined the blockchain (BC)-based confidentiality-privacy (CP) preserving scheme, which improved the accuracy by 12% compared with the traditional algorithm, verifying that it is a good solution for big data storage and privacy protection. At the same time, they also designed a COUNTERACT system that can calculate the incubation period of new crown objects (29) and an environmentally assisted living system (30) that well combines the latest sensor fusion technology. These designs will be the trend of future applications.

The Deficiency of Existing Research

Although improvements have been made in the performances of various methods based on deep learning, there is still room for breakthroughs in some areas. The motivations for the proposed methods can be summarized in the following two aspects:

First, the existing TD identification task relies mostly on the data collected by physicians in the diagnosis process, most of which needs to be visually observed by professionals and written into the diagnosis report. Since TD lesion sites are not obvious, identification and diagnosis by manual means are prone to fatigue, misdiagnosis, and missed diagnoses. In existing models of lung diseases based on deep learning, most of the focuses are on cancerous sites (31, 32), pulmonary nodules (33–35), etc. Many studies have ignored the effect of paramediastinal air cysts on the subsequent disease.

Secondly, the existing methods are not robust, but in TD semantic segmentation, the identifiable lesion covers only a small area with low pixels, and edge restoration is needed. Moreover, the TD's position in CT image needs to be identified, which can hardly be achieved by applying existing methods to these datasets. The advancement and the limitations of the current study can be concluded in **Table 1**.

The Novelties and Contributions of the Proposed Work

To address the above limitations, we propose a novel structure to classify every pixel of TD through a dual-channel attention-based

TABLE 1 | The conclusion of advancement and the limitations of the current study.

Advancement	Limitations
TD Case reports	Not robust
Machine learning, with deep learning focused on other areas of interest on regions	Few scholars have automated the diagnosis of TD

segmentation network. The main features of the proposed method are as follows:

1. Unlike the traditional bounding box-based target detection, or the entire image-based classification task, we performed the semantic segmentation on the TD lesions identification by classifying each pixel point by pixel. This method helps to better utilize the original data to present a clearer image, which is convenient for subsequent diagnosis. This proposed method is the first semantic segmentation network for TD diagnosis.
2. The proposed method saves the traditional intermediate steps (feature extraction) by taking the end-to-end loss function as the features of the generated evaluation and the GT confirmation. It can directly and automatically learn the overall lesion characteristics instead of manual identifications that undermine the generalization performance.
3. Given the outstanding performance of the attention mechanism on semantic segmentation tasks, we proposed a novel dual-channel attention TD segmentation network with position coding and contour coding modules, which has better accuracy and robustness. We compared the proposed model with the traditional various semantic segmentation models based on deep learning. The MA and MIOU of our method can be as high as 0.92 and 0.87, respectively. On this basis, we also carried out corresponding ablation experiments to verify the advantages of the added modules.

Paper Organization

The rest of the paper is organized as follows: first, in the "Experimental Methods and Materials" section, we introduced the data sources and preprocessing methods; also, the proposed model is elaborated in this section. As for the "Results and discussion" section, a series of comparative and ablation experiments are described. Finally, we summarized this work and pointed out the directions for future research in the conclusion section.

EXPERIMENTAL METHODS AND MATERIALS

Experimental Data and Preprocessing

The cases included in this study were patients who underwent routine chest CT scanning using Philips Brilliance 16- and 64-slice spiral CT machine in the Department of Medical Imaging, Fengxian People's Hospital, Jiangsu Province, from October 2020 to January 2021. The patients were scanned by CT from the superior border of the thyroid cartilage to the bottom of the lung. The field of vision was 350 mm, 120 kV, 250 mA, and the collimator width was 0.75 mm. The original data of each period were reconstructed with 1 mm layer thickness and 0.15 mm layer spacing, and postprocessing techniques such as multiplane recombination (MPR), maximum density projection, and volume reconstruction were applied at the workstation. The ground truth we annotated based on the original image was all annotated and verified by experienced radiologists. The image size is 512*512, and all data used for training, testing, and verification are desensitized. **Figure 2** shows a set of examples.

In the collected pathological images, the lesion area is highly obscure, where light environment or photographing can easily lead to background pollution, so it is challenging to segment the lesion area accurately. Therefore, we mainly used two methods to preprocess the data. Firstly, the data of HSV hue transformation were enhanced, which can avoid the influence of light on the image, making the network more robust and the color space clearer compared with the method of RGB color space. HSV can be described as follows:

$$\text{Output} = \text{HSV}(\text{x}_{\text{i=r,g,b}} \cdot \alpha_{\text{i=h,v,s}}) \tag{1}$$

where, x is the single channel of input image ($i = r, g, bi = r, g, b$); a ($j = h, s, vj = h, s, v$) is the disturbance factor; HSV is the augmented model of color space. In our experiment, $h = 0.015, s = 0.7, v = 0.4h = 0.015, s = 0.7, v = 0.4$.

Secondly, we adopted the nonlinear signal processing technique based on ranking statistical theory to suppress noise for effective preprocessing. Specifically, in the small lesion area, it is more prominent with the effect of salt and pepper noise. Therefore, we created a sliding window near the lesion area, which traverses all pixels of the area, accumulates all pixel values, and takes the median one as the enhanced pixel. It can effectively protect the edge information of the image while suppressing noise points. The equation can be expressed as:

$$\text{h}(\alpha, \beta) = \text{med}\left\{f(\alpha - m, \beta - n), m, n \in W\right\} \tag{2}$$

where $f(\alpha, \beta)$ and $h(\alpha, \beta)$ denote the original image and the processed image, respectively, and W is the two-dimensional input template. *med* represents the convolutional implementation of the sliding window. All the original images used for network design were 512 × 512 pixel in size, with a horizontal and vertical resolution of 96 dpi. The image size was kept the same to accommodate the CNN network training.

Network Structure

Overall Structure

This part mainly introduced the network based on attentional tracheobronchial diverticulum segmentation, as shown in **Figure 3**. Firstly, the resnet101 network was employed as the backbone to extract the deep and shallow features of the image. In addition, considering the smallness of the lesion and its complex background, a two-channel network was designed to achieve the segmentation task with both rough and fine-grained results, which consisted of two parts—one was location feature extraction and encoding module, which extracts multiscale spatial features of the object to be segmented and locating the target area in the

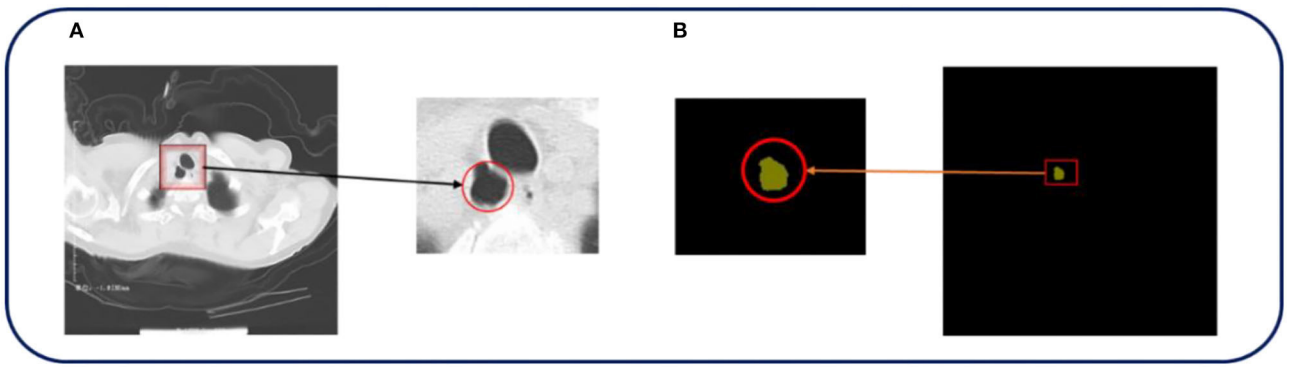

FIGURE 2 | The original CT image and the corresponding ground truth are shown in **Figure 1**. **(A,B)** In the above pictures, red represents TD, which is the part that we are interested in.

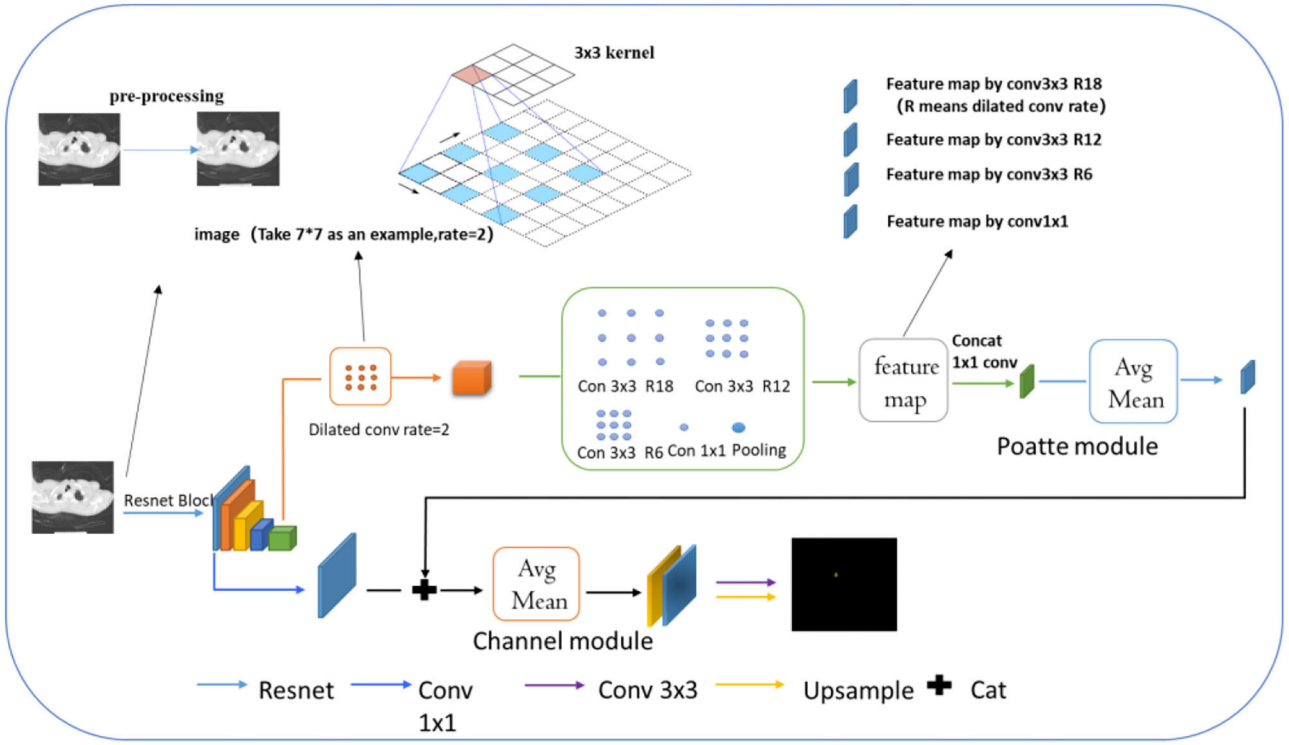

FIGURE 3 | Attention-based tracheobronchial diverticulum segmentation network.

image, and the other was the contour encoding module, which was in charge of fusing and upsampling (mapping) the output of the initial Conv-2 feature of Resnet101 and the location encoding module, so as to further enhance abilities of details recovery of contour edges of the image.

Further explanation about the model is made in the following. Before extracting features by Resnet, we used the preprocessing model mentioned above to process the TD image. Dilated convolution is a common one whose working mode is explained in the image by arrows. Compared with conventional convolutions, its receptive field offers more lesion information. Then, different feature maps by various types of dilated convolution can be received, which are processed by concat in the next step.

Location Encoding Module (Poatte Module)

Using Resnet101, we extracted features of deep and shallow layers. In the location encoding module, the target area should be first located in the image, around the left hand and close to the surrounding trachea and the right upper lung tip. Then we employed the deep layer to extract the trachea and right upper lung tip features and further identified the esophagus

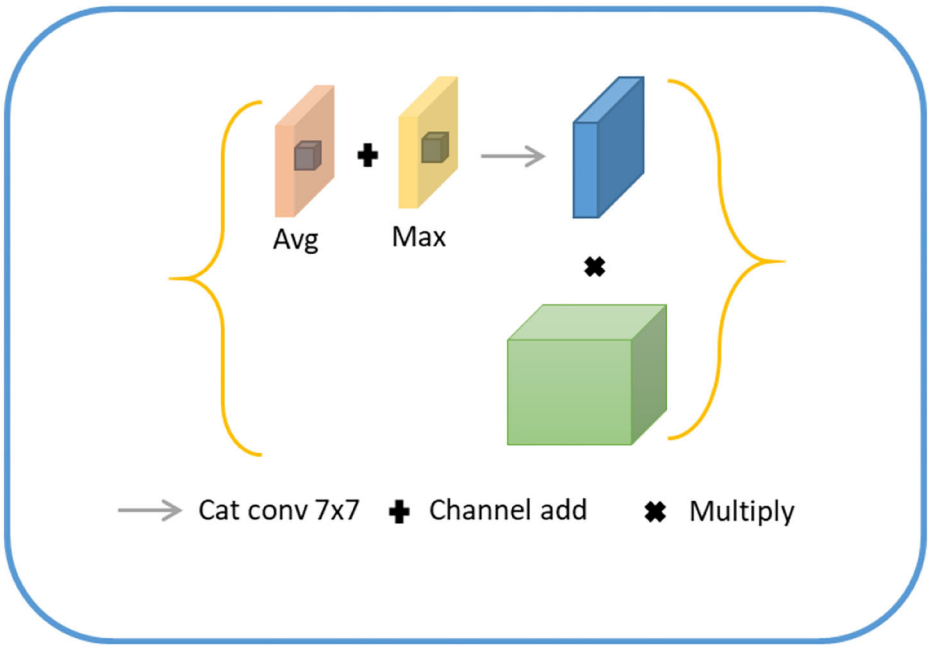

FIGURE 4 | Schematic diagram of location coding module.

area. However, in this layer, smaller targets tended to disappear after multiple convolution pooling. For that, the dilation (ASPP) convolution (36) (expansion rate of 2) was used to increase the receptive field of the image and decrease the probability of the disappearance of small targets in the deep feature map. In the case of two-dimensional signals, for each position *i* and *a* convolution filter *w* on the output feature map *y*, they were applied by atrous convolution on the input feature map *x*, as follows.

$$y[i] = \sum_{k} x[i + r \cdot k]\, w[k] \tag{3}$$

In the above function, the atrous rate *r* determined the stride, with which we sample the input signal, and the output y of ASPP through the position module was:

$$Ms(F) = \sigma\left(f\left(\left[AvgPool(F); MaxPool(F)\right]\right)\right) \tag{4}$$

$$Ms(F) = \sigma\left(f1 \times 1\left(\left[Fs\ avg; Fs\ max\right]\right)\right) \tag{5}$$

In the formula, f1 × 1 was the convolution kernel of 1 × 1, and σ was the sigmoid function.

Besides, the chosen single deep scale was conducive to large target detection but poor for the small one. On this single scale, what 3 × 3 convolution and 1 × 1 convolution can capture was only local region features rather than the global ones. Therefore, the feature map obtained by the upper expansion convolution was conducted by different expansion rates. With the increase of convolution layers, the convolution kernel degenerated into 1 × 1 when the expansion rate of convolution was large, which could not capture global ones. To solve the problem caused, we first added image-level features, specifically, the average pooling of each channel of the feature map, and then the original scale resolution was sampled up. Secondly, we set the expansion rates of these convolutions to 6, 12, 18, and ultimately fused the average pooling features with the features of different expansion rates. The fused features possessed characteristics of global context so that the target at different scales can be roughly located. Meanwhile, because the ultimate goal was to find small lesion areas around the large target esophagus, fused features were put into the location attention module, as shown in **Figure 4**. The module first pooled the input features into global maximum and global average pooling and fused them into 7 × 7 convolutions, which were positionally expressed, and this generally made the target location more salient. Finally, the information of location was multiplied by the characteristics of the previous layer to further identify the small target position.

Contour Coding Module (Channel Module)

For lesion being a small object, the spatial information of the target was usually lost after deep convolution so that shallow features were employed to restore the contour information of the target. Specifically, we first conducted a 1 × 1 convolution of shallow features, fused with the input of the position-coding module to endow them with the contour information of shallow features and position of deep features. Next, the fused feature was processed through the attention module of channel fusion, as shown in **Figure 5**, where two 1 × 1 × C feature maps were obtained by planar and maximum pooling of the fused features in terms of the long and wide directions. The final channel feature was strengthened by a shared convolution layer and pixel-level sum operation, making the initial feature profile the target area.

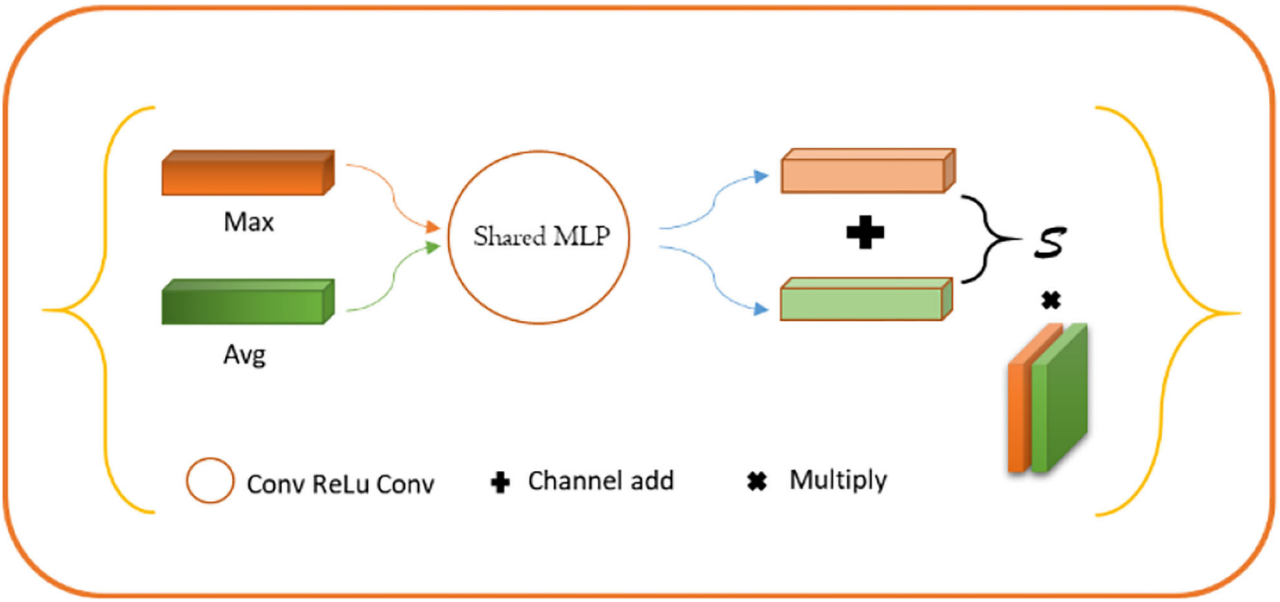

FIGURE 5 | Schematic diagram of contour coding module.

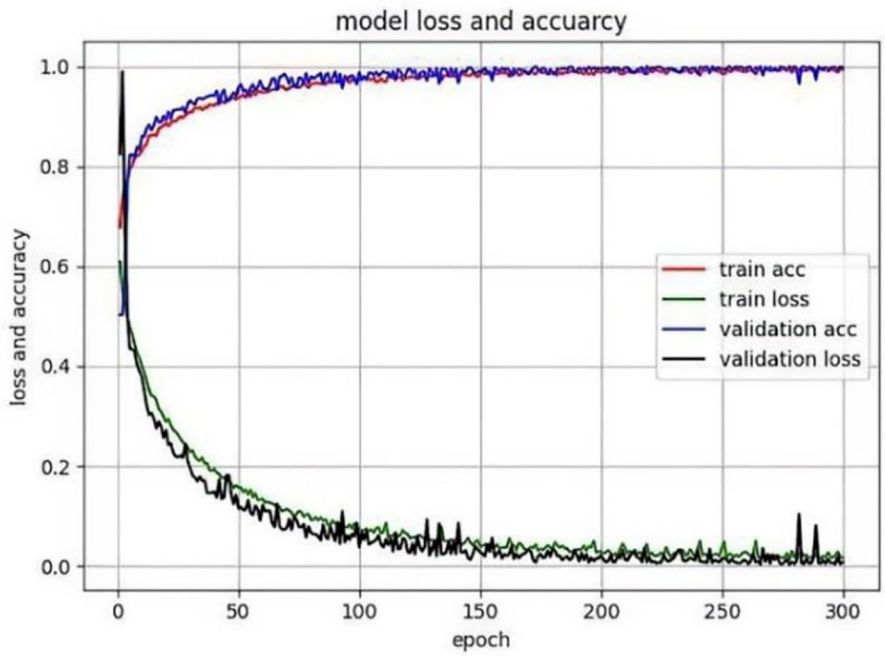

FIGURE 6 | Model training chart.

Finally, the feature map was recovered to the original scale size by convolution and upsampling.

Experiment Settings

The method was implemented based on the Pytorch library and ubantu environment, with the learning rate being 0.0001, the momentum and weight decay coefficients 0.9 and 0.0001, respectively. The model was trained by GTX 2080 Ti, Batchsize = 4, and the training epoch was 300. When the epoch was 0 to 150, the model converged quickly, improving accuracy. But it was relatively stable and converged moderately with slow-moving accuracy between 150 and 300, as shown in **Figure 6**. In addition,

the TD lesion dataset was obtained from the hospital, and 218 images (190 images in training set, 10 images in validation set, and 18 images in test set) and 218 lesion area markers were constructed under the guidance of pathologists.

Based on this, the pretraining model with fine adjustment is applicable in a resource-constrained environment. The resources consumed are only the computational ones that are returned in the following gradient. Moreover, the following multiscale module of feature extraction and feature attention do not require a great number of computing resources. In the multiscale feature extraction module, we used dilated convolution to expand the receptive field and decrease the representation of feature maps, and even the demand for resources. We repeatedly utilized 1*1 convolution in the module to compress features to integrate representation of features and lower demands for resources. Based on the above two points, the model can be trained and tested in a resource-constrained environment.

Evaluation Indexes

We adopted two most essential evaluation indexes of semantic segmentation, namely, mean pixel-level accuracy (MPA) and mean intersection over union (MIoU), which were as follows :

$$\mathrm{MPA} = \frac{1}{\mathrm{T}}\sum_{\mathrm{T}=1}^{\mathrm{T}}\left[\frac{1}{\mathrm{C}+1}\sum_{\mathrm{m}=0}^{\mathrm{C}}\frac{\mathrm{p}^{(\mathrm{mm})}}{\sum_{\mathrm{n}=0}^{\mathrm{C}}\mathrm{p}^{(\mathrm{nn})}}\right] \tag{6}$$

$$\mathrm{MIoU} = \frac{1}{\mathrm{T}}\sum_{\mathrm{T}=1}^{\mathrm{T}}\left[\frac{1}{\mathrm{C}+1}\sum_{\mathrm{m}=0}^{\mathrm{C}}\frac{\mathrm{p}^{(\mathrm{mm})}}{\sum_{\mathrm{n}=0}^{\mathrm{C}}\mathrm{p}^{(\mathrm{mn})}+\sum_{\mathrm{n}=0}^{\mathrm{C}}\mathrm{p}^{(\mathrm{nm})}-\mathrm{p}^{(\mathrm{mm})}}\right] \tag{7}$$

In the above functions, $p^{(mn)}$ denotes the true value of m, predicting the correct number of TD lesions. $C + 1$ was the number of categories (including empty classes). T was the number of CT images of the tracheobronchial diverticulum, which was 218 in this study. *MPA* was the average value of the correct classification of calculating pixel categories, *MIoU* was generally calculated based on the categories, that is, the *IoU* of each category was accumulated after the calculation, and then their average was the holistic evaluation.

RESULTS AND DISCUSSION

Comparison With Advanced Semantic Segmentation Algorithms

In this part, we selected the classic and novel semantic segmentation networks, including FCN, DENSE, DANet, PSPNet, and DoubleUnet. Among these networks, FCN (37) was the first network that applied CNN structure to semantic segmentation tasks and altered many classification networks into fully convolutional networks. Then, by introducing Atrous convolution, DENSE solved the coding problem of multiscale information and obtained the spatial pyramid structure suitable for semantic segmentation. DANet (38) proposed a dual attention network for segmentation, which could introduce spatial and positional attention to adjust the local semantic information in the adaptive integrated image. PSPNet (39) proposed a pyramid network that could extract context semantic information, improving the segmentation performance in complex scenes. DoubleUnet (40) employed two stacked U-Net (one pretrained coding network was used to capture more abundant semantic information, and the other was set at the bottom to extract information) to improve the segmentation performance of multiple sets of medical images.

TABLE 2 | Results of common semantic segmentation methods in identifying tracheobronchial diverticula.

Method	Backbone	MPA	MIoU
FCN32S	VGG16	0.77	0.50
FCN16S	VGG16	0.74	0.49
FCN8S	VGG16	0.75	0.49
FCN	ResNet50	0.78	0.59
FCN	ResNet50	0.81	0.53
DENSE	DENASPP121	0.87	0.64
DENSE	DENASPP161	0.89	0.78
DENSE	DENASPP169	0.78	0.62
DENSE	DENASPP201	0.78	0.63
DANet	ResNet50	0.77	0.55
DANet	ResNet101	0.77	0.58
DANet	ResNet152	0.88	0.63
PSPNet	ResNet50	0.60	0.34
PSPNet	ResNet101	0.63	0.34
PSPNet	ResNet152	0.63	0.34
DoubleUnet	ResNet50	0.78	0.53
Ours	ResNet101	**0.92**	**0.87**

The meaning of the bold values is that the network we designed in this article (We call it ours for short).

To verify the effectiveness of our dual-channel network, MPA and MIOU were adopted as evaluation indexes to compare (SOTA) FCN32S, FCN16S, FCN8S, FCN, DENSE, DANet, PSPNet, DoubleUnet network, and build different algorithms. We selected VGG-16 (41) and ResNet-50 (42) as feature extraction networks, respectively. The former obtained more semantic information by deepening the network depth. The latter solved the problem of gradient explosion and disappearance by introducing residual structure and enhancing the generalization performance of the network with wide applications in classification and segmentation tasks in many scenarios. We conducted the experiment combining the above backbones with the segmentation network, and the results are shown in **Table 2**. It can be seen from **Table 1** that the MIOU value of FCN network, after establishing VGG16 and ResNet50, was about 0.4–0.5, the figure after DENASPP121,161,169,201 as about 0.6–0.7, the one after ResNet series network was about 0.5–0.6, the figure after ResNet series network was approximately 0.3, and the accuracy of DoubelUnet network was about 0.53. However, the MIOU accuracy of the proposed network was 0.87, much higher than the currently popular algorithms, mainly due to the effective extraction of spatial features and the efficient use of boundary information in the network.

In addition, Resnet50, Mobilnetv2 (43), Drn16 (44), and Xcepotionv2 (45) were also selected as backbones for the dual-channel network. As for their results, the highest MIOU was 0.87 and the lowest was 0.77, both lower than the proposed algorithm, showing the robustness and efficiency of the proposed network. The comparison is shown in **Table 3**.

First of all, we compared the indexes of different backbones, and their good performance proved the universality and validity of the segmentation of modules. ASPP module was proposed for the multiscale problem of objects. Before the convolution, it was resampled at a given feature layer with multiple sampling rates. We used multiple paralleled dilated convolution layers with different sampling rates to expand the receptive field and enhance the expression of features. In the model, the convolution with a convolution kernel of 1 was used repeatedly to compress, integrate, and increase nonlinearity. In view of the obscure feature points of the object, we adopted the global average pooling to enhance the response in the channel further, making the feature more prominent and conducive to the segmentation. Channel attention is to strengthen the learning of different fields of vision features. Furthermore, spatial attention is to enhance the learning of spatial expression features of objects and the response of feature points. Based on the above points, the model we designed strengthens feature learning, thereby improving segmentation accuracy.

TABLE 3 | Comparing the results of our model with different backbones for identifying tracheobronchial diverticula.

Method	Backbone	MPA	MIoU
Ours	Resnet50	0.90	0.87
Ours	Mobilenetv2	0.90	0.83
Ours	Drn16	0.92	0.87
Ours	Xceptionv2	0.84	0.77

For a more direct exhibition of the algorithm, we selected algorithms used for the above comparison and the TD lesion segmentation map (**Figure 7**) by the improved algorithm, which was compared with ground truth.

In the experiment, we found that the recognition results of popular algorithms (such as DoubleUnet) were overfitting, causing the incomplete identification of the lesion area for its smallness and distraction of organs around it. However, the network was designed by setting a position-coding module and a contour-coding module, introducing positional and spatial attention to focus on extracting the semantic information of the lesion area, which made its segmentation effect better than the existing algorithms.

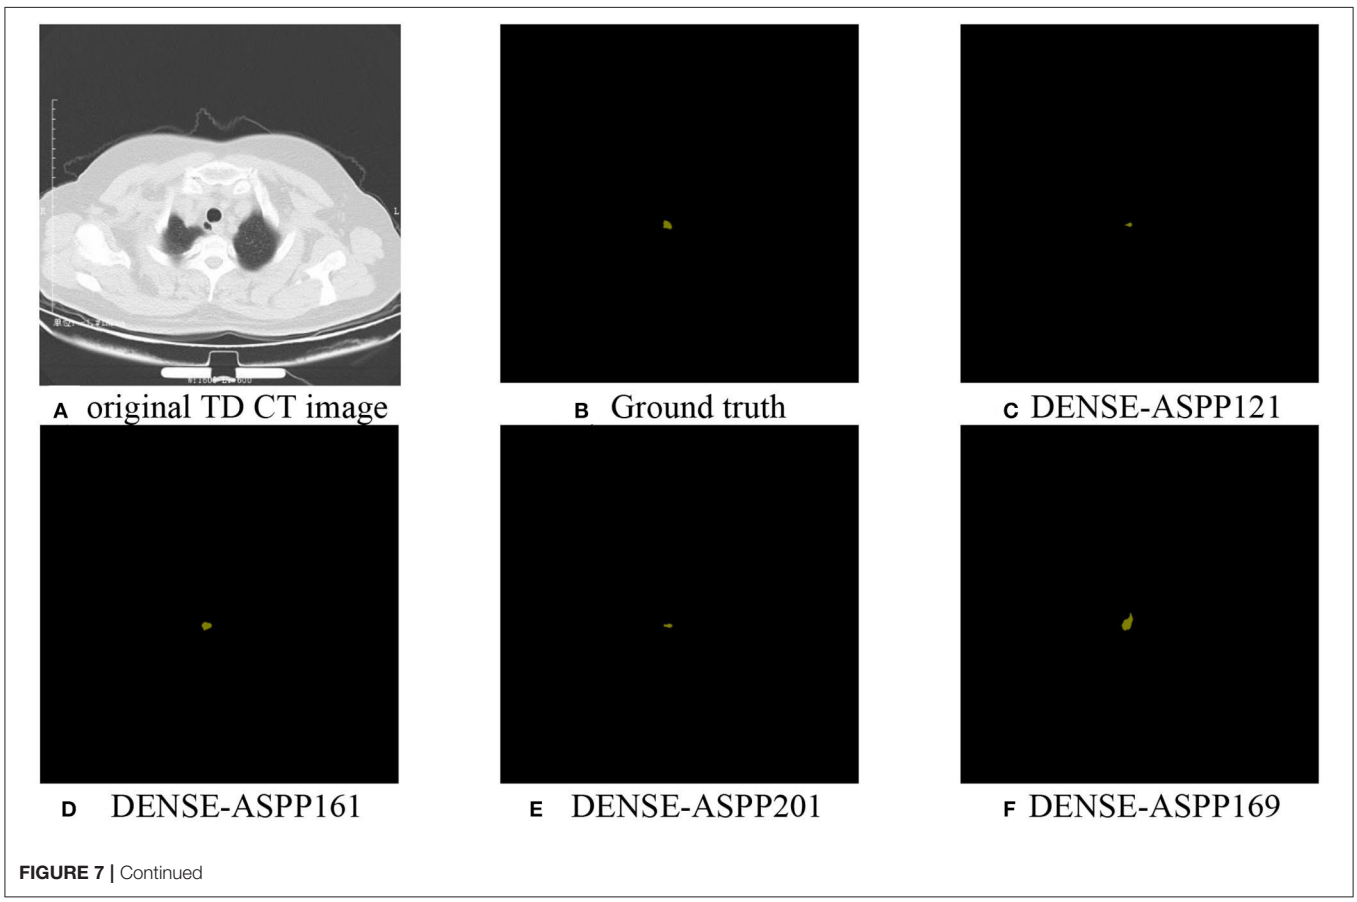

FIGURE 7 | Continued

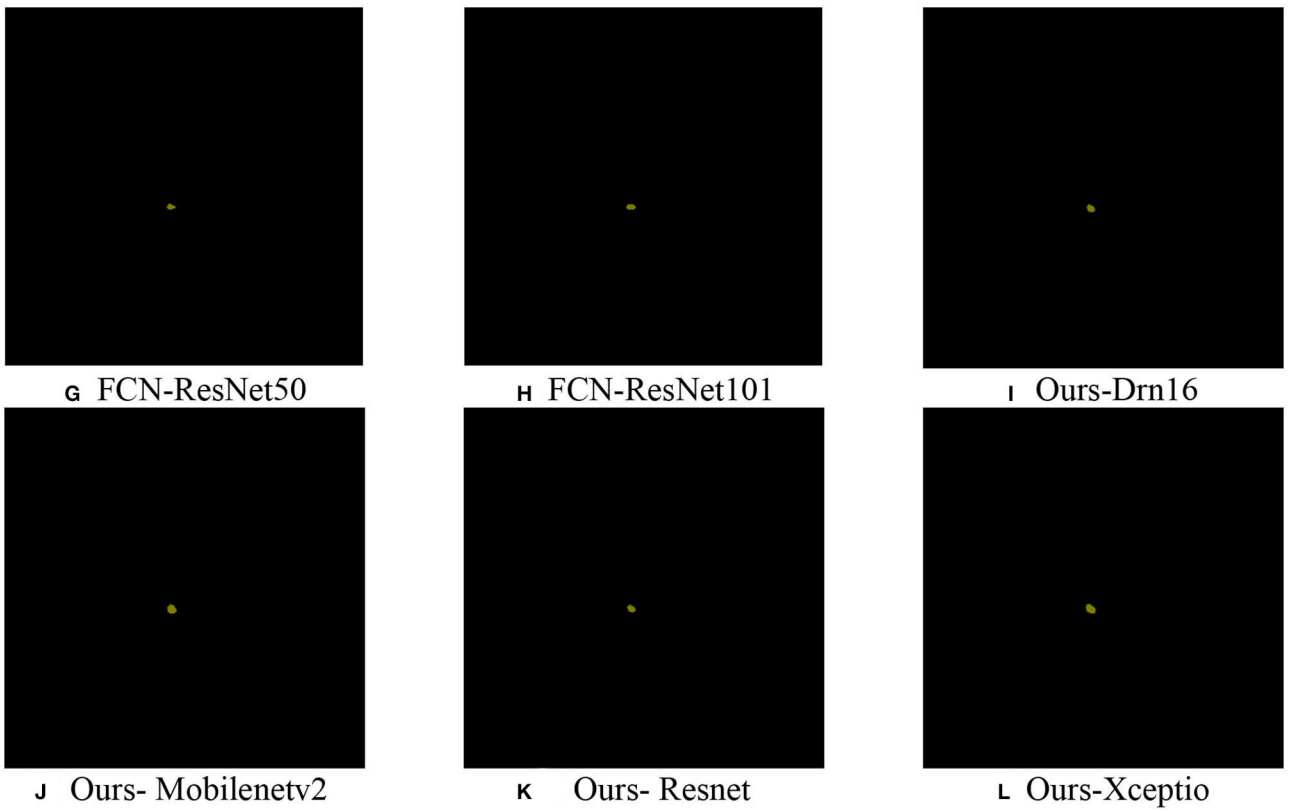

FIGURE 7 | TD lesion segmentation diagram: **(A)** the original CT data; **(B)** ground truth; **(C–H)** partially selected comparison algorithm; **(I–L)** predicted results using Drn16, Mobilenetv2, Resnet, and Xception as the encoder extraction network, respectively.

Atrous convolution	PCM	CAM	MIoU
×	×	×	0.68
√	×	×	0.79
×	√	√	0.82
√	√	√	0.87

Ablation Experiment

Atrous convolution and positional attention module, and spatial attention module (PCM) were added to the network. To verify the effectiveness of the two modules, we performed the following ablation experiments in **Table 4**. When there was no module in the network, the evaluation index MIOU was 0.68. When deep and separable convolution was added, it was 0.79, and the accuracy value was higher than that of the original network 0.11. The reason was that it selected convolutions with different expansion rates when extracting features at high scales to increase the receptive field, making features more holistic and avoiding the loss of target information. When positional and spatial attention modules (PCM) were added, the MIOU accuracy was 0.82 without dilated convolution, higher than 0.14 of the original network. The reason behind it was that the two attentional modules made the target position prominent. Combining the deep and separable convolution (convolution with different expansion rates, Atrous convolution), positional attention module, and spatial attention module (PCM) with the network, the accuracy was 0.87, higher than the original accuracy of 0.68. The ablation experiment further verified the effectiveness of the modules.

Furthermore, combined with the visualized results of the above segmentation, it can be clearly found that the proposed algorithm can effectively locate and segment TD lesions. Meanwhile, the addition of attentional modules improved performance, especially reducing the false detection of small objects and providing richer positional, spatial, and background information than the ordinary network.

In addition, we drew a box diagram (**Figure 8**) to demonstrate the overall and critical features of the data. There were Danet, Dence, Fcn, PSPNet, and the MIoU indicators of segmentation network under different backbones, and all model indexes were drawn into a box diagram.

It can be seen from the five models that the median accuracy of PSPNet algorithm was only 30%, but the lower

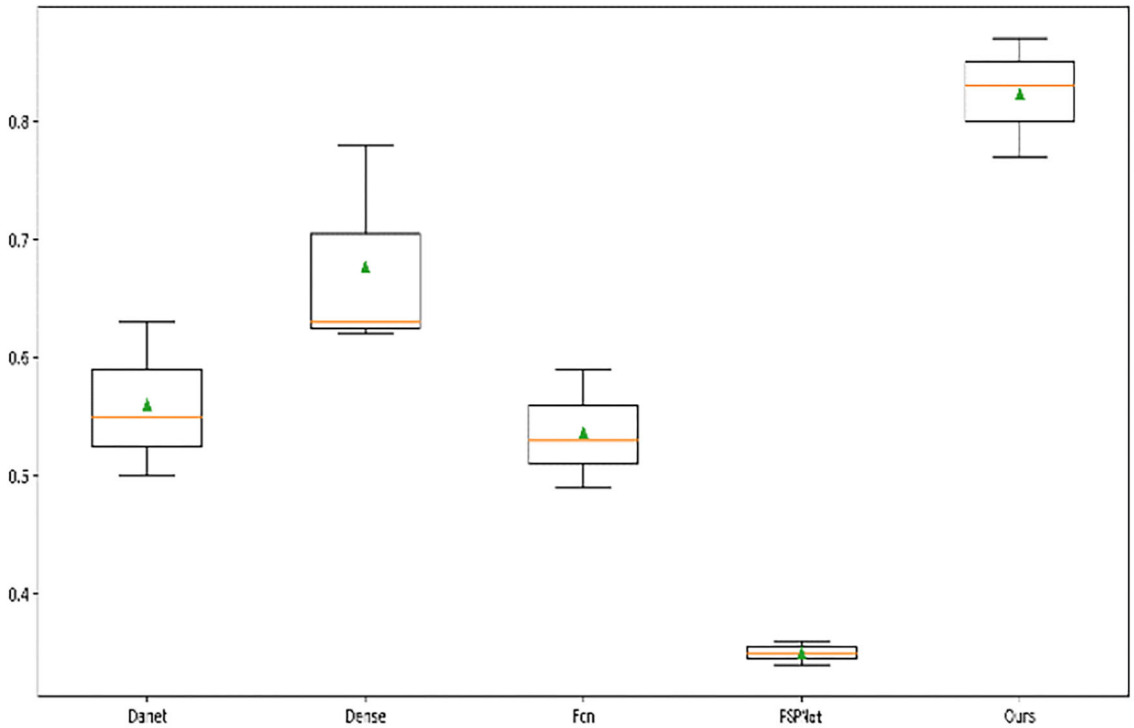

FIGURE 8 | Box diagram of different model indexes.

quartile accuracy of Danet, Dense, and FCN were higher than 50%. The median of the algorithm was higher than 80%, displaying that our attention-based strategy had better performance in most samples and showed the robustness of the algorithm. Although other algorithms have achieved excellent performance on many datasets, the overall recognition effect of TD lesions is not satisfying. It is believed that the reason is that TD lesion is a small target and easily confused with other surrounding organs, especially the esophagus area. Even many experienced doctors often confuse or fail to identify the lesion, which results in obstacles to later diagnosis of diseases.

CONCLUSION AND FUTURE WORK

This work presented a new method of TD lesion recognition based on CT image semantic segmentation. Most of the previous studies focused on case reports, rather than using the deep learning method for segmentation to reduce the workload of doctors. In terms of that, we conducted pixel-level segmentation for the lesion area of CT images (that is, semantic segmentation) instead of traditional classification and target detection tasks. Inspired by the great success of attentional mechanism in image segmentation, we adopted the dual-channel attention model to automatically identify TD lesions and different pretrained feature extraction networks, including VGG16, DENASPP121, and ResNet50 as the backbone of the encoder, to improve the prediction performance of the network. Also, the position-coding and contour-coding module were redesigned with the integration of spatial and positional attention into the network, improving the identification of lesion position with coarse and fine-grained information. It has been proved that the segmentation network with Resnet, Mobilnetv2, Drn16, and Xcepotionv2 as the backbone of the encoder and the proposed coding module can effectively restore the details of the lesion area, superior to other popular semantic segmentation models, and novel algorithms based on U-net deformation. In other words, the value of MioU was 0.87, fully explaining that the semantic segmentation method is conducive to identifying TD lesions.

However, it should be noted that the research still has some limitations. First of all, because the above CT image resolution was low even with occlusions somewhere, it will be helpful to improve the network's performance once they are improved. Furthermore, more complex CT data should be introduced to enhance the robustness of the model. Ultimately, other ignored diseases like TD deserve further study so that deep learning can be applied to disease diagnosis and be integrated into a network with stronger generalization and migration ability. Once similar lesions with fixed positions and small targets are met, we can segment the network to obtain the needed results. Moreover, we will design an application to assist in the diagnosis of TD, with the aim of improving the diagnosis efficiency of medical practitioners.

Background: This study aimed to construct a clinical prediction model for osteosarcoma patients to evaluate the influence factors for the occurrence of lymph node metastasis (LNM).

Methods: In our retrospective study, a total of 1,256 patients diagnosed with chondrosarcoma were enrolled from the SEER (Surveillance, Epidemiology, and End Results) database (training cohort, $n = 1{,}144$) and multicenter dataset (validation cohort, $n = 112$). Both the univariate and multivariable logistic regression analysis were performed to identify the potential risk factors of LNM in osteosarcoma patients. According to the results of multivariable logistic regression analysis, A nomogram were established and the predictive ability was assessed by calibration plots, receiver operating characteristics (ROCs) curve, and decision curve analysis (DCA). Moreover, Kaplan-Meier plot of overall survival (OS) was plot and a web calculator visualized the nomogram.

Results: Five independent risk factors [chemotherapy, surgery, lung metastases, lymphatic metastases (M-stage) and tumor size (T-stage)] were identified by multivariable logistic regression analysis. What's more, calibration plots displayed great power both in training and validation group. DCA presented great clinical utility. ROCs curve provided the predictive ability in the training cohort (AUC = 0.805) and the validation cohort (AUC = 0.808). Moreover, patients in LNN group had significantly better survival than that in LNP group both in training and validation group.

Conclusion: In this study, we constructed and developed a nomogram with risk factors, which performed well in predicting risk factors of LNM in osteosarcoma patients. It may give a guide for surgeons and oncologists to optimize individual treatment and make a better clinical decision.

Keywords: nomogram, SEER, osteosarcoma, lymph node metastases, multicenter

INTRODUCTION

Osteosarcoma is a common malignant bone tumor. The primary treatment consisting of neoadjuvant therapy, surgery and postoperative chemotherapy have resulted in the 5-year overall survival rate of ∼60% (1, 2). However, even with the treatment of surgery and chemotherapy, the prognosis for patients with metastatic osteosarcoma remains dismal (3, 4).The lung metastases, the primary target of metastasis in osteosarcoma, has five-year survival rates of ∼30% (5, 6). In extrapulmonary metastatic osteosarcoma, patients with lymph node metastases (LNM) have worse clinical outcomes, with five-year survival rates of 10% (7). However, only 3% of patients with osteosarcoma are diagnosed with LNM, leading to the lack of adequate clinical data for exploring osteosarcoma LNM (8).Therefore, a population-based study to assess the LNM in osteosarcoma is imminent.

Furthermore, disease forecasting is a vital part of the medical research (9–18). As a visual prediction tool, nomogram lists each variable separately and assigns a corresponding score for each status (19). Based on these considerations, we mined the Surveillance, Epidemiology, and End Results (SEER) database to construct the nomogram and used data from four academic hospitals for independent validation. This study contributes to providing more personalized guidance for patient care and improving patients' prognosis.

MATERIALS AND METHODS

Data Collection

In the present study, patients diagnosed with osteosarcoma between 2010 and 2016 were collected. The training group were extracted from the Surveillance, Epidemiology, and End Results (SEER) database with the SEER * Stat software version 8.3.6. And the third edition of the International Taxonomy of Oncology (ICDO-3), morphological code (9220) was used to identify osteosarcoma. The exclusion criteria of the training group were as follows: (1) patients with no positive pathology; (2) patients with unknown lymph node status and survival time; (3) more than one primary tumor.

Data of the validation group were obtained from four academic institutions, the Second Affiliated Hospital of Jilin University, the Second Affiliated Hospital of Dalian Medical University, the Liuzhou People's Hospital affiliated to Guangxi Medical University, and the Xianyang Central Hospital. And during the period of investigation, each center was responsible for the acquisition of data by three investigators. Two investigators were responsible for data extraction and the accuracy check was conducted by the third investigator. The exclusion criteria were consistent with the training group. For multicenter data, the study was approved by the ethics review committee of four medical institutions in China, the Second Affiliated Hospital of Jilin University, the Second Affiliated Hospital of Dalian Medical University, Liuzhou People's Hospital, and Xianyang Central Hospital (No. 2021-00-22) and was conducted in accordance with the guidelines of the Helsinki Declaration.

Demographic and clinical variables, including race, age, survival time, sex, primary site, grade, laterality, tumor size (T-stage), distance metastases (M-stage), surgery, radiation, chemotherapy, bone metastases and lung metastases were considered in this study.

Abbreviations: SEER, Surveillance, Epidemiology, and End Results database; ROC, receiver operating characteristic; DCA, decision curve analysis; CI, confidence interval; AUC, area under the curve; LNN, lymph node negative; LNM, lymph node metastases; ICD, International Classification of Diseases; SD, standard deviation; KM curves, Kaplan-Meier curves; OR, odds ratio.

Statistical Analysis

Continuous variables were expressed as mean ± standard deviation (SD), and categorical variables were expressed as frequency (proportions). The Student's *t*-test, Chi-square tests and Mann–Whitney tests were applied to continuous variables and categorical variables respectively with IBM SPSS Statistics version 26.0 (SPSS Inc., Chicago, Illinois, USA). Risk factors of the osteosarcoma were assessed using logistic regression. All analyzes were performed using R software version 3.6.2 (http://www.r-project.org) including multiple R packages (Including regplot, rms, rmda and pROC). P values < 0.05 were considered statistically significant, and confidence intervals (CIs) were expressed as 95% confidence levels.

Construction, Validation and Clinical Utility of a Nomogram

The following variables were included in the univariate logistic regression analysis: race, age, survival time, sex, primary site, grade, laterality, tumor size, lymphatic metastasis, surgery, radiation, chemotherapy, bone metastases and lung metastases. According to the result of the univariate logistic regression analysis with the P value < 0.05, we performed the multivariable logistic regression analysis. And the Nomogram was constructed based on the results of multivariable logistic regression analysis with the P value < 0.05. Calibration plot and receiver operating characteristic (ROC) curves were used to evaluate the prediction performance of the nomogram. The higher the area under the curves (AUC) of ROC indicated the better model performance. In addition, the decision curve analysis (DCA) was used to evaluate the clinical utility of nomogram in decision-making. Based on the established nomogram, an interactive convenient web calculator was provided (https://drliwenle.shinyapps.io/LMOOapp/).

RESULTS

Demographic Baseline Characteristics

As shown in **Table 1**, a total of 1,256 patients were enrolled. There was no statistically significant difference between the training group ($n = 1{,}144$) and validation group ($n = 112$) except the Race ($P < 0.001$) and Chemotherapy ($P = 0.017$).

Additionally, these patients were divided into two subgroups according to the LNM in **Table 2**. There were no significant differences in race, sex, laterality and radiation between the lymph node negative group (LNN, $n = 1{,}104$) and the lymph node positive (or unable to evaluate) group (LNP, $n = 152$). However, the other characteristics showed significant differences between the two groups.

Univariate and Multivariable Logistic Regression Results

According to the univariate logistics regression analysis, we identified 10 prognostic factors including age, survival time, primary site, laterality, tumor size, lymph metastasis, surgery, chemotherapy, bone metastases and lung metastases in the training set ($P < 0.05$) (**Table 3**). Then, based on the above result, applying the multivariable logistics regression analysis, we figured out five independent prognostic factors including T-stage [TX: odds ratio (OR) 3.602,95%CI 1.710–5.483, $P < 0.001$], M-stage (M1: OR = 2.890, 1.463–5.709, $P < 0.01$), surgery (Yes: OR = 0.418, 0.247–0.706, $P < 0.01$), Chemotherapy (Yes: OR = 0.475, 0.267–0.819, $P < 0.01$)and Lung metastases (Unknown: OR = 9.407, 1.955–45.261, $P < 0.01$) (**Table 3**).

Construction and Validation of Nomogram for Chondrosarcoma Patients

The nomogram contained five risk factors confirmed to be statistically significant by logistic regression analysis, including T-stage, M-stage, surgery, chemotherapy and lung metastases (**Figure 1A**). Calibration chart of nomogram showed a good consistency in the training and validation groups (**Figures 1B,C**). The AUC values of nomogram were 0.805 (95% CI 0.781–0.827) and 0.808 (95% CI 0.723–0.877) in the training group and

the validation group respectively (**Figures 2A,B**). Furthermore, the ROC curve demonstrated a superior performance of the nomogram compared to the single variable, including chemotherapy (AUC = 0.631, 95%CI 0.602 to 0.659), lung metastases (0.697, 0.669 to 0.723), M-stage (AUC = 0.592, 95%CI 0.563 to 0.621), surgery (AUC = 0.667, 95%CI 0.639 to 0.694) and T-stage (0.706, 95%CI 0.678 to 0.732). The statistical results of validation group were consistent with the training group as shown in **Table 4**. In addition, an online web calculator was designed (https://drliwenle.shinyapps.io/LMOOapp/).

Clinical Applicability of the Nomogram

The Kaplan-Meier survival curves of training group were plotted (**Figure 3A**). The results revealed that the overall survival (OS) significantly decreased in patients with LNP comparing with the LNN ($P < 0.001$). Moreover, the threshold about 0.1 to 0.9 had the maximum benefit range of the model as shown in the DCA curve (**Figures 3C,D**). The Kaplan-Meier survival curves of validation group displayed the same trend between the two groups ($P < 0.001$) (**Figure 3B**).

DISCUSSION

Osteosarcoma metastases, which are typically secondary to hematogenous dissemination and the occurrence of lymph system is extremely rare, have been identified to be significantly associated with poor prognosis (1–4, 7, 20, 21). Comparing to

the most common lung metastases, osteosarcoma patients with lymph node involvement have a worse prognosis, suggesting that the invasion of the lymph nodes is an important indicator for the assessment of malignancy stage and the selection of a correct treatment protocol (22, 23).Meanwhile, studies points out that FDG-PET and ^{99m}Tc-labeled biomineralization

nanoprobe are effective in early diagnosis of metastatic lymph nodes in osteosarcoma (24–27). Therefore, real-time lymph node surveillance and radical treatment for osteosarcoma patients with a high risk of lymph node metastasis will improve patient survival (8). In this study, we identified five independent risk factors associated with LNM and provided a convenient nomogram prediction model and a web calculator on the basis of the model.

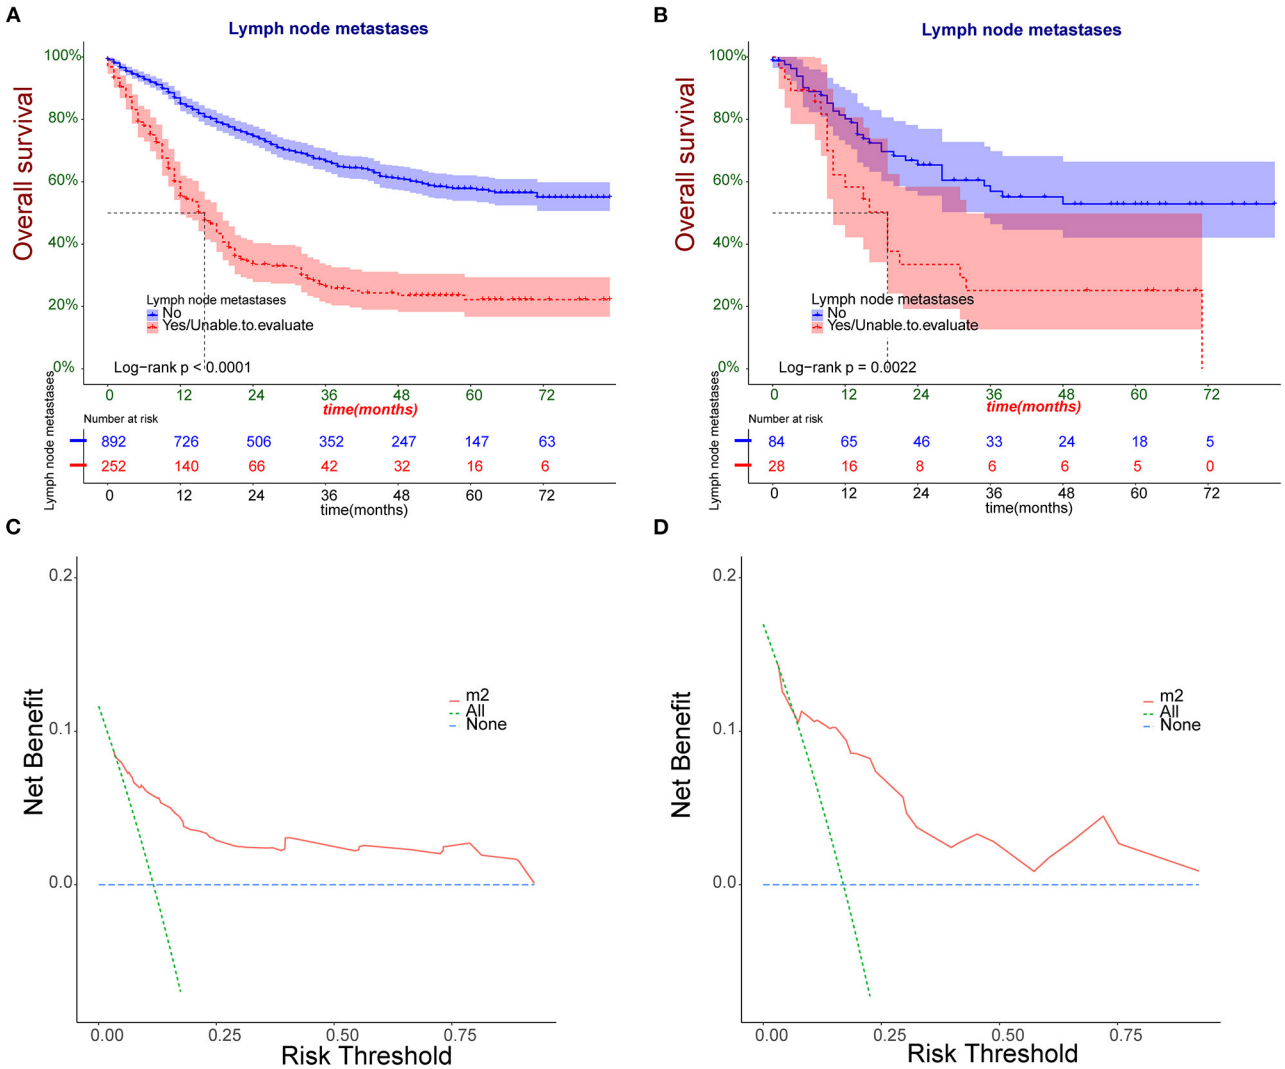

FIGURE 3 | (A,B) The Kaplan-Meier survival analysis patients with osteosarcoma in training and validation group. **(C,D)** Nomogram decision curve (DCA) of the training and validation group.

Surgery and chemotherapy are the most reliable and effective treatment options for prolonging the lives of patients and have been followed in several clinical trials (28–30). According to the multivariable logistic analysis, chemotherapy and surgery were crucial prognostic indicators. Surgery and chemotherapy contributed to improve patient prognosis, which were consistent with the result of the KM survival curve. This suggests that timely and effective treatment plays an important role in controlling lymph node metastasis and enhancing OS (15, 17, 31, 32). Unfortunately, the relationship between radiotherapy and lymph node metastasis has not been proved. A possible reason for these results would be the uncertainty of radiation therapy in cancer treatment along with the development of radiation-associated osteosarcoma make the safety of chemotherapy need to be further ensured (33, 34).

Due to the lack of lymphatic drainage in normal cortical bone and spongy bone, LNM is rare in bone sarcomas (35, 36).Regional lymph node involvement in osteosarcoma may be owing to the infiltration of the enlarged tumor parenchyma into the periphery, such as the joint capsule or synovium, leading to dissemination into the lymphatic system (37, 38).Our study reported T-stage as a significant predictor of LNM, which was also consistent with previous findings (7).Meanwhile, because of the fact that the peak incidence of the osteosarcoma is 15–19 years of age, more than 80% of patients achieve limb salvage through surgery (4, 28, 38).In this respect, the surgeons need pay more attention to the status of the regional lymph nodes during the resection of larger osteosarcoma in order to eradicate the sarcoma and preserve the limb. M-stage indicates distant metastasis in osteosarcoma, and it is also a risk factor associated with LNM. In the study by Thampi et al. osteosarcoma lymphatic

metastasis was significantly associated with distant metastasis (7).Furthermore, since the lung was the most important target organ for distant metastasis in osteosarcoma, we separated this variable from distant metastasis to emphasize the significant role played by lung metastasis in assessing lymph node status. Patients with lung metastases express the characteristic biomarker, such as KEAP, Matrix-Gla and Rab22a (39–41). Considering the intense correlation we found between lung metastasis and lymph node involvement, these reported biomarkers would be triggers for LNM. Therefore, this provides inspiration to further molecular biology studies focusing on lymph node metastasis in osteosarcoma.

We constructed a novel nomogram to assess the risk of developing lymph node metastasis in osteosarcoma, and the discriminatory of any individual predictor was inferior to that of nomogram, suggesting that the nomogram model indicated promising prospects for tumor surveillance and clinical decision making. Although some predictive nomograms have been reported in previous studies, our study complements previous work. Compared to Dong et al.'s study, external independent validation consisting of multiple academic centers is a prominent feature of this study, and the inclusion of multiple ethnic groups enhances the credibility of the results (8). Moreover, we provide a convenient and digital prediction tool for users. By analyzing the clinical characteristics and associated risk factors, we improve the prediction of lymph node metastasis risk in osteosarcoma and provide a basis for individualized treatment and follow-up strategies. The web-based calculator constructed in this study is an easy-to-use clinical tool that helps to promote personalized treatment.

Finally, one obvious limitation in this study was that the statistically significant difference between the training group and validation groups in chemotherapy may have an influence on the results. Another limitation was the lack of a more thoroughly analysis due to the inadequacy of systematic and prospective data.

CONCLUSION

In conclusion, we constructed a novel nomogram model to predict risk factors for osteosarcoma patients developing LNM, including T-stage, M-stage, surgery, chemotherapy and lung metastases based on epidemiological characteristics obtained from the SEER database and the multicenter hospitals. By combining DCA curve, ROC curve, KM curve, web calculator and external validation, our nomogram provided an accurate assessment for individualized risk of lymph node metastasis which was helpful for clinicians to make better surgery decisions.

DATA AVAILABILITY STATEMENT

The raw data supporting the conclusions of this article will be made available by the authors without undue reservation.

ETHICS STATEMENT

The SEER database is a comprehensive data source developed based on population data and updated annually since its launch in 1973. It is public and identifiably accessible that data analysis is treated as non-human subjects by the Office for Human Research Protections. As such, no institutional review board approval and informed consent were required. For multicenter data, the study was approved by the ethics review committee of four medical institutions in China, the Second Affiliated Hospital of Jilin University, the Second Affiliated Hospital of Dalian Medical University, 291 Liuzhou People's Hospital, and Xianyang Central Hospital (No. 2021-00-22) and was conducted in accordance with the guidelines of the Helsinki.

AUTHOR CONTRIBUTIONS

CY, RW, QL, and XL designed the study. WeL and SD performed the study, analyzed the data, and wrote the manuscript. BW and HW provided the expert consultations and clinical suggestions. CX and KZ conceived of the study, participated in its design and coordination. WaL and ZH helped to draft the manuscript. All authors reviewed the final version of the manuscript.

ACKNOWLEDGMENTS

We thank China's multicenter for providing us individual patient data. The multicenter data were obtained from four medical institutions in China, the Second Affiliated Hospital of Jilin University, the Second Affiliated Hospital of Dalian Medical University, Liuzhou People's Hospital, and Xianyang Central Hospital.

Tang J, Wang J and Pan X (2022) A Web-Based Prediction Model for Overall Survival of Elderly Patients With Malignant Bone Tumors: A Population-Based Study. Front. Public Health 9:812395. doi: 10.3389/fpubh.2021.812395

Background: Malignant bone tumors (MBT) are one of the causes of death in elderly patients. The purpose of our study is to establish a nomogram to predict the overall survival (OS) of elderly patients with MBT.

Methods: The clinicopathological data of all elderly patients with MBT from 2004 to 2018 were downloaded from the SEER database. They were randomly assigned to the training set (70%) and validation set (30%). Univariate and multivariate Cox regression analysis was used to identify independent risk factors for elderly patients with MBT. A nomogram was built based on these risk factors to predict the 1-, 3-, and 5-year OS of elderly patients with MBT. Then, used the consistency index (C-index), calibration curve, and the area under the receiver operating curve (AUC) to evaluate the accuracy and discrimination of the prediction model was. Decision curve analysis (DCA) was used to assess the clinical potential application value of the nomogram. Based on the scores on the nomogram, patients were divided into high- and low-risk groups. The Kaplan-Meier (K-M) curve was used to test the difference in survival between the two patients.

Results: A total of 1,641 patients were included, and they were randomly assigned to the training set (N = 1,156) and the validation set (N = 485). The univariate and multivariate analysis of the training set suggested that age, sex, race, primary site, histologic type, grade, stage, M stage, surgery, and tumor size were independent risk factors for elderly patients with MBT. The C-index of the training set and the validation set were 0.779 [0.759–0.799] and 0.801 [0.772–0.830], respectively. The AUC of the training and validation sets also showed similar results. The calibration curves of the training and validation sets indicated that the observed and predicted values were highly consistent. DCA suggested that the nomogram had potential clinical value compared with traditional TNM staging.

Conclusion: We had established a new nomogram to predict the 1-, 3-, 5-year OS of elderly patients with MBT. This predictive model can help doctors and patients develop treatment plans and follow-up strategies.

Keywords: nomogram, elderly patients, malignant bone tumors, overall survival, SEER

INTRODUCTION

The most common malignant bone tumors (MBT) in elderly patients include osteosarcoma, chondrosarcoma, and chord sarcoma. Osteosarcoma is the most common malignant bone tumor in children and adolescents. About 60% of osteosarcoma patients occur under 20 years of age, and ∼10% of patients occur over 60 years of age (1). Osteosarcoma usually occurs in the metaphysis of long tubular bones, most commonly around the knee joint. Osteosarcoma in adults can affect the axial and maxillofacial bones (2). Patients with osteosarcoma over 65 years of age are often secondary to Paget's disease (3). At the time of diagnosis of osteosarcoma, 10–20% of patients have already developed distant metastases, most of which are lung metastases. The prognosis of patients with osteosarcoma metastasis is inferior, and the overall 5-year survival rate is 20–30% (4). Chondrosarcoma accounts for about 9.2% of all primary MBT, with an annual incidence of 1/200,000 and an average age of onset of about 50 years old (5, 6). It is the second most common bone malignant tumor after osteosarcoma. Recent studies on chondrosarcoma report that the 5-year survival rate is about 75.2%, and the 10-year survival rate is about 70% (7, 8). Chondrosarcoma is mainly of the conventional type, and only 8–10% are of the unconventional kind. There is a big difference in survival and prognosis (9, 10). Chord sarcoma accounts for 1% to 4% of primary bone tumors, and the ratio of males to females is about 1.8:1. It can occur at any age, including children and adolescents, and is most common in patients between 50 and 60 years old (30%). Chord sarcoma grows slowly and occurs more frequently in the sacrococcygeal region (50–60%), skull base (25–35%), cervical spine (10%), thoracolumbar spine (5%), and rarely occurs in areas other than the axial bone (11). Although chord sarcoma is low to moderately malignant, 8% to 43% of patients still have distant metastasis (pulmonary metastasis is the most common), and the prognosis is poor. The overall 5-year survival rate of patients with metastatic chord sarcoma is only about 50% (11, 12).

Studies have reported that the main prognostic factors of osteosarcoma include tumor site, size, age, metastasis, metastasis site, chemotherapy, and surgery (13, 14). The significant prognostic factors of chondrosarcoma include primary tumor, histological type, tumor site, histological grade, and tumor size (15–17). One study showed that age, distant metastasis, and surgery are risk factors for chord sarcoma. However, there is no study on the prognostic factors of MBT in the elderly. There are very few elderly patients with MBT, and single-center studies cannot provide accurate estimates of prognostic factors.

Artificial intelligence has been widely used in human health care. Hassan et al. (18) summarized machine learning to predict the occurrence of sepsis to prevent patients from developing severe sepsis. Alhazmi et al. (19) used machine learning to predict the risk of oral cancer. Cho et al. (20) conducted a systematic review of the literature on machine learning to predict the risk of cancer brain metastasis.

The nomogram is a numerical model that predicts an outcome event by using estimated values generated based on various variables (21, 22). The construction of the nomogram is based on big clinical data, and a small number of cases may cause inaccurate predictions. The United States Surveillance, Epidemiology, and End Results (SEER) project is a cancer data center established in the United States in 1973, collecting information on cancer patients in 18 registries (23). The SEER database can provide enough cases to build a nomogram prediction model. Accurate prediction of survival time can help doctors better monitor patients. The prognostic factors of cancer-specific survival in elderly patients with bone tumors are not yet fully understood. Our purpose is to explore the prognostic factors affecting the survival of elderly patients with malignant bone tumors. Accurate prediction of survival time can help doctors better monitor patients. The prognostic factors of cancer-specific survival in elderly patients with bone tumors are not yet fully understood. Our purpose is to explore the prognostic factors affecting the survival of elderly patients with malignant bone tumors. We aim to construct a nomogram to predict the survival and prognosis of elderly patients with MBT to help doctors and patients formulate clinical treatment plans and follow-up strategies. After the model was established, we also conducted a series of validations on the prediction model's performance.

METHODS

Data Source and Data Extraction

The clinicopathological information of all patients over 60 years old with chondrosarcoma, osteosarcoma, and chord sarcoma from 2004 to 2018 was extracted from the SEER database. The extracted information includes age, gender, race, primary sit, histological grade, histological type, tumor size, TNM stage, surgery, radiotherapy, chemotherapy, and follow-up information. The selection criteria are: (1) age $\geq$ 60 years old; (2) histological classification includes: chondrosarcoma, osteosarcoma, and chord sarcoma. The exclusion criteria are: (1) survival time is less than one month; (2) tumor size is unknown; (3) TNM stage is unknown (4) surgical method is unknown; (5) tumor stage is unknown. The flow chart of patient screening is shown in **Figure 1**.

The age of all patients was divided into five groups, including 60–64, 65–69, 70–74, 75–79, $\geq$80 years old. The race was divided into three categories: white, black, and others (American Indian/AK Indian, Asian/Pacific Islander). The tumor grade was divided into four grades: well-differentiated, moderately differentiated, poorly differentiated, and undifferentiated, and some were unknown graded. The tumor stage was divided into three categories, including localized, regional, and distant. Surgical methods included no surgery, partial resection, radical resection, and amputation.

Nomogram Construction and Validation

All patients were randomly divided into a training set (70%) and a validation set (30%). Univariate and multivariate Cox regression models were used to determine independent risk factors for patients. These risk factors were included in the nomogram to predict the 1-, 3-, and 5-year OS of elderly patients with MBT. The consistency index (C-index) was used to test the discrimination of the nomogram. The area under the receiver

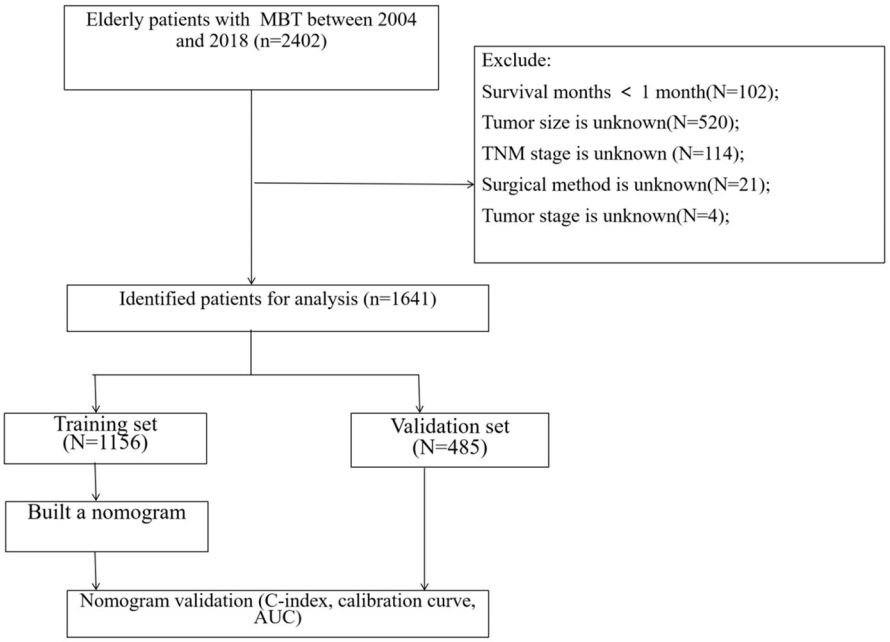

FIGURE 1 | The flowchart of including and dividing patients.

operating curve (AUC) was also used to evaluate the training and validation set's accuracy and discrimination. A calibration curve of 1,000 bootstrap weight samples was used to test the accuracy of the prediction model.

Clinical Utility

Decision curve analysis (DCA) of the training set and validation set was used to evaluate the clinical value of the nomogram. A new algorithm assesses the model's weight by calculating the net benefit under the risk threshold (24). We also compared the DCA benefit of the nomogram and traditional TNM staging. According to the nomogram score, all patients were divided into low-risk and high-risk groups. Kaplan-Meier curve and the log-rank test were used to test the difference in survival between the two groups. We also compared the survival differences of patients in different risk groups under different surgical methods.

Statistical Analysis

All statistical analyses were performed using SPSS version 26.0 and R software version 4.1.0. The median (inter-quartile range) was used to describe the data that did not follow the normal distribution for measurement data. The non-parametric test (U-test) was used to analyze the difference. For count data, used frequency (%) to describe, used chi-square analysis and non-parametric *U*-test for analysis. Univariate and multivariate Cox regression models were used to analyze survival risk factors. This study believes that $P<0.05$ is statistically significant, and this test is two-sided.

RESULTS

Clinical Features

A total of 1,641 patients were included, and they were randomly assigned to the training set ($N = 1{,}156$) and the validation set ($N = 485$). The clinical-pathological data of the patient is shown in **Table 1**. There were 887 males (54.1%) and 1,424 whites (86.8%). There were 958 cases (58.4%) of chondrosarcoma, 328 cases (20.0%) of osteosarcoma, and 355 cases (21.6%) of chord sarcoma. Patients with tumor grade I, II, III, and IV were 229 (14.0%), 404 (24.6%), 245 (14.9%), and 259 (15.8%), respectively; 504 (30.7%) patients were unknown grades. In the tumor stage, 713 cases (43.4%) were localized, 696 cases (42.4%) were regional, and 232 cases (14.1%) were distant. There were 336 (20.5%) without surgery, 458 (27.9%) with partial resection, 661 (40.3%) with radical resection, and 186 (11.3%) with amputation. Tumor primary sites included 623 cases (38.0%) in limbs, 231 cases (14.1%) in skull, 134 (8.17%) in spine, 246 cases (15.0%) in thorax, and 407 cases (24.8%) in pelvis. There is no significant difference between the clinical-pathological data of the patients in the training set and the validation set.

Univariate and Multivariate Cox Regression Analysis

We used univariate Cox regression analysis to confirm the risk factors for the prognosis initially. The selected risk factors were then included in the multivariate Cox regression analysis. In the end, we found that age, sex, race, primary site, histologic type, grade, stage, M stage, surgery, and tumor size were independent risk factors for elderly patients with MBT. The independent

risk factors screened by univariate and multivariate analysis are shown in **Table 2**.

Nomogram Construction and Validation

A nomogram was constructed based on the identified independent risk factors to predict the 1-, 3-, and 5-year OS of elderly patients with MBT (**Figure 2**). It can be seen from the nomogram that tumor size has the most significant impact on OS, followed by primary tumor site, grade, and surgery. The calibration curves of the training set and the validation set showed that the observed value and the predicted value were highly consistent, indicating the accuracy of the nomogram prediction (**Figure 3**). The C-index of the training set and the validation set were 0.779 [0.759–0.799] and 0.801 [0.772–0.830], respectively, indicating that the nomogram had good discrimination. The AUC of the training set and the validation set also showed similar results (**Figure 4**).

Clinical Application of the Nomogram

DCA suggested that nomogram had potential clinical value compared with traditional TNM staging (**Figure 5**). Based on the score of each patient in the nomogram, the patients were divided into a low-risk group (total score $\leq$ 149.4) and a high-risk group (total score $>$ 149.4). Apparent differences in survival were observed from the K-M curves of the training set and validation sets' K-M curves (**Figure 6**). The K-M curve indicated that the nomogram has an excellent discriminating ability. We found that patients in the high-risk group who chose partial resection had a higher survival rate according to risk groups. At the same time, there is no significant difference in the prognosis of patients in the low-risk group with various treatment methods (**Figure 7**).

Online Application for OS Prediction

We have developed a web calculator based on the nomogram, which can be accessed at https://jietang.shinyapps.io/DynNomapp/. Enter the clinicopathological characteristics of the patient on this web page to get the corresponding survival probability. This calculation is easy to use and friendly to both patients and doctors.

DISCUSSION

Cancer is one of the most common causes of death in elderly patients. The morbidity and mortality of bone tumors are high. A study has reported 3,600 new bone tumor patients in the United States each year and 1,720 deaths from bone tumors (25). Although MBT is not common, their mortality is still high. The three most common MBT in elderly patients include chondrosarcoma, osteosarcoma, and chord sarcoma, of which chondrosarcoma is the most common (5, 6). Our study also found that most elderly patients with MBT over 60 years old are chondrosarcoma. Giuffrida et al. (7) found considerable differences in the 5-year survival rate of patients with different chondrosarcoma subtypes. The 5-year survival rate of dedifferentiated chondrosarcoma is 0%, while the exact cell type reaches 100%, the mucinous type is 71%, the paracortical type is 93%, the mesenchymal chondrosarcoma is 48%, and the malignant chondroblastoma is 85%. Strotman et al. (10) found that the 5-year overall survival rate of dedifferentiated chondrosarcoma is only 18%. The prognosis is worse for patients with axial bone, tumor size $>$8 cm, and lung cancer metastasis. A study by Bielack et al. (2) showed that age, location, and metastasis are the prognostic factors of patients with osteosarcoma. Previous studies have reported the predictive factors of osteosarcoma and predicted overall survival and cancer-specific survival (26, 27). Chord sarcoma is also a malignant bone tumor with high incidence in elderly patients. Previous studies have reported that chordoma mainly occurs in patients over 30 years old, and most of them are people over 60 years old (28). Chord sarcoma rarely metastasizes, but the 5-year survival rate will drop to about 50% (12). The incidence and prognostic factors of MBT in elderly patients have not yet been reported in the literature. Accurate prediction of patient survival is conducive to future treatment and follow-up. Therefore, we developed and validated nomograms to predict the survival of elderly patients with MBT.

In our study, we found that the increase in age will reduce the survival rate of elderly patients. Previous studies have also reported that age is a risk factor for bone tumors (27, 29). The reason may be that the increase in age leads to a decrease in the suppression of tumors by the immune system and an increase in the probability of comorbidities. In addition, our study also

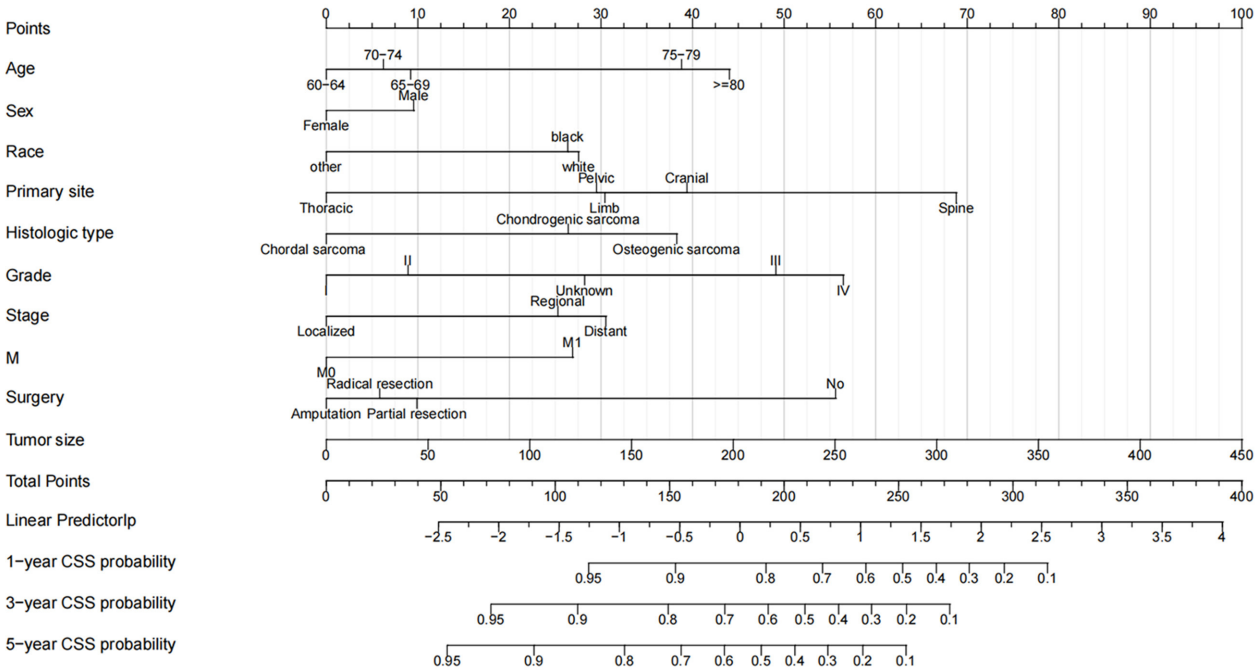

FIGURE 2 | Nomogram for 1-, 3-, and 5-year OS of elderly patients with MBT. The first row of the nomogram is the scoring ruler, rows 2–11 are the variables, and the 12th row is the patient's total score. 13–16 are the full score corresponding to the patient's 1-, 3-, and 5- survival rates.

found that the tumor site and size are also important factors affecting the prognosis. Similar to previous studies, patients with axial and large tumors have a higher risk of death (30–32). It may be because larger tumors are more likely to metastasize, and tumors in the axial position, especially the spine, are more likely to metastasize and invade surrounding tissues (33). Previous studies have found that the tumor stage is also a significant risk factor. The prognosis of distantly metastatic tumors is worse than localized tumors (34, 35). Our study also found that the tumor stage is an independent risk factor for prognosis. Besides, we found that sex and race are also significant risk factors, which have not been seen in previous studies. Women have a better survival prognosis than men. American Indians and Asians seem to have higher survival rates than whites and blacks.

In this study, we found that surgery significantly improved the prognosis of patients, similar to the results of previous studies (36, 37). In addition, according to risk stratification, we found that patients in the high-risk group benefited the most from partial tumor resection. At the same time, there is no significant difference in the prognosis of patients in the low-risk group with various treatment methods. Since most of the patients in the high-risk group are in the late stage of the disease and

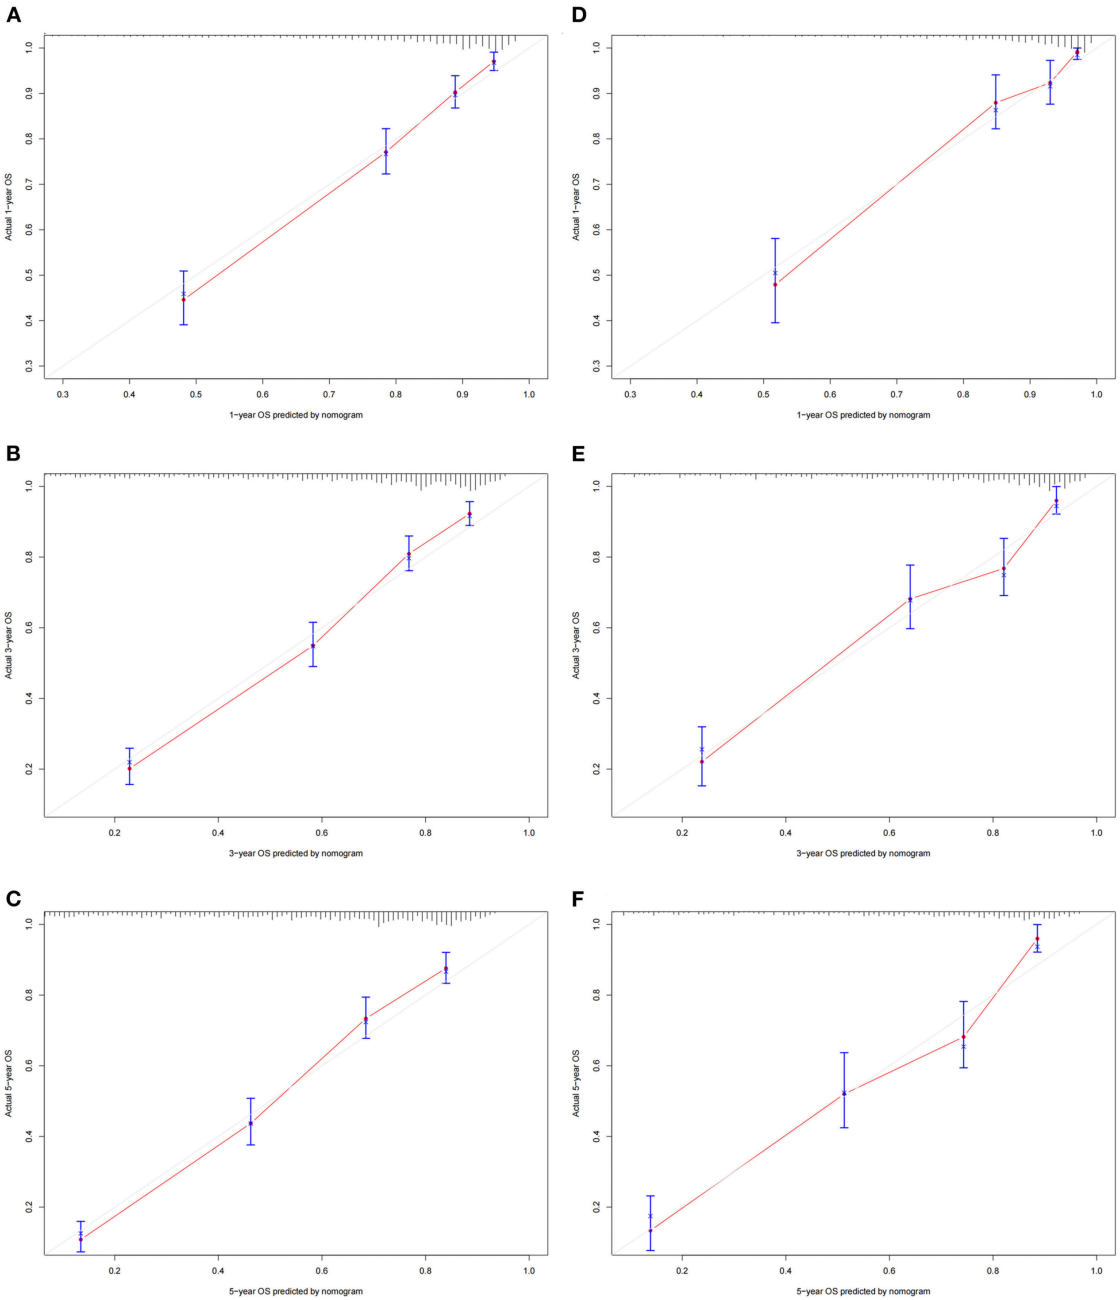

FIGURE 3 | Calibration curves of the nomogram. **(A–C)** For 1-, 3-, and 5-year OS in the training set; **(D–F)** For 1-, 3-, and 5-year OS in the validation set. The horizontal axis is the predicted value of the nomogram, and the vertical axis is the actual observed value of the nomogram. The coincidence between the predicted curve and the diagonal line means that the predicted value and the actual observed value are almost the same.

have already developed distant metastases, radical resection does not seem to improve the prognosis of the patients. This has some enlightenment for doctors and patients in choosing surgical methods for patients with different risks. On chemotherapy, our study found that chemotherapy does not affect patient survival, similar to previous studies (38).

Although our nomogram includes three histological types of MBT, it has been validated that the prediction model has good accuracy and discrimination. The C-index of the training set and the validation set were 0.779 [0.759–0.799] and 0.801 [0.772–0.830], respectively, proving the discriminative ability of the nomogram. The predicted value of the calibration curve is

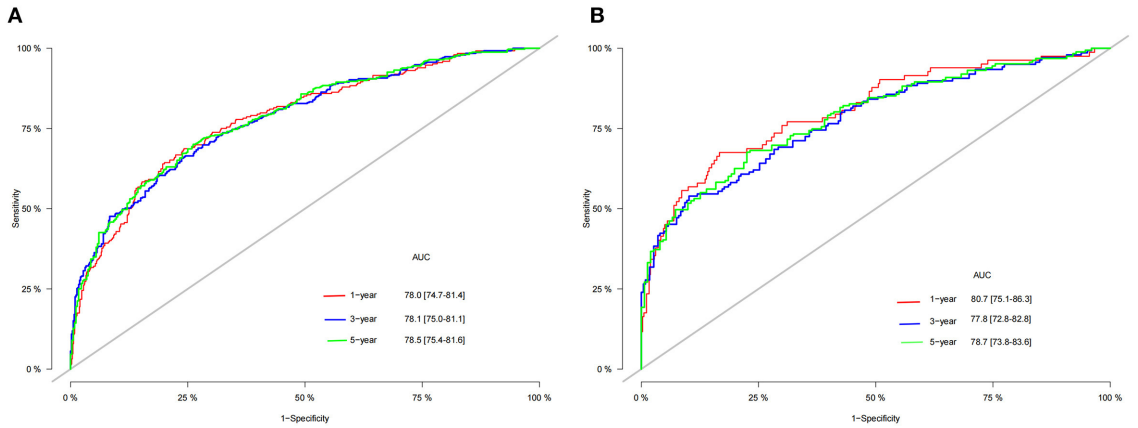

FIGURE 4 | The AUC of 1-, 3- and 5-year training set **(A)** and validation set **(B)**.

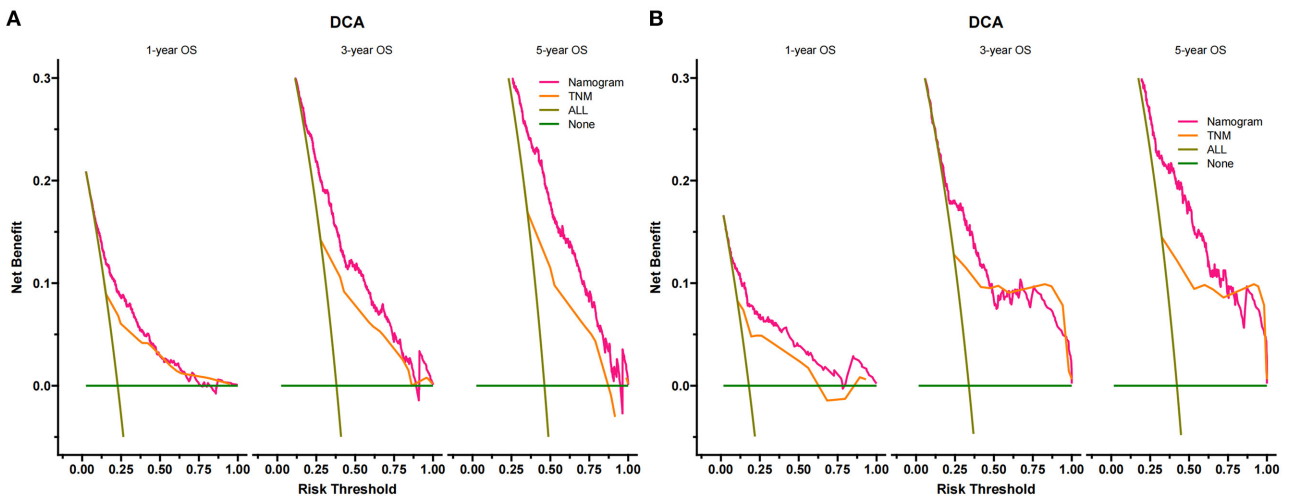

FIGURE 5 | Decision curves of the nomogram predicting OS in the training set **(A)** and validation set **(B)**. The y-axis represents the net benefit, and the x-axis represents the threshold probability. The green line indicates that no patients have died, and the dark green line indicates that all patients have died. When the threshold probability is between 20 and 100%, the net benefit of the model exceeds all deaths or no deaths.

highly consistent with the observed value, which indicates the accuracy of the prediction model. We compared the 1-, 3-, and 5-year DCA of the nomogram with the traditional TNM staging system and proved that the clinical value of the nomogram is higher than that of the traditional TNM staging system. Risk stratification also accurately distinguished high-risk and low-risk patients, and treatment and follow-up strategies should be different for patients in other risk groups. Patients in the high-risk group should choose appropriate treatment and receive closer follow-up.

This study is the first to explore risk factors for death in elderly patients with MBT using data from the SEER database. The overall survival rate of elderly patients with MBT was predicted based on risk factors. In other words, when elderly patients with MBT are admitted to hospitals, doctors can accurately inform patients of the 1-, 3- and 5-year survival rates based on these critical prognostic factors and make corresponding treatment decisions and follow-up strategies according to the survival rate of patients. This nomogram is of great significance for elderly patients with MBT.

However, our study still has some limitations. First, the SEER database cannot obtain detailed information on some variables such as surgical margins, BMI, smoking, and drinking, so it has a specific impact on prediction accuracy. However, we include essential variables such as tumor stage, size, surgery, and other factors that affect the prognosis of patients so that the results will not cause a devastating deviation. Second, The lack of information on some critical variables will cause errors in the prediction results. For example,

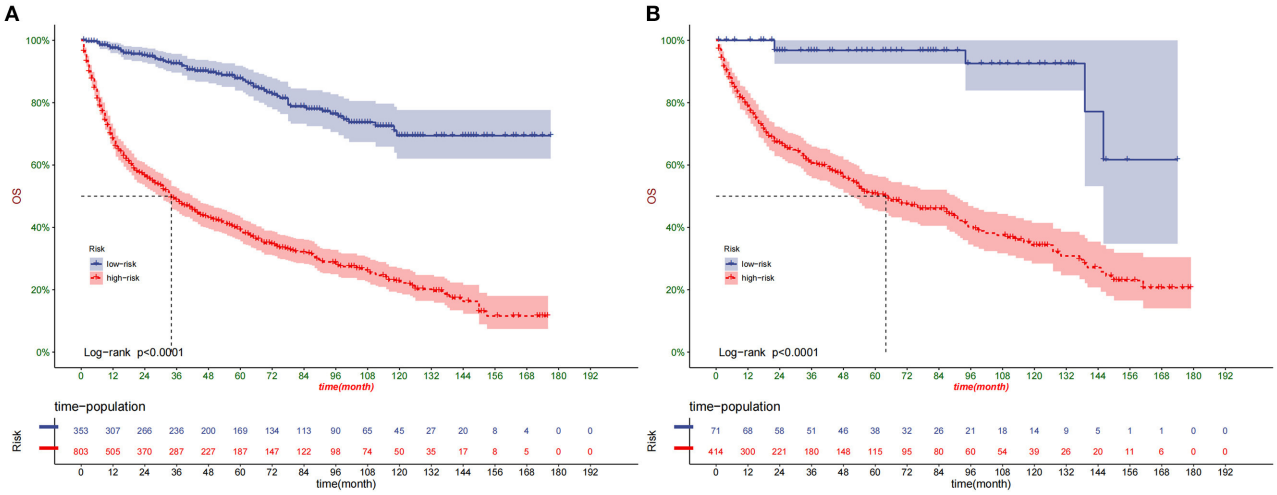

FIGURE 6 | Kaplan–Meier curves of OS for patients in the low- and high-risk groups in the training set **(A)** and validation set **(B)**.

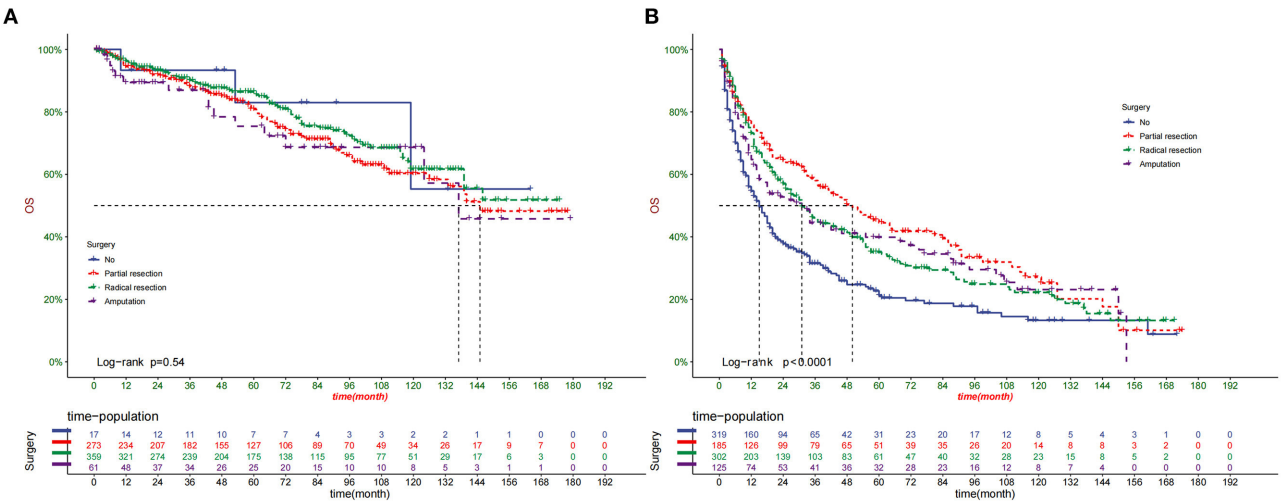

FIGURE 7 | Comparison of different surgical methods of Kaplan–Meier curves in low-risk **(A)** and high-risk **(B)** groups.

the tumor grade of some patients is unknown. However, it can be seen from the nomogram that the lack of tumor grade of some patients did not cause serious bias. Finally, our nomogram has only been validated internally, and external validation is necessary to test the predictive power of the nomogram.

CONCLUSION

A comprehensive nomogram was constructed to predict the 1-, 3-, and 5-year overall survival of elderly patients with MBT. This nomogram has been validated to have good accuracy and reliability and help patients and doctors predict survival prognosis and formulate treatment and follow-up strategies.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://seer.Cancer.gov.

Xue X, Yang X, Deng Z, Tu H, Kong D, Li N and Xu F (2022) Global Trends and Hotspots in Research on Rehabilitation Robots: A Bibliometric Analysis From 2010 to 2020. Front. Public Health 9:806723. doi: 10.3389/fpubh.2021.806723

Background: In recent years, with the development of medical science and artificial intelligence, research on rehabilitation robots has gained more and more attention, for nearly 10 years in the Web of Science database by journal of rehabilitation robot-related research literature analysis, to parse and track rehabilitation robot research hotspot and front, and provide some guidance for future research.

Methods: This study employed computer retrieval of rehabilitation robot-related research published in the core data collection of the Web of Science database from 2010 to 2020, using CiteSpace 5.7 visualization software. The hotspots and frontiers of rehabilitation robot research are analyzed from the aspects of high-influence countries or regions, institutions, authors, high-frequency keywords, and emergent words.

Results: A total of 3,194 articles were included. In recent years, the research on rehabilitation robots has been continuously hot, and the annual publication of relevant literature has shown a trend of steady growth. The United States ranked first with 819 papers, and China ranked second with 603 papers. Northwestern University ranked first with 161 publications. R. Riener, a professor at the University of Zurich, Switzerland, ranked as the first author with 48 articles. The *Journal of Neural Engineering and Rehabilitation* has the most published research, with 211 publications. In the past 10 years, research has focused on intelligent control, task analysis, and the learning, performance, and reliability of rehabilitation robots to realize the natural and precise interaction between humans and machines. Research on neural rehabilitation robots, brain–computer interface, virtual reality, flexible wearables, task analysis, and exoskeletons has attracted more and more attention.

Conclusions: At present, the brain–computer interface, virtual reality, flexible wearables, task analysis, and exoskeleton rehabilitation robots are the research trends and hotspots. Future research should focus on the application of machine learning (ML), dimensionality reduction, and feature engineering technologies in the research and development of rehabilitation robots to improve the speed and accuracy of algorithms. To achieve

wide application and commercialization, future rehabilitation robots should also develop toward mass production and low cost. We should pay attention to the functional needs of patients, strengthen multidisciplinary communication and cooperation, and promote rehabilitation robots to better serve the rehabilitation medical field.

Keywords: machine learning, bibliometric analysis, CiteSpace, trend, artificial intelligence, rehabilitation robot

INTRODUCTION

In the era of the COVID-19 pandemic, reducing doctor–patient contact is an important measure to prevent crossinfection. The use of rehabilitation robots to assist healthcare workers in treating patients with COVID-19 has reduced doctor–patient contact and increased productivity. Rehabilitation robotics is a relatively young and rapidly growing field with increasing penetration into the clinical environment (1, 2). Functional rehabilitation and the auxiliary robot have gradually become important technical means of clinical rehabilitation treatment in the world and have spawned several new rehabilitation robot technologies and systems (3). They have received great attention from all countries and have developed with each passing day (4). Rehabilitation robots, originating from the research field of engineering, are the perfect combination of rehabilitation medicine and robot technology, which makes up for the deficiency of traditional rehabilitation treatment methods in ensuring the high intensity of rehabilitation training, the persistence of endurance, and the standardization of training effects. They integrate the knowledge of artificial intelligence, biomechanics, information science, and rehabilitation medicine and use intelligent bionic technology to assist patients to complete limb-training movements and achieve the purpose of rehabilitation. These robots are used mainly for the assistance and rehabilitation of the daily life of the disabled (5–8).

According to the functional classification, rehabilitation robots are mainly divided into three types: full-body rehabilitation robots (9), upper limb robots (10), and lower limb rehabilitation robots (11). According to the means of application, they can be divided into fixed wearable robots, such as exoskeleton robots. The exoskeleton robot is mainly used to assist walking and is a special type of rehabilitation robot. Stationary robots are mainly used for rehabilitation training. Exoskeletons and soft-bodied robots are divided according to how the driving force is transmitted (12–14). Functional rehabilitation robots are mainly applied to chronic patients with stroke, cerebral palsy, spinal cord injury, paraplegia, traumatic brain injury, and limb injury. Due to the limited function recovery effect of traditional rehabilitation training methods on chronic injury, rehabilitation robot-assisted training is being studied and applied more and more (15–20). At present, rehabilitation robots have been widely used in rehabilitation nursing, prosthesis, and rehabilitation therapy, which not only promotes the development of rehabilitation medicine but also drives the development of new technologies and new theories in related fields. At the same time, there are still many challenges in the development of rehabilitation robots, there are still controversies in the research on rehabilitation robots, such as safety problems, and the actual operation is not simple and convenient, so that it is limited to large hospitals; moreover, the number of people who are suitable and can use rehabilitation robots is small, and the actual utilization rate is low (21, 22). For various rehabilitation robots with different characteristics and advantages, the application effect of different rehabilitation programs is not clear, so it is particularly important to formulate the user guide of rehabilitation robots to guide the clinical application of rehabilitation robots.

CiteSpace visual analysis software is a Java application that generates cocitation networks based on reference citations to reveal the structure of a particular research area, enabling visual exploration through knowledge discovery in bibliographic databases. Through progressive knowledge domain visualization, the most cited and critical documents, areas of expertise within the knowledge domain, and the emergence of research topics can be intuitively plotted to detect and visualize trends and patterns in the scientific literature (23). The key issue in evidence-based medical practice is to find the best available evidence about a clinical problem, and the task can be simplified by combining visual analysis techniques with traditional methods developed in evidence-based medicine (24–27). After consulting the database, it was found that the research in the field of rehabilitation robots increased significantly after 2010. Therefore, this study took the literature related to rehabilitation robots collected in the core data collection of the Web of Science database from 2010 to 2020 as the research object (28). It uses CiteSpace 5.7 visualization software, combining the qualitative analysis of the online platform and the traditional method of literature metrology, research focus from the literature field, high-influence countries or regions, institutions, the author, the high-frequency keywords and mutation term, etc., on the international research hotspot in the field of rehabilitation robots and frontier parsing and tracking. The study also provides some references for the research on rehabilitation robots and the development of related subjects. At the same time, the future development trend of rehabilitation robots is prospected, which is of great significance to improve the function of rehabilitation robots and to develop and improve the future medical field.

METHODS

Data Sources and Retrieval Strategies

The core data set of the Web of Science database was retrieved by computer, and the retrieval condition was "TS = (Rehabilitation Robot OR Rehabilitation Robotics)." The period is set as December 31, 2010 to December 31, 2020. The article is a peer-reviewed journal paper with good authority and representativeness. To ensure high-quality visualization results, the literature type in this study is limited to "article," and the

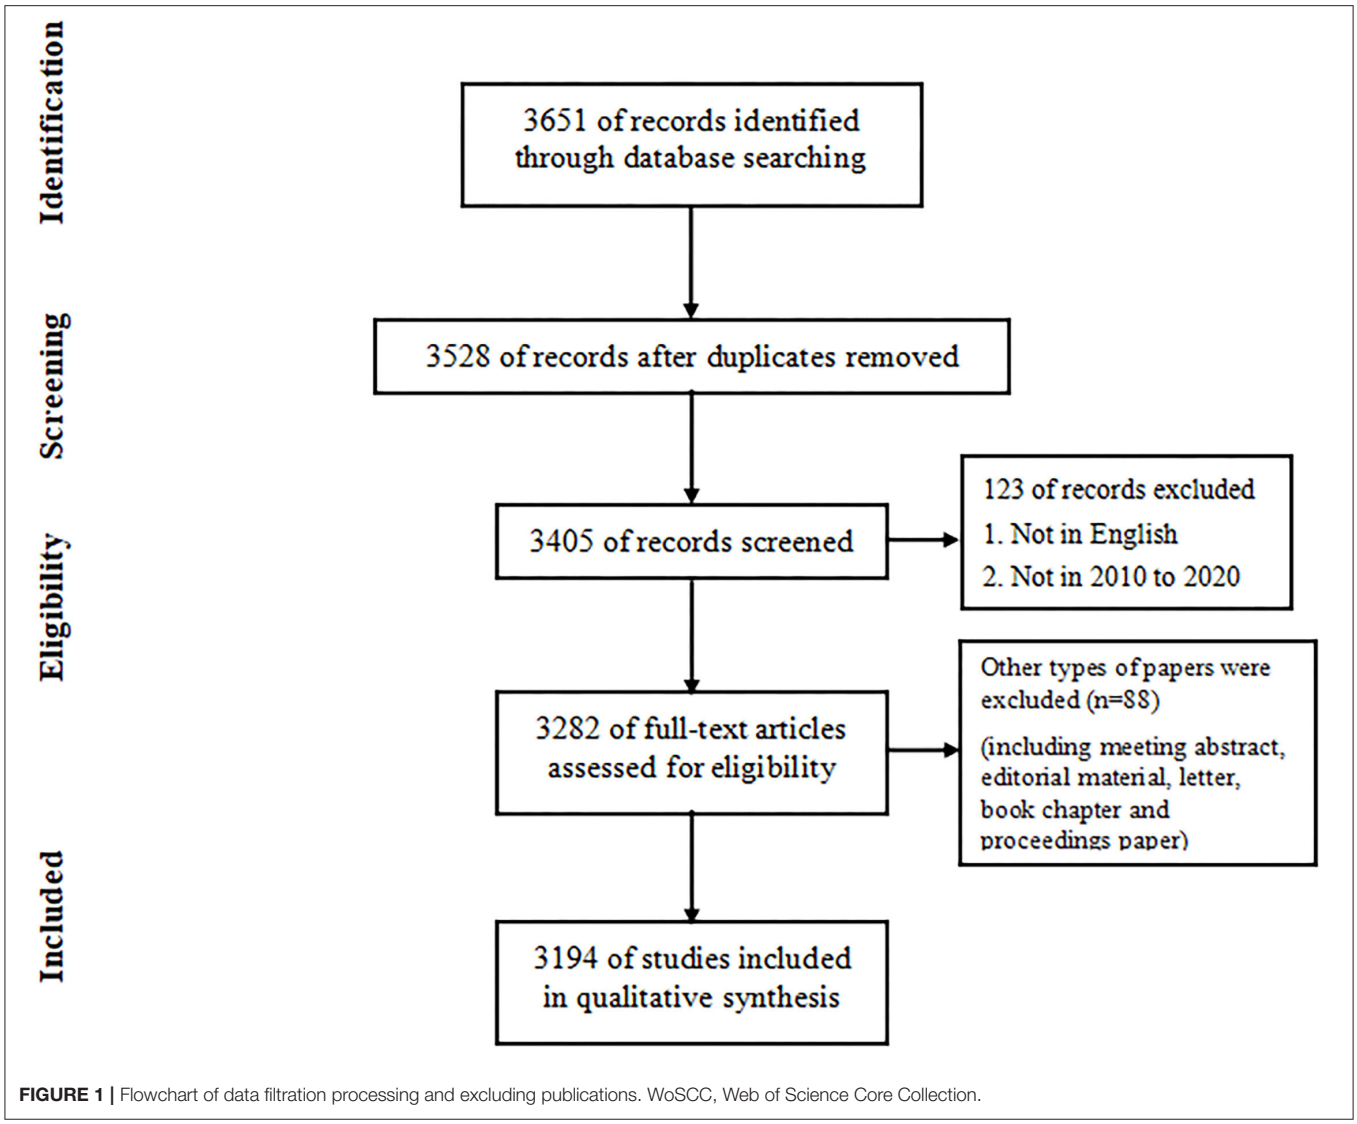

FIGURE 1 | Flowchart of data filtration processing and excluding publications. WoSCC, Web of Science Core Collection.

language type is set as "English." It excludes conference abstracts, letters, reviews, news, journal reviews, and other literary types.

Literature Screening

Two evaluators read the literature independently. First, preliminary screening was carried out according to the title and abstract of the article, and then screening was carried out again according to the inclusion and exclusion criteria. After the screening, if there was any dispute, the third evaluator read the whole paper, discussed it together, and decided whether or not to reject it.

Data Analysis

CiteSpace 5.7 visualization software determines the information related to the literature according to the information of the first author in the article, mainly including the country, author, keywords, research institution, and so on. In the CiteSpace 5.7 visual software parameter setting, the period is set to 2010–2020; the time scale is set to 1 year; the threshold is set to "top N" and set to 50; and the top 50 representative papers are selected for systematic review and analysis. We chose Pathfinder as the clipping connection to simplify the network structure and highlight important features. Countries (regions), institutions, authors, cited authors, and keywords were selected for node type cooccurrence analysis to draw a visual atlas. CiteSpace was used to detect the mutation rate of keywords and generate a keyword ranking table with a high mutation rate. In the network graph, different nodes represent various elements, such as authors, institutions, countries, and keywords, whereas the size of nodes reflects the number or frequency of publications, and the connections between nodes represent relations such as cooperation, cooccurrence, or cocitation (23, 29–31).

RESULTS

Bibliometric of Publication Output

A total of 3,194 publications met the inclusion criteria from 2010 to 2020 (**Figure 1**). **Figure 2** shows the total number

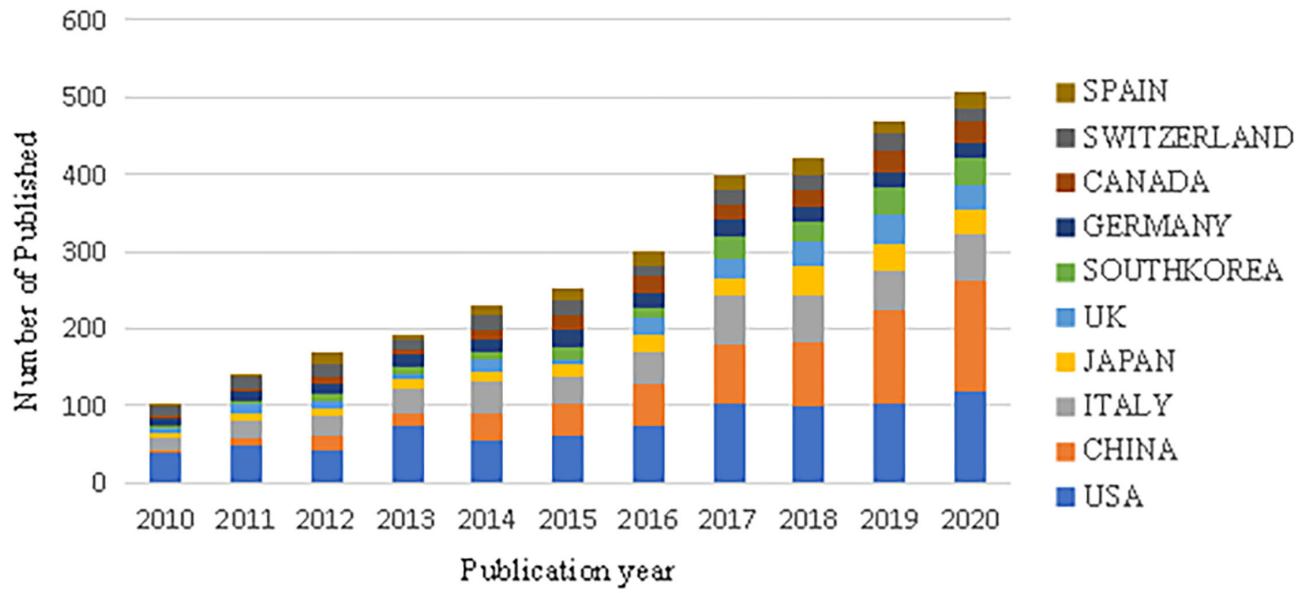

FIGURE 2 | Bibliometric analysis of WoS core database output. From 2010 to 2020, the number of published publications by different countries on rehabilitation robot research has changed over the years.

of publications annually, where the number of papers in rehabilitation robot research maintained a gradually increasing trend from 2010 to 2020.

Hot Topics in Literature Research

Among the 3,194 retrieved publications, according to the distribution analysis of literature research hotspots, the literature with more than 50 articles was classified into 25 categories (**Figure 3**). Of these, 809 belong to the category of rehabilitation medicine, 721 biomedical engineering, and 589 neuroscience. It can be seen from the data that rehabilitation robots are widely studied and applied in the fields of rehabilitation medicine, biomedical engineering, and neuroscience.

Country or Geographic Analysis

A total of 82 countries or regions contributed to the research on rehabilitation robots, as shown in **Table 1**, among which the United States published the most articles (819). China ranked second with 603 publications. The third was Italy, with 444. A total of 2,605 institutions have published research related to rehabilitation robotics, the most prolific of which is Northwestern University (USA), with 161 publications. The second is the University of Tsukuba (Japan), with 133 publications. The University of Maryland ranked third with 81 publications (**Table 1**). Visualization of the study countries shows that the top three countries in centrality are Spain (0.4), the USA (0.26), and Germany (0.17). These three countries have established good research cooperation with other countries. The detailed cooperation between countries or regions is shown in **Figure 4**.

Research Hotspots Based on Cooccurrence of Research Institutions

Through the analysis of cooperative cooccurrence of research institutions, CiteSpace software was used to draw the view of research hotspots of cooperative cooccurrence of research institutions of rehabilitation robots. A total of 411 nodes and 616 connections were generated, and the density of the topological network was 0.0073. Visualization of research institutions shows that Scuola Super Sant Anna (0.24), Northwestern University (0.23), and MIT (0.12) rank in the top three in centrality, respectively. These three institutions have established good research cooperation with other institutions (**Figure 5**).

High-Influence Authors and Cooperative Relationships

R. Riener, a professor at the University of Zurich in Switzerland, is the most prolific author with 48 articles, followed by S.K. Agrawal, a professor at Columbia University in the US, and Y. Sankai, a professor at the University of Tsukuba in Japan, with 29 articles. G. Kwakkel, a professor at the University of Amsterdam (512 times), followed by S. Hesse, a professor at Freie Universitat Berlin (512 times), and J. Mehrholz, a professor at Technische Universitat Dresden (335 times) (**Table 2**). In the author collaboration atlas, Professor R. Riener holds the leading

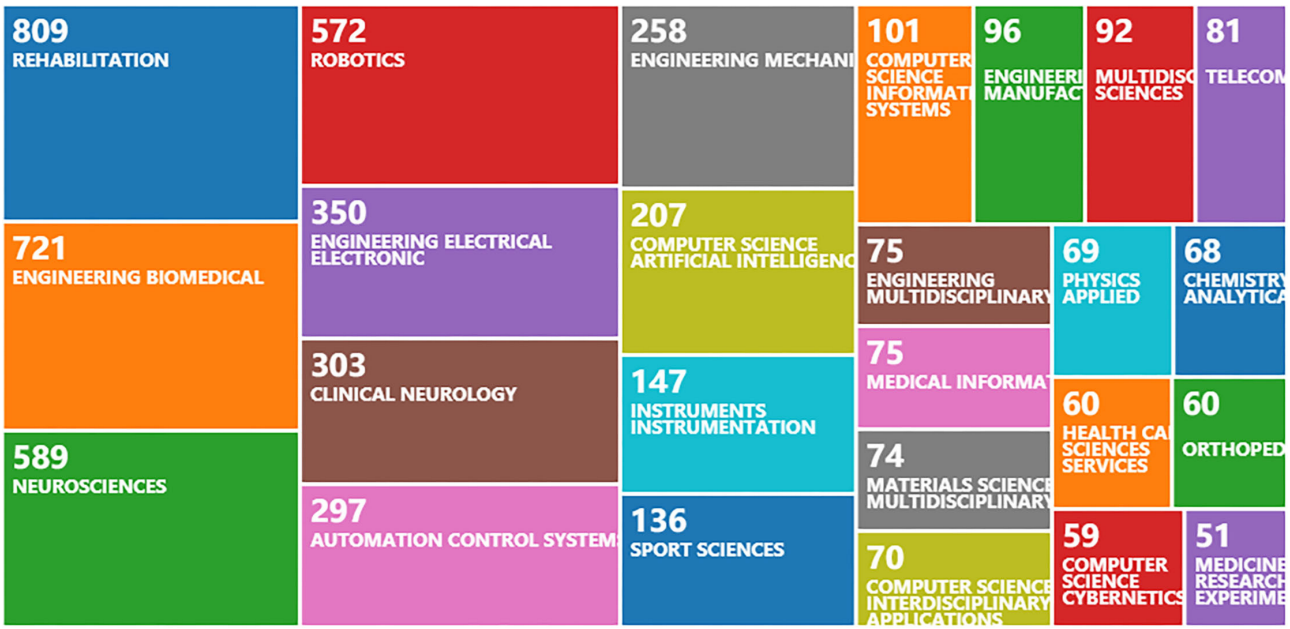

FIGURE 3 | 2010–2020 rehabilitation robot literature research hotspot distribution.

TABLE 1 | Influence of high-yield countries and institutions on rehabilitation robot research literature from 2010 to 2020.

Ranking	Countries/regions	No. of publications	Centrality	Institutions	No. of publications
1	USA	819	0.26	Northwestern Univ	161
2	China	603	0.08	Univ Tsukuba	133
3	Italy	444	0.15	Univ Maryland	81
4	Japan	221	0.06	Scuola Super Sant Anna	81
5	UK	208	0.15	Univ Auckland	80
6	South Korea	187	0.03	Chang Gung Univ	80
7	Germany	181	0.17	Natl Univ Singapore	79
8	Canada	180	0.15	MIT	76
9	Switzerland	177	0.07	Columbia Univ	75
10	Spain	159	0.4	Univ Twente	61

position in this field by absolute advantage. However, there is no cooperative relationship with other authors with a high number of publications, and the cooperative relationship between other highly influential authors is also average (**Figure 6**).

High-Influence Journals

Among the 3,194 articles retrieved, there are 515 source journals and the top 10 journals in terms of publication volume (**Table 3**). The top three journals in terms of publications are J Neuroeng Rehabil, IEEE T Neur Sys Reh, and IEEE Robot Autom Let.

Highly Cited Literature

Among the 3,194 retrieved articles, the total citation frequency was 47,224, and the top 10 cited (32–41) kinds of literature with high citation frequency (**Table 4**). The top three sources are LANCET, NEJM, and ROBOT AUTON SYST.

Research Hotspots Based on Keyword Cooccurrence

Through keyword cooccurrence analysis, 20 high-frequency keywords with a frequency greater than 150 times were statistically ranked. The top three high-frequency keywords were "rehabilitation" (1,276 times), "stroke" (940 times), and "design" (471 times). The top three high-frequency keywords in centrality are "robot" (0.15), "walking" (0.15), and "movement" (0.15) (**Table 5**). CiteSpace software was used to draw the hotspot view of rehabilitation robot research. A total of 607 nodes and 2,728 connections were generated, and the density of the topological network was 0.0148 (**Figure 7**).

Keywords Clustering Research Hotspots and Frontier

CiteSpace was used for clustering analysis of keywords, and the classic LLR algorithm was adopted to obtain nine clustering

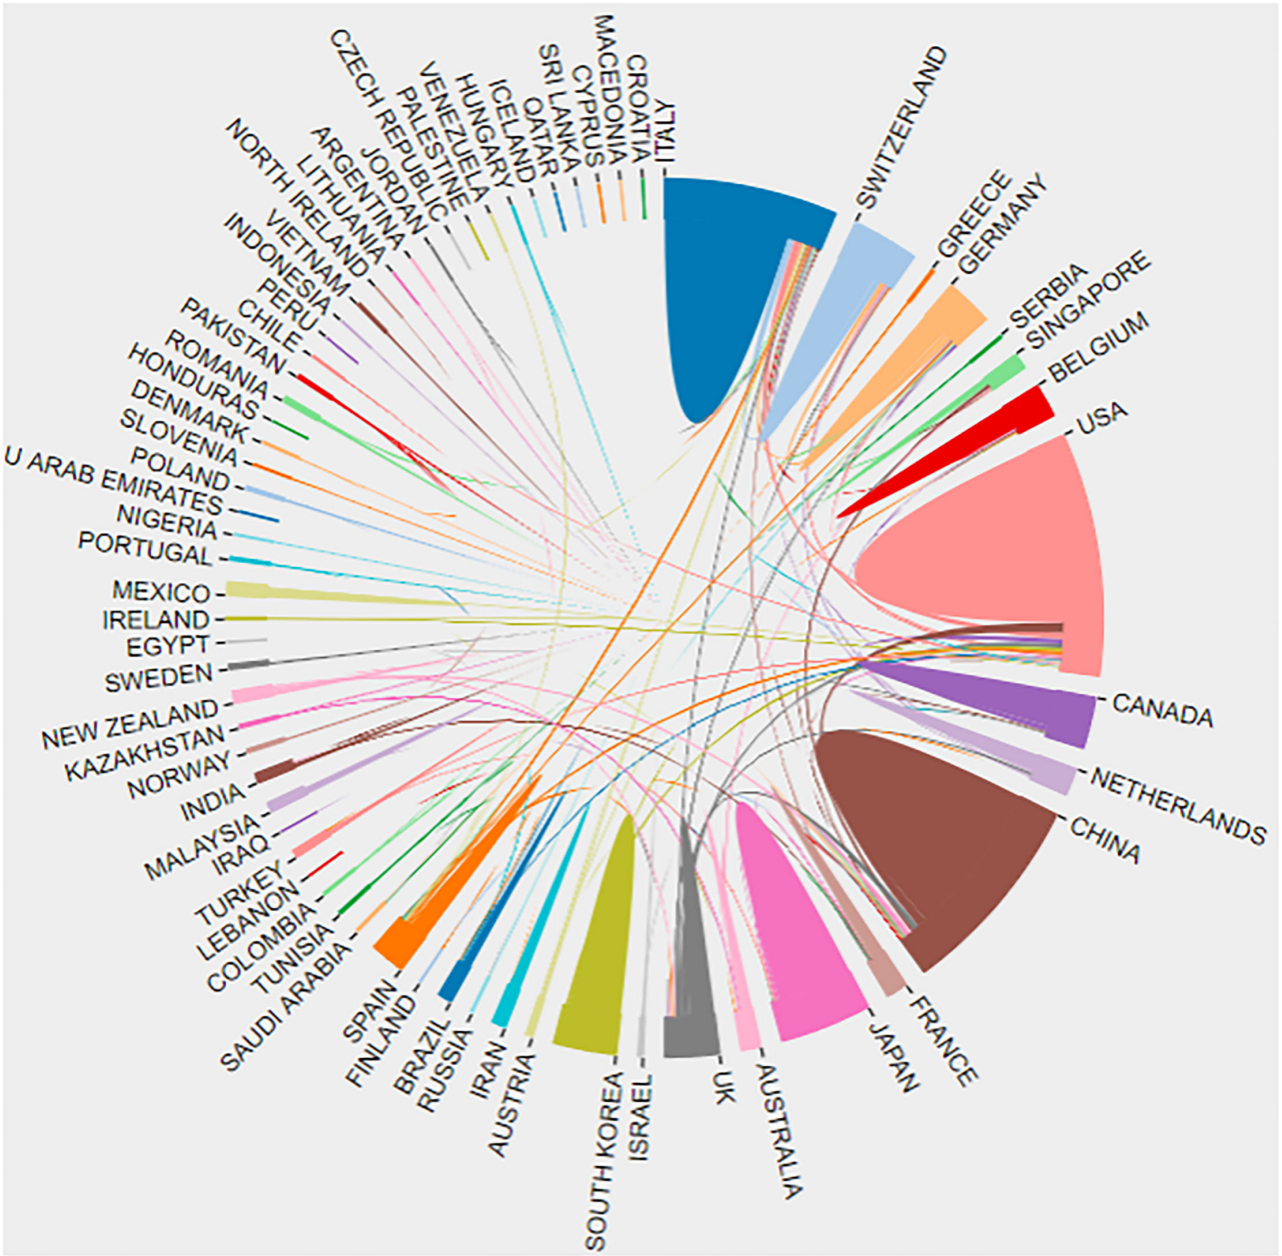

FIGURE 4 | Bibliometric analysis of the cooperation of countries in the field of rehabilitation robot research.

groups: (0) walking, (1) stroke, (2) brain–computer interface, (3) stroke, (4) electromyography, (5) proprioception, (6) task analysis, (7) soft actuators, and (8) soft robotics (**Figure 8**). The timeline view is used to display the dynamic time change of clustering keywords. From 2010 rehabilitation robots, cerebral apoplexy, exoskeleton, the stability of the robot, rehabilitation, spinal cord injury, stroke, nerve rehabilitation, motor learning, virtual reality, and other keywords widely attention, among them, the rehabilitation robot and cerebrovascular accident, exoskeleton robot hand, adaptive control, and touch the heart of the study on the relationship between the recovery began in 2011. Rehabilitation robot and brain–computer interface, upper limb rehabilitation, and meta-analysis research began to appear in 2014. Research on the relationship between rehabilitation robots and upper limb rehabilitation and meta-analysis was hot until 2019. In 2019–2020, robot sensing system, actuator, pneumatic artificial muscle, telemedicine, task analysis, wearable robot, and flexible robot were new words. It is predicted that further research will focus on rehabilitation robots and robot sensing systems, pneumatic artificial muscle, wearable robot, and flexible

robot. The time dynamic evolution of keywords is presented in **Figure 9**.

Cocitation Clustering Analysis of Related Kinds of Literature

Through literature cocitation cluster analysis, CiteSpace software was used to draw a cocitation map of the rehabilitation robot research literature, generating 868 nodes and 1,884 connections, and the density of the topological network was 0.005. With the lowest citation times of 15, 28 of the 3,194 cited kinds of literature were included from the research scope, and the top three cited kinds of literature with high centrality were "Lo et al. (33)" (0.88), "Maciejasz et al. (42)" (0.68), and "Klamroth-Marganska et al. (39)" (0.45).

Funding Support Institutions

There are 2,637 funded institutions, among which the top 10 funded institutions have funded 1,535 studies, accounting for 48% of the literature in the field of rehabilitation robot research. The top three funders were the China National Natural Science Research Foundation (337), the US Department of Health and Human Services (247), and the US National Institutes of Health (240). These results indicate that China has strong support for the research on rehabilitation robots and a large amount of research fund investment, which may be related to the incentive

mechanism initiated by the government. However, there is still a gap between the total number and that of the United States, which needs to be improved (**Table 6**).

Frontier Analysis of an Emergent Word Detection Algorithm

We used CiteSpace to detect emergent words. A total of 108 mutants were detected. Among the 25 keywords with the highest citation frequency, the mutation cycles of 16 mutation words were concentrated from 2010 to 2015. The strongest mutation intensity was "arm" (8), followed by "motor control" (7.13). The third place was "hemiparetic patient" (6.13), the fourth place was "body weight support" (5.14), and the fifth place was "arm movement" (5.11). Keywords with high mutation intensity in the last 5 years include "modulation" (2015–2016), "computer interface" (2015–2017), "treadmill therapy" (2016–2017), "series elastic actuator" (2017–2020), and "prosthetics and exoskeleton" "wearable robotics" (2018–2020). These emergent words in the past 5 years may also be the main direction of future research.

DISCUSSION

International Research Status of Rehabilitation Robots

The research on rehabilitation robots can be traced back to the 1960s, but the development was relatively slow due to

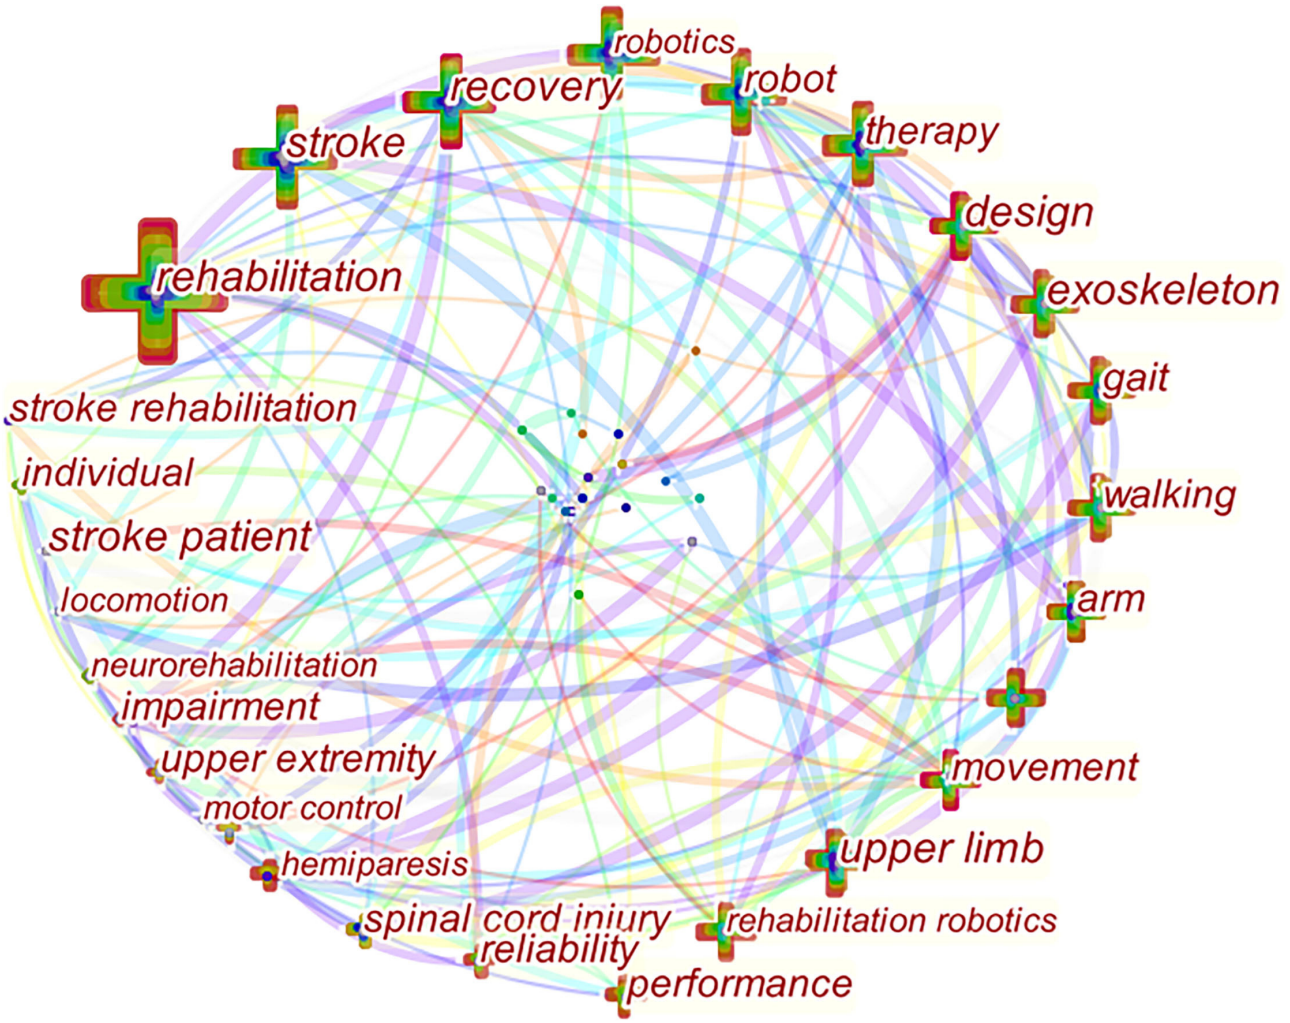

FIGURE 7 | Co-occurrence spectrum of high-frequency keywords in rehabilitation robot field. The cross represents keywords; the larger the cross, the thicker the cross, the higher the frequency of keywords; the line refers to the connection between keywords; the thicker the line, the closer the connection.

design and funding problems. The 1980s was the initial stage of the research on rehabilitation robots, and the United States and the United Kingdom were at the leading level. After the 1990s, the research on rehabilitation robots entered a period of comprehensive development (43). In 1987, the British man Michael developed the prototype of the Handy I rehabilitation robot. In 1989, the Massachusetts Institute of Technology developed the first clinical trial robot for rehabilitation treatment. In 2020, Elon Musk reported the latest research results on the brain–computer interface: a coin-sized chip implanted into a pig's brain can read the pig brain's information in real time. A functional device implanted into a surgical robot can perform all the steps of craniotomy, implant sensors, and glue. With the continuous development of interdisciplinary integration, researchers are making progress in the field of rehabilitation robots. It can be predicted that the vision of human–machine integration will be realized soon (44, 45).

Research Hotspots by Country (Region), Author, and Founding

In this study, the research literature related to rehabilitation robots was obtained from the core data collection of the Web of Science database in the past 10 years as the research object, and CiteSpace visual analysis software was used to analyze and track the hotspots and frontiers of international research in the field of rehabilitation robots. This study presents the international research status of rehabilitation robots in the past 10 years intuitively and forms a general understanding of its research hotspots, frontiers, and trends. Overall, international rehabilitation robot research identified steady growth year by year, nerve rehabilitation, stroke, brain–machine interface, virtual reality, flexible wearables, task analysis, and the exoskeletons of rehabilitation robot research more and more aroused people's interests, becoming increasingly important areas of research.

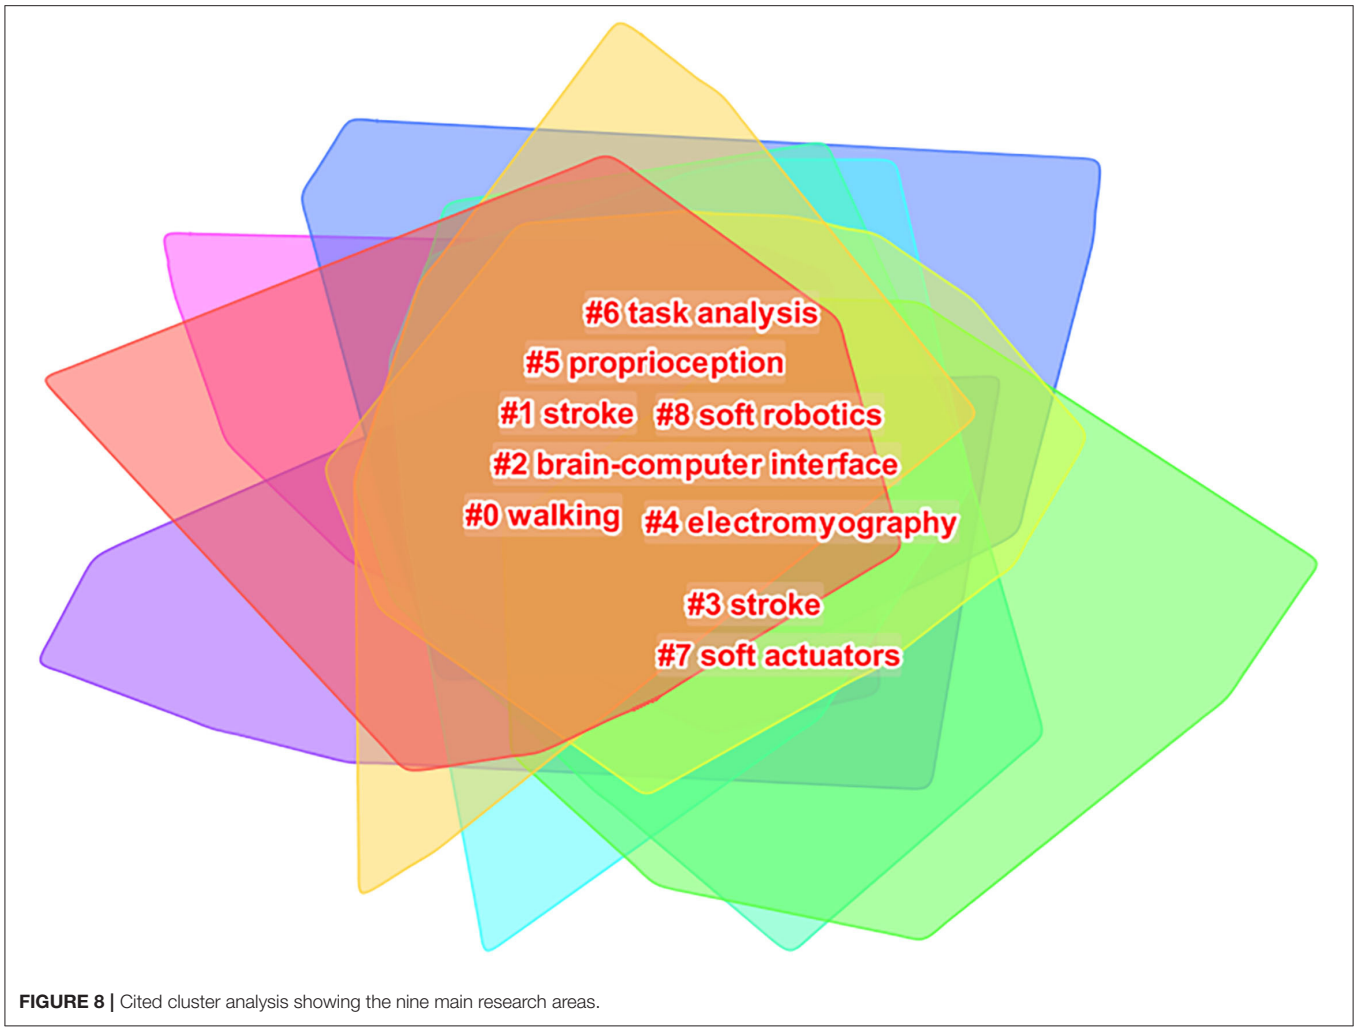

FIGURE 8 | Cited cluster analysis showing the nine main research areas.

The number of articles published in the world in the field of rehabilitation robots generally shows an upward trend, mainly focusing on the fields of rehabilitation medicine, biomedical engineering, and neuroscience, indicating that the research on rehabilitation robots is popular in the field of medicine. The United States, China, Italy, Japan, and the United Kingdom are the major research exporters. The United States has the most articles about rehabilitation robots, followed by China. China is the only developing country, which shows great progress in the field of rehabilitation robots in the past decade and playing an important role. In terms of research institutions, Northwestern University, the University of Tsukuba, the University of Maryland, Santa Anna University of Pisa, Italy, and the University of Auckland, New Zealand occupy a certain position in the field of rehabilitation robots with a high number of publications. Northwestern University ranked first with 161 publications.

Among the prolific authors, R. Riener, a professor at the University of Zurich in Switzerland, ranked first with 48 articles, and the second and third were from the United States and Japan, respectively. It is worth noting that Professor Song from Southeast University of China ranked eighth with 18 articles. Studies by Chinese scholars in the field of rehabilitation robots are moving toward the international community, even catching up abroad.

In terms of cocitation of authors, the top five are Prof G. Kwakkel, Vrije Universitat Amsterdam; Prof S. Hesse, Medical University of Charlotte, Berlin, Germany; Prof J. Mehrholz, Dresden Medical School, Technical University of Dresden, Germany; Prof H.I. Krebs, MIT, USA; and Prof N. Hogan, MIT, USA. It can be seen that scholars from the Netherlands, Germany, and the United States have high influence in the research on rehabilitation robots. The above data can provide potential collaborators and teams' information for future research. According to Price's law, half of all papers on the same subject are written by a group of highly productive authors roughly equal to the square root of the total number of authors (46). A total of 9,163 authors were included in 3,194 publications. Of these, the first 93 authors completed 50% of the papers, in line with Price's law. It indicates that the core authors in the field of rehabilitation robots have been established. Paying attention to these authors can help us better understand the frontier and trend

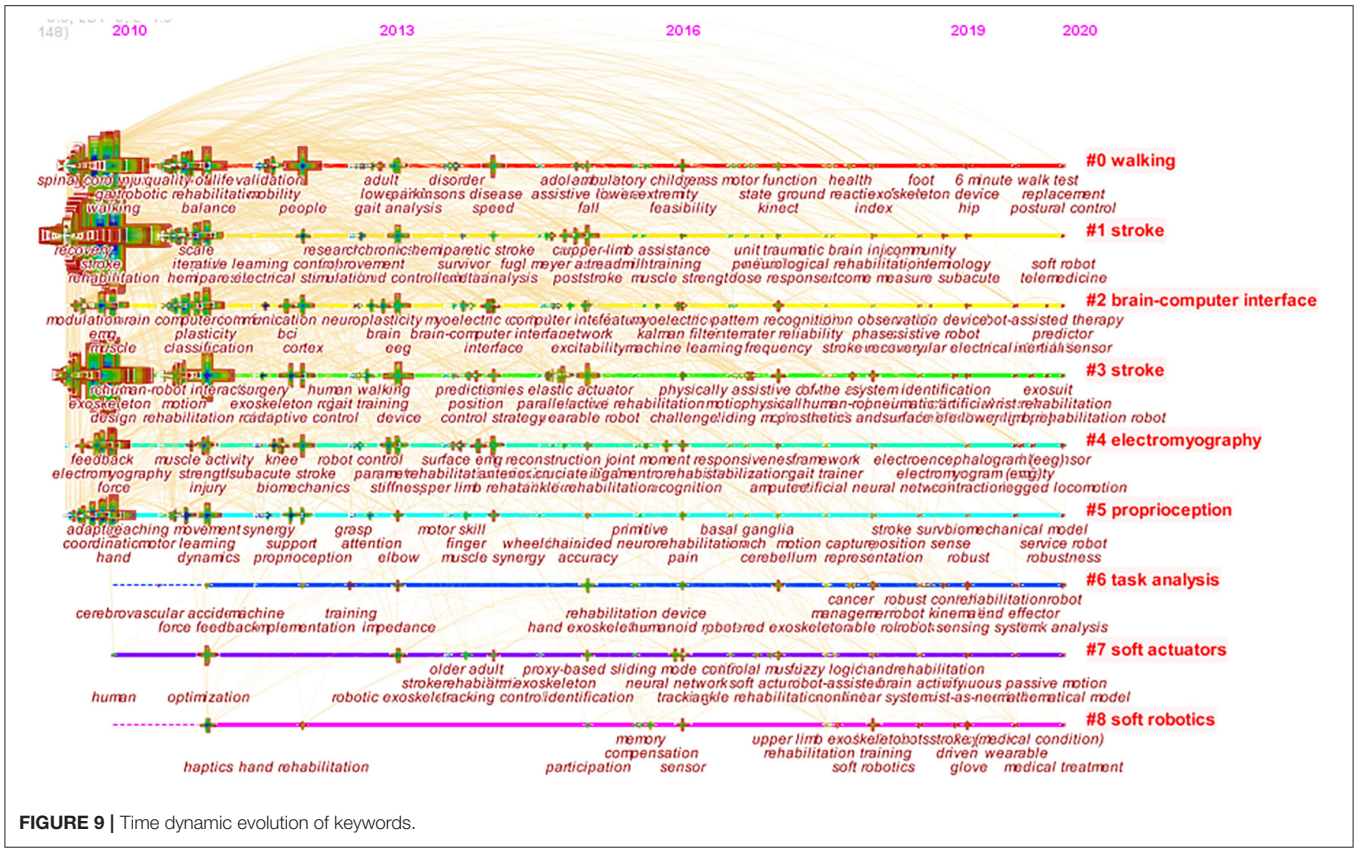

FIGURE 9 | Time dynamic evolution of keywords.

TABLE 6 | Funding institutions of rehabilitation Robot Fund from 2010 to 2020.

Ranking	Funding	No. of publications	Percentage
1	National Natural Science Foundation of China NSFC	337	10.541
2	United States Department of Health Human Services	247	7.726
3	National Institutes of Health NIH USA	240	7.507
4	National Science Foundation NSF	162	5.067
5	NIH Eunice Kennedy Shriver National Institute of Child Health Human Development NICHD	117	3.66
6	European Union EU	111	3.472
7	Ministry of Education Culture Sports Science and Technology Japan MEXT	95	2.972
8	Japan Society for the Promotion of Science	86	2.69
9	Grants in AID for Scientific Research Kakenhi	72	2.252
10	NIH National Institute of Neurological Disorders Stroke NINDS	68	2.127

of rehabilitation robots. Among the top five foundations, one is from China, and four are from the United States. The research area involves many scientific research grants, but the main funding areas are natural sciences, medicine, bioengineering, and material science.

Research Hotspots in the Field of Rehabilitation Robots

Citation status is one of the important indicators to reflect research hotspots. Through reading and analyzing the literature with high citation frequency and centrality, some research results with high attention in the research field of rehabilitation robots can be learned to reveal the areas of concern (47). Through reading and analysis of the top ten cited studies, the results show that stroke, spinal cord injury, paraplegia, upper limb functional rehabilitation, neuroplasticity, actuator technology, flexible robot gloves, etc., have received extensive attention from researchers in a certain stage in the research field of rehabilitation robots. The research hotspots of these highly cited papers help to identify the major hotspots of rehabilitation robot research. At present, the number of cited papers in China is low, which may be due to the late publication of many studies in other countries.

Keywords with high centrality and frequency represent research hotspots in a period. According to the analysis of the

hot keywords, research in the field of rehabilitation robots mainly focuses on rehabilitation, stroke, design, exoskeleton robotics, upper limbs, gait, spinal cord injury, performance, and reliability. Through keyword clustering analysis, the higher the degree of aggregation, the better the homogeneity between studies (48).

In the last 10 years, the rehabilitation of upper limb function for stroke has been a research hotspot. With the rapid growth of new technologies and equipment, there is much different training equipment for rehabilitation robots designed to move or assist arm movement. There are significant differences in the types of treatment provided by different devices in terms of the techniques employed and the treatments provided. In a systematic review, there is increasing evidence that rehabilitation robot training can benefit the recovery of arm function after stroke (49). Human–robot interaction (HRI) is one of the hot topics in the current research on rehabilitation robots, which is how to realize the natural and precise interaction between humans and machines through the fusion of machine intelligence and biological intelligence.

Research Frontiers and Trends in Rehabilitation Robots

Emergent words represent frequently cited keywords in a given period, thus indicating cutting-edge features and trends. Combined with the time dynamic evolution and burst analysis of keywords, we can get a general understanding of the research field, development, and future trend of rehabilitation robots. The top five post-2014 breakout words are "modulation," "computer interface," "treadmill therapy," "series elastic actuator," and "prosthetics and exoskeleton." Modulation refers to the adjustment and control of the signal and program of the rehabilitation robot to achieve the purpose of precise rehabilitation. Computer interface refers to the popular brain–computer interface technology. Treadmill therapy mainly refers to lower limb rehabilitation robots that are similar to treatments done on a treadmill. A Lokomat lower limb rehabilitation robot is a typical hanging weight loss standing rehabilitation robot of the treadmill therapy type, which combines with the treadmill platform to complete the exercise (50). In the control system, the series elastic actuator can convert control signals into power devices that can drive the controlled system, which is the core of the power development and design of the rehabilitation robot (51). Research on prosthetics and exoskeleton robots is currently a hot topic in comparison, and because of the rapid development of mechanical design and control algorithms for electro-mechanical systems, exoskeletons have been significantly developed but are still limited to larger body areas, such as the upper and lower limbs. Due to their small size and strong tactile perception, hand exoskeletons still face many challenges in many technical fields, such as hand biomechanics, neurophysiology, rehabilitation, actuators and sensors, human–robot physical interaction, and ergonomics.

In addition, machine learning (ML) is one of the technologies that have developed rapidly in the past 10 years. It is widely used in computer vision, bioinformatics, health care, business analysis, trend forecasting, and other fields. ML allows computers to learn from large samples of data and predict patterns that exist in the data (52, 53). ML algorithms to help realize the future of improved health care by unleashing the potential of large biomedical and patient data sets are used in different research areas to predict and classify accurate results from test data (54). They have proven to be helpful for diagnosis in a variety of medical and clinical data sets. In the field of rehabilitation, ML can help predict the recovery function of walking level of the patients with stroke and assist in research on the development of walking assistance robots. AI-based virtual reality rehabilitation (55) and forecasting mortality of patients with stroke after complete rehabilitation with tree-based ML models have been studied (56). For any type of human disease prediction, data sets need to be preprocessed. In this regard, dimensionality reduction plays a vital role in reducing the high-dimensional data into reduced dimensionality (57). Over the past few decades, several dimensionality reduction techniques have been used to filter data samples from the data set under consideration. Dimensionality reduction requires the mapping of higher-dimensional inputs to lower-dimensional inputs so that similar points in the input space are mapped to adjacent points on the manifold (54, 58). Feature engineering is an important preprocessing step that helps in the extraction of transformed features from the raw data that will simplify the ML model and also improve the quality of the results of an ML algorithm.

In the field of medical rehabilitation, more and more people tend to interact with machines naturally and accurately. With personalized AI task analysis, ML, electromechanical interaction, intelligent control, and other technologies combined with robots applied to the field of rehabilitation medicine, the rehabilitation robot "therapist" will become the main force in the field of rehabilitation therapy in future. The wearable exoskeleton robot can help elderly people with severe limb dysfunction, hemiplegia, and spinal cord injuries walk normally. In addition, it can help humans maintain balance function and increase strength to achieve "human–machine integration" (5). The "mind control" of brain–computer interface is gradually switching from science fiction to reality, helping the movement, feeling, and other functions of damaged limbs return to normal. In 2020, *MIT Technology Review* published a breakthrough in the brain–computer interface by Professor Eduardo Fernandez of Miguel Hernandez de Elche University: the electronic artificial eye, which restores sight to patients who are completely blind (59, 60).

With human intelligence and machine intelligence, combining human–computer interaction as a representative of technological breakthroughs between man and machine combined with the increasingly close, with the help of human–computer interaction technology and method, and combining human intelligence and machine intelligence make the two complementary advantages, to work together, and in the aspect of medical rehabilitation which spawned a significant theoretical innovation and breakthrough technology method. The brain–computer interface will be widely applied in future (61, 62). How to establish the ability of high-broadband data connection between human and machine is also an important trend in the current international rehabilitation robot research. At present, rehabilitation robots of limb function still cannot provide intuitive tactile neurofeedback,

and patients can only rely on visual feedback to judge the size of the object to be grasped and other sensory information. How to achieve accurate neural feedback of sensory information still needs further research. It is the challenge and trend of the development of rehabilitation robots in future to make that rehabilitation robots have emotional characteristics and make patients feel happy while helping patients to achieve their rehabilitation goals.

Regarding rehabilitation robot technology and the research and development and application of the system, there is still a gap between China and developed countries such as Europe and the United States. To improve the performance of rehabilitation robot system, it is necessary to master the key core technologies of rehabilitation robot, such as EMG information perception and control technology, force feedback control technology, joint angle and torque control technology, and space motion detection technology (4). In particular, the research on these technologies in brain–computer interface, virtual reality, robot sensing system, actuators, pneumatic artificial muscle, and the wearable flexible robot can better promote the development of rehabilitation robots to meet the future demand of Chinese people for health services.

Application and Development Trend of Rehabilitation Robots

It can be predicted that rehabilitation robots will be used more and more in an era when the cost of manual treatment is becoming more and more expensive. To better popularize and commercialize the application, future development needs to increase the universality of rehabilitation robots, focusing on lightweight, portable, reconfigurable, intelligent, and AI-based equipment, thus bringing new treatment methods and thinking to the rehabilitation field under the premise of ensuring safety, mass production, and cheap direction development (63). Intelligent rehabilitation is the future development trend (64). It should break through the barrier of the human–machine interface, develop multidisciplinary cooperation and communication, strengthen collaboration with rehabilitation medicine and artificial intelligence, actively participate in the design and development of rehabilitation robots, and promote rehabilitation robots to better serve the rehabilitation medicine field.

When thinking about the application and development of rehabilitation robots, Professor Li first mentioned the "human nature" of rehabilitation robots. Rehabilitation robots should have the basic human nature—namely, perception, thinking, expression and communication, action and cooperation, and learning and adaptability—and complete training and operations independently or with the assistance of an automatic machine (14). At present, rehabilitation robots cannot complete all the techniques and operations of professional rehabilitation personnel; particularly, the self-learning ability, adaptability, and creativity of robots need theoretical breakthroughs. The most difficult thing for rehabilitation robots to break through is the benevolence and moral sense of medical workers (65). The twenty first century is an era of health and life science. Health is the most powerful driving force for scientific and technological revolution and social development. Rehabilitation robots as one of the most important technologies in the human health industry will undoubtedly provide innovative means and paths for rehabilitation medicine, preventive medicine, and clinical medicine, making the previously invisible visible and the impossible possible (66). Rehabilitation robots will also provide strong impetus for the reform of the medical system, the renewal of the medical model, and the extension of the human healthy life span (67).

Study Limitations

This study included only studies on rehabilitation robots published in the core data collection of SCIE, the Web of Science database, and the paper type was English literature, which may have ignored high-quality kinds of literature in other languages in the field of rehabilitation robots, resulting in certain limitations in literature retrieval. In cluster analysis, different categories of content may overlap. In addition, the cocitation frequency of kinds of literature is related to time. The kinds of literature published in recent years may have a relatively low total cocitation frequency due to their short publication time, resulting in differences between research results and the actual situation. The cooccurrence of keywords is limited by the number of nodes, which may affect the accuracy of conclusions. However, accuracy itself is relative and does not affect the reliability of conclusions obtained in the paper. Due to different algorithms, there is no standardized setting process for time partition, threshold, or clipping mode in the process of using CiteSpace to generate visual atlas, which may cause some bias.

CONCLUSION

Based on the Web of Science database and CiteSpace software, this study for the first time conducted bibliometric and visual analysis of the international research on rehabilitation robots in the past 10 years from multiple perspectives and presented the research overview of rehabilitation robots in the past 10 years relatively scientifically and intuitively. At present, the brain–computer interface, virtual reality, flexible wearables, task analysis, and exoskeleton rehabilitation robots are the frontiers and hotspots of research, representing the development trend of future research, and they can be used as a reference direction for future research. Future research in the field of rehabilitation robots should focus on the following aspects: first, focus on the functional needs of patients to improve the quality of life; second, strengthen interdisciplinary cooperation and build a regional cooperation network among countries.

Challenges

Formulating better rehabilitation robots in such an evolving field is important. Until today, numerous technical challenges and insufficient safety standards have prevented the large-scale development of rehabilitation robots. As it is multidisciplinary technical research, it faces many challenges in the actual research and development process. The primary challenge of rehabilitation robots is safety, which is the most basic

requirement to help patients with rehabilitation training. On the premise of ensuring the effectiveness of the product, it is more important to ensure the safety of use and avoid secondary injuries to patients. Intelligent control, ergonomics, at present, and the movement energy consumption of the robot bionic man are much higher than that of the simple skeletal muscle movement, the operation process of the wearable exoskeleton robot is generally more complex, and the large weight makes the rehabilitation training more difficult, but the precision is much worse. The man–machine interface design is a challenging problem. This interface is the medium and dialogue window for transmitting and exchanging information between humans and computers. A good man–machine interface is key to improve the operation efficiency of rehabilitation robots. For example, patients' subjective feelings and physiological reactions, especially visual perception, cannot be timely perceived in the training process. Both need constant optimization and learning. Existing rehabilitation robots generally lack tactile feedback. It is suggested to study various sensors to enhance the interaction between rehabilitation robots and the human body, involving multidisciplinary cooperation and communication. In addition, a key challenge regarding the control of rehabilitation robots is to design shared control or ML technologies that are predictable to patients and do not exceed their needs. Because not all technical components of rehabilitation robots are well developed or designed for daily life and outdoor applications, a lot of collaborative work and utilization of resources from medical technology, biomechanics, engineering, and product development are needed. The price of the current rehabilitation robots is relatively expensive, which is a great burden on ordinary families. It is suggested that future research can find cost-effective materials to popularize rehabilitation robots in ordinary life.

Future Direction

In terms of technology, ML, dimensionality reduction, feature engineering, and other technologies play an important role in the research and development of rehabilitation robots. In future, the effectiveness of these technologies can be tested on high-dimensional data such as images and text data. They can also be used for more complex algorithms, such as deep neural networks, convolutional neural networks, and recursive neural networks. The new ideas of mixing and matching hardware, programs, algorithms, and expected neural pathways may lead to more focused research and, ultimately, significant advances in robot-assisted rehabilitation. For various rehabilitation robots with different characteristics and advantages, the application effect of different rehabilitation programs is not clear, so it is particularly important to formulate the user guide of rehabilitation robots to direct the clinical application of rehabilitation robots. To achieve widespread application and commercialization, future rehabilitation robots should be developed toward mass production and low cost. In addition, in future, rehabilitation robots will still be the focus and hotspot in the fields of rehabilitation medicine and intelligent engineering, and with the development of rehabilitation robots with different functions, their usage guidelines will become more and more perfect, and the cooperation between rehabilitation therapists and rehabilitation robots is bounded to open a new chapter in rehabilitation therapy.

DATA AVAILABILITY STATEMENT

The data analyzed in this study is subject to the following licenses/restrictions: when used on a reasonable request, it can be obtained by contacting the corresponding author. Requests to access these datasets should be directed to lining@cdsu.edu.cn.

AUTHOR CONTRIBUTIONS

XX and XY: designing this study and writing initial draft and revision. ZD and HT: reviewing the literature and analyzing. DK: making figures and tables. FX: rechecking the manuscript and putting forward suggestions for amendment. NL: revising language and content, supervision, project administration, and funding acquisition. All authors contributed to the article and approved the submitted version.

FUNDING

This work was supported by the Key Laboratory of Sports Medicine of Sichuan Province, Institute of Sports Medicine and Health, Chengdu Sport University (No. 2021-A030) and the National Key Research and Development Program of China (No. 2018YFF0300904).

The unbounded increase in network traffic and user data has made it difficult for network intrusion detection systems to be abreast and perform well. Intrusion Systems are crucial in e-healthcare since the patients' medical records should be kept highly secure, confidential, and accurate. Any change in the actual patient data can lead to errors in the diagnosis and treatment. Most of the existing artificial intelligence-based systems are trained on outdated intrusion detection repositories, which can produce more false positives and require retraining the algorithm from scratch to support new attacks. These processes also make it challenging to secure patient records in medical systems as the intrusion detection mechanisms can become frequently obsolete. This paper proposes a hybrid framework using Deep Learning named "ImmuneNet" to recognize the latest intrusion attacks and defend healthcare data. The proposed framework uses multiple feature engineering processes, oversampling methods to improve class balance, and hyper-parameter optimization techniques to achieve high accuracy and performance. The architecture contains <1 million parameters, making it lightweight, fast, and IoT-friendly, suitable for deploying the IDS on medical devices and healthcare systems. The performance of ImmuneNet was benchmarked against several other machine learning algorithms on the Canadian Institute for Cybersecurity's Intrusion Detection System 2017, 2018, and Bell DNS 2021 datasets which contain extensive real-time and latest cyber attack data. Out of all the experiments, ImmuneNet performed the best on the CIC Bell DNS 2021 dataset with about 99.19% accuracy, 99.22% precision, 99.19% recall, and 99.2% ROC-AUC scores, which are comparatively better and up-to-date than other existing approaches in classifying between requests that are normal, intrusion, and other cyber attacks.

Keywords: healthcare, network security, neural networks, artificial intelligence, big data, deep learning

INTRODUCTION

Network intrusion recognition is challenging since the attacks evolve daily because of new technologies, frameworks, and software. In 2020, the number of cyber-attacks increased by 17%, in that 77% were targeted attacks, with attackers' main targets being personal data and credentials. Attacks on organizations aimed mainly at stealing private user data. These metrics show a vital backdrop in modern-day cyber-attack detection and prevention. Moreover, the healthcare industry is increasing, and most hospitals are integrating e-healthcare systems to meet the patients' needs as soon as possible. Hospitals must maintain the Electronic Health Records (EHR) and Patient Records or Personal Health Records (1) since these details contain a patient's medical data required to infer a diagnosis and treatment. The vast development in the Internet of Things (IoT) has led to a boom in smart medical devices and systems. These edge devices can contain patient records, which must be kept secure and accurate at all times. Any change or corruption in these details can lead to wrong diagnosis and treatment, causing the fatality of the patient. Therefore, to ensure cyber-safety in healthcare systems, there is a need for up-to-date and advanced Hybrid Intrusion Detection Systems.

The common goal of any Intrusion Detection System is to recognize, flag, and log/block intrusion attacks by identifying any malicious network activity (1, 2). Most of the existing real-time software for IDS uses a rule-based approach like signature-based detection, stateful protocol analysis, and statistical packet analysis. Primarily the IDS classifies a request into benign and malicious, benign being regular requests, and malicious being anomalous or intrusion requests. The IDS are also specifically designed to identify a specific set of attacks like DDoS.

However, Artificial Intelligence-based systems come with specific backlogs; the rate of false positives can be overwhelmingly frequent compared to actual threats. The algorithms may also be biased toward particular attacks based on class imbalance and features present in the dataset used for training the algorithm. Inaccurate and biased intrusion detection systems don't stand a chance in protecting patient records as they may falsely flag an attack as benign or a benign request as malicious. The issue with the existing intrusion detection systems is that they are trained on outdated or old datasets like KDD-Cup'99, making the system vulnerable to the latest attacks and leading to leakage and illegal modification of EHRs. Traditional Machine Learning algorithms such as K-Nearest Neighbors (3) and Logistic Regression usually need repeated fine-tuning and updating parameters to adapt the algorithm to new types of attacks that may require frequent retraining, which is computationally expensive and time-consuming. Ensemble learning (4) and deep learning-based (5) approaches have proven better because of their adaptability and ease of fine-tuning or pruning on new data. Faster and efficient algorithmic techniques are still vital for such critical applications as time complexity is a significant overhead in medical and IoT-based systems. A state-of-the-art, present-day attack-oriented, faster, and efficient methodology is required for Intrusion Detection Systems to safeguard patient records in e-healthcare.

This paper proposes a new hybrid framework for intrusion detection using deep learning for healthcare systems named "ImmuneNet." We have benchmarked its performance against various machine learning algorithms on the Canadian Institute for Cybersecurity's IDS 2017 (6), IDS 2018 (7), Bell DNS 2021 (8) datasets. These are realistic datasets containing more than 17 types of the latest cyberattacks, which would be beneficial in implementing real-time deep learning-based intrusion detection systems and achieving high accuracy. A data-centric approach was used to promote class balance (9) and extensive feature selection processes like recursive feature elimination (10, 11), which can help better perform models with fewer parameters. Over five types of machine learning algorithms were compared: Logistic Regression, Decision Trees, Random Forests, Extreme Gradient Boosting Trees (12), and a custom neural network architecture named "ImmuneNet" as seen in **Figure 1**. ImmuneNet obtained the highest accuracy of almost 99.19% and other vital metrics from all the experiments. The neural network architecture contains around 830,000 parameters, making the fine-tuning process faster and deployment-friendly for medical devices and systems.

Our experiments were based on several data-centric and algorithmic approaches to create a lightweight, fast, high-performance classifier without compromising accuracy. We have divided our paper into the following sections based on different schemes:

1. The current state-of-the-art methodologies and existing research for implementing intrusion detection systems in healthcare and general.
2. Comparison between KDD Cup99, CIC-IDS variants, and CIC Bell DNS 2021 datasets to know in detail about the attack types, size, number of samples, and state of relevance.
3. Extensive feature selection, oversampling, and hyper-parameter optimization techniques involved in training, validating, and testing the algorithms on the three datasets.
4. Comparison of multiple machine learning algorithms, namely logistic regression, ensemble methods such as decision trees, extreme gradient boosting trees, and a custom neural network architecture named "ImmuneNet" using various metrics like accuracy, loss, precision, recall, F1, and loss.
5. A detailed discussion on the proposed system's performance, advantages, and limitations.

RELATED WORKS

Our literature survey primarily focused on analyzing the data preprocessing and algorithmic approaches to derive new novel solutions for developing a sound intrusion detection system. There are tons of cyber vulnerabilities to cope within the medical sector as these attacks threaten patients' healthcare and put them in jeopardy. Tervoot et al. (13) performed a scoping review by categorizing and analyzing these attacks and found 18 solutions, each fitting at least one of the categories of intrusion detection and prevention, communication tunneling, or hardware protections. Thamilarasu et al. (14) proposed an intrusion detection system for the internet of medical things

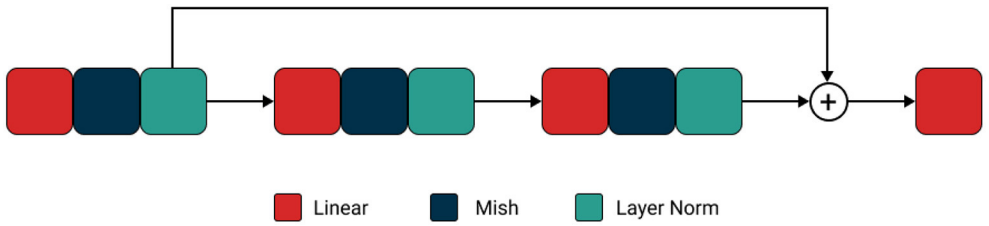

FIGURE 1 | Neural network of ImmuneNet architecture.

based on Wireless body area networks (WBAN). They simulated a hospital network topology and performed detailed experiments for various subsets of the Internet of Medical Things, including wireless body area networks and other connected medical devices. The system performs best at 99.6 and 98.2% accuracy for network and device-level intrusion detection, respectively.

Subas et al. (4) proposed an IDS with multiple Machine Learning techniques with some complex attack data. They concluded that the Bagging ensemble algorithm and Random Forest perform better with 97.67% accuracy than other classifier models. Hence, a Smart E-Healthcare System could be built on top of this system to ensure better cyber security. The Internet of Medical Things (IMoT) has its drawbacks as technical advancements progress since any security and privacy issues exist. Therefore, Priya et al. (5) developed a deep neural network (DNN) for constructing an effective IDS to classify and predict unforeseen cyberattacks. They also carried out practical feature engineering in hyperparameter selection. The proposed DNN model performs better than the existing machine learning approaches, with an increase in accuracy by 15% with an overall accuracy of 99.7 % on NSL-KDD. Šabić et al. (15) proposed an anomaly detection system that focuses on the system's ability to detect anomalies in heart rate data. They used five algorithms to fit the data, two of them were unsupervised, and the rest were supervised to detect the anomalies. They concluded that random Forest and ensemble methods had above 99% accuracy to model such systems effectively.

Hady et al. (16) proposed and built a real-time Enhanced Healthcare Monitoring System (EHMS) that monitors the patients' biometrics and collects network flow metrics. Then this system applies different machine learning methods for training and testing the dataset against these attacks. Hence by collecting their data dynamically, they developed a robust intrusion detection system. by analyzing in 10-fold accuracy score comparison, they noted that the SVM algorithm performed better than the rest with an accuracy of about 92.44%. Nguyen et al. (17) used data fusion as an integral part of multidisciplinary research to design an intrusion detection system. Their proposed model involves a decision-based fusion model with different processes such as initialization, preprocessing, Feature Selection, and multimodal classification to detect intrusions effectively. The proposed model offers maximum accuracy of 99.21%, precision of 98.93%, and a detection rate of 99.59%. Iwendi et al. (18) proposed an intrusion detection system in the Security of Things (SoT) paradigm for smart healthcare and will continue to impact medical infrastructures. Their study used the NSL-KDD dataset on RF, Naive Bayes (NB), and logistic regression classifiers for machine learning. To optimize the functionality of their approach, they used a weighted genetic algorithm, and Random Forest was coupled to generate achieved a high detection rate and neglect false positives and true negatives. The combination of their genetic algorithm and RF models achieved an accuracy rate of 98.81%.

Yeng et al. (3) conducted a systematic review of various machine learning algorithms and data resources to assess them across multiple criteria. They have also evaluated and analyzed the design considerations of the methods toward mitigating false positives. Their comprehensive study determines the associated challenges in using the algorithms and how they can be overcome. Their study suggests that most of the existing literature for intrusion systems in healthcare uses K-Nearest Neighbors. Mahdavifar et al. (8) have proposed a method to classify benign, phishing, spam, and malware-based domains using DNS traffic analysis with the K-Nearest Neighbors algorithm. They have used the CIC Bell DNS 2021 dataset, which is balanced to 60/50 and 97/3%, achieving an F1 score of around 94.8 and 99.4%, respectively. Seth et al. (19) built a unique framework based on creating an ensemble by ranking the detection ability of different base classifiers to identify various types of attacks. They have experimented with numerous algorithms and achieved 96.65% accuracy with neural networks on the CIC-IDS 2018 dataset and have also given a deep analysis of the metrics on classwise performance. Benedetto Serinellia et al. (20) analyses open-source intrusion detection datasets by validating them to detect well-known zero-day attacks. They have built their predictors based on KDD99, NSL-KDD, and CIC-IDS-2018 datasets, giving a comparative case study among them in their research work. They achieved over 99.97% accuracy on the NSL-KDD datasets. Thilagam et al. (21), on the other hand, proposed an Intrusion detection system on a more complex basis using RCNN (Recurrent Convolutional Neural Networks) using the culmination of CNN and LSTM (Long Short Term Memory) on the KDD Cup 99 and CIC-IDS 2018 datasets. They achieved over 94% accuracy on both datasets with the same model.

Class Imbalance is another critical attribute to be considered for building a novel and efficient architecture. Zuech et al. (22) analyzed web attacks using random undersampling ratios under various ensemble learning algorithms and discussed

TABLE 1 | Comparison of KDDCup99, CIC IDS variants, and CIC Bell DNS 2021 datasets.

class balance's significant importance. They observed that undersampling at different ratios could have a drastic effect on the model's performance and achieved an accuracy of about 94.01% accuracy on CIC IDS 2018 dataset using RCNN. Yu et al. (23) had proposed a packet byte-based CNN, called PBCNN, which focuses on the statistical features of network traffic, giving another insight on the importance of network traffic and its hierarchical nature. PBCNN obtained 99.99 % accuracy on the CIC IDS 2017 and CIC IDS 2018 datasets. Gopalan et al. (9) carried out a balancing approach and surveyed the CIC-IDS-2018 dataset. They also researched the impact of bias and class imbalances in the CIC-IDS-2018 dataset. As observed, signature-based intrusion detection approaches prove to be the weaker counterpart of various methods.

Most of the research on Intrusion detection mechanisms was based on the ensemble learning approach. Fitni et al. (24) made comparisons with seven single classifiers to identify the most appropriate basic classifiers for ensemble learning; they compared the accuracy metrics of tested architectures and made a cumulative study on it. They also used effective feature selection techniques like filter methods and Spearman rank's correlation and used only 23 features to achieve 98.8% accuracy on the CIC IDS 2018 dataset. We used the MISH activation function in our custom neural network architecture. Misra (25), the author of MISH. Discussed in detail its scope and found that. Mish outperformed other activation functions like Leaky ReLU on YOLOv4 with a CSP-DarkNet-53 backbone on average precision. Hua et al. (26) proposed using the LightGBM ensemble method, which proved to be quite a popular and efficient ensemble method for Intrusion Detection. By achieving 98.37% accuracy, the study also compared their approach with other ensemble methods and traditional machine learning algorithms to prove its efficiency.

Catillo et al. (27) presented an autoencoder-based bi-level anomaly detector, which used a specific Artificial Neural Network to reconstruct their vectorized input on the CIC IDS 2017 and 2018 datasets with a maximum detection rate of 99.2 %. It seems to be an overwhelming algorithmic approach to a relatively simple problem with minimal feature space. Khan and Kim (28) have proposed a Convolutional auto-encoder (Conv-AE) based Intrusion Detection System using a heterogeneous dataset. The Conv-AE algorithm proves to efficiently combine the advantages of traditional state-of-art approaches and identifies malicious attacks in the case of both anomaly and misused-based ID systems. They have also mentioned the distributed and big-data-friendly processing pipelines for training their algorithms and achieved 98.2 % accuracy. Meryem and Ouahidi (29) overcame the limitations of anomaly and misuse detection by using a hybrid approach. They have employed the K-Nearest Neighbors on the KDD-Cup99 dataset. They had achieved more than 98.77% and an Area Under the Curve (AUC) score of 0.58, which is sub-optimal. Thakkar and Lohiya (30) briefly discuss CIC-IDS-2017 and CIC-IDS-2018 datasets by analyzing their features and iterating them across many Machine Learning and Deep Learning models. They had suggested that the CIC IDS datasets were significantly better than NSL KDD because of the type of attacks, data capturing techniques, and attack infrastructure.

According to Gao et al. (31), an adaptive and ensemble system to the same anomaly-based approach proved better. Using the KDD Cup99 dataset, they used multiple algorithms such as KNN, DNN, random forest, and to architect an ensemble adaptive voting algorithm. They compared the algorithms and found that the Adaboost model achieved 99.99% accuracy. Reviewing and understanding the dataset is vital for building innovative and novel solutions. Chawla et al. (32) in their paper, had attempted to build an efficient intrusion detection system that was anomaly-based, using Recurrent Neural Networks like Gated Recurrent Units rather than the vanilla LSTM networks. However, convolutions and recurrent methods can be computationally intensive and time-consuming compared to other methodologies applied for non-sequential tabular data.

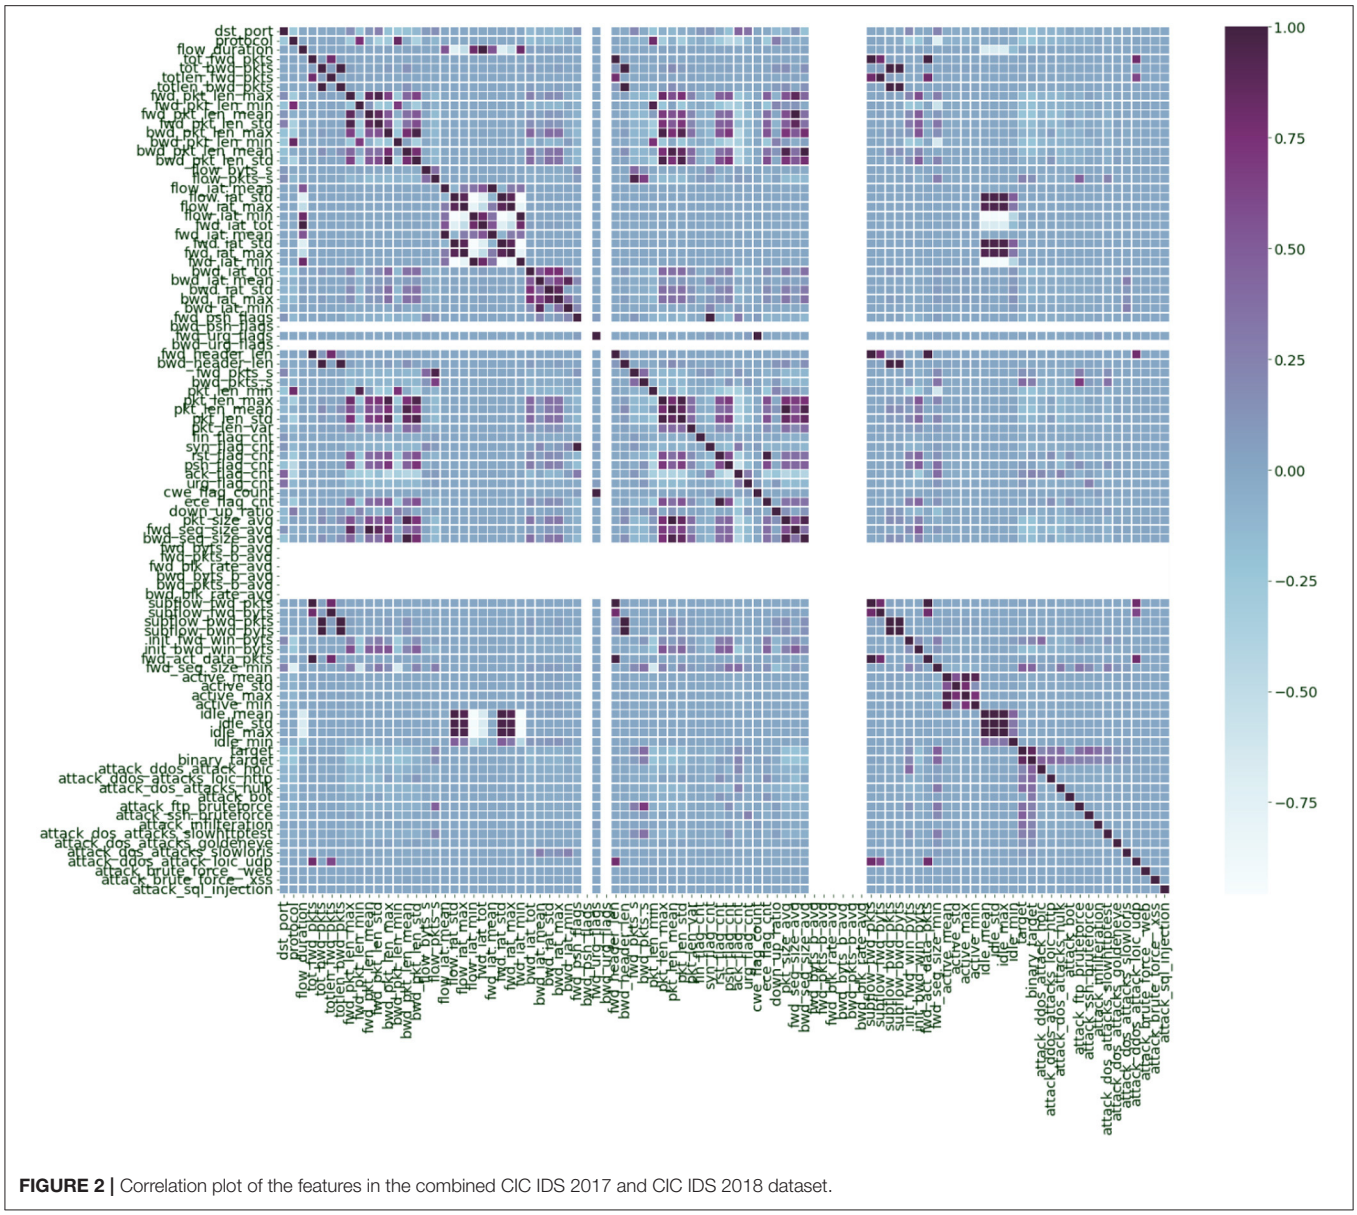

FIGURE 2 | Correlation plot of the features in the combined CIC IDS 2017 and CIC IDS 2018 dataset.

They have obtained an accuracy of only around 81% on the ADFA Intrusion Detection dataset. Anomaly-based detection has its disadvantages, supporting the opinion of Feras et al. (33) proposed a hybrid model that leverages the functionalities of SVMs and decision trees. Using the CIC IDS 2018 and KDD Cup 99 datasets, they have accuracy of 97.881 and 99.982%, respectively. Wankhede and Kshirsagar (34)–"DoS Attack Detection Using Machine Learning and Neural Network" uses the dataset CIC IDS 2017 dataset and uses Random Forest and Multi-Layer Perceptron approach. The Random Forest algorithm provides more optimized results than Multi-Layer Perceptron from their experiments, obtained around 99% accuracy on the CIC-IDS 2017 datasets.

Mubashar et al. (1) created a framework for an IoT-based medical data archival system by combining a novel block chain-based technique for medical data encryption with an optimization algorithm. Loshchilov and Hutter (35) proposed Stochastic Gradient Descent with Warm Restarts, from which

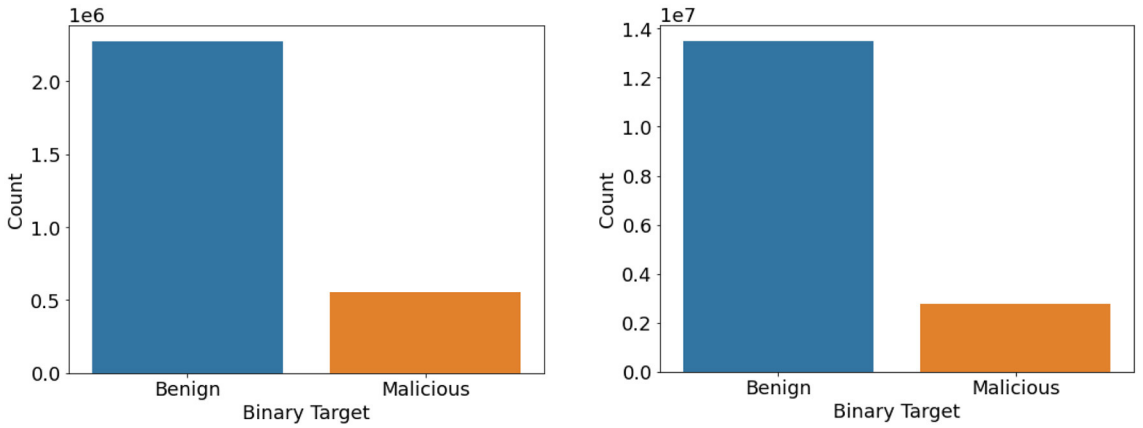

FIGURE 3 | Binary class count plot of CIC IDS 2017 (left) and 2018 (right) datasets.

we have used the Cosine annealing learning rate scheduling technique as an optimization strategy in our experiments. Glorot and Bengio (36) had proposed a new weights initialization technique for neural networks that leads to better convergence and performance of the model. Sharma and Yadav (10) in their paper have proposed recursive feature elimination technique for feature selection and have achieved an accuracy of about 99% accuracy for DOS attacks and other attacks using Decision Trees on KDD Cup 99 dataset. Correlation based feature selection was proposed by Thaseen et al. (37) in their paper as a feature selection method, and obtained an overall accuracy of 97.9 % with an artificial neural network on the NSL-KDD dataset (38–42).

From our observation, most of the research used the KDD-Cup99, and the approaches done with CIC-IDS datasets support the latest intrusion attacks. They are performing better while also supporting better classes of attacks. The features in the CIC-IDS 2017 and 2018 datasets are quite the same. They can also be used together with multiple feature selection techniques and sampling techniques to produce better results for the classifiers. The Intrusion Detection mechanism must be trained on the latest cyber-attack repositories to be up-to-date hence protecting the patient records without any compromise. It is also essential that the algorithm is not biased toward benign or malicious classes, which may cause high false positive rates (43–50). Hence, a balanced dataset should be used for training the IDS mechanism. Our paper has proposed the methodologies followed for feature selection, class balancing, data preparation, and preprocessing under multiple sub-sections in section Methodology. The results, comparison for the algorithms, and discussion on the pros and cons of the proposed system are discussed under sections Results and Discussion, respectively.

METHODOLOGY

Our approach deals with building a hybrid intrusion detection mechanism that can support the latest cyberattacks without following any traditional rule-based methods. The IDS should protect electronic Health Records (EHR) from any type of attack. An algorithm that can be pruned or fine-tuned to adapt to new attacks is crucial since recent attacks are evolving daily. We experimented with a new dataset by the Canadian Institute for Cybersecurity that supports over 15 types of latest intrusion attacks and compared the same with the widely available datasets for intrusion detection. A statistical feature selection process has been done on the dataset to extract the most valuable features that can boost the performance of the classifiers. We also dealt with the class imbalance of the dataset to not make our model biased toward particular positives or negatives. We compared five machine learning algorithms: Logistic Regression, Decision Trees, random forests, XGB (12), and Artificial Neural Network. We have created a new Artificial Neural Network architecture that surpassed performance compared to the other algorithms obtaining ∼99.2 % accuracy. We conducted our experiments on a Linux machine running Ubuntu 21.04 OS with 32 GB RAM and 8 GB NVidia GTX 1080 GPU to use distributed training of our algorithms to obtain results faster. We used Python and popular data science libraries like NumPy, Pandas, Scikit-Learn, and TensorFlow to implement the data processing and algorithms. We have discussed all the aspects of our methodology in detail in the following subsections.

Dataset Comparison

Datasets used for Intrusion Detection and Coping purposes evolve a lot with time since there is a perennial and dynamic change in cybersecurity threats and new attacks rise around the horizon day in and out. The most traditional dataset used for this purpose is the KDD Cup 99 dataset, which is proven to have a lot of anomalies. NSL-KDD is the dataset suggested to solve some of the problems of the KDD 99 dataset. It removes all the redundant records in the KDD 99 train set, ensuring no duplicate records in the proposed test sets. NSL-KDD's KDD training set contains 22 attack types, and KDDTest data contains additional 17 attack types. It has 41 attributes and one class attribute, respectively. Another dataset commonly explored for this use case is The ISCX dataset 2012 by the Information Security Center of Excellence at the University of New Brunswick. It contains over 2 million traffic

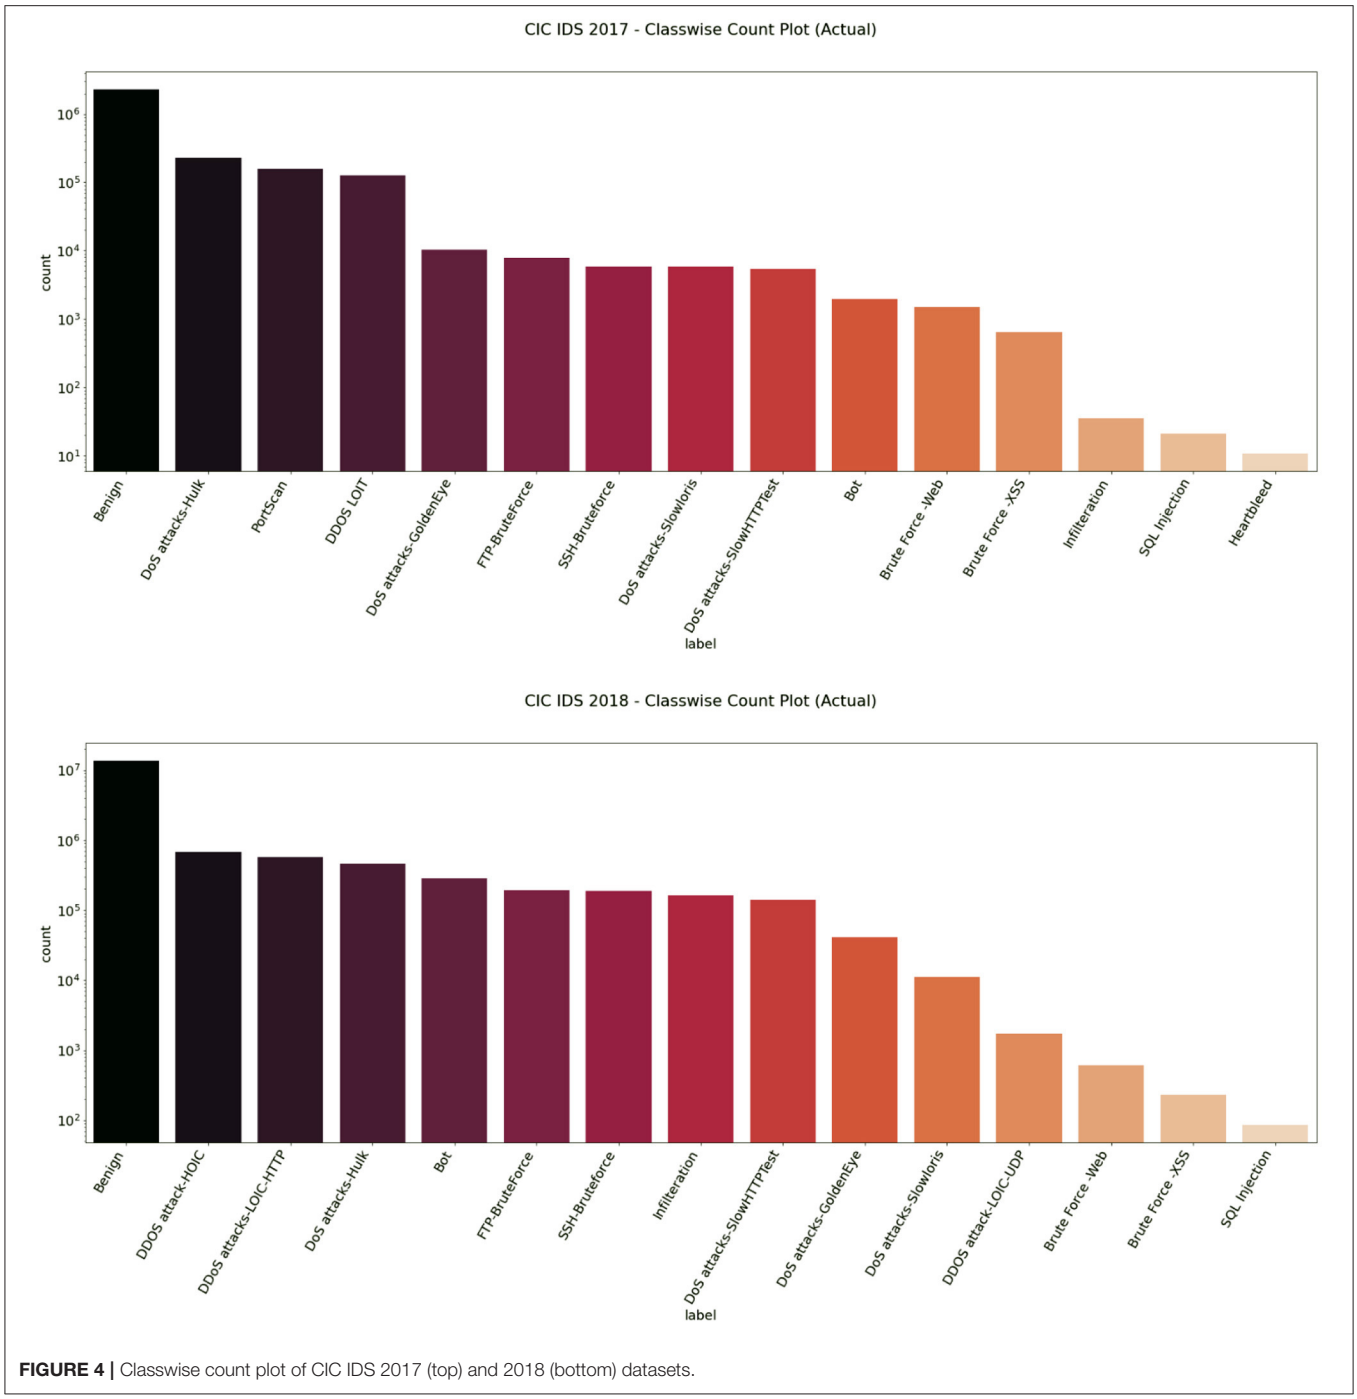

FIGURE 4 | Classwise count plot of CIC IDS 2017 (top) and 2018 (bottom) datasets.

packets categorized under 20 features. It covers attacks such as Brute Force SSH, HTTP DoS, DDoS and Infiltrating attacks. CIC analyzed these attacks under regular traffic rates on seven successive days, and they logged the corresponding metrics. It is one of the most up-to-date datasets.

CIC IDS 2017–2018 is the dataset we prefer for our Intrusion Detection System as it contains benign and the most up-to-date common attacks, which resembles the actual real-world data (PCAPs). It also includes the results of the network traffic analysis using CICFlowMeter with labeled flows based on the timestamp, source and destination IPs, source and destination ports, protocols, and attack. It is a labeled dataset containing a total number of 84 features, including their corresponding traffic status. Moreover, CIC IDS 2017 covers various attacks such as Brute Force Attack, HeartBleed Attack, Botnet, DoS Attack, Distributed DoS (DDoS) Attack, Web Attack, and Infiltration Attack. The total number of records in the dataset is 3,830,743. The benign traffic lists around 2,273,097 records, whereas the

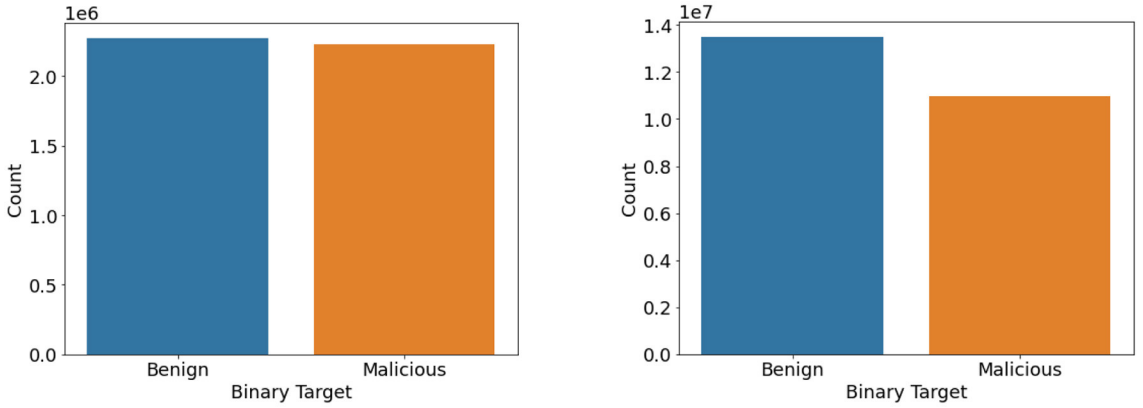

FIGURE 5 | Binary class count plot of oversampled CIC IDS 2017 (left) and 2018 (right) datasets.

malicious samples are 5,57,646 in number. The CIC IDS 2018 dataset consists of the same attack classes but with a large number of samples for benign and malicious classes. It consists of around 13,484,708 benign samples and 2,748,235 malicious samples.

Apart from this, we have also used the latest CIC Bell DNS 2021 dataset, which contains up-to-date real-time DNS-related data that can be useful for flagging a particular request as benign, spam, phishing, and malware. CIC created this dataset in collaboration with Bell Canada and Cyber Threat Intelligence, Canada. There were 32 features in the dataset, formed from DNS-statistical features and lexical features. The classes in the dataset were further grouped into 400,000 benign entries and 13,011 malicious entries, from which they balanced the classes by grouping 20,000 benign scans and 13,011 malicious scans together. **Table 1** displays the meta-data such as dataset size, number of entries, provider, and attack classes in detail for KDD Cup 99, CIC IDS 2017–2018, and CIC Bell DNS 2021.

Feature Selection

There were 82 features present in both CIC IDS 2017 and 2018 datasets. **Table 2** displays some of the features present in the dataset. Out of these, there were a lot of similar features that were highly related to each other, like the forward packet's total length and header length of packets. Deriving features with less correlation would help the algorithm learn diversely as they comparatively have lesser variance. Since both CIC IDS 2017 and 2018 had the same features, we calculated the correlation by combining both datasets as they belong to the same distribution.

We have employed Correlation-based Feature Selection (CFS) (37). By plotting the correlation matrix of the features (**Figure 2**), we analyzed which features were highly correlated to elucidate which ones were independent. Features with high correlation are more linearly dependent, and they tend to have the same effect on the dependent variable. So, when we observe two features with a relatively high correlation, we can drop one of those features, which reduces the computation complexity and dataset size to be processed. Around 56 features were derived that were correlated <75%. Further, we used recursive feature elimination (11, 37) by using a logistic regression classifier and selected 38 features based on their significance with an alpha value (p-value) of 0.05. **Table 2** represents some of the features in the dataset with corresponding correlation scores and p-value based significance.

Table 3 displays some of the selected features from the CIC Bell DNS 2021 dataset. The dataset was subject to multiple feature engineering techniques in processing the raw PCAP files into DNS statistical, lexical, and third-party features, as Mahdavifar et al. (8) suggested. We have used all 32 derived features from the dataset and have applied different preprocessing techniques discussed in section Data Preparation.

Improving Class Balance

Balanced datasets lead to good accuracy and performance of the classifiers. We found that the dataset had a heavy class imbalance by plotting the count of benign and intrusion samples. The number of benign samples was higher than the number of intrusion samples. One way to overcome this quickly would be to under-sample it. Since we have samples <100 for a few classes like SQL Injection in the CIC IDS 2018 dataset as referred to in **Figures 3**, **4**, under-sampling the imbalance dataset would still yield an imbalanced dataset with fewer samples. It may cause a bias toward higher-sample labels while training any algorithm.

We then used the Synthetic Minority Oversampling Technique algorithm to oversample the CIC IDS 2017 and 2018 datasets by a factor of 3 only for the intrusion class. Imbalance classification involves developing models on datasets that have a severe class imbalance. Synthetic Minority Oversampling Technique or SMOTE algorithm is a data augmentation technique that selects features in close feature space. It creates as many synthetic examples for minority classes, making them more effective in learning the decision boundary and performing better. SMOTE uses K-Nearest Neighbors to select points near the neighbor of each data point randomly and generates synthetic instances to upsample the minority class. SMOTE oversampling is effective because the new synthetic samples generated from the minority class have relatively close feature space to existing samples. In this way, we were able to get an almost balanced dataset, leading to better performance of the model. **Figures 5**, **6**

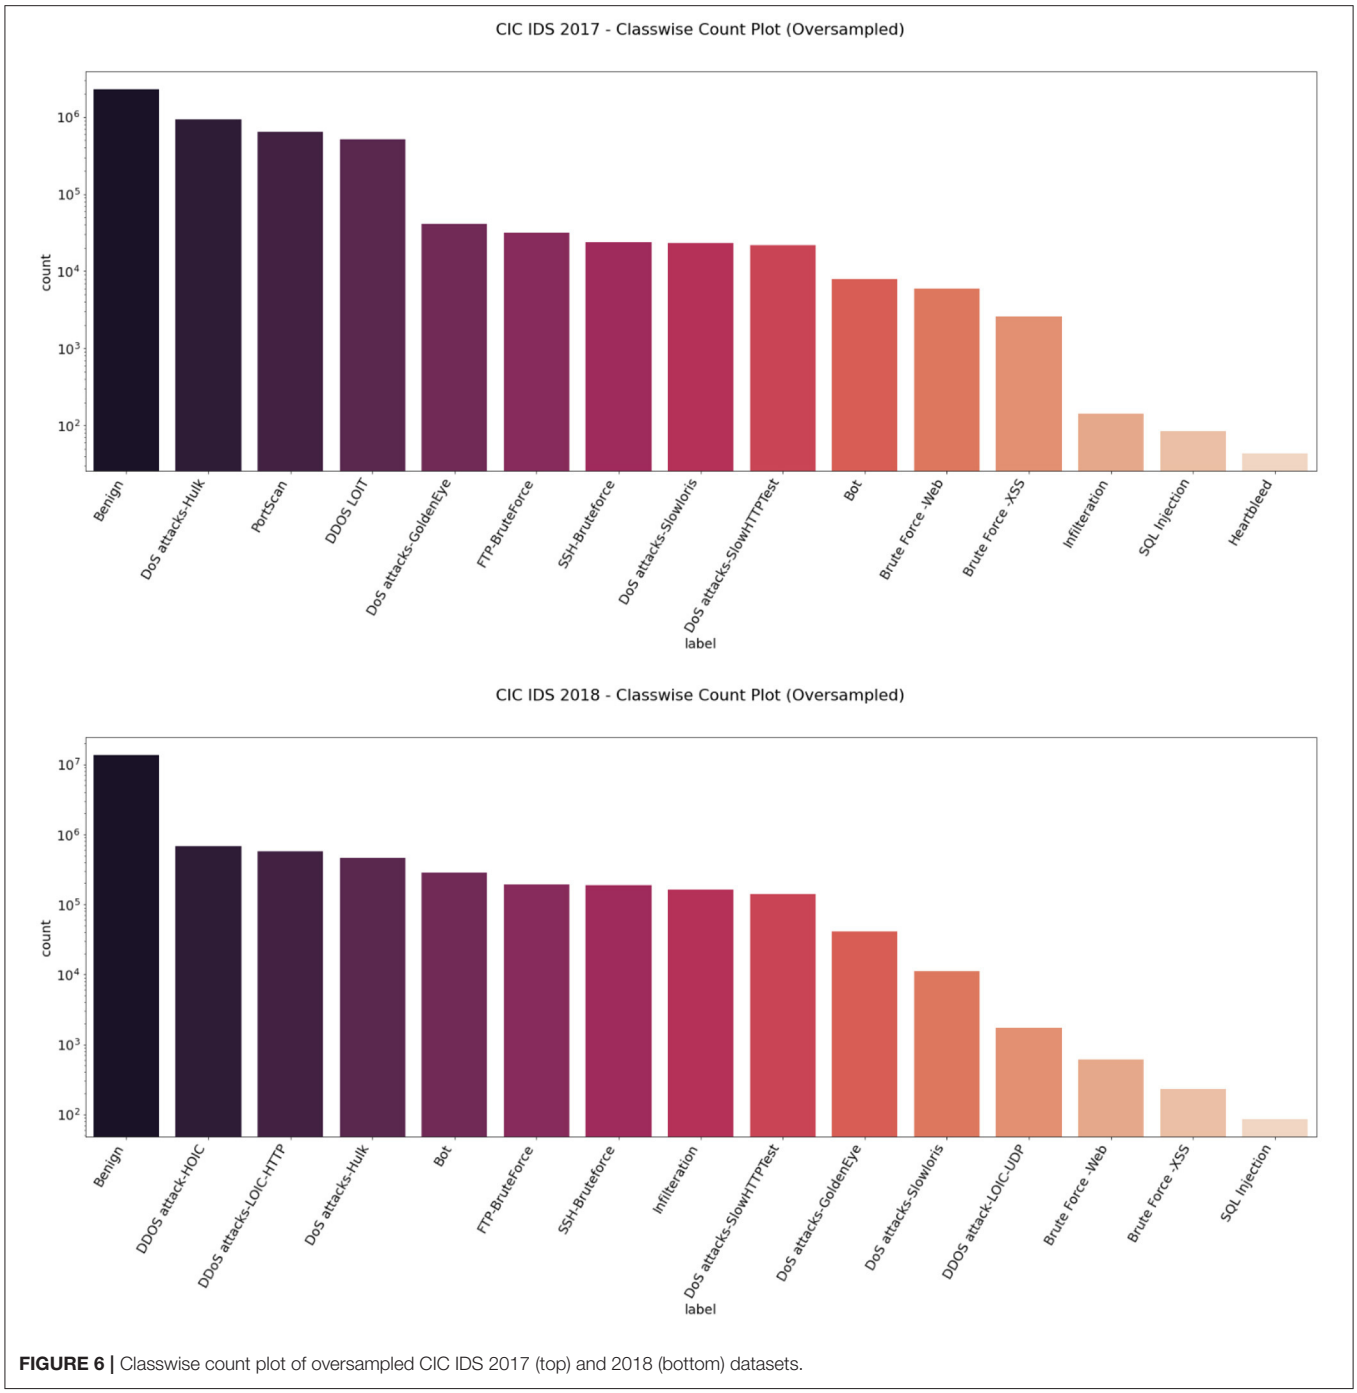

FIGURE 6 | Classwise count plot of oversampled CIC IDS 2017 (top) and 2018 (bottom) datasets.

represent the oversampled binary count plot and classwise count plot of the CIC IDS 2017 and 2018 datasets.

We performed both undersampling and oversampling for the CIC Bell DNS 2021 to promote class balance. The dataset had a heavy class imbalance with 400,000 benign samples and only 13,011 malicious samples. Random shuffling and selection were performed on the dataset to gather only around 25,000 benign samples. Apart from this, SMOTE oversampling was done on the rest of the three classes: spam, phishing, malware. We also removed entries that contained null values since they were not usable. After this process, we had a balanced dataset with 23,716 benign samples and 22,929 malicious samples. **Figures 7**, **8** illustrate the binary and classwise count plots of samples in the CIC Bell DNS 2021 dataset before and after the class balance improvement process.

Table 4 shows the number of samples and benign to malicious sample ratio before and after class balance improvement for CIC IDS 2017, CIC IDS 2018, and CIC Bell DNS 2021 datasets.

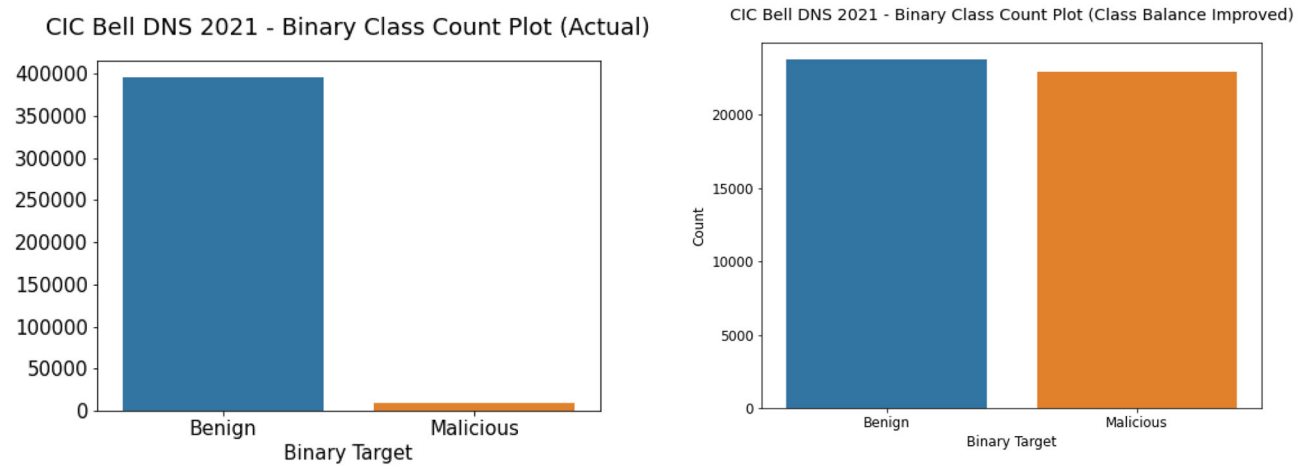

FIGURE 7 | Binary class count plot of actual (left) and class balance improved (right) CIC Bell DNS 2021 dataset.

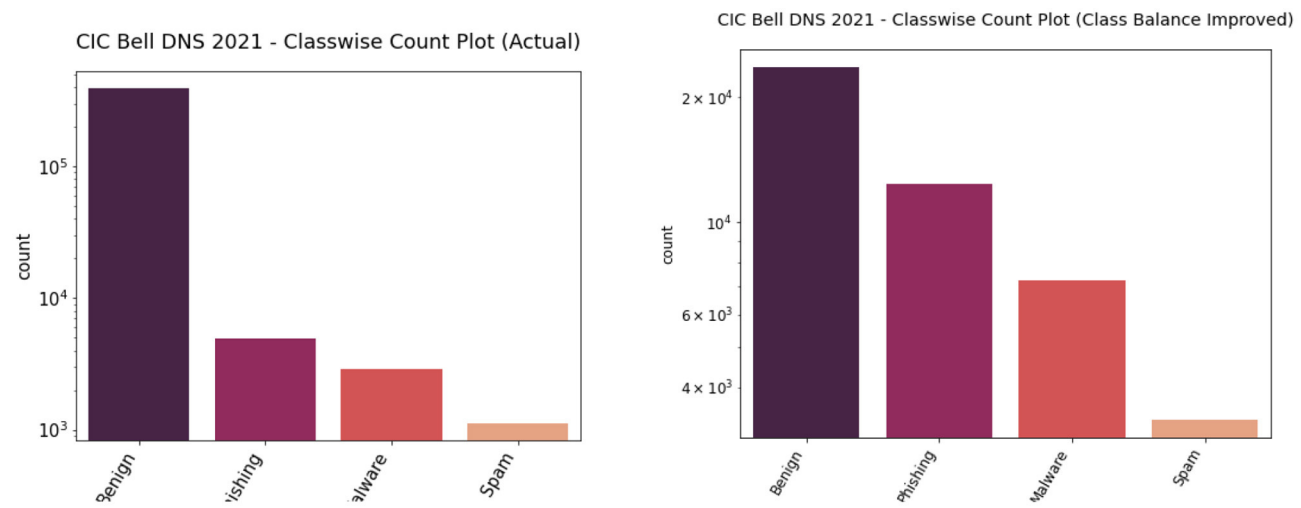

FIGURE 8 | Classwise count plot of actual (left) and class balance improved (right) CIC Bell DNS 2021 dataset.

Data Preparation

The dataset was made publicly available by the Canadian Institute for Cybersecurity (CIC). The CIC Bell DNS 2021 dataset's processed CSV files were downloaded from their website. We performed standard data cleaning to remove null values and encode categorical text such as domain names, countries, and states with numbers. The CIC IDS 2017 and 2018 datasets were downloaded from their AWS S3 bucket using the AWS CLI and split into multiple CSV files based on the type of attack. We then combined these CSV files as a single data frame during runtime to save memory for further preprocessing as the entire dataset was more than 7 GB. The dataset was subject to multiple feature selection and sampling processes as mentioned in the previous sections to promote the most valuable features for classification

to achieve better accuracy. We combined the attack columns into three feature columns: labels as the attack's name, binary targets denoting whether the packet is benign or malicious, and target column representing the id of which attack had occurred. Later this data was z-scored using the standardization formula (1). Standardization of the data leads to faster and more accurate convergence of the machine learning models.

$$y = \frac{(x - \bar{x})}{\sigma}$$

We followed a stratified cross-validation split with a 30% test size on all three datasets while running our algorithmic experiments. The cross-validation split yielded a 70% training set, 15% validation set, and 15% testing set for every fold with a random shuffling of the data entries. Since the split was stratified, we contained the same benign to malicious samples ratio in all three sets for each dataset.

Machine Learning Approaches

We experimented with five machine learning algorithms inspired by different pieces of contemporary machine intelligence literature whose methods proved to work well for tabular data and critical applications. Logistic Regression is a statistical learning algorithm used to model the probability of an event happening or not. The logistic function or sigmoid function approximates the output values from a multinomial linear equation to predict whether a particular class is occurring. We used L2 regularization and "lbfgs" solver to optimize the algorithm. Equation 2 defines the logit calculation by summation over the dot product of inputs and weights added to bias, which is then applied inside sigmoid, equation 3, to get a probability-like value between 0 and 1, which denotes the occurrence of a class.

$$z = w^T x + b$$

$$\sigma(z) = \frac{1}{1 + e^{-(z)}}$$

Binary Cross entropy Loss

$$= -\frac{1}{output\ size} \sum_{i=1}^{output\ size} y_i \cdot \log \hat{y}_i + (1 - y_i) \cdot \log(1 - \hat{y}_i)$$

Binary Cross Entropy or BCE (4) is used as the cost function with L2 regularization for the optimization process using gradient descent.

Further, we used Decision trees with the ID3 implementation and Gini criterion. We also ran Random forests with 100 trees and criteria as Gini, equation 5. This algorithm establishes the outcome based on the predictions of the decision trees, which uses the information gain, equation 6, as an optimization metric.

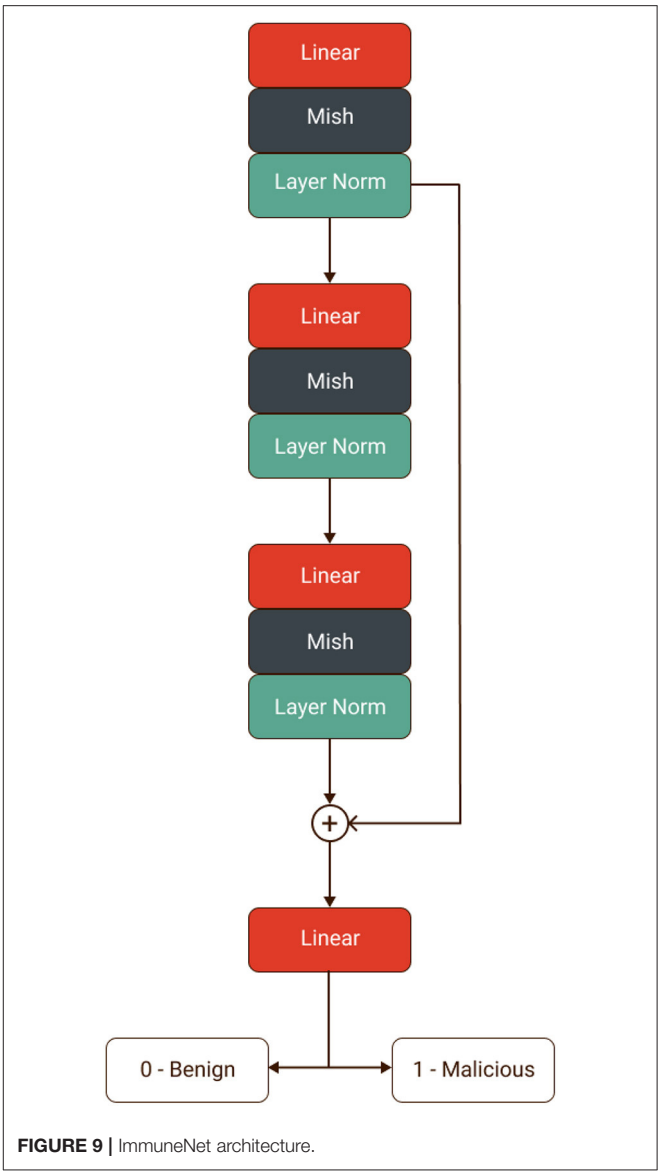

FIGURE 9 | ImmuneNet architecture.

$$Gini: I_G(f) = \sum_{i=1}^{m} f_i \ (1 - f_i)$$

$$Information\ gain: I_E(f) = \sum_{i=1}^{m} f_i \ \log_2 \quad f_i$$

Extreme Gradient Boosted Trees (XGB) (12) have recently gained momentum for their outstanding results on different kinds of tabular data. With regularization techniques and effective pruning of the trees, only significant splits with positive information gain are retained. We observed that the above methods, namely Extreme Gradient Boosted Trees, Random Forests, and Decision Trees, worked better with given use cases than Logistic Regression because ensemble models use

multiple independent learners from which the entire predictions are derived.

Finally, we built our own Artificial Neural Network named the "ImmuneNet" that uses simple linear projections followed by mish activation and layer normalization with a residual operation between the first and the final block. **Figure 9** displays the neural network architecture of ImmuneNet.

The first and last linear layer has 512 neurons, and the hidden layer has 784 neurons. Since there were fewer features for all three datasets, we used a minimal number of neurons in the layers. The number of neurons per layer was set arbitrarily and increased by a factor of 2 after observing the performance of the earliest models by using a grid search with different hyper-parameter settings for the hidden layer units. The first and the last layer are connected with a residual (38) operation, and hence they have the same number of neurons. Equation (7) defines the perceptron or linear equation, which is chained with the mish (25) activation (8) followed by the layer normalization (39) (10), creating a forward block for the immune net. We have used Sharma and Yadav (10) technique for the neural network's weights initialization for training all three datasets. **Table 5** describes the hyperparameters we used for ImmuneNet and its optimization for all three datasets with corresponding feature dimensions. The number of samples used for training, validating, and testing the algorithms is mentioned below in **Table 6**.

We used the Adam optimization (40) set to a learning rate of 1e-4 with cosine annealing (36) technique for learning rate scheduling and binary cross-entropy (4) as the cost function. The hyper-parameters for the optimizer except for the learning rate, like beta1, and beta2 have been set with values as suggested by the authors of Adam optimizer (40). The learning rate will be changed after every few iterations based on the validation loss obtained, with the help of the cosine annealing (36) learning rate scheduler. The cosine function is used to vary the lower rate after each epoch. The objective of cosine annealing is to prevent the model from saturating after reaching a local minima and varying the learning rate using the cosine function to periodic lower learning rates to converge at an optimal point like the global minima. The model was trained with a batch size of 64 for 15 epochs with an early stopping mechanism which stops the training process when the model's performance starts to saturate, which acts as a regularization technique. We have avoided larger batch sizes because models with larger batch sizes and higher learning rates can cause unstable training, bad convergence, and lead to different asymptomatic test metrics. The results of all

RESULTS

Evaluation Metrics

The following metrics for evaluating our machine learning models can help derive more significant insights into our various algorithms' performance and bias:

Confusion Matrix (**Table 7**) is a matrix that summarizes the performance of the given algorithm on the classification. Since the dataset is not entirely balanced, using measures like accuracy alone can be misleading.

Accuracy, equation (11), or correct rate is how right the model is for the given classification problem.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN}$$

Precision (12) is the ratio of true positives to all the positives, i.e., the sum of true positives and false positives.

$$Precision = \frac{TP}{TP+FP}$$

Recall (13) is the ratio between true positives and the sum of true positives and false negatives.

$$Recall = \frac{TP}{TP+FN}$$

The F1 (14) score provides the balance between the precision and recall, suggesting how similar the predicted set is to the true set.

$$F1 = \frac{2^*\text{Precision}^*\text{Recall}}{Precision+Recall} = \frac{2^*\text{TP}}{2^*\text{TP}+FP+FN}$$

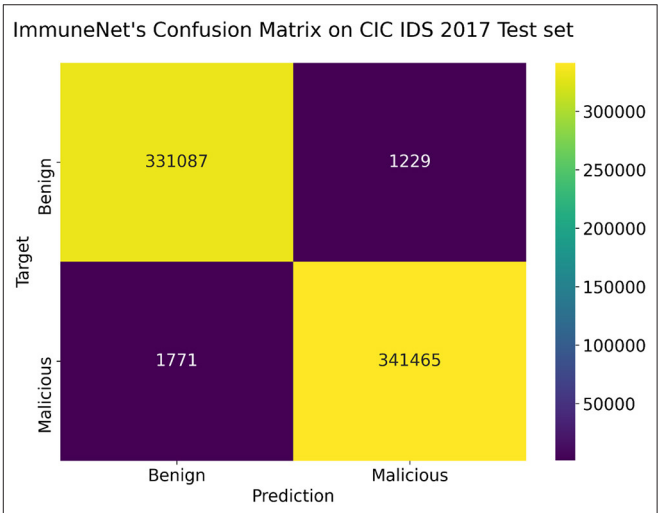

FIGURE 10 | Confusion matrix on the CIC IDS 2017 test set for ImmuneNet.

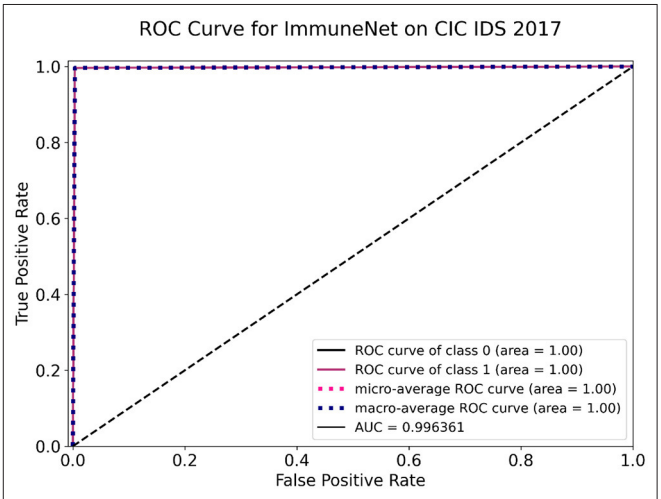

FIGURE 11 | Receiver operating characteristic (ROC) curve of ImmuneNet on CIC IDS 2017 dataset.

ROC Curve is the rate of true positives against false negatives describing how well a binary classifier can classify between two classes. The area of the region under the ROC curve defines the performance of the binary classifier. The model performs better when it has a high AUC score (15) and performs the lowest when

TABLE 9 | Comparison of models based on respective evaluation metrics for CIC IDS 2018.

Model	Accuracy	Precision	Recall	F1	ROC-AUC Score	Training loss	validation loss	Testing loss
ImmuneNet	99.78	99.77	99.78	99.7	99.786	0.0036	0.0023	0.0025
XGB	99.00	99.03	99.00	99.01	98.98	0.0141	0.0366	0.0389
Random forest	98.81	98.82	98.81	98.81	98.31	0.0989	0.0782	0.0801
Decision trees	98.69	93.41	98.79	96.03	98.731	0.1054	0.1031	0.1053
Logistic regression	87.96	90.8	87.96	88.99	81.537	0.3520	0.2877	0.2798

the AUC score is low.

$$AUC = \frac{Specificity + Sensitivity}{2}$$

$$Sensitivity = Recall = \frac{TP}{TP + FN}$$

$$Specificity = \frac{TN}{FP + TN}$$

Binary Crossentropy (3) is a cost function that gives the log distance between two probability distributions containing probabilities of an event occurring or not for any binary classification problem.

$$Binary\ Crossentropy\ Loss = \frac{1}{output\ size} \sum_{i=1}^{output\ size} y_i \cdot \log \hat{y_i} + (1 - y_i) \cdot \log(1 - \hat{y_i})$$

Model Comparison

The above models were tested on the test sets of CIC IDS 2017, CIC IDS 2018, and CIC IDS Bell DNS 2021 datasets, as mentioned in section Improving Class Balance. **Table 8** contains the evaluation metrics of the algorithms' performance on the CIC IDS 2017 dataset. **Figures 10**, **11** display the confusion matrix and ROC curve of ImmuneNet on the CIC IDS 2017's test set.

From **Table 8**, we can observe that the Immune Net algorithm performs the best, with an accuracy of 99.63%. Compared to the other algorithms like XGB (12) and Random Forests, ImmuneNet has better accuracy and minimum loss. From the Confusion Matrix represented in **Figure 10**, we can also see that only 1,229 benign samples were flagged as malicious in total, implying a less false positive rate. On the other hand, XGB (12) and Random Forest perform better when compared to Decision Trees and Logistic Regression with an accuracy of 99.09 and 98.81 %.

The Receiver Operating Characteristic curve for ImmuneNet, as seen in **Figure 11**, has an AUC score of 99.6% for the CIC DIS 2017 test set. This makes it evident that the algorithm's true positive rate against the false positive rate is better and is almost a typically perfect binary classifier.

Table 9 comprises the evaluation metrics of the five machine learning algorithms on the CIC IDS 2018 dataset. The confusion matrix and ROC curve of ImmuneNet are represented by **Figures 12**, **13** for the CIC IDS 2018's test set.

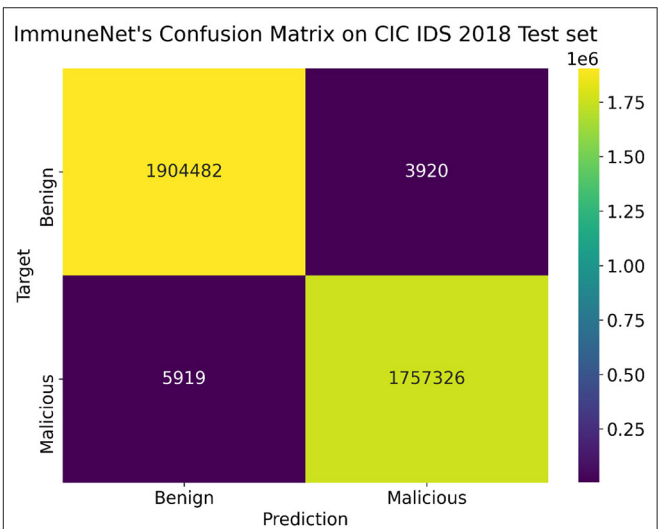

FIGURE 12 | Confusion matrix on the CIC IDS 2018 test set for ImmuneNet.

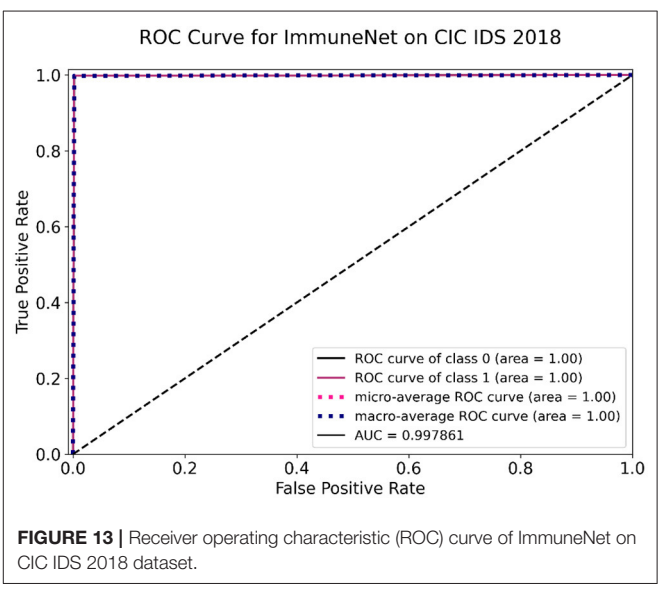

FIGURE 13 | Receiver operating characteristic (ROC) curve of ImmuneNet on CIC IDS 2018 dataset.

ImmuneNet has an accuracy of 99.78, 99.77% precision score, 99.78% recall score, and a test loss of 0.0025, which is better when compared to the other algorithms. Logistic Regression had the lowest accuracy of 87.96% and had a high loss. **Figure 12** depicts

TABLE 10 | Comparison of models based on respective evaluation metrics for CIC Bell DNS 2021.

Model	Accuracy	Precision	Recall	F1	ROC-AUC Score	Training Loss	Validation Loss	Testing Loss

XGB	99.10	98.89	99.10	98.99	99.01	0.0235	0.0228	0.0226
Random forest	98.21	95.60	98.17	96.86	96.25	0.0789	0.0631	0.0655
Decision trees	97.66	95.41	98.78	97.06	96.30	0.0808	0.0748	0.0752
Logistic regression	92.87	89.93	92.60	91.24	90.10	0.3356	0.3579	0.3467

the Confusion Matrix, from which we can observe that the false positives and false negatives are very low, having only samples around 3,920 and 5,919, respectively.

From the ROC curve, as presented in **Figure 13**, we can observe that ImmuneNet's performance has a better True Positive rate against False Positive rate producing a ROC-AUC score of 99.78%. The obtained metrics are higher than other existing methods for CIC IDS 2018, such as the LighGBM and HBGB method proposed by Seth et al. (19).

Several evaluation metrics in **Table 10** depict the algorithms' performance on the CIC Bell DNS 2021 dataset. ImmuneNet's confusion matrix and ROC curve on the CIC Bell DNS 2021's test set are represented by **Figures 14**, **15**.

From **Table 10**, it is observed that the ImmuneNet has the highest accuracy of about 99.2% and a test loss of 0.00141. These metrics are much better when compared with the algorithms like Decision Trees, Random Forest and Logistic Regression, which have comparatively lower accuracies and higher losses.

From **Figure 14**, we can see that ImmuneNet has an excellent true positive rate against false positive rate, having a ROC-AUC score of 99.19%. It is evident that ImmuneNet is performing better on the CIC Bell DNS 2021 dataset from the metrics mentioned above compared to Mahdavifar et al. (8). They achieved about 94.8 and 99.4% accuracy on the 60/40% balanced dataset and the 97/3% balanced dataset. The discussion on the performance of the algorithms mentioned above for all three datasets with their advantages and limitations is elaborated under the next section.

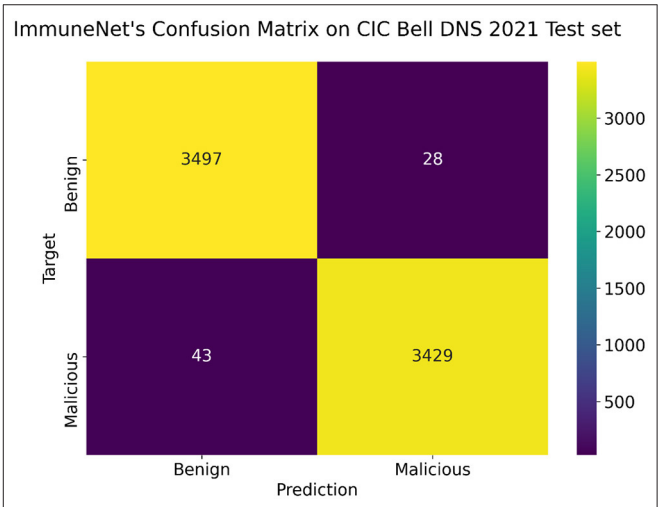

FIGURE 14 | Confusion MATRIX on the CIC Bell DNS 2021 test set for ImmuneNet.

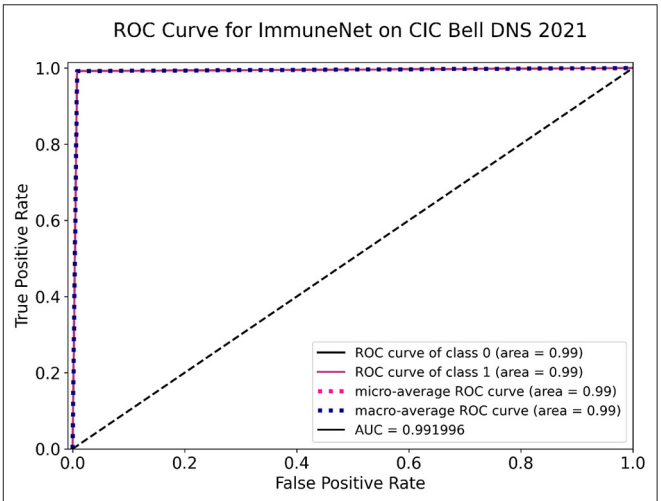

FIGURE 15 | Receiver operating characteristic (ROC) curve of ImmuneNet on CIC Bell DNS 2021 dataset.

DISCUSSION

Out of all the experiments run on the CIC IDS 2017 (6), CIC IDS 2018 (7), and CIC Bell DNS 2021 (8) datasets with over five types of machine learning algorithms, ImmuneNet performed the best for all three datasets. This is because the algorithms' training, validation, and testing phases were data-centric and highly dependent on the class balancing and feature engineering techniques we followed for the three datasets. ImmuneNet achieved ∼99.2% accuracy for the CIC Bell DNS 2021 dataset, 99.8% accuracy for CIC IDS 2018 dataset, and 99.63% accuracy for the CIC IDS 2017 dataset during the testing phase. These metrics are better than the existing approaches that have been suggested for IDS in healthcare, such as methods proposed by Subasi et al. (4), Šabić et al. (15), Hady et al. (16) since the model has been trained on an extensive real-time dataset containing latest cyberattacks post multiple feature engineering and sampling techniques. The algorithm has also performed well-after performing a different sampling and preprocessing approach for the CIC Bell DNS 2021 dataset, achieving an

TABLE 11 | ImmuneNet's model parameters and size for CIC IDS 2017–2018, and CIC Bell DNS 2021 datasets.

S. No	Dataset	Number of trainable parameters	Model weights size (in megabytes)
1	CIC IDS 2017	828,209	3.265
2	CIC IDS 2018	828,209	3.265
3	CIC Bell DNS 2021	825,137	3.253

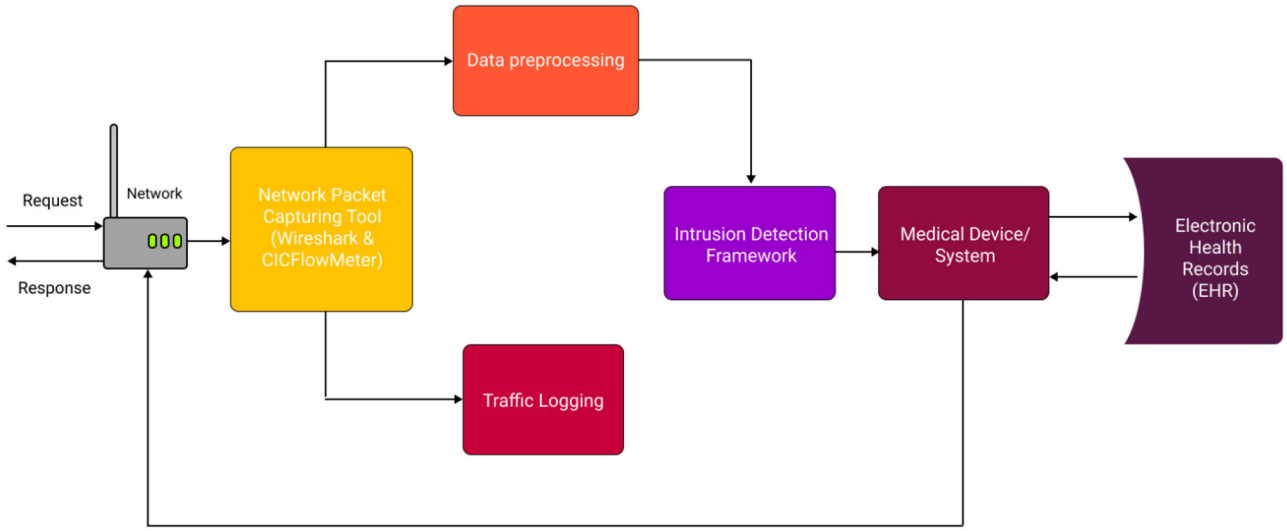

FIGURE 16 | System architecture diagram for the proposed intrusion detection system.

accuracy of about 99.2%, which is comparatively better than the method proposed by Samaneh Mahdavifar et al. (8).

The four reasons behind ImmuneNet's good performance are the data preprocessing, residual operation (38), mish activation (25), and layer normalization (39). By adding the tensors from the first layer and the tensors from the last layer, we preserve features learned by the first layer even if the features learned by the last layer were terrible. This also makes a difference during backward propagation. Mish activation (25) is unbounded above, allowing positive values and slight negative values to flow through the network without any saturation caused by capping during the forward and backward propagation. Layer normalization (39) normalizes the input tensor to zero mean and unit variance along the feature direction. The feature selection, synthetic sampling techniques, and data standardization during preprocessing have led to well-balanced and processed data from which the model was able to learn better.

Apart from ImmuneNet, other algorithms like XGB (12) and Random Forest also performed competitively, having the best subsequent metrics for all three datasets. The learning algorithms must be trained on balanced datasets to achieve better performance and unbiased detection of malicious requests. The CIC Bell DNS 2021 had a heavy class imbalance, and the number of samples obtained after the data preparation was low compared to CIC IDS 2017 (6) and 2018 (7) datasets. The CIC Bell DNS dataset can be improved by including more real-time samples for the phishing, spam, and malware domains to make it more balanced, and the algorithm can be fine-tuned to improve its performance. The ImmuneNet model is very lightweight, containing <1 million parameters. **Table 11** displays the parameters and size of the model's weight in megabytes for all three architectures. This makes it easy to deploy it on any medical device or healthcare system without occupying much memory and would also be fast during inference and fine-tuning. However, the model has to be fine-tuned to support new types of attacks in the future to keep it abreast and safeguard healthcare systems with high accuracy. The neural network's weights can be frozen except the final classification layer, and the framework can be trained again with new data to fine-tune the model. The training process can be done again with new data to retrain the model and improve its performance. **Figure 16** displays the system architecture of the proposed intrusion detection system showing the typical deployment setting and entire process flow.

CONCLUSION

The proposed neural network model, ImmuneNet, has given the highest accuracy of over 99.2% on the class balance improved CIC Bell DNS 2021 dataset, 99.8 and 99.63% accuracy on the oversampled CIC IDS 2018 and 2017 datasets. The model obtained a ROC-AUC score of 99.19%, which is considerably better than the score achieved by the other approaches. We followed a data-centric approach and used several feature

selection and sampling techniques to improve class balance and the pre-processing of the datasets, leading to these results. This architecture is the latest in terms of Intrusion Detection as it has been trained with three latest real-time and extensive datasets. It is deployment-friendly for medical devices and healthcare systems because of its lightweight and fast characteristics. This would help protect the patient records from any kind of cyber attack, leading to consistency in patients' medical data. It is also highly critical that the models are not biased toward specific attacks since bias can allow certain attacks to bypass the IDS and manipulate the patient records by entering into the system. ImmuneNet has an excellent true positive rate against false positive rate, implying it is not biased toward false positives and negatives. However, the CIC DNS 2021 dataset needs to be improved with more samples from phishing, spam, and malware domains to promote natural class balance and better benchmarking of the algorithms. The proposed system must also be frequently fine-tuned with new cyber attack data to protect patient records from cyber attacks that emerge in the future. Fine-tuning the model on the latest cyber-attack data from time to time would improve the model's performance and keep it up-to-date, but it is a time-consuming and tedious process. To overcome these disadvantages, our future work would include a self-supervised learning-based neural network architecture that can make systems like intrusion detection adapt by themselves to new attacks without any manual retraining or fine-tuning and focusing on the recent datasets with better class balance and adversarial reweighting strategies to improve the fairness of the model.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

AUTHOR CONTRIBUTIONS

C-YC did the conceptualization, supervised the research, and carried out the funding acquisition. MA and DS investigated the data, performed the methodology, and implemented the software code. KS and C-YC carried out the project administration, validated the results, reviewed, and edited the manuscript. MA, DS, PV, and HG wrote the manuscript. All authors contributed to the article and approved the submitted version.

FUNDING

This research was partially funded by Intelligent Recognition Industry Service Research Center from the Featured Areas Research Center Program within the framework of the Higher Education Sprout Project by the Ministry of Education (MOE) in Taiwan and Ministry of Science and Technology in Taiwan (Grant No. MOST 109-2221-E-224-048-MY2).

Aiming to increase the shelf life of food, researchers are moving toward new methodologies to maintain the quality of food as food grains are susceptible to spoilage due to precipitation, humidity, temperature, and a variety of other influences. As a result, efficient food spoilage tracking schemes are required to sustain food quality levels. We have designed a prototype to track food quality and to manage storage systems at home. Initially, we have employed a Convolutional Neural Network (CNN) model to detect the type of fruit and veggies. Then the proposed system monitors the gas emission level, humidity level, and temperature of fruits and veggies by using sensors and actuators to check the food spoilage level. This would additionally control the environment and avoid food spoilage wherever possible. Additionally, the food spoilage level is informed to the customer by an alert message sent to their registered mobile numbers based on the freshness and condition of the food. The model employed proved to have an accuracy rate of 95%. Finally, the experiment is successful in increasing the shelf life of some categories of food by 2 days.

1. INTRODUCTION

Food wastage has been a topic of concern in recent years, and studies are being conducted to identify innovative ways to reduce it. It has been described as a major concern in the long-term sustainability of food production, demand, and food supply chains. Since meals are the essential source of diet for all living beings, the quality and security of meals have always been in high demand. The Internet of Things (IoT) links anything, everywhere, and at any time (1–4) and by incorporating the IoT into the Food Supply Chain (FSC) management, it is possible to improve food shelf life by measuring and monitoring the state of the food and exchanging data to and from customers. Currently, the whole use of IoT technologies in FSC is only in its early stages, with a long way to go (5, 6). To avoid food wastage, food sanitation and safety are of paramount importance. The consistency of meals should be regulated. As a result, wastage can be reduced by installing quality control systems in grocery stores. It will further help in controlling diseases (7). These types of quality control systems keep an eye on the environmental conditions that may maintain the food quality. Previously, atmospheric effects were monitored by procedures such

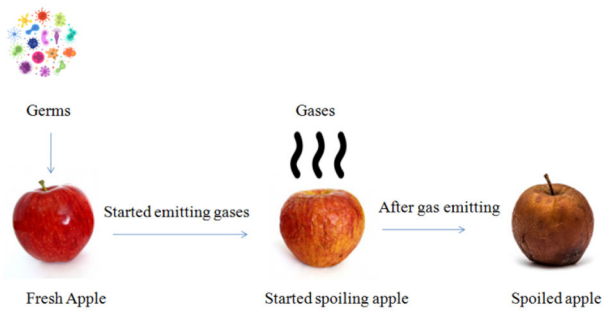

FIGURE 1 | Food spoilage process.

as refrigeration, vacuum storage, and so on. Food pollution can occur during the manufacturing process, although it is most often caused by inefficient food handling activities due to unsuitable environmental conditions during food transportation and storage.

1.1. Food Spoilage Process

Food spoilage occurs when a food product becomes unfit for use by the customer. The factors of such a process are a result of a variety of external factors, including the type of food item, how it is packaged and processed. Every year, one-third of the world's melded are lost which is provided for human consumption due to meal wastage (8, 9). In **Figure 1**, it could be visualized that once the germs start attacking fresh apples, gas emission takes place and after few hours, the apple is spoiled completely.

Bacteria, virus, protozoa, and fungi are factors of food spoilage. These factors can create harmful results for consumers, but we can apply prevention techniques to them to save the life and quality of food. Usually, bacteria can not cause food poisoning and most of the microorganisms that cause food borne illness are odorless and tasteless, otherwise owing to mycotoxins and microbial wastes. Therefore, eating spoiled food is never recommended. Two pathogenic bacteria *Clostridium perfringens* and *Bacillus cereus* can spoil the food.

1.2. Key Component of Food

There is a very important key component i.e., seed. If we want healthy fruits and veggies, that seed must be strong and healthy. The fruits and veggies completely depend on the seeds. There are two types of seeds:

- **Hybrid seeds:** Cross-pollinated plants produce hybrid seeds in cultivation and gardens. Hybrids are selected for their ability to enhance the characteristics of the resulting plants, such as yield, uniformity, color, and disease resistance.
- **Non-hybrid seeds:** These seeds are called heirloom seeds or free pollinated seeds. Non-hybrid seeds originate from naturally pollinated trees. Any of these cultivars have been around for millennia.

The hybrid seeds give hybrid fruits and vegetables and non-hybrid seeds give non-hybrid fruits and veggies. The lifetime of hybrid fruits and veggies is less than the non-hybrid fruits and veggies. But everyone cannot identify which fruit or vegetable is hybrid or not; that is why everybody needs to know the knowledge of their routine work.

Food poisoning can be caused by a variety of factors, including humidity and temperature fluctuations. As a result, it is important to provide a measurement device that can measure humidity and temperature differences during food preparation and transportation (10). Currently, nearly everyone is influenced by the foods they consume daily, not only because of junk food, but also because of canned vegetables and other food items eaten in daily life, which lack consistency because their oxygen, temperature, and moisture content differ from time to time. In the smart house, devices are installed which have the capacity to diagnose wastage of food and then alert caregivers. The study and execution of repetitive measurements, which are aimed at detecting improvements, do not guarantee the nutritional content of the food (11). The details gathered by tracking and monitoring should be reviewed and properly submitted to the administrator for purposes of policy research, pattern forecasting, program assessment, and planning.

The expanded use of smart phones, connected devices, and controllers in food production and other domains has wreaked havoc across the globe. The advantages of IoT technology are rapidly being tapped by the food industry and other sectors (12–14). It accesses *via* broadband (modem) and begins scanning input from the wired up to sensors, the heat, and humidity sensor until properly mounted and turned on. The temperature and moisture controller sensor is a wireless sensor with an active moisture controller sensor. We have employed this idea in the proposed scheme.

Again, the primary function of the proposed monitoring and control systems is to keep track of a certain operation and ensure that it continues as desired. The surveillance process can be accomplished using a variety of different types of sensors. The data collected from the Arduino-based sensors will be compared with the target values (15). If the reading value of the sensor is found to be different from the target values, the control circuit will intervene to affect the allocated operation to keep it at the desired level of quality. As a result, the Smart food spoilage monitoring system focuses primarily on healthy food storage by surveilling and regulating a variety of parameters that affect food products. This control system employs storage units that are equipped with a variety of sensors that read the parameters influencing food quality (16).

1.3. Reasons for Food Spoilage

The recycling bins and the waste made are evidence of the food spoilage circumstances. The big reason for food spoilage is that a larger portion of food waste occurs in office eateries, small and large roadside eateries, group get-together events, and wedding receptions. These food surpluses are not only a widespread indicator of toxicity to the earth's atmosphere, but they also pose a slew of economic problems. According to current calculations, half of all of these foods are lost globally; the global amount of meal wastage is estimated as 1.3 billion tons, and it is projected to rise even more in the upcoming year, which is a concerning problem (17).

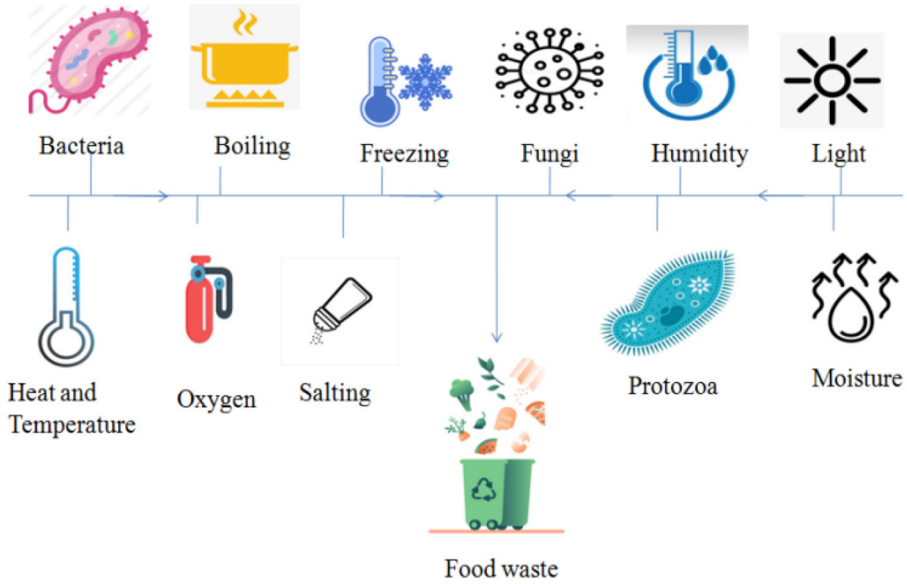

FIGURE 2 | Factors of food spoilage.

Food spoilage can be caused by a variety of human, chemical, and biological causes, including plants, enzymes found in plant food tissues, insects, parasites, and microbes (18). The most common and serious cause of food spoilage is microbial degradation. Food will invariably be polluted by such forms and amounts of microorganisms when microbes are commonly spread in nature.

Figure 2 shows the factors that can destroy fruits and veggies. In terms of heat, humidity, moisture, temperature, and oxygen content they have a threshold value. If the threshold value crosses then food spoiling starts. If we maintain a threshold value then we can vary the life of fruits and vegetables.

1.4. Motivation

The motivation behind Monitoring and analysis of food spoilage using Machine Learning is to keep track and manage food products in order to avoid spoilage caused by climatic and atmospheric changes. Food wastage concerns are focused on healthy eating habits and also concerns with the quality of food as there have been instances where poisonous chemicals have been discovered in fruits and veggies. Monitoring and analysis of food spoilage using Machine Learning saves time and provides accurate and consistent results.

1.5. Our Contribution

While reviewing the articles on food wastage, we have found that there are a few contributions to increasing the shelf life of food. To this end, we have found the research questions for this field. The major and novel contributions of this study are:

- Designing a smart system to keep track of the quality of food using gas, humidity, and temperature sensing mechanism.
- Designing an alert generation system to alert the user about the quality of food and the time spans of its deterioration.
- Development of a system to increase shelf life of food by maintaining the environment according to food.

2. LITERATURE REVIEW

Continuous sensing in a smart home is a unique sensor modality that has the ability to distinguish diverse everyday activities and indicate potentially dangerous situations for the person who lives there. One such situation is food rotting, which is the subject of this study (19). The authors have evaluated the smell signatures of two typical meals (milk and yogurt) that were kept at 25°C for a week using a metal-oxide sensor (MOS) based electronic nose. The highest absolute sensor responses were used to create feature vectors, and their components followed a smooth trajectory as the data aged. The two chemicals followed different trajectories during spoiling, according to principal component analysis (PCA).

Rajesh Megalingam et al. introduce a unique method for detecting food deterioration by combining picture classification with machine learning techniques and artificial intelligence (20). They have used AI, deep CNN networks, computer vision, and ML techniques such as the k clusters method for color classifications in pictures and its HSV values for spoiling detection to identify food rotting. The anaconda prompt is used to complete this project on the jupyter notebook platform. Also, Iwendi et al. employed an Artificial Intelligence approach for detecting and analyzing security levels on IoT using a network classifier. The study shows an impressive accuracy rate for the proposed application. In this view, we can say that AI is useful in almost every field nowadays.

Green et al. presented an electronic nose (e-nose) that consists of four gas sensors made of functionalized single-walled carbon nanotubes (f-SWNTs) and polymer nanocomposites, with the goal of becoming a simple monitoring device for microbiological spoilage and pollutants in canned food (21). The gas sensing signals were utilized as early indications of deterioration to assist in averting negative health impacts. In a static environment, the gas sensor array was tested to see how it responded to different volatile organic compounds (VOCs). Because they have an excellent sensing response to ammonia, which is one of the gases generated by microorganisms. These sensors are suitable for detecting microbial deterioration of canned food. The sample, which was canned tuna in mineral water, was opened and kept at room temperature (25°C). The odor linked with the deterioration of canned tuna was then monitored for 10 days using e-nose. PCA was also used to visualize the discrimination of microbial canned tuna spoilage status and analyze the smellprint of a specific level of ammonia contamination. PCA was found to be able to track changes in canned tuna deterioration, demonstrating its potential to be used for quality assurance of canned food in the daily life of a smart home resident.

When food is reversed in an inadvertent situation, such as an insufficient temperature, foodstuff rots as a result of the rapid breeding of food spoilage bacteria in warm and wet conditions where bacteria can easily be generated (22). The consequences can be even worse if humans eat those degenerative foodstuffs, as they may develop bromatoxism. The goal of this study is to design and simulate a wearable RFID patch for food spoilage monitoring with smart packaging that can be recognized and read temperature information by a device that supports near NFC technology *via* an attached circular antenna.

Everyone has a distinct opinion on whether or not a meal is rotten, which can lead to incorrect conclusions about the item's state (23). Foodborne sickness might result from a misinterpretation of the food condition. Due to this forecast ambiguity, there is still a desire for an electronic nose system to categorize if a meal is rotten. The goal of this study is to use an electronic nose to identify food deterioration in tomato-based Filipino cuisines. This study seeks to create a device with an array of sensors that can detect gases released by rotten tomato-based Filipino cuisines and to use an Artificial Neural Network as an algorithm to classify the sensor's data readings. The e-nose system's hardware includes a Gizduino 1281, a Raspberry Pi 3 Model B, a 20x4 LCD screen, seven MQ gas sensors, and one temperature/humidity sensor. The Artificial Neural Network data (24, 25) is trained using Stochastic Gradient Descent and the Back Propagation technique. The sensor chamber is positioned underneath the tomato-based Filipino food for simple detection of the gas sensors generated by the cuisine. The research might be beneficial in determining whether or not food has gone bad. This electronic nose device may detect the degree of rotting in a certain tomato-based Filipino dish. The researchers assigned rotting levels ranging from 0 to 12. Starting at 7:00 a.m. on Day 1, these levels correlate to the period when the meal is monitored every 4 h. As the trial progressed, the food deteriorated often between levels 5 and 6. The electronic nose system has a 3.85% mistake rate, according to the confusion matrix.

Benjamin et al. described a flexible UHF RFID sensor for detecting food quality (26). This sensor is based on inter-digital capacity found in an RFID antenna, onto which a coating of vegetal biopolymer has been placed. Electromagnetic coupling between the capacity and the biopolymer is, therefore, employed to vary the adaption coefficient between the chip and the antenna of the RFID tag based on food deterioration. Experimental measurements of an RFID-sensor exposed to a genuine food gas environment in the process of deterioration.

Food losses after harvest can range from 10 to 30%, owing to a variety of fungal and other microbes that degrade the food during transportation and storage (27). In addition to these direct losses due to spoiling, several bacteria generate natural poisons that make foods unsuitable for human ingestion. Other fruits and vegetables require waxes and water-loss barriers on the surface to retain quality and ideal sensory characteristics between farm and market. This study describes a study and development of an effective electrostatic spray application technology as well as a processing-line prototype designed particularly for food postharvest protection. The study provides experimental findings of comprehensive assessments of electrostatically applied protective sprays onto bananas for international transport, where both microbiological and mass-transfer data show usually 2.1–3.4-fold deposition benefits for food protection.

Microbial deterioration in milk is a major source of concern for those who want to eat healthily (28). The goal of this research is to use an electronic nose system (e-nose) with a variety of gas sensors as an initial tool for monitoring food deterioration in order to preserve food safety and human health. Nanoparticles gas sensors made of various polymers and f-SWCNTs are used in this device. When these gas sensors are exposed to the headspace of the milk, they respond to the VOCs present in the milk. Pasteurized milk was stored at 4 and 25°C for 9 days to monitor the development of spoiling. The odor pattern was examined using PCA to assess the capabilities of an electronic nose for freshness and milk spoiling detection. Monitoring the change in detecting responses revealed each sensor's capacity to identify the strength of the odor level. The findings of the discrimination demonstrate that the odor levels of samples maintained at 4°C do not change from the first to the ninth day, but the odor levels of samples held at ambient temperature increase with storage duration.

Food planning and quality assessments are becoming increasingly essential aspects of modern society (29). We may effectively analyze crop quality utilizing various learning approaches thanks to the scientific vision and agricultural advancements, which certainly replace inconsistent, unpredictable, and time-consuming human labor. The use of fuzzy logic to crop quality has effectively demonstrated its worth and established itself as a viable alternative to automation, indicating that it has a bright future ahead of it. This article examines some of the most important research findings on this subject.

Food safety is currently a key problem for the food business (30). Food businesses must develop quality monitoring systems in order to discover food quality issues early in the production process. Data manipulation and centralized storage, on the other hand, have become obstacles to dependability in a typical quality monitoring system. Furthermore, traditional quality monitoring techniques are typically ineffective due to a lack of effective automation. Fortunately, block-chain is a promising, tamper-proof, and decentralized technology. Furthermore, smart contracts, which are self-executing and self-verifying programs on the blockchain network, may execute transactions between mutually untrustworthy parties. This article offers an intelligent quality monitoring system for fruit juice manufacturing that combines smart contracts and quality rating algorithms. This system offers a high level of automation as well as a high level of dependability. Response surface models are created based on preproduction data in this system, and the best production condition for each step is determined. Smart contracts are used to capture production data on a blockchain during the actual production process.

Food is extremely essential in our day-to-day lives. The quality of food is deteriorating day by day as globalization progresses. To keep the food fresh, various food processing is done most of the time. Various preservatives or substances are added to the meal to give it a fresh or appealing appearance. The majority of food is now preserved using chemicals, resulting in food contamination. As a result of the pollution, numerous illnesses develop, prompting consumers to seek out healthier foods. Organic food is desired by the public in order to maintain a healthy lifestyle. So, in order to prevent difficulties linked with food that cannot be interpreted by humans, we need a gadget that can assist in determining the quality of food. There is a need for such a device that instructs us on how to eat sanitary meals. As a result, in order to meet this customer need, we created a gadget that determines if the food quality is good or terrible. This article examines the application of several sensors in the food business. Sensors such as pH sensors, gas sensors, and temperature sensors aid in determining the state of food. This system has a strong presence in restaurants, homes, and small businesses (31).

3. EXISTING METHODS AND SOLUTIONS

The goal of the smart meal tracking device is to track and regulate food products to avoid harm caused by atmospheric or climate variability. Food waste may also be caused by insufficient storage of foods. Through tracking and regulating different criteria concerning foodstuffs, the smart food monitoring system focuses on healthy food storage. This device employs storage units that have been implanted with a variety of electronic sensors that can interpret the parameters that affect foodstuffs.

3.1. Techniques for Food Preservation

Food preservation's main goal is to save food from spoiling so it can be eaten. Gardeners also grow too much food at once, much more than can be consumed until it spoils. Food preservation also allows you to enjoy a wide range of foods all year long. The four techniques for food preservation are shown in **Figure 3** (32).

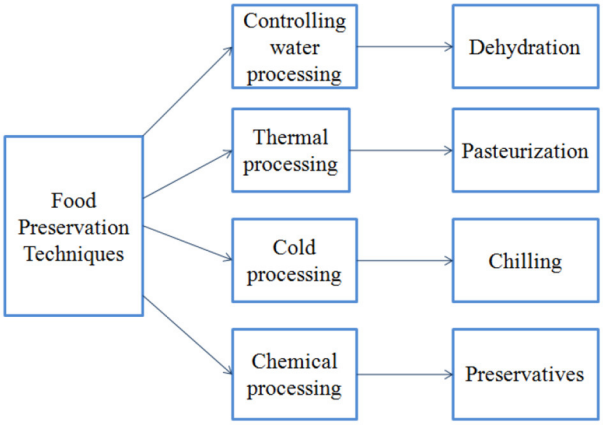

FIGURE 3 | Food preservation techniques.

3.2. Alternatives of Artificial Preservatives

Various natural preservatives derived from plants, insects, fungi, and alloy have antioxidant, antimicrobial, and anti-enzymatic effects in studies. Neem, basil, rosemary, and clove take out are encouraging alternatives for their synthetic equivalent (33).

Studies show that manufacturing companies are using chemical antioxidants which is the cause of hyperactivity in previously non-hyperactive people. Natural compounds derived from plants, organisms, or alloy may be useful substitutes. They may even be found as preservatives in meats, cosmetics, and pharmaceuticals, where they could be used as flavoring, binding, disintegrating, gelling, thickening, or suspension agents, even as automobiles.

Researchers also used extracts from natural sources such as green tea, grape seed, and nisin, a bacteriocin known as a nutritious food preservative, to make chicken and turkey hot dogs in a series of trials (34). **Table 1** represents the information regarding various food preservatives used for different kinds of fruits and vegetables. **Table 2** represents the diseases caused using preservatives.

3.3. Importance of Food Preservation

- Bacterial development and other forms of spoilage are inhibited by preservation processes, ensuring that the food is healthy enough to consume.
- Pickling competes with freezing, canning, and drying as a way to save produce from spoiling. Antioxidants, amino acids, and beneficial bacteria are commonly found in fermented foods.
- Food preservation delays the breakdown of rancid-causing fats while also inhibiting the development of microorganisms (such as yeasts) and other microorganisms.
- Feed storage expands the stock of food.
- Feed storage helps to reduce food waste. Excess foods that would have been discarded otherwise are processed and stored, adding to available stocks and reducing food waste (35).

TABLE 1 | Different types of food containing various kinds of preservatives.

Preservatives	Food
Sorbic acid	Syrups, sweets, dairy products, fruit products, fermented products, beverages
Tert butyl hydroquinone (TBHQ)	Fats, oils, snack foods
Tocopherols (vitamin E)	Oils
Ascorbic acid (vitamin C)	Fruit and acidic products
Butylated hydroxyanisole (BHA) and Butylated hydroxy -toluene (BHT)	Fats and oils, bakery products, cereals
Sodium sorbate	Mayonnaise, processed meats, dairy products, fermented products
Sodium and calcium propionate and Potassium propionate and propionic acid	Breads and other baked goods
Benzoic acid and sodium benzoate	Fruit products, margarine, and acidic foods
Calcium lactate	Olives, frozen desserts, jams, jellies, and dairy products
Calcium sorbate	Mayonnaise, dairy products, syrups, and margarine
Ethylene diamine tetra acetic acid (EDTA)	Dressings, canned veggies, and margarine
Methylparaben	Relishes, dressings, and beverages
Propylparaben	Cake, pastries, beverages, and relishes
Sodium nitrate and nitrite	Cured meats, fish, and poultry

- Dietary shortages can be reduced by storing food. Preserved foods help to bring diversity to the diet. In certain Middle East nations, there is a shortage of plantations due to arid environmental conditions. Importing new and dried fruits and veggies makes up for this shortcoming.

3.4. Reasons for Food Preservation

- The product could not be stored for a longer time as it could be spoiled.
- Using a new product that is in season and produced locally, remaking preserving jars, cutting food waste, and reducing food miles are all eco-friendly choices.
- Buy in bulk and seasonally to save costs.
- Artificial preservatives, BPA, and other artificial additives may not be used in home-prepared food.
- Convenience - in minutes, it is ready to eat.
- Both the canning process and sharing with families, colleagues, and neighbors need community participation. Teach the next generation how to do things.
- Have plans for unexpected events and/or injury.
- Personal fulfillment, we enjoy coming up with different flavor blends that you would not find in your grocery supermarket, as well as demonstrating how to use packaged foods in recipes.
- Learn new skills, such as how to use all of the fruit and how to cut down on food waste. Consider the following scenario: Apples - cut into slices (or use as pie filling) and squeeze the juice from the peels and cores.

4. ARCHITECTURE

The proposed solution includes new device architecture with few configuration modifications as per the requirement. The new device architecture includes a humidifier to maintain the humidity of the device and a cooling module that maintains the temperature for the food items. The prototype of the device is represented in **Figure 4**. Various electronic instruments have been used for monitoring. Furthermore, the registered values are used for monitoring purposes (36). The information gathered by various sensors can be correlated to the target values. The speed control kicks in and interprets the provided procedure to keep it running in the correct direction if the sensor readings do not match the key parameters. This theory can be used to create a method that can protect raw foods. This architecture consists of the following components:

- **Controller:** Arduino is used as a microcontroller.
- **Gas detection sensor:** A gas detector is a device that measures the number of gases in a given environment, and is often used as part of a protection system. Operators in the field where the leak is happening will be alerted by a gas detector (37, 38).
- **Humidifier:** A humidifier is a system that raises humidity (moisture) in a single room or a whole house. It is essentially an electrical appliance. Point-of-use humidifiers are widely used in the home to humidify a single room, and humidifiers are used in medical ventilators for greater patient convenience.
- **Heat sensor:** The key function of a heat sensor is to detect the heat that is present inside it. When the temperature around the heat sensor rises above its fixed point, it detects the heat and alerts us, allowing us to protect the devices from injury (39).
- **Humidity sensor:** A humidity sensor is a sensor that senses humidity and converts the information into an electrical current. Humidity sensors are available in a range of shapes and sizes, as well as with different features (40). The Humidity sensor first senses any humidity or moisture in the fruits or vegetables and it sends some value to the microcontroller if any moisture content is detected then an alert message sends to our mobile phone if the moisture content is not detected then again taking values from the microcontroller.
- **Cooling module (TEC1-12715-Thermoelectric Cooler 15A Peltier Module):** The heater, condenser, and fan device are all included in this element. A heater and a condenser are included in this module.
- **Light sensor:** Light sensors are electronic devices that monitor the intensity of natural or artificial light. Light energy is converted into an electrical signal by these devices. Light sensors are used in a variety of manufacturing application areas.

In **Figure 5**, the Gas detection sensor senses any gas or air coming from the fruits or vegetables, and it sends some value to the microcontroller if any gas content is detected then it alerts the user. If gas content is not detected then again values are taken from the microcontroller.

In **Figure 6**, the Humidity sensor first senses any humidity or moisture in the fruits or vegetables, and it sends some value to the microcontroller. If any moisture content is detected then it alerts

TABLE 2 | Dangerous food preservatives cause various diseases.

Preservatives	Cancer possibility (Yes/No)	Asthma possibility (Yes/No)	Hypersensitivity possibility (Yes/No)

the user and if the moisture content is not detected then again values are read by the microcontroller. As shown in **Figure 7**, the heat sensor and cooling module senses any heat in the fruits or vegetables and it sends some value to the microcontroller. The complete process is given in **Algorithm 1**.

5. WORKING PRINCIPLE

We have different types of sensors that play a major role in the detection and monitoring of food spoilage. It includes the camera sensor, humidity sensor, gas sensor, and heat sensor. The camera sensor captures the image of fruit or vegetable. The humidity sensor senses the humidity of the environment. If it is below the threshold value then the humidifier increases the humidity up to the threshold value. The temperature sensor monitors the temperature for the predefined threshold value which is controlled by Arduino. Arduino is directly connected to the Raspberry pi, which acts as a mini computer having own processing unit and memory. Whenever temperature reaches above the value of the threshold, the cooling module gets turned on. The gas sensor detects early spoilage *via* detecting a little amount of gas emission of the food items. It sends the value to the Arduino, after receiving the values, Arduino pushes the values to the cloud. The web application notifies the user *via* a buzzer or voice-activated commands or through the display messages.

6. SMART FOOD LIFE PREDICTION

The food life cycle has different stages which include the following stages: Fresh Food; Food spoilage just started; Spoilage Food. For prediction, we have trained 50 types of fruits and vegetables over different three classes. We proposed a CNN for object detection and prediction model. This is trained over three different classes.

Object detection is a difficult task in the realm of computer vision. Machine learning models when trained on a large enough number of photos can be used to detect and distinguish objects. We will identify the fruit or vegetable by using the Convolutional Neural Network (CNN) to calculate the threshold values for different parameters e.g., gas, temperature, and heat as these values are different for a different type of food. The networks will be trained in a supervised way, with photos of the fruits serving as input and tags serving as a result. The CNN model will be able to correctly anticipate the fruit label after successful training.

18: **else**
19: go to step 21
20: **end if**
21: Send alert to the user
22: Capture an image of fruit or vegetable
23: go to step 7

We have utilized the deep learning approach to train our model on datasets of fruits and vegetables. We used the Fruits360 dataset, which is openly available and may be downloaded from GitHub or found on Kaggle (41). It has around 90,380 pictures in various categories. This dataset contains high-resolution pictures, which are required for a successful classifier.

In our model, there are a total of 11 layers. The output layer is SoftMax, and there are four convolutional layers, four max pooling layers, and two fully connected layers. The input layer is a convolutional layer with a 16, 5 x 5 x 4 filter and 2 x 2 max-pooling with stride = 2. Convolutional layer 4 has a parameter of (5 x 5 x 64) and a dimension of 128. The model has been trained on 50 different types of fruits and vegetables, and it is also capable of identifying multiclass images.

7. RESULTS AND DISCUSSION

Information gathering is an important and time-consuming task. Regardless of the field of study, precise data collection

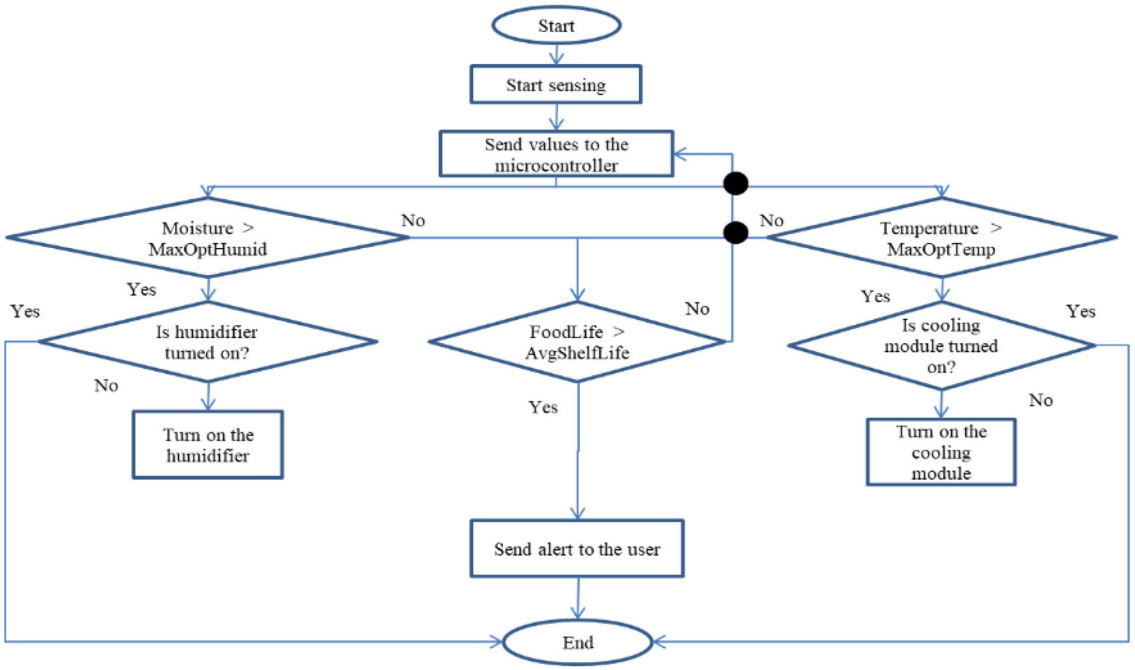

FIGURE 7 | Heat sensor and cooling module.

TABLE 3 | Description of the fruits and veggies dataset.

Columns	Description	Value	Type
Names of fruits and vegetables	Different types of fruits and vegetables	NA	String
Minimum optimal storage temperature	Minimum temperature in which fruit or vegetable remain fresh	Multiple minimum optimal temperature values	Numeric
Maximum optimal storage temperature	Maximum temperature in which fruit or vegetable remain fresh	Multiple maximum optimal temperature values	Numeric
Freezing point	This cooling point in which fruit or vegetable remain fresh	Multiple freezing point values	Numeric
Minimum optimal humidity	Minimum humidity in which fruit or vegetable remain fresh	Multiple minimum optimal humidity values	Numeric
Maximum optimal humidity	Maximum humidity in which fruit or vegetable remain fresh	Multiple maximum optimal humidity values	Numeric
Minimum approximate storage life	At least number of days in which fruit or vegetable remain fresh	Multiple minimum approximate storage life values	Numeric
Maximum approximate storage life	At most number of days in which fruit or vegetable remain fresh	Multiple maximum approximate storage life values	Numeric
Average shelf life	Average of minimum (start spoiling) spoilage time and maximum (after spoiled) spoilage time	Multiple average shelf life values	Numeric

is crucial to maintaining cohesion. Food spoilage is a very concerning topic nowadays because this time is needed to have a strong immune system, and there is no existing solution that helps to prevent spoilage to some extent. The Fruit360 is the data set that was used in this study. We have to gather a dataset from the Kaggle dataset website. The dataset contains images of different fruits and vegetables. We have used this dataset for CNN model training and object detection.

Fruits and Veggies—We have created a dataset after careful research. The dataset contains 50 types of fruits and vegetables with their optimal storage temperature range, optimal humidity range, approximate storage life range, and freezing point are included in this collection (42). Dataset is used for spoilage alert

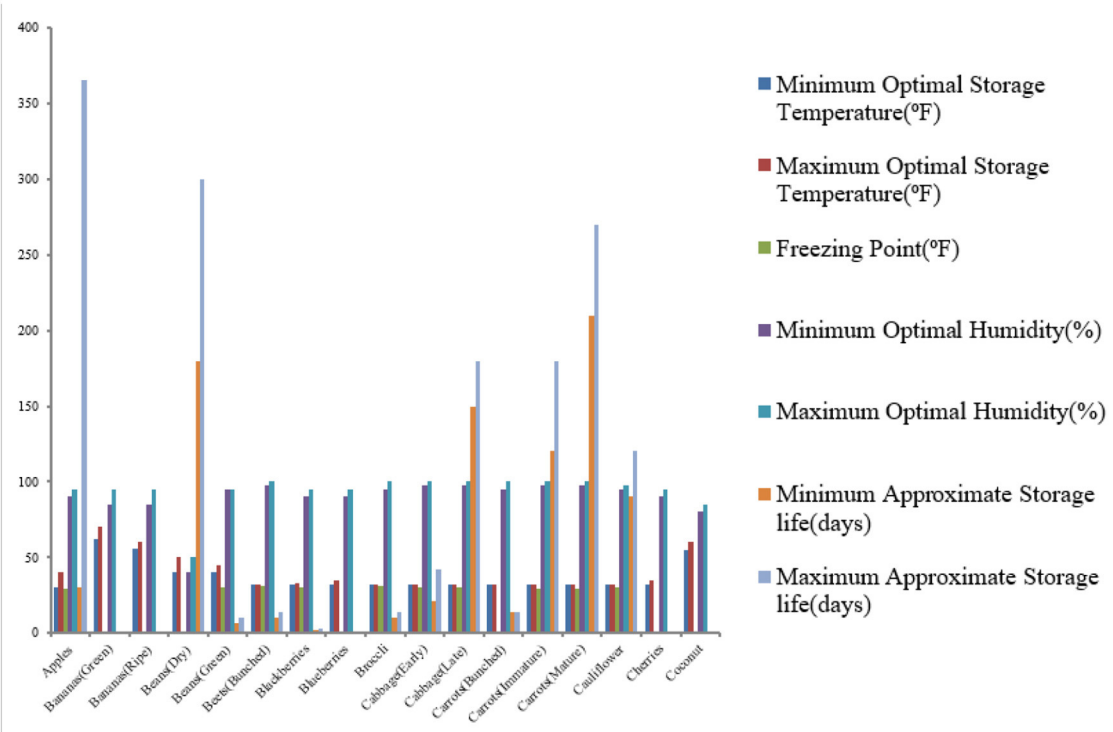

FIGURE 8 | Comparison among different fruits and vegetables with respect to their various attributes.

generation messages in mobile. **Table 3** describes the dataset attribute with its value, type, and description. All the value of each column represents numeric and floating point values except the first column.

Figure 8 represents the relation between attributes like minimum optimal storage temperature, maximum optimal storage temperature, Freezing Point, minimum optimal humidity, maximum optimal humidity, minimum approximate storage life, and maximum approximate storage life of 17 fruits and vegetables. We have selected 15 fruits or vegetables out of 50 fruits or vegetables for our experimental purpose. This figure represents the comparison among standard parameter settings of different food items. Then we put the food item in the proposed device, which further analyzes the item and sets the parameter values accordingly. Finally, the proposed approach is used to monitor the item and maintain the environment accordingly. In the end, we monitored the final shelf life of the food item. In this experiment, we try to extend the maximum approximate storage life of fruits and vegetables, which is represented in **Table 4**.

The average shelf life of any fruit or vegetable is a time period in which fruits or vegetables are healthy for eating. After this period of time, it is harmful for health to consume this fruit or vegetable as spoilage may have taken place previously before the average shelf life. Every fruits or vegetables have a different minimum optimal storage temperature below which they started spoiling. So, careful minimum optimal storage temperature must be maintained.

The performance graph for our model is plotted for both the training and validation data. We show the training data loss vs. validation data loss graph, as well as the training data accuracy and validation data accuracy of the CNN model for fruits and vegetables, for object detection. The performance graph plot shows the improvement in accuracy as the number of epochs increases, as well as whether or not our model has been correctly trained. The CNN model's training data loss vs. validation data loss, as well as training data accuracy and validation data accuracy, are shown on the graph shown in **Figures 9**, **10**. There are three different fit situations for the model: over fitting, under fitting, or perfect fit.

- **Over fitting:** When the Training loss is considerably less than the Validation loss, this scenario occurs.
- **Under fitting:** This situation occurs when the Training loss exceeds the Validation loss, i.e., Training loss > Validation loss.
- **Perfect fit:** This circumstance occurs when Training and Validation losses are approximately equal or converging over time, indicating that we are doing things correctly.

As seen in our graph of **Figure 9**, it is virtually converging to indicate that our model is free of over fitting and under fitting. The plot of training and validation accuracy after each epoch is shown in **Figure 10**, our model is virtually ideal in this case since the validation and training accuracy are nearly identical. So, our model has a 95% accuracy rate, which is excellent enough to recognize the kind of vegetable and fruit from a picture. It also

TABLE 4 | Experimental analysis of fruits and vegetables.

works well for single items, such as single fruits or vegetables. It also has the ability to forecast the class of numerous objects. For 50 different sorts of categories, the approach works perfectly. It provides extremely precise results for the photos that are fed into the model.

8. CONCLUSION AND FUTURE SCOPE

This study presents a novel technique for Monitoring and analysis of food spoilage using a sensor bases system. The device proposed in this study is able to preserve food for more days. Additionally, food items can be prevented from getting spoiled by increasing their lifespan. It monitors the quality of food items and keeps notifying the user with voice-activated commands or *via* display, and it also generates alerts to the user with the predicted remaining time of the food spoilage. The proposed device shows an accuracy of 95%.

The proposed smart device can be improved by applying image processing and machine learning algorithms to detect early spoilage. This can be utilized in refrigeration systems for detecting food items, spoilage and monitoring for prevention of food spoilage. The device can be incorporated into food transportation containers which would allow tracking and detecting the spoilage if any during transportation. The device could also be tested for different variety of foods as well.

DATA AVAILABILITY STATEMENT

Wang J, Liu X, Tang J, Zhang Q and Zhao Y (2022) A Web-Based Prediction Model for Cancer-Specific Survival of Elderly Patients With Hypopharyngeal Squamous Cell Carcinomas: A Population-Based Study. Front. Public Health 9:815631. doi: 10.3389/fpubh.2021.815631

Background: Hypopharyngeal squamous cell carcinomas (HPSCC) is one of the causes of death in elderly patients, an accurate prediction of survival can effectively improve the prognosis of patients. However, there is no accurate assessment of the survival prognosis of elderly patients with HPSCC. The purpose of this study is to establish a nomogram to predict the cancer-specific survival (CSS) of elderly patients with HPSCC.

Methods: The clinicopathological data of all patients from 2004 to 2018 were downloaded from the SEER database. These patients were randomly divided into a training set (70%) and a validation set (30%). The univariate and multivariate Cox regression analysis confirmed independent risk factors for the prognosis of elderly patients with HPSCC. A new nomogram was constructed to predict 1-, 3-, and 5-year CSS in elderly patients with HPSCC. Then used the consistency index (C-index), the calibration curve, and the area under the receiver operating curve (AUC) to evaluate the accuracy and discrimination of the prediction model. Decision curve analysis (DCA) was used to assess the clinical value of the model.

Results: A total of 3,172 patients were included in the study, and they were randomly divided into a training set (N = 2,219) and a validation set (N = 953). Univariate and multivariate analysis suggested that age, T stage, N stage, M stage, tumor size, surgery, radiotherapy, chemotherapy, and marriage were independent risk factors for patient prognosis. These nine variables are included in the nomogram to predict the CSS of patients. The C-index for the training set and validation was 0.713 (95% CI, 0.697–0.729) and 0.703 (95% CI, 0.678–0.729), respectively. The AUC results of the training and validation set indicate that this nomogram has good accuracy. The calibration curve indicates that the observed and predicted values are highly consistent. DCA indicated that the nomogram has a better clinical application value than the traditional TNM staging system.

Conclusion: This study identified risk factors for survival in elderly patients with HPSCC. We found that age, T stage, N stage, M stage, tumor size, surgery, radiotherapy, chemotherapy, and marriage are independent prognostic factors. A new nomogram for predicting the CSS of elderly HPSCC patients was established. This model has good clinical application value and can help patients and doctors make clinical decisions.

Keywords: nomogram, HPSCC, elderly patients, cancer-specific survival, online application

BACKGROUND

Hypopharyngeal carcinoma, which can occur in the pyriform sinuses bilaterally, the posterior and lateral pharyngeal walls, and the postcricoid region (1), accounts for approximately 3–5% of all head and neck carcinoma (2, 3). According to the Surveillance, Epidemiology, and End Results database (SEER), from 1973 to 2008, elderly over 65 years old with head and neck cancer accounted for about 47% of the total head and neck cancer in the United States (4). Most hypopharyngeal cancers are squamous cell carcinomas (HPSCC), which are less common than other head and neck malignancies and account for about 3–5% of squamous cell carcinomas of the head and neck. The incidence rate of cancer in the elderly increases with age and is higher in people over 65 (5, 6). So as aging intensifies, the number of elderly with HPSCC is expected to rise in the future. The prognosis of HPSCC is poor, with a 5-year survival rate being 25–47% (7, 8). Elderly patients are a heterogeneous population with their performance status (9). Comorbidity, organ dysfunction and immunosenescence as adverse factors affect the treatment options of elderly patients and let patients experience more treatment-related toxicity and poor prognosis (4, 9).

Gang et al. found that T3-4 stage, N2-3 stage, and poor tumor differentiation were risk factors for the Development of vascular invasion in HPSCC and reduced patients' overall survival (OS) and cancer-specific survival (CSS) (10). Iuchi et al. explored the modified Glasgow prognostic score as a beneficial prognostic factor for patients with HPSCC (11). Zhongyang et al. constructed a nomogram to predict survival in HPSCC and found that age, race, TNM stage, surgery, radiotherapy, chemotherapy, and marriage were independent risk factors for patients (12). Although there are nomograms to predict the prognosis of patients with head and neck cancer and even hypopharyngeal squamous cell carcinoma, there is no study to specifically construct the nomogram for elderly patients with HPSCC to predict the CSS. As a high-risk cancer population, the elderly have particular survival and prognostic factors. Therefore, a special nomogram can improve the accuracy and practical value of the prediction model.

Artificial intelligence has been widely used in human public health. Javed et al. applied Cognitive Assessment of Smart Home Resident to detect individuals with early cognitive impairment (13). Abbas et al. used a new machine-learning algorithm, BCD-WERT, to detect breast cancer, which has better accuracy than the traditional machine learning method (14).

At present, many prediction models are applied to human health, such as software metrics by Grey Wolf Optimization proposed by Yenduri et al. (15). The traditional line chart is also a commonly used prediction model. Nomogram is a visually reliable statistical tool to calculate conveniently and present the survival probability of a certain time-point for a particular patient based on risk factors included (16–18). However, there have been few Analyses of influencing factors and survival trends for hypopharyngeal cancer within the elderly population. Accurate prediction of the survival of elderly patients with HPSCC can help doctors answer patient inquiries. It also can help doctors and patients to develop treatment and follow-up strategies. We aim to explore the risk factors for CSS in elderly patients with HPSCC and construct a nomogram for predicting CSS to help doctors and patients make treatment and follow-up decisions.

PATIENTS AND METHODS

Data Source and Data Extraction

The clinicopathological data of all patients with HPSCC from 2004 to 2018 were downloaded from the SEER database. Including age, gender, race, year of diagnosis, marriage, tumor location, tumor size, histopathological grade, histological type, TNM stage, surgery, radiotherapy, chemotherapy, and other information. Since the information in the SEE database is public and anonymous, our study does not require ethical approval and patient informed consent. Our research methods follow the guidelines of the SEER database.

Inclusion Criteria

(1) age $\geq$ 60 years; (2)primary tumor site is hypopharynx; (3) histopathological type is squamous cell carcinoma.

Exclusion Criteria

(1) Survival time is $<$1 month; (2) tumor size is unknown; (3) TNM staging is unknown; (4) surgical method is unknown. The age of the patients was divided into three groups, including 60–69 years old, 70–79 years old, $\geq$80 years old. The race included white, black, and other races (American Indian/AK Indian, Asian/Pacific Islander). The tumor site was divided into the pyriform sinus and others, including the postcricoid region, aryepiglottic fold, hypopharyngeal, posterior wall of the hypopharynx. The histological grades of tumors were grade I-IV, well-differentiated, moderately differentiated, poorly differentiated, and undifferentiated. The tumor size is the most significant part of the tumor diameter, divided into $\leq$2 cm, 2–4 cm, $\geq$4 cm. The screening process for all patients is shown in **Figure 1**.

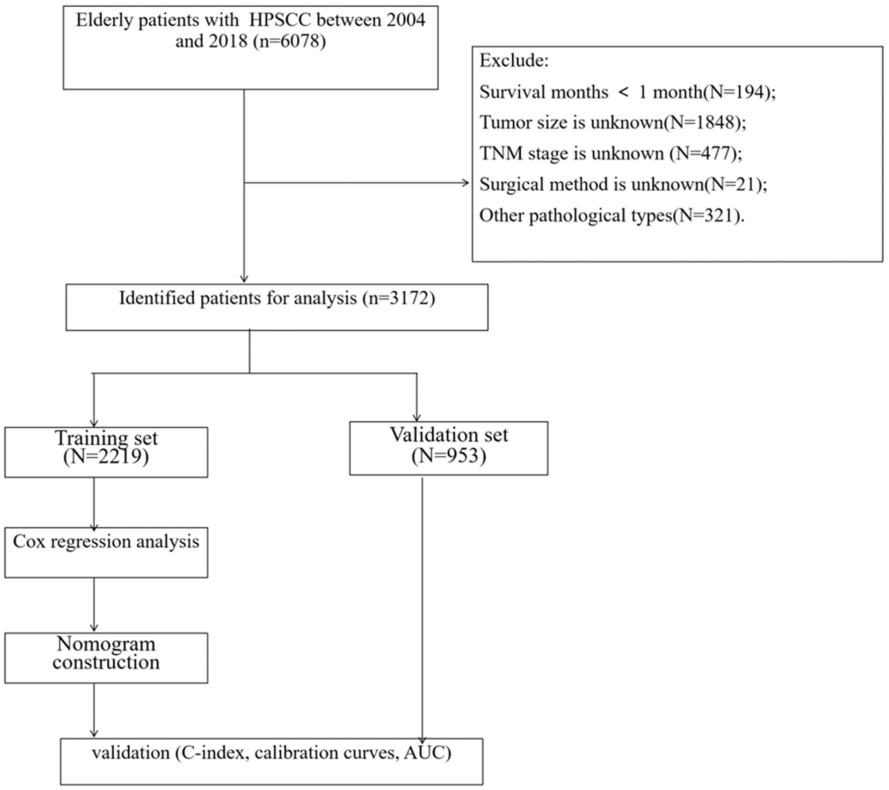

FIGURE 1 | The flowchart of including and dividing patients.

Nomogram Construction and Validation

All patients were divided into a training set (70%) and a validation set (30%). The prognostic factors of patients need to be clarified. Cox proportional hazard regression model is the most commonly used regression model to explore the prognosis of cancer patients. The patients in the training set were subjected to univariate Cox regression analysis to screen out the prognostic factors of HPSCC. The confirmed related elements were included in the multivariate Cox regression analysis to screen out independent risk factors for HPSCC. A new nomogram was constructed to predict 1-, 3-, and 5-year CSS in elderly patients with HPSCC. Then, the consistency index (C-index) and the area under the receiver operating curve (AUC) were used to evaluate the accuracy and discrimination of the prediction model. The calibration curve of 1000 bootstrap weight samples was used to verify the accuracy of the nomogram.

Clinical Utility

Decision curve analysis (DCA) was used to evaluate the clinical value of the nomogram. It is a new algorithm to consider the application value of the model based on various risk thresholds (19). At the same time, the clinical significance of nomogram and traditional TNM staging system was compared based on DCA. Subsequently, the patient's survival risk value was calculated based on the nomogram, and then the patients were divided into high-risk and low-risk groups based on the cut-off value. Kaplan-Meier (K-M) curve and log-rank test were used to compare the difference in survival of patients in each group.

Statistical Analysis

All statistics were performed using SPSS 26.0 and R software 4.1.0. The count data were described by frequency (%) and analyzed by chi-square and non-parametric U-test. Univariate and multivariate Cox regression analyses were used to analyze the prognostic factors of patient survival. Kaplan-Meier curve and log-rank test were used to compare the survival differences of patients. A $P < 0.05$ was considered statistically significant.

RESULTS

Clinical features

A total of 3,172 elderly patients with HPSCC were included. These patients were randomly divided into a training set ($N = 2,219$) and a validation set ($N = 953$). The clinicopathological information of the patients is shown in **Table 1**. Among them, 1,578 cases (49.7%) were 60–69 years old, 1,122 cases (35.4%) were 70–79 years old, and 472 cases (14.9%) were ≥80 years old. There were 2,513 whites (79.2%), 2,558 men (80.6%), and

1,590 married (50.1%). The histological tumor grades were 124 (3.91%), 1,259 (39.7%), 1,063 (33.5%), and 29 (0.91%) patients with tumor histological grades I, II, III, and IV, respectively. There were 1,635 cases (51.5%) whose tumor site was pyriform sinus. There were 747 cases (23.5%), 1,547 cases (48.8%), and 878 cases (27.7%) with tumor sizes of $\leq$2 cm, 2–4 cm, and $\geq$4 cm, respectively. There were 2,336 cases (73.6%) that underwent surgery, 2,393 cases (75.4%) underwent radiotherapy, and 1,863 cases (58.7%) underwent chemotherapy. There is no significant difference between the clinical-pathological information of the training set and the validation set.

Univariate and Multivariate Cox Regression Analysis

Univariate Cox regression analysis was used to screen the prognostic factors of HPSCC in elderly patients, including age, race, T stage, N stage, M stage, surgery, radiotherapy, chemotherapy, tumor size, and marriage. Multivariate analysis found that age, T stage, N stage, M stage, surgery, radiotherapy, chemotherapy, tumor size, and marriage were independent risk factors for the prognosis of patients. The results of univariate and multivariate factors are shown in **Table 2**. The results showed that older patients had a worse prognosis. The higher the TNM stage, the worse prognosis. In addition, patients with larger tumors have a worse prognosis. Patients have higher survival rates after surgery, radiotherapy, and chemotherapy. Marital status is a favorable factor for the survival of patients.

Nomogram Construction and Validation

The multivariate Cox regression analysis identified the independent risk factors used to construct a nomogram to predict elderly swallowing at 1-, 3-, and 5-year CSS (**Figure 2**). The nomogram indicated that TNM staging is still the most significant factor affecting the prognosis of patients. In addition, surgery and radiotherapy are the most important prognostic factors among other variables. They are then followed by age, tumor size, chemotherapy, and marriage. The C-index of the training set and the validation set were 0.713 (95% CI, 0.697–0.729) and 0.703 (95% CI, 0.678–0.729), respectively, indicating that the nomogram has good accuracy. The calibration curves of the training and validation sets are consistent with the 45° diagonal, meaning that the observed value is consistent with the predicted value (**Figure 3**). The 1-, 3-, 5-year AUC of the training set and validation set indicates that the nomogram has better accuracy than TNM staging (**Figure 4**).

Clinical Application of the Nomogram

The DCA of the training set and the validation set still suggested that the nomogram has a better clinical application value than the traditional TNM staging (**Figure 5**). According to the constructed nomogram, each patient received a risk score. According to the score, patients were divided into high-risk groups (total score $\geq$198.9) and low-risk groups (total score $\leq$198.9). The K-M curves of the validation set and the training set proved that the survival of patients in each risk group is significantly different (**Figure 6**). The K-M curve result proved the discriminative power of the nomogram prediction model. We analyzed the difference in survival of patients in other risk groups under different treatments. In the low-risk group, we found no significant difference in survival between patients with and without surgery (**Figure 7A**). Similarly, there was no difference in survival between patients who have been treated with radiation and those who have not (**Figure 7C**). However, patients in the low-risk group who received chemotherapy had a lower survival rate than those who did not (**Figure 7B**). In the high-risk group, patients with surgery have a higher survival rate than patients without surgery (**Figure 7D**). Patients with radiation therapy had a higher survival rate than patients without radiation therapy (**Figure 7F**). Patients with chemotherapy had a higher survival rate than patients without chemotherapy (**Figure 7E**).

Online Application for CSS Prediction

Based on this nomogram, we developed a network calculator at https://prediction-app.shinyapps.io/DynNomapp/. Enter the clinicopathological characteristics of the patient on this website to get the patient's predictive CSS. This website is straightforward and practical, convenient for patients and patients.

DISCUSSION

HPSCC is one of the most malignant head and neck carcinomas with a poor prognosis (1, 20). More than 50% of patients with HPSCC were usually diagnosed at a more advanced stage (21). Various factors lead to this result, such as minor symptoms in the early stages, early nodal metastasis, and poor differentiation (22, 23). The prognosis of HPSCC is one of the worst for head and neck tumors. The reason for this is that the hypopharynx has a rich lymphatic network, and cancer cells can metastasize through the lymphatic system at a very early stage of the disease (24, 25). Also, early diagnosis of HPSCC is often tricky as there are almost no specific clinical symptoms in the early stages. As a result, most patients are already in the advanced stages of cancer by the time the disease is diagnosed (26, 27). Elderly patients with HPSCC are a high-risk group and should receive special attention. An accurate predictive assessment can provide advice to patients and provide a basis for individualized treatment.

TNM staging is the primary tumor staging system, which is an essential factor in evaluating cancer prognosis (28). However, precise evaluation of TNM staging can only be obtained after surgery (29), and prognostic heterogeneity generally exists among patients with the same TNM stage (30). Hypopharynx is rich in lymphoid tissue and prone to mucosal infiltrative metastases (31). Sometimes, physical examination of lymph nodes is inaccurate, and small metastases cannot be detected by imaging (32), limiting prognostic evaluation accuracy by TNM staging. It should be noted that the prognosis of cancer is affected by many factors, especially in the

elderly. Previous studies showed that demographics, clinicopathological parameters, and treatment factors determine survival outcomes for hypopharyngeal carcinoma (33). In our research, the multivariable Cox regression analysis revealed that age at diagnosis, marital status, tumor size, TNM stage, surgery, radiotherapy, and chemotherapy is associated with the prognosis of HPSCC.

This study found that age was still a prognostic factor for patients and that survival was lower in patients of higher age. Age as a prognostic factor is consistent with previous findings (34, 35). It is worth noting that married patients have a higher survival rate than those who are not married. Not surprisingly, marriage gives patients more emotional comfort and better financial support (36). In addition, various treatments have been shown to impact the survival of elderly patients with HPSCC significantly. Currently, radical laryngectomy is gradually becoming laryngeal preservation surgery as the procedure improves (37). Our study found that patients who had surgery still had a higher survival rate than those who did not have surgery. In addition, radiotherapy and chemotherapy offer patients the option of laryngeal preservation surgery (38). Our study showed that patients had significantly better survival rates with radiotherapy and chemotherapy.

In addition, patients were divided into high-risk and low-risk groups based on the scores of the line graphs. We found that surgery and radiotherapy for patients in the low-risk group did not significantly improve patient survival. However, chemotherapy appeared to improve the survival prognosis of elderly patients significantly. Therefore, chemotherapy should be routinely recommended for elderly patients with HPSCC in the low-risk group. For patients in the high-risk group, surgery, radiotherapy, and chemotherapy are all necessary as they effectively improve patient survival.

Although nomograms have been constructed to predict OS and CSS in hypopharyngeal cancer, no nomograms have been explicitly built to expect CSS in elderly patients with HPSCC (39, 40). Due to the population-specific nature of the elderly, there may be prognostic factors that differ from those of other populations. Therefore, based on these factors, we developed a nomogram to predict the prognosis of the elderly with HPSCC. The calibration curve and C-index of the prediction model suggest good accuracy and reliability. Based on the AUC and DCA results, this new nomogram is superior to conventional TNM staging.

Our research also has some defects. First, there is no information about the comorbidity of the elderly in the SEER database, such as coronary heart disease, hypertension, and diabetes. These complications affect the choice of treatment options. We cannot incorporate these factors into the prognosis analysis, so the accuracy is limited. However, we included essential patient factors such as age, TNM stage, surgery, radiotherapy, chemotherapy, etc. These factors are critical determinants of patient survival. Second, as this study was a retrospective case

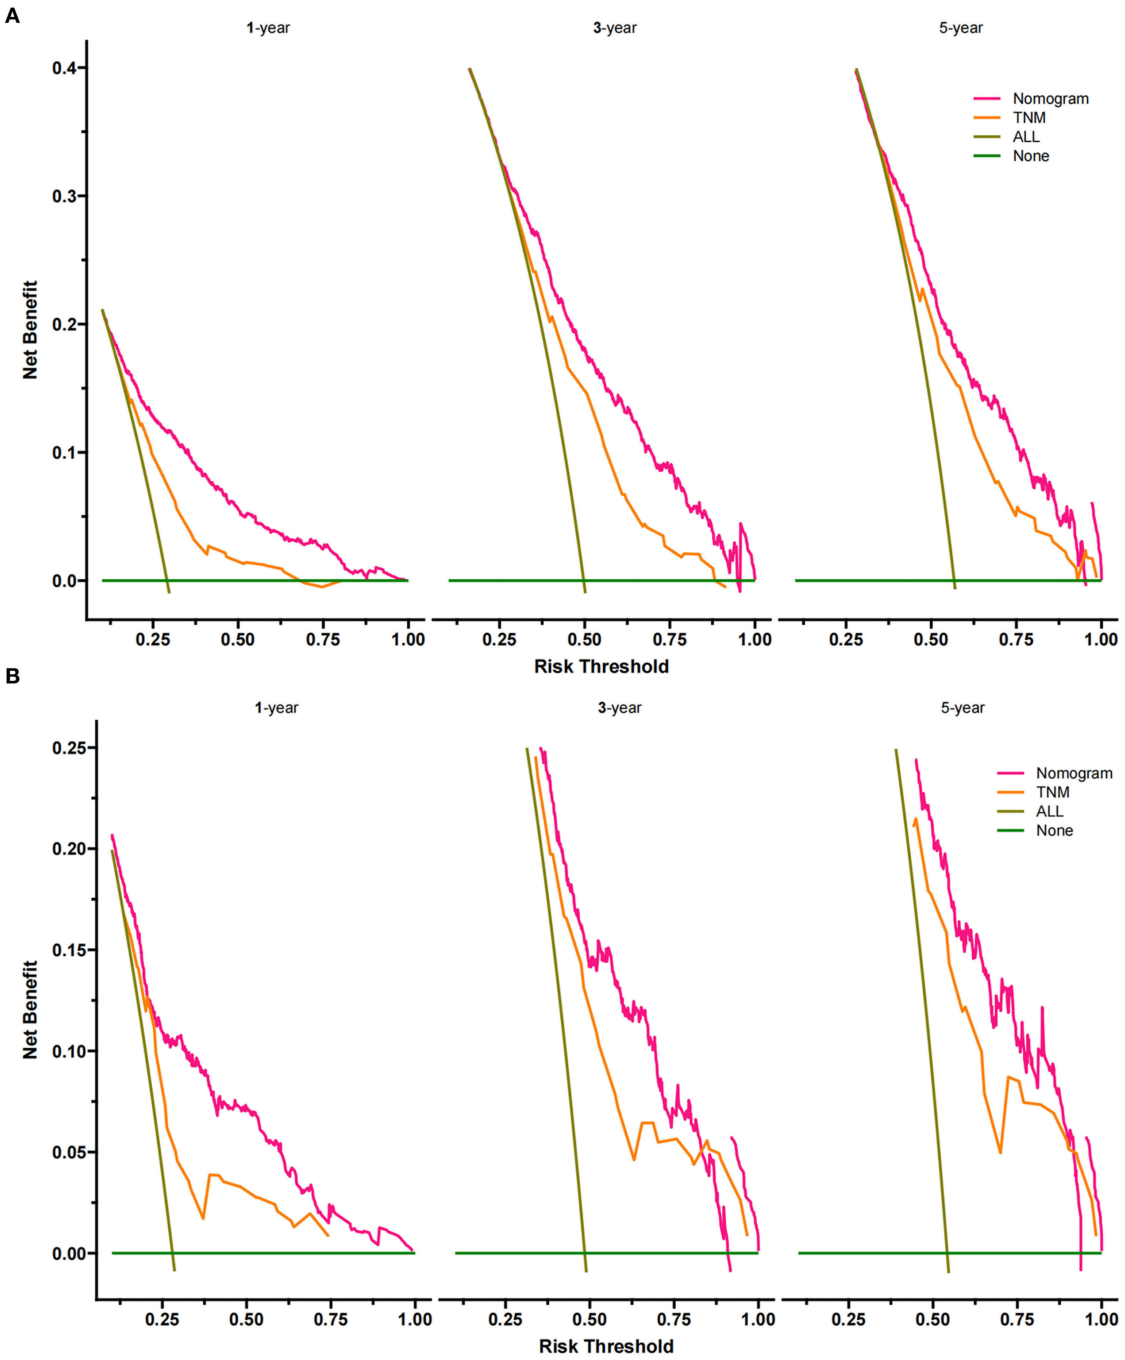

FIGURE 5 | Decision curves of the nomogram predicting CSS in the training set **(A)** and validation set **(B)**. The Y-axis represents net income, and the X-axis represents threshold probability. The green line means no patients died, and the dark green line means all patients died. When the threshold probability is between 25 and 90%, the net benefit of the model exceeds all deaths or none.

study, a selection bias was difficult to adjust for and may have contributed to some errors in the results. Finally, although we have conducted split internal validation on the SEER database, we lack multi-center external validation, especially data validation from China. This limits the application of the nomogram in areas other than the United States. We intend to further validate the accuracy of the prediction model through external patient data. The data were collected prospectively according to the variables of this model, and the patients were further

followed up. Then the patients were included in the model for external validation.

CONCLUSION

In conclusion, we established and validated a new nomogram to predict the prognosis of elderly patients with HPSCC. Through this model, clinicians can estimate the survival rate of elderly patients with HPSCC more accurately, which plays an essential role in guiding the choice of clinical treatment.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://seer.Cancer.gov/.

The coronavirus disease 2019 (COVID-19) pandemic has influenced the everyday life of people around the globe. In general and during lockdown phases, people worldwide use social media network to state their viewpoints and general feelings concerning the pandemic that has hampered their daily lives. Twitter is one of the most commonly used social media platforms, and it showed a massive increase in tweets related to coronavirus, including positive, negative, and neutral tweets, in a minimal period. The researchers move toward the sentiment analysis and analyze the various emotions of the public toward COVID-19 due to the diverse nature of tweets. Meanwhile, people have expressed their feelings regarding the vaccinations' safety and effectiveness on social networking sites such as Twitter. As an advanced step, in this paper, our proposed approach analyzes COVID-19 by focusing on Twitter users who share their opinions on this social media networking site. The proposed approach analyzes collected tweets' sentiments for sentiment classification using various feature sets and classifiers. The early detection of COVID-19 sentiments from collected tweets allow for a better understanding and handling of the pandemic. Tweets are categorized into positive, negative, and neutral sentiment classes. We evaluate the performance of machine learning (ML) and deep learning (DL) classifiers using evaluation metrics (i.e., accuracy, precision, recall, and F1-score). Experiments prove that the proposed approach provides better accuracy of 96.66, 95.22, 94.33, and 93.88% for COVISenti, COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C, respectively, compared to all other methods used in this study as well as compared to the existing approaches and traditional ML and DL algorithms.

Keywords: healthcare, COVID-19, pandemic, sentiment analysis, Twitter, internet of things

1. INTRODUCTION

Coronavirus disease 2019 (COVID-19) has severely impacted the daily lives of individuals across the globe (1). People worldwide use online media to state their viewpoints and general feelings concerning this phenomenon that has assumed control over the world by storm (2, 3). Social media platforms like Twitter have experienced exponential growth in tweets related to the pandemic in a short period (4, 5). The social networking site Twitter is a commonly used online media platform. It provides real-time information

related to ongoing events concisely and captures the emotions and thoughts of the people. During this pandemic, people use the online media platform Twitter to express their feelings, opinions, emotions, and thoughts related to the worldwide pandemic (6, 7). It rapidly spread throughout the world by an increasing number of corona cases in a short time (8). This disease has affected many countries, even the countries with hardly any or no infections because if someone is in close proximity to other people and one of them becomes affected, they will undoubtedly be impacted (9). According to Naseem et al. (1), the World Health Organization (WHO) declared COVID-19 a pandemic on January 30, 2020. All the biomedical experts worldwide are relentlessly trying to control the disease and find possible cures for this viral infection. To control this pandemic situation, vaccination is the most effective strategy to prevent the spread of COVID-19 disease all around the world (10, 11). Vaccination is the first and crucial step to stop the coronavirus outbreak. People with COVID-19 symptoms must isolate themselves and get examined, and all must get vaccinated.

During the isolation process, people express their feelings on social media; however, social media contains real-time and valuable information about COVID-19; still, data from social media might be useless or misleading at times. Sufferings get multiplied if they find misleading and depressing information on social media. With a new normal of "staying at home," "work from home," and "isolation time," social networking media has been extensively used to share news, opinions, emotions and advice. Misinformation information is defined as trying to mystify/mislead others with false or irrelevant information, such as "eating bananas is a preventative against the COVID-19 coronavirus disease." A person going through this disease passed through several physical and mental. This brings about the need to quickly apply logical strategies to comprehend informative data streams. Online Social media platforms such as Twitter and Facebook contain a lot of noisy data, so identifying informative content from large and noisy data is a challenging task, but after cleaning it, this noisy data captures human feelings and emotions, expression, and thoughts. When analyzed carefully, it conveys a lot about the present mood, attitude, and nature of a large human community.

The social media users are increasing with time because they depend on social media for informative content, and the volume of data is also increasing; this focused on the use of Natural Language Processing (NLP) with different algorithms of Artificial intelligence (AI) to extract meaningful information efficiently (12). NLP and its applications have had a significant impact on social media text analysis and classification; however, the challenges of determining a content's inherent importance using NLP-strategies, such as contextual phrases and words, ambiguity in text or speech, necessitate the use of ML-based algorithms (13–15).

In this study, we use Twitter data for sentiment analysis to identify public sentiments to investigate the increased fear associated with coronavirus. Many traditional approaches have been used to identify human behavior and nature, which presents the possibility of increasing analyses by quickly doing sentiment classification using NLP techniques. Sentiment analysis and classification of COVID-19 and other disaster-associated scenarios and keywords associated with the Twitter data analysis are essentially analyzed using the proposed methodology presented in this study outlines. This study focused on the tweets analysis and identified global people sentiments from February 2020 to March 2020. We use machine learning (ML) and deep learning (DL)-based classification methods primarily used in AI applications; however, the discussion and the comparison of tweets' sentiment classification mechanisms is one of the essential contributions of this research. Various studies in the past focused on the identification of sentiment from COVID-19 tweets but, less work is available for the identification of both the topic and sentiment considered together (16).

The tweets from February 2020 to March 2020 are collected using the Twitter API. The tweets' sentiments are categorized into three classes (positive, negative, and neutral) (1). This article focused on creating a new dataset rather than efficient categorization of users' sentiment. Therefore, we propose a new model to categorize the user's sentiments about COVID-19.

The main contributions of this study are as follows:

- Design a Transformation-based Multi-depth DistilBERT model for sentiment analysis of tweets to identify sentiments concerning coronavirus from tweets.
- Extract sentiment-related concise information from tweets to automatically learn features without human intervention.
- Present a broad comparison between existing ML and DL text classification methods and discuss the given baseline results. The proposed model outperformed on real-life datasets compared to all previously used methods.

The remainder of this article is organized as follows. Existing work related to COVID-19 sentiment analysis is presented in section 2. Section 3 provides a detailed explanation of the selected dataset. The proposed methodology is described in section 4. Experimental analysis and results are explained in section 5, and finally, the conclusion of this study is presented in section 6.

2. LITERATURE REVIEW

Since the outbreak of the coronavirus pandemic, researchers have discussed its origin, effects, and trends. This section presents the tweet sentiment analysis using different ML, DL, and NLP methods. Extracting meaningful information from noisy data is a challenging task. ML and DL techniques are necessary tools (17) to do this task. Twitter is one of the finest social media platforms for news collection (18). For sentiment analysis on India, 24,000 tweets regarding COVID-19 were crawled from Twitter (19). They just extracted the tweets related to COVID-19 and visualized the sentiments of people regarding this pandemic, and they did not perform experiments using ML techniques.

Another research focused on the topics and sentiments of people expressed on Twitter about COVID-19. They collected tweets about COVID-19 and labeled them as positive, negative, and neutral, then analyzed these tweets for sentiment classification using different feature sets and classifiers. This work used only one evaluation metric, which is accurate, and obtained the highest accuracy using the Bidirectional

TABLE 1 | Summary of the existing work.

Paper title	Methodology	Dataset	Results
COVIDSenti: A Large-Scale Benchmark Twitter Data Set for COVID-19 Sentiment Analysis (34)	Proposed a COVIDSenti dataset and performed sentiment analysis using multiple classifiers	COVIDsenti	Achieved highest result using BERT with 94.80% accuracy.
Sentiment analysis of nationwide lockdown due to covid 19 outbreak: Evidence from india (19)	Visualize Sentiments on COVID-19 tweets	Crawled 24000 COVID-19 tweets	Extracts sentiments of Indian's about COVID-19
COVID-19 Public Sentiment Insights and ML for Tweets Classification (24)	Used Naive Bayes and Logistic Regression for sentiment classification	Created their dataset	Obtained 91% with Naive Bayes and 74% accuracy with logistic regression
Deep Sentiment Classification and Topic Discovery on Novel Coronavirus or COVID-19 Online Discussions: NLP Using LSTM Recurrent Neural Network Approach (12)	Used LSTM model for sentiment classification of COVID-19 tweets	Coronavirus Posts in Reddit Platform	LSTM model achieved an accuracy of 81.15%
Bidirectional Long Short-Term Memory Networks for Relation Classification (28)	Extract the most important features for sentiment classification using BILSTM	SemEval-2010 task 8 dataset	Achieved the best F1-score of 83.6% using BILSTM model

Encoder Representations from Transformers (BERT) model, which is 94.80%. Sometimes, we utilize only classification accuracy to assess our model's performance; nevertheless, this is insufficient to evaluate our model. We need to testify the model's performance using precision, recall, and F1-score along with accuracy (1).

Another research work focused on the psychological effect of COVID-19 to analyze the nature and prevailing mood of human behavior (20). It analyzed that people are in crisis due to coronavirus and increased anxiety levels because of COVID-19 news. Multiple studies show analysis about the industrial crisis and economic impact of the COVID-19 crisis across industries and countries (21). Over the past few years, sentiment analysis based on tweets has been utilized in numerous applications due to the large amount of data collected from various social media platforms (22). It includes Twitter, Facebook, Reddit, and YouTube. The analysis shows flaws in the collected information (23). Different ML and DL classifiers test the short and long text information. For evaluation of a short text, logistic regression, and Naive Bayes give average results of 74 and 91%, respectively, but in the case of long text testing, both the models performed very poorly (24). Recently, people have been heavily dependent on social media news, and they are conveying their viewpoints, emotion, and feelings about this novel virus *via* social media posting (25).

The recent COVID-19 studies rely on public opinion, emotion, and sentiment analysis in English social media posts from various social Critical Legal Studies (CLS). This study uses RNN models such as LSTM, BiLSTM, and SAB-LSTM to train and test the dataset. They have used the F1-score performance measure; based on this performance measure, SAB-LSTM achieved a higher F1-score when compared to LSTM, and BiLSTM Model for COVID-19 sentiment detection (26). Social media platforms such as Reddit allows healthcare service providers to collect data related to public opinions, which can be used for human behavior analysis and knowledge discovery. This study presents a generic approach based on NLP, which can extract the most critical topics about COVID-19 related comments (27). Zhang et al. (28) proposed a sentiment classification system to classify the text not at document level only at a sentence level. This approach extracts features related to public opinions and uses WordNet lexical method dataset to organize the opinion words. So this method categorized the elements under the relevant opinion sentences. The extracted features are scored according to the frequency in the reviews. The authors provide a summary based on features. They identified the most important features from the dataset and achieved the best F1-score of 83.6% using the BILSTM model. Mukherjee et al. (29) used the RNN model (bidirectional long short-term memory) to use NLP methods and utilize a bidirectional RNN to learn patterns of relations from textual data for sentiment analysis. There is much work done in tweet sentiment analysis using different DL and NLP approaches as mentioned in the study (30, 31). This study proposed a sentiment classification approach using DL and NLP models (12). NLP techniques are used for topic modeling to identify valuable topics related to coronavirus, while the LSTM model is used for classification using the sentiment-140 dataset (32). Another research gathered 1 million tweets to capture people's sentiments toward mask usage as a preventative strategy in the COVID-19 pandemic (33). They also utilized NLP to analyze the growth in the frequency of positive tweets. Our analysis finds the most common topics the public addresses in their posts concerning all preceding works. We also reported benchmarked findings for identifying tweet sentiments using NLP approaches. We compare the performance of COVID-19 tweet sentiment analysis using several ML and DL algorithms. We propose a valuable feature set with the goal of improving accuracy. The suggested system examines the sentiments of collected tweets for sentiment classification and extracts the most significant feature sets, which aids in improving classification outcomes when compared to the baseline technique. **Table 1** presents the summary of the existing work.

3. DATASET SELECTION

We used four real-world datasets for experimental analysis. The dataset is obtained through the Github repository (1) shown below to assess the classifier's classification performance. **Table 2** provides an overview of the datasets utilized in this study.

The social media users indicate more negative sentiments than the positive sentiments corresponding to the COVID-19. The trend of negative sentiments concerning time shows that people using the Twitter platform are more intended toward negative sentiments than positive sentiments during the lockdown session from February 2020 to mid of March 2020. After mid of March 2020, the negative sentiment curve dropped because people followed SOP's and kept social distancing policies applied by the Government authorities. Naseem et al. (1) divided the COVIDSenti dataset into three parts for evaluation and generalization purposes: COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C, which have three sentiments, positive, negative, and neutral for classification purposes. They labeled tweets as positive, negative, and neutral by following the Fellah and Bandi guidelines (35). The COVIDSenti dataset consists of two months of tweets fetch from Twitter using Tweepy, Python Twitter API library. **Figure 1** represents the sentiment tweets in the COVIDSenti dataset.

Selection Criteria: COVIDSENTI is a two-month archive of tweets. Only English-language tweets were included in our search. The keywords guaranteed that the literary corpus focused on COVID-19 and related issues. Section 4.2 presents the keywords that are used to collect the tweets.

COVIDSenti: The COVIDSenti dataset consists of 90,000 unique tweets. These tweets are collected from 70,000 users from Twitter. A total of 2.1 million sentiment tweets from 2 months (February 2020 to March 2020) are collected. From these 90,000 unique instances, we have 6,280 positive sentiments, 16,335 negative sentiments, and 67,835 neutral sentiments for the classification task. The COVISenti dataset is further divided into three sub-datasets.

COVISenti_A: The COVIDSenti_A dataset consists of 30,000 tweets instances. From these 30,000 unique tweets, we have 1,968 positive sentiments, 5,083 negative sentiments, and 22,949 neutral sentiments for the classification task of the COVIDSent_A dataset. The COVIDSenti_A dataset contains tweets relevant to the action taken by government authorities to protect people from COVID-19. For example, "Coronavirus warning: UK threat increases as chief medical officers urge Government action."

COVIDSenti_B: The COVIDSenti_B dataset consists of 2,033 positive sentiments, 5,471 negative sentiments and 22,496 neutral sentiments with overall 30,000 unique instances. COVIDSENTI-B dataset tweets mainly relate to four topics (COVID-19 disasters, keep social distancing, lockdown, and stay at home). COVISenti_B dataset shows tweets related to lockdown and stay at home even if one suffers from the disease. For example, "Stay Home If You Are Sick, or If you are sick stay home regardless of what you have."

COVIDSenti_C: This dataset contains 2,279 positive sentiments, 5,781 negative sentiments, and 21,940 neutral sentiments, collectively 30,000 tweets from the Twitter platform related to three different topics (COVID-19 cases, stay at home, and outbreak). The COVIDSenti_C is a collection of tweets on COVID-19 cases, outbreaks, and stay-at-home advice. We find people's behavior from these topics and analyze that COVID-19 cases are increasing daily. For example, "Airport screenings for the Wuhan coronavirus increase around the world."

TABLE 2 | Overview of datasets.

Dataset\Label	Positive	Negative	Neutral	Total
COVIDSenti-A	1,968	5,083	22,949	30,000
COVIDSenti-B	2,033	5,471	22,496	30,000
COVIDSenti-C	2,279	5,781	21,940	30,000
COVIDSenti	6,280	16,335	67,835	90,000

4. PROPOSED APPROACH

The proposed approach is divided into four phases: 1) pre-processing, 2) keyword trend analysis, 3) word embeddings for feature extraction, and 4) classification methods. The CovidSenti

FIGURE 1 | Representation of sentiment tweets in COVIDSenti.

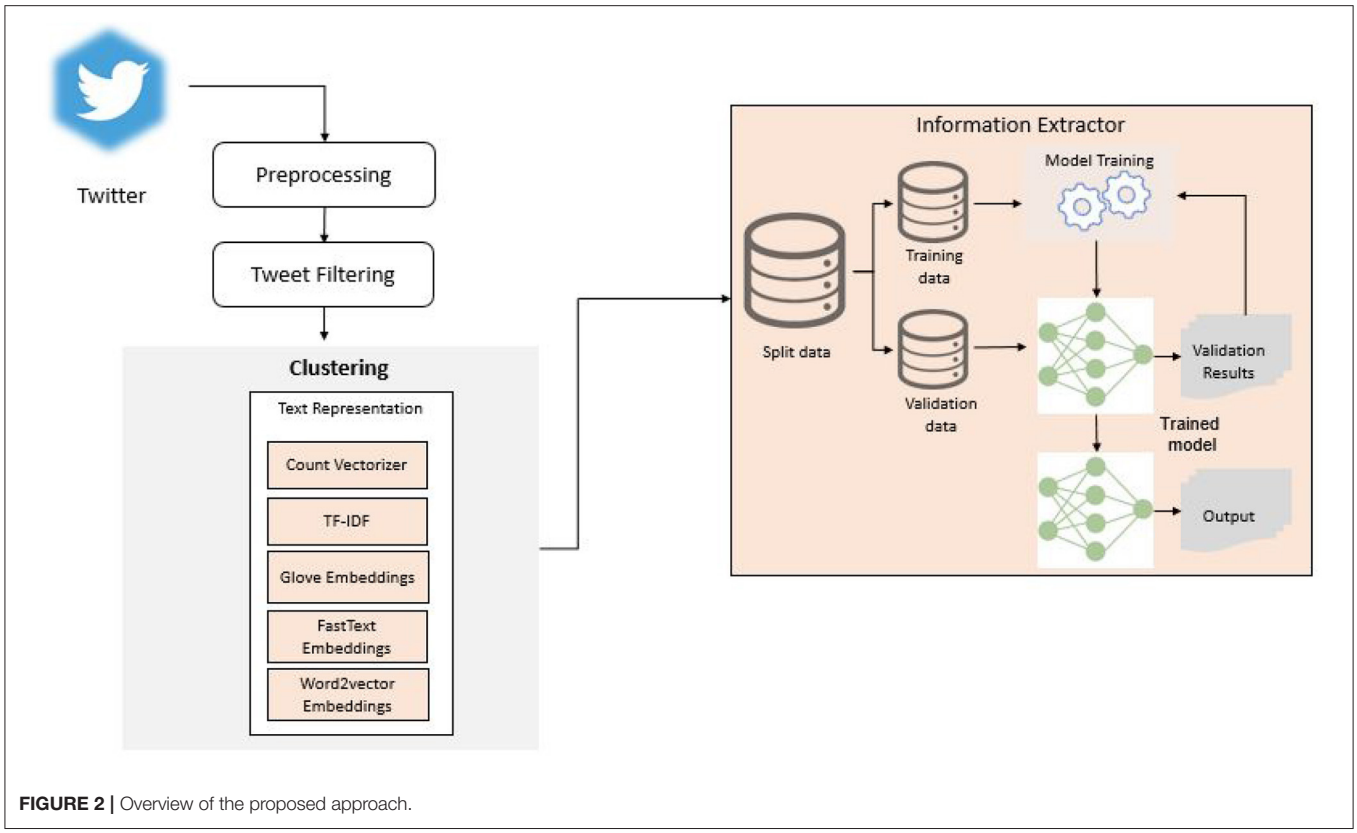

FIGURE 2 | Overview of the proposed approach.

dataset is divided into two chunks, training and testing. We take care of the various factors of the dataset, such as over-fitting, noisy or small and large datasets. The main objective of this study is to evaluate the classification performance of state-of-the-art classifiers on the COVIDSenti dataset and then attempt to improve performance by extracting key features of tweets. The proposed technique classifies the CovidSenti dataset with higher accuracy and competently for the COVIDSenti dataset containing COVID-19 associated Twitter posts. **Figure 2** demonstrates our proposed approach with each of the methods explained in the following figure.

4.1. Data Pre-processing

Information gathered from social networking media platforms is more often noisy and heterogeneous. We make the Twitter stream ready for exploratory analysis; the pre-processing step first changes the uppercase letters to lower case, then removes all the special characters, stop words, mentions, and URLs from the dataset tweets. For hashtag, first, it separates the total hashtags into tiny fragments as divided hashtags that positively affect the data clusters. A few hashtags are written using camel case, for example, "#StayHome," which are easy to convert into the segment. Still, on the other hand, some hashtags that do not involve any camel case, e.g., "#stayhome," a vast vocabulary is needed to discover the longest string suits in the hashtag. The pre-processing step uses a set of vocabulary of almost 70,000 English words to handle these challenges. Identifying informative content from a large and noisy dataset such as tweets is a challenging task. To achieve this, the following techniques are carried out inside the given order to enhance the text.

1. One common way to analyze COVIDSenti data is to calculate word frequencies to understand how often words are used in tweets. So, the first step is lemmatization that processes with the use of a vocabulary and morphological analysis of phrases and returns root words. We used lemmatization with the nltk method that converts a phrase to its base form, for example, "deaths" to "death" or "caring" to "care").
2. The second step is to remove the stop words. It is the most suitable technique to overcome the noise from the textual tweets (such as "the," "a," "an," "in"). Stop words can be filtered from the text to be processed, and it does no longer affect understanding of a tweet sentence's valence. We removed the most common stop-words that are present in a text, for example, "a," "an," "in," and "the."
3. Some time model understand the actual word as two different words because words are taken as case sensitive (i.e., COVID, covid). To avoid it, we convert all capital letters or words into the lower case. This method does not change the word's actual meaning or original word.
4. Contraction is a process of shortening the by through replacing or dropping letters with the aid of an apostrophe. Nowadays, people move to online media to connect with others *via* textual content or posts like Facebook, WhatsApp, Instagram, and Twitter. Many people communicate with each

other; people mostly use shortened forms and abbreviations of words in their text. We used the contraction mapping method that drops the vowels from the words. Removal of contraction mapping is related to text standardization, and it is helpful while working with Twitter data in sentiment analysis.
The main advantage of using textblob is its many capabilities like noun phrase extraction, pos-tagging, and sentiment analysis.

5. Part of speech is the essential step of pre-processing. It is essential to build parse trees, which might be utilized in constructing "most named entities are nouns" (NERS). It is also used to extract relations among words. Part of speech tagging is essential for building lemmatizers to return a phrase to its root form.
6. Twitter data is noisy, which affects the performance of a classifier, so the pre-processor eliminates URLs, @user_mentions. We remove alphanumeric or special characters and remove non-ASCII characters and numbers from our dataset because they do not help us detect sentiment. We also replace emojis with their corresponding reaction in text.
7. For hashtags, we eliminate the "#" symbol from the start of the phrase. We used tokenizer to split hashtags into appropriate words, for example, "#stayhomestaysafe," tokenizer converted it into "stay," "home," "stay," "safe." Many words are concatenated in other words, and we also performed word-segmentation to achieve this.

4.2. Keyword Trend Analysis

We performed keyword trend analysis on our pre-processed corpus to find the most frequent words. The top 10 most commonly used keywords are "Coronavirus", "Corona", "COVID-19", "Virus", "Coronavirus Cases", "Cases", "Social distance", "Coronavirus pandemic", "Coronavirus Crisis", and "Stay home" with 156,668, 87,661, 26,239, 22,289, 16,638, 10,269, 5,768, 3,125, 1,981 and 1,181 number of frequencies, respectively. We conclude that most people talk about coronavirus cases, the social distancing, COVID-19 outbreak, the coronavirus crisis, and stay-home.

To analyze the main topics across the dataset, we discover the topic distributions using Glove embeddings. We used Glove embeddings because it has an extensive vocabulary size. We can also find the words from COVIDSenti data that are not present in the Glove embeddings, such as contractions, misspelled words, concerted words, or emojis, which can decrease our model's performance. We discovered that most social media users discuss coronavirus cases, the coronavirus epidemic, social distance, the need to stay at home, the coronavirus crisis, and the crises caused by the coronavirus. Based on this analysis, we examine the distribution of the 15 topics across the corpora, in which topics 1 ("coronavirus"), 2 ("virus"), and 3 ("corona") were the top three in the entire corpora.

4.3. Feature Extraction

In this study, count vectorizer, TF-IDF, and word embeddings techniques are used for feature extraction. The count vectorizer feature extraction technique is used to convert given tweets into a vector space, and it covers the tweets based on the most commonly used words (count) that frequently occur in the tweets. The count vectorizer creates a word matrix where every unique word represents the column of the matrix, and the selected text from the document represents the row of the matrix. In this way, we count the word in that particular text sample. We also used the term frequency-inverse document frequency (TF-IDF) feature extraction technique along with a count vectorizer. In this study, the TF-IDF is used for tweet analysis, and it has weighted features for execution boosting. The TF-IDF takes the TF and its corresponding IDF as a product to get the weights of features in a document. The length determines the TF of features in a single document. It is defined in Equation (1).

$$TF = \frac{count_{t,d}}{totalcount_d} \tag{1}$$

In equation 1, the number of TF t in document d is represented by $count_{t,d}$, while the overall number of terms in that document is represented by $totalcount_d$. IDF thinks that the text's increase in term t will be more informative for model training. It can be defined as in equation 2.

$$idf^{'} = i^{'}/df_t^{'} \tag{2}$$

Where $i^{'}$ is the total number of documents, and $df_t^{'}$ is the number of documents that include the phrase t. When a term t frequently appears in many documents, IDF computes the weights of a phrase t low. For example, stop words have a lower IDF value. So finally, the TF-IDF can be defined as in equation 3.

$$tf - idf = tf_{t,d} \quad * \quad \log(idf). \tag{3}$$

We also employed the word embeddings model for feature extraction, such as pre-trained models Word2Vec, Glove, and fastText embeddings with 300-D vectors. Furthermore, we used RCNN hybrid models for better sentiment classification tasks and reduced the over-fitting by decreasing bias because there are many variances. We also used transformer-based language models that have been widely used in the NLP research area. We used Multi-depth DistilBERT transformer-based model to pre-train a smaller general-purpose language representation model. We fine-tuned the Multi-depth DistilBERT model to achieve high performance on multiple tasks like better sentiment classification. Most of the previous work investigated that the used-ability of the distillation is only for building task-specific models. Still, the primary purpose is to decrease the size of the BERT transformer model. We decreased the BERT transformer model by 40% and retained its actual language understanding capabilities by 97%, and it was 60% faster than BERT.

These transformer-based language models (LMS) show how the training methods are used. We used unsupervised learning in the training process to generate an LM. The NLP models are trained on extensive data; these models attain more improved context word representations than conventional and non-contextual word representation methods because of the large data size.

4.4. Classification Methods

To analyze the classification performance on the COVIDSenti dataset, we used different ML and DL-based classifiers to measure the performance in the sentiment classification tasks.

We used XGBoost (eXtreme Gradient Boosting) in our analysis. XGB classifier is similar to the Gradient Boosting classifier. It consists of multiple trees, and it is a tree base model which is why it has gained lots of attention in the past few years. Many weak learners are working parallelly distinct to Gradient Boosting; XGboost gives a speed boost because of this technique. XGboost uses L1 and L2 regularization methods to control over-fitting, which are not present in Adaboost and Gradient Boosting techniques. XGBoost has a new feature of scalability so that it performs better in the distributed environment than a single system. At every iteration of XGBoost, we calculate some errors. We used this error to correct the previous prediction and optimize the loss function. Regularizer is utilized in the loss function to evaluate the classifier performance, which is defined by

$$X^{'}(\otimes) = L^{'}(\otimes) + \Omega(\otimes). \quad (4)$$

In equation (4), we train the parameters using $\otimes$, for the training Loss function, we used $L^{'}$, and to measure the model's complexity, we used ω regularization. In this study, we set different parameters for the proposed XGBoost classifier. The XGB classifier is composed of 1,000 n_estimators with a 0.1 learning rate. Learning rate (LR) is used to handle the over-fitting. The XGB used a minimum of one child weight and a maximum depth of 6.

For DL-based models, we used the Conv1D-LSTM model. While using the DL classifier, we used Adam optimizer and L2 regularization. We trained the model on 50 epochs. Our Conv1D-LSTM consisted of four layers: the embedding layer with weights and vocab_size as input, then the Conv1D layer with a relu activation function. Next, we used the LSTM layer, and then at the end, the dense layer is used, also called an output layer. The softmax is employed as an activation function. In the experiments, we used a hybrid model named RCNN. We used this hybrid model for the sentiment classification task. RCNN model consisted of six layers in which one CNN layer with relu activation function, and then we used BiLSTM, an LSTM layer. After that, we used a dropout of 0.4 to control over-fitting; finally, we used a dense layer with softmax as an activation function. The RCNN uses Adam optimizer with verbose = None. We used the Multi-depth DistilBERT transformation model at the end of our experiments. The parameters of the Multi-depth DistilBERT model are presented in **Table 3**.

TABLE 3 | The parameter settings of multi-depth DistilBERT.

Value	Setting
Model name	distilbert-base-uncased
Number of epochs	3
Batch size	80
Max sequence length	256
Learning rate	5e-05
Accumulation steps	4
Random seed	42

5. EXPERIMENTAL ANALYSIS AND RESULTS

The main aim of this study is to evaluate the classification performance on COVIDSenti datasets and provide benchmarked results. This paper applies ML, DL, and hybrid methods to COVIDSenti datasets and examines their performance using several evaluation measures. The performance assessment metrics in this study include accuracy, precision, recall, and F1-score. These standard performance indicators have been carefully chosen to attest to the model's capacity to generate the best categorization performance. Following the experimentation procedure, the experimental outcomes are compared to state-of-art-methodologies.

5.1. Results

This work consists of different ML, DL, hybrid-based, and transformer-based models on four COVIDSenti datasets and analyzes their performance using the defined evaluation metrics. The proposed approach is used to gauge the performance in the sentiment classification task. The highlighted results in **Tables 4–9** represent the highest achieved accuracy as compared to baseline results.

5.1.1. COVIDSenti

Figure 3 and **Tables 4–9** present the results achieved on the COVIDSenti dataset for tweet sentiment classification. In the case of the count vectorizer feature extraction technique, for sentiment classification on the COVIDSenti dataset, the XGB model attains the best accuracy of 89.81%, other ML techniques, such as KNN, LR, and Ensemble model, achieve the accuracy of 79.21, 89.03, and 88.75%, respectively. The xgb model achieves the highest accuracy of 89.81% with 89% precision, 90% recall, and 89% F1-score compared to KNN, LR, and Ensemble model.

While using the TF-IDF feature extraction technique for sentiment classification again, the xgb model outperforms other ML models, such as SVM, RF, NB, and DT with the highest accuracy of 88.46% with 88% precision, 88% recall, and 88% F1-score. We also used different word embedding techniques, such as FastText, Word2Vec, and Glove with different ML classifiers. We fine-tuned FastText with a Glove, resulting in 80% accuracy on the COVIDSenti dataset. We also measure other evaluation metrics like precision, recall, F1-score, 79% precision for the COVIDSenti dataset, 79% recall, and 73% F1-score. While working with the Word2Vec word embedding technique, we used the xgb model and achieved an accuracy of 79.71% which is the highest accuracy compared to other Word2Vec models (RF with 79.09% and DT with 76.06%). Along with the accuracy, we measure the precision, recall, and F1-score of the xgb model, which is 79, 79, and 74%, respectively. Finally, we employ the Glove word embedding technique with the ML model. We fine-tuned Glove with the xgb model and gained an accuracy of

79.19% with the precision of 79%, recall of 79%, and F1-score of 74%. After ML with word embeddings, we employ DL with word embeddings. The proposed model Conv1D-LSTM with Glove gains an accuracy of 87.60%. The best precision, recall, and F1-score were gained from the Conv1D-LSTM classifier, 87, 87, and 88%, respectively.

We used the RCNN hybrid model for the sentiment classification task, and it performs very well on the COVIDSenti dataset. The best accuracy of hybrid models is achieved from the RCNN model, which is 95.40%. RCNN model shows a better 95, 96, and 95% in terms of precision, recall, and F1-score. Finally, we used a transformer-based language classifier which shows the overall highest accuracy of 96.66% with the highest precision of 96% also with 96% recall and 95% accuracy.

5.1.2. COVIDSenti_A

The results achieved on the COVIDSenti_A dataset are presented in **Tables 4–9** and plotted in **Figure 3**.

We used the count vectorizer feature extraction technique to classify sentiments first. The highlighted XGB model gains the highest accuracy of 88.71% compared to other ML models: KNN, LR, and Ensemble, 79.65, 87.75, and 88.51%, respectively. We also measure the other evaluation metrics (precision, recall, and F1-score) for the XGB classifier. The precision score of the XGB model for the COVIDSenti_A dataset is 88%, recall score is 89%, and the F1-score score is 88%. We also used different ML classifiers with the TF-IDF feature extraction technique. The XGB classifier on the COVIDSenti_A dataset exhibits the highest accuracy of 88.31% with 88% precision, 88% recall, and also 88% F1-score as compared to other ML models such as SVM, RF,

NB, and DT. We also apply different word embedding techniques (FastText, Word2Vec, and Glove) on the COVIDSenti_A dataset.

In the case of FastText word embedding with XGB classifier on COVIDSenti_A, we achieve 78.33% accuracy with 77% precision, 79% recall, and 73% F1-score. We also used Word2Vec embedding with XGB classifier on COVIDSenti_A dataset. XGB classifier with Word2vec word embedding achieves an accuracy of 78.33% which is the highest accuracy compared to other word2vec techniques with ML classifiers. The XGB classifier with Word2Vec gains a precision score of 77%, recall score of 78%, and F1-score of 73%. Finally, we used Fine-tuned Glove word embedding with XGB classifier, which achieves the highest accuracy compared to Word2vec and Glove word embeddings with ML. The fine-tuned Glove with XGB classifier achieves an accuracy of 78.39% on the COVIDSenti_A dataset. We also measure other performance metrics to testify to the model's capability. Other performance metrics are precision with 77%, recall with 79%, and F1-score with 73%.

After ML word embedding, we move on to DL word embedding for better sentiment classification. While working with DL classifiers with word embeddings, we apply Conv1D-LSTM with the Glove word embedding technique. Conv1D-LSTM with Glove word embedding achieves the best accuracy of 86.10% with other performance metrics such as precision, recall, and F1-score. The Conv1D-LSTM model observes the maximum F1-Score, precision, and recall, i.e., 86%, 86%, 87%, respectively, while having a maximum accuracy of 86.10%. We propose a hybrid model named RCNN. The best performance is achieved on the COVIDSenti_A dataset in terms of accuracy, precision, recall, and F1-score by the RCNN model with a maximum accuracy of 92.90% and maximum precision-recall, and F1-score of 92, 92, and 92%, respectively, as compared to other hybrid models. Finally, we proposed a Multi-depth DistilBERT transformer-based model, which performed very well on the COVIDSenti_A dataset and all other methods on the COVIDSenti_A dataset. The maximum accuracy on COVIDSenti_A using Multi-depth DistilBERT is 95.22% with precision, recall, and F1-score of 95%, 96%, 95%, respectively.

5.1.3. COVIDSenti_B

Figure 3 and **Tables 4**–**9** depict the sentiment classificaition results in the COVIDSenti_B dataset by different ML, DL, Hybrid models, and transformer based models. First, we used the count vectorizer feature extraction technique to extract useful features and pass them to models for sentiment classification tasks. We used the XGB model for sentiment classification on the COVIDSenti_B dataset. The XGB model obtains the maximum accuracy of 88.03% compared to other ML models such as KNN, LR, and Ensemble, which acquire 79.65, 87.75, and 88.51% accuracy. The best precision, recall, and F1-score on COVIDSenti_B are gained from the XGB classifier, 88, 89, and 88%, respectively.

Another feature extraction technique is used with ML classifiers for sentiment classification. Features are extracted

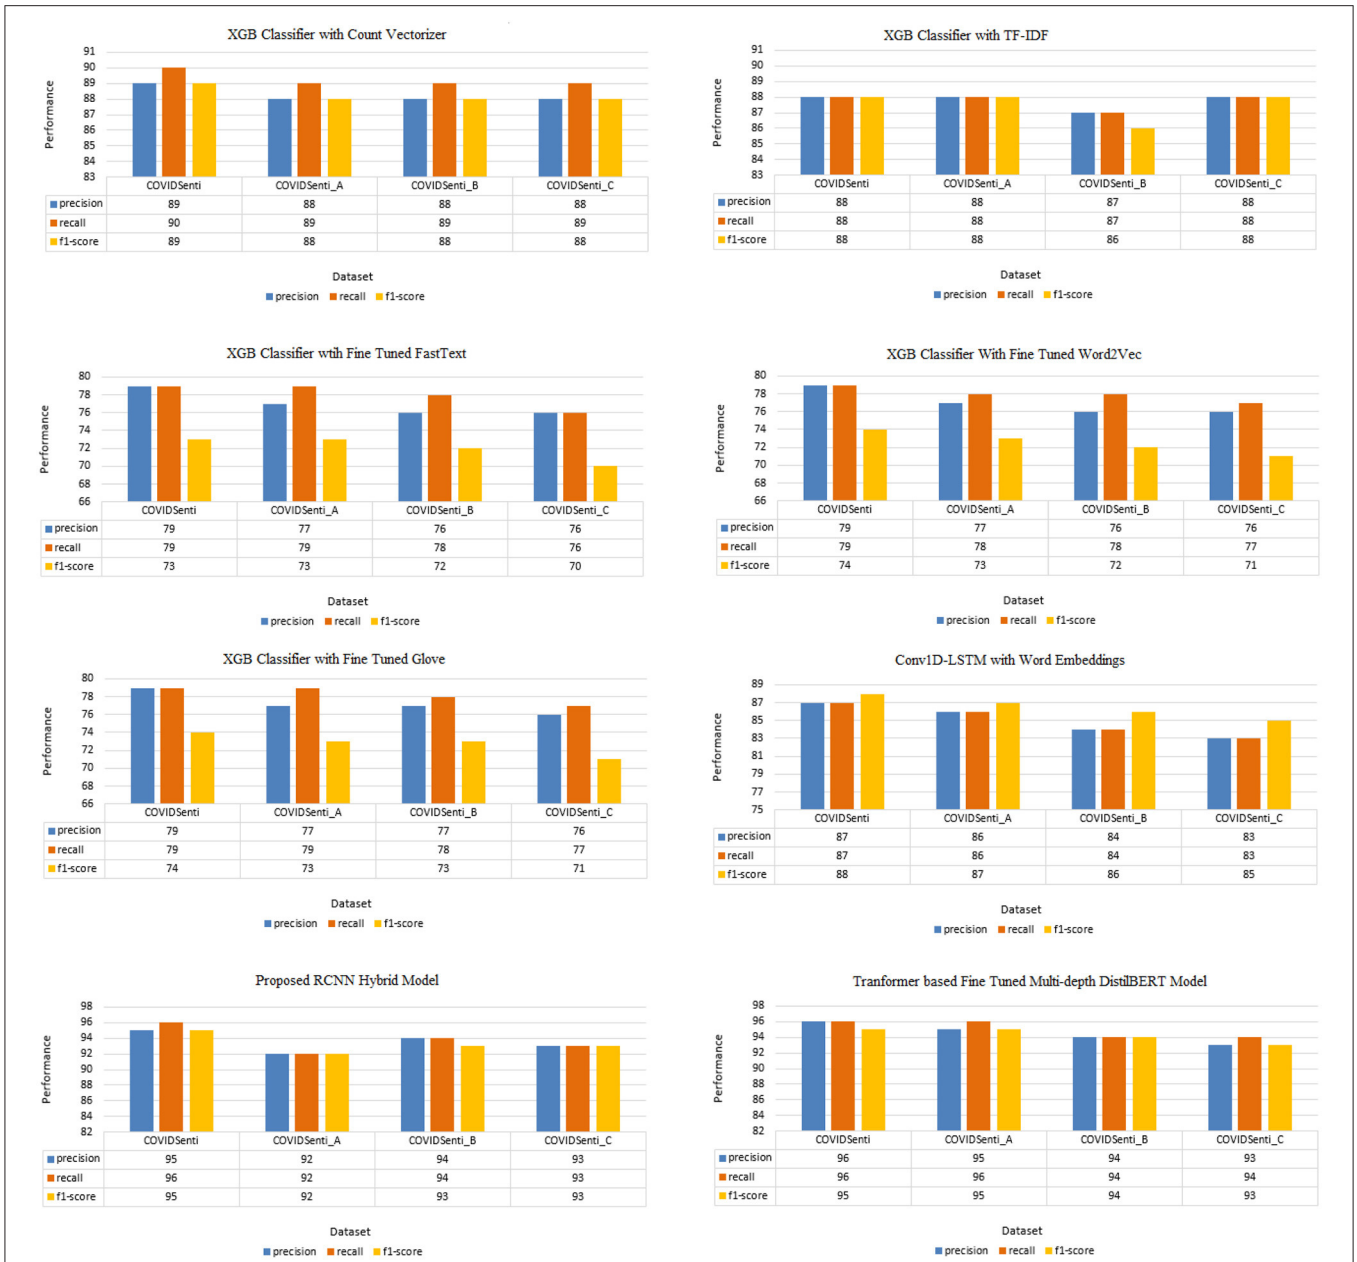

FIGURE 3 | Precision, Recall, and F1-score of classifiers used in proposed approach (percentage results).

using TF-IDF, and then we apply ML classifiers on these features for COVIDSenti_B dataset sentiment classification. We pass these TF-IDF features to the XGB model for better classification results, and XGB shows the accuracy of 87.41% on the COVIDSenti_B dataset with better precision, recall, and F1-score of 87, 87, and 86%, respectively. We used three different word embedding techniques with ML models to reduce the computational cost. First, we used Fine-tuned Glove with XGB ML model, which obtains an accuracy of 78.23% which is quite well as compared to other Word2Vec and Glove word embedding in **Table 8**. With the best accuracy of 78.23%, the Fine-tuned Glove with the XGB ML model gets the precision, recall, and F1-score of 77, 78, and 73%, respectively.

Second, we used the Word2Vec word embedding technique using the XGB ML model. The fine-tuned Word2Vec with XGB model gets the accuracy of 77.85% on the COVIDSenti_B dataset with a precision score of 76%, recall 78%, and F1-score of 72%. In the end, we used fine-tuned FastText word embedding with an XGB ML classifier. The fine-tuned FastText word embedding with XGB ML classifier gains less accuracy of 77.61% compared to proposed Glove and Word2Vec embeddings methods. The precision, recall, and F1-score of fine-tuned

FastText word embedding with XGB ML classifier is 76, 78, and 72%, respectively.

We used Conv1D-LSTM with Glove word embedding for better results, so we used DL with word embeddings to achieve the highest results for sentiment classification. For this purpose, we train the Conv1D-LSTM model on the COVIDSenti_B dataset and get the evaluation result of 84.44% with other different performance metrics. The other performance metrics are precision, recall, and F1-score with 84, 84, and 86%, respectively. We also proposed a hybrid model by adding multiple layers of LSTM, BiLSTM, and CNN for better classification on the COVIDSenti_B dataset. To achieve better classification on the COVIDSenti_B dataset, RCNN hybrid model gets 92.93% with better precision, recall, and F1-score. The precision, recall, and F1-score of the RCNN model are 94, 94, and 93%, respectively. Finally, we apply a transformer-based model named Multi-depth DistilBERT on the COVIDSenti_B dataset, which gives an accuracy of 94.33% with 94% precision, 94% recall, and 94% F1-score. F1-score of 94% shows that this model performed very well on the COVIDSenti_B dataset.

5.1.4. COVIDSenti_C

The results of the COVIDSenti_C dataset are shown in **Tables 4**–**9** and plotted in **Figure 3**. We used different ML, DL, hybrid models, and transformer-based models for COVIDSenti_C dataset classification. We used the count vectorizer technique to extract essential features from the COVIDSenti_C dataset as shown in **Table 4**. When we extract essential features, we send these features to ML models to perform sentiment classification tasks. We used KNN, LR, Ensemble, and XGB models for sentiment classification on the COVIDSenti_C dataset. For sentiment classification in the COVIDSenti_C dataset, the XGB model obtains the best accuracy of 87.07%. Other conventional techniques, KNN classifier, LR classifier, and Ensemble classifier, get the accuracy of 77.75, 86.04, and 86.36%, respectively. XGB classifier shows a proficient gain of 88, 89, and 88% in terms of precision, recall, and F1-score, respectively, compared to other models.

Furthermore, we apply another technique to extract important features for better results. We extract important features using TF-IDF and send those features to multiple ML classifiers for classification purposes. Finally, the XGB classifier using these TF-IDF features delivers the best accuracy of 88.31% on the COVIDSenti_C dataset. The precision, recall, and F1-score of the XGB model with 88.31% accuracy are 88, 88, and 88%, as shown in **Figure 3**. The computational time plays an important role during the model's training process, so to reduce computational time, we apply different word embeddings to ML and DL models. For ML, first, we apply FastText with the XGB model. We fine-tuned FastText word embedding and passed this word embedding to the XGB model to reduce computational time, which results in 76.30% accuracy, 76% precision, 76% recall, and 70% F1-score. Less F1-score indicates that we need to improve the classification result. The second embedding technique to reduce computational time is Word2Vec. While using fine-tuned Word2Vec embeddings with the XGB model, we achieved better accuracy, 76.05%, and quite well precision, recall, and F1-score, which is 76, 77, and 71%. The last and essential word embedding technique we used in this study is Glove. While using fine-tuned Glove with the XGB classifier again, we obtained an accuracy of 76.05% with the same precision, recall, and F1-score of 76, 77, and 71%. We moved to DL with word embeddings; first, we used Conv1D with LSTM and Glove. This proposed model worked very well on the COVIDSenti_C dataset and gave the accuracy of 86.91% which is the highest accuracy of the COVIDSenti_C dataset as shown in **Table 5** and also gives the best precision, recall, and F1-score of 83, 83, and 85% shown in **Figure 3**.

Furthermore, we propose our hybrid model, which performed very well on the COVIDSenti_C dataset. The proposed RCNN model achieves the best accuracy of 93.27% which is the highest accuracy in the COVIDSenti_C dataset is shown in **Table 6**. The evaluation metrics include precision, recall, and F1-score with 93% precision, 93% recall, and 93% F1-score. To cover all the methods with better classification results, we proposed a transformer-based language model that achieves the highest accuracy compared to all other methods used with COVIDSenti_C. The Multi-depth DistilBERT gives the highest accuracy of 93.88%, which is the highest accuracy of the COVIDSenti_C dataset compared to all other methods applied on the COVIDSenti_C dataset. It also gives the highest precision, recall, and F1-score of 93%, 94%, and 93% on the COVIDSent_C dataset.

5.2. Comparative Analysis With Baseline Approach

To assess the performance of the suggested strategy, we compare our experimental findings to those of the state-of-the-art approach (1), whose experimental circumstances are identical to those used in our work. The baseline approach used only accuracy as an evaluation metric to testify classifier's ability. As compared to baseline proposed approach used precision, recall, and F1-score along with accuracy metric. The proposed framework analyzes tweets' sentiments for sentiment classification and extracts the most important features that help increase the classification results compared to the baseline approach. Furthermore, we proposed a fine-tuned transformer-based Multi-depth DistilBERT model that achieved the highest results in terms of accuracy as compared to all the baseline results. The comparative results are reported in **Tables 4**–**9**. To achieve the higher performance for ML classifiers, we used different conventional methods: count-vectorizer, TF-IDF, different word embeddings based models like Word2Vec, fastText, and Glove. The results of count-vectorizer-based classification are shown in **Table 4**.

When using count vectorizer with KNN, logistic regression, ensemble method, and XGB ML classifiers on COVIDSenti datasets, the count vectorizer with XGB classifier exhibited better performance on the COVIDSENTI dataset than other ML classifiers(KNN, LR, and Ensemble). The classification accuracy of the XGB model using the count vectorizer method is 89.81% on COVIDSenti, 88.71% on COVIDSenit_A, 88.03% on COVIDSenit_B, and 87.07% on COVIDSenti_C, respectively.

In addition, we conducted a comparison using TF-IDF-based classification. The obtained results are shown in **Table 7**. On all COVIDSenti datasets, the TF-IDF was used in conjunction with the SVM, RF, NB, DT, and XGB models. Compared to other baseline ML classifiers, the TF-IDF approach with XGB classifier performs better on the COVIDSENTI-A dataset, COVIDSENTI-B dataset, COVIDSENTI-C dataset, and COVIDSENTI dataset. The classification accuracy of the XGB model using the TF-IDF method is 88.46% with 4.41% gain on COVIDSenti, 88.31% accuracy with 5.22% gain on COVIDSenit_A, 87.41% accuracy with 4.41% gain on COVIDSenit_B, and 86.03% accuracy with 3.95% gain on COVIDSenti_C, respectively. For the comparison of ML with word embeddings, we employed different word embeddings techniques like FastText, Glove, and Word2Vec with various ML classifiers: RF, DT, SVM, NB, and XGB as shown in **Table 8**. In the case of word2vec embedding, we fine-tuned word2vec with an XGB classifier, which shows better performance (79.17, 78.33, 77.85, and 76.07% on COVIDSENTI, COVIDSENTI-A, COVIDSENTI-B, and COVIDSENTI-C, respectively) as compared to baseline ML models with word2vec embeddings.

Furthermore, we fine-tuned the Glove with an xgb classifier for Glove word embedding, which outperforms the baseline Glove embedding with different ML classifiers. The xgb model achieves the highest accuracy of 79.19% on COVIDSenti, 78.39% on COVIDSenti_A, 78.23% on COVIDSenti_B, and 76.05% on COVIDSentiC as compared to baseline ML models. We detect a decrease in accuracy for the proposed FastText embedding model that is minor when compared to the yield inaccuracy for other word embedding techniques. We get the loss in terms of accuracy while comparing the proposed DL classifier with the word embedding approach to the baseline FastText approach, which is 4.05% for COVIDSenti, 3.64% for COVIDSenti_A, 5.78% for COVIDSenti_B, and 3.97% for COVIDSenti_C datasets. To compare DL-based classifiers, we apply various word embeddings models like Glove and 1D convolutional neural network (1DCNN) with LSTM, where Glove is utilized for word representations. The comparative results of DL-based classifiers are presented in **Table 5** with baseline, Word2Vec, and Glove with DL classifiers on all three COVIDSenti datasets. Compared to baseline word embedding-based classifiers, our proposed approach Conv1D-LSTM with Glove showed better performance (87.60% with 0.97% gain, 86.10% with 3.06% gain, 86.44% with 1.42%, and 86.90% with 0.86% accuracy gain on COVIDSenti, COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C).

In **Table 6**, we also compare hybrid models to baseline models such as the hybrid ranking model and IWV model. The baseline approach used a hybrid ranking model that includes sentiments and context of Twitter posts for Twitter sentiment analysis (36). The comparative results with baseline Hybrid ranking and IWV model are shown in **Table 6**. Notice that the proposed hybrid model (RCNN) outperforms the baseline Hybrid ranking model and IWV model with the performance score of 95.40% with 7.39% accuracy gain, 92.90% with 7.86% accuracy gain, 92.93% with 6.88% accuracy gain, and 93.27% with 6.20% accuracy gain on COVIDSenit, COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C, respectively.

Table 9 shows the final comparison of transformer-based models. The previous study fine tuned the transformer-based models such as BERT, DistilBERT, XLNET, and ALBERT. Compared to previously fine-tuned transformer-based models, we fine-tuned the Multi-depth DistilBERT model that performed very well compared to all other transformer-based models and all the other approaches used before in this study. Experiments prove that the proposed Multi-depth DistilBERT model achieves better accuracy of 96.66% with 2.58% gain on COVIDSenti, 95.22% with 1.21% gain on COVIDSenti_A, 94.33% with 1.26% gain on COVIDSenti_B, and 93.88% with 1.82% gain on COVIDSenti_C, respectively.

6. CONCLUSION

Since the outbreak of the COVID-19 pandemic and with a new normal of staying at home, working from home, and "isolation time," social networking media has been extensively used to share news, opinions, emotions, advice; however, most of the data on social media are irrelevant and do not belong to the actual scenario. This study proposed an approach to deal with the Twitter sentiment using the COVIDSenti dataset. We evaluate ML and DL classifiers using novel feature extracting methods that automatically learn features without human interference. We observed that people follow government policies and Standard Operating Procedures (SOPs) and began to favor lockdown and keep social distancing in March 2020, but the order by the government is in February 2020. There is much misinformation on social media; therefore, health organizations need to develop a stable system for detecting coronavirus precisely to preclude the spread of fake news. The proposed approach performed very well on the given dataset and showed higher accuracy when compared to similar state-of-the-art studies. In future work, we plan to analyze public sentiments toward other essential topics, such as government response to the pandemic situation, healthcare facilities by government, offline examination, and mental health by using DL algorithms to increase their performance on the dataset. One limitation of this work is that it is specific and does not look at the mood and emotions of the people. Further work can be done on the detection of mood-based sentiment analysis.

DATA AVAILABILITY STATEMENT

Ltd., Chennai, India

The proliferation of wearable sensors that record physiological signals has resulted in an exponential growth of data on digital health. To select the appropriate repository for the increasing amount of collected data, intelligent procedures are becoming increasingly necessary. However, allocating storage space is a nuanced process. Generally, patients have some input in choosing which repository to use, although they are not always responsible for this decision. Patients are likely to have idiosyncratic storage preferences based on their unique circumstances. The purpose of the current study is to develop a new predictive model of health data storage to meet the needs of patients while ensuring rapid storage decisions, even when data is streaming from wearable devices. To create the machine learning classifier, we used a training set synthesized from small samples of experts who exhibited correlations between health data and storage features. The results confirm the validity of the machine learning methodology.

INTRODUCTION

In the modern era, clinicians no longer manage health data exclusively, but are increasingly responsible for obtaining consent from patients (1). The rights of patient's access to, analysis of, and exchange of their health information have evolved dramatically (2). The majority of patients are dissatisfied with their health care providers after sharing self-tracking data (3). It is still possible to enhance patient health care by incorporating patient health data into the current health data systems. Literature has identified various categories of patient health information (4). These categories include information about medications, biometrics, behavioral information, data about social interactions, genetics, psychological data, data about symptoms, and reports. Blockchain-based interplanetary file system secondary storage of health data has been implemented to safeguard the privacy and security of patient health information (5). Yet very few studies have evaluated how patients' health data is stored. A key component of the proper management of health data is protecting the privacy and confidentiality of the patient while maintaining data accessibility for relevant stakeholders. Studies indicate that health data security poses a massive threat. This is evidenced by the proliferation of medical devices with limited memory and power (6, 7) and substantial medical data repositories (8). Many types of organizations are responsible for managing the massive amount of health data.

Health data is often portrayed as being sensitive to all patients with the same level of privacy and confidentiality; however, this is not true in practice because it is not equally sensitive to everyone at the same time. When a patient reaches a high level of public prominence, she may surrender the ECG data she generated on her own and to her cardiologist. This data can be accessed by other healthcare providers through an electronic health record. A patient who wishes to keep her pregnancy test results private may be forced to allow her provider to store her pregnancy test results. The dissemination of health data between multiple providers who manage data repositories now enables the storage medium to be customized based on patient needs. This includes the cost, size, security, confidentiality, and privacy of each chunk of data. Hybrid execution models, such as those described by the author (9), allow sensitive data to be stored in private clouds while no sensitive data is maintained in public clouds. Nevertheless, it does not specifically address health data processing. Communication between the two cloud platforms also takes time, and computations that rely on bandwidth use a lot of resources. A hybrid cloud platform was developed by (10) for solving this problem. Medical sensors, apps, and devices provide data to artificial intelligence, which enables the automatic diagnosis of health conditions. Health data, including ECG, blood pressure, and pulse rate, can be classified as normal or abnormal by algorithms based on a range of conditions and thresholds set by healthcare professionals. Clinical research and clinical care are usually aided by abnormal data. Using the Body Area Sensor Network, (8) developed an agent-based system developed for elderly people to preserve abnormal data. Health information is generated in enormous quantities nowadays, so a diverse storage solution is needed (11). Several researchers have examined the performance and cost parameters of various Cloud Service Providers (CSPs) to design methods for selecting suitable CSPs for storing consumers' data (12–14). High-performance cloud services minimize the time spent in operations but incur high costs. Additionally, researchers are investigating blockchain technology for its promise of security and privacy for health data management. Combining blockchain-based eHealth with traditional health databases is possible, which can be arranged based on users' preferences and the possibility of utilizing the data in the future. However, due to the design of blockchains, they are not suitable for hosting large amounts of health data. A software agent that knows the patient's preferences is inserted inside the application in (15). Nonetheless, they never described a way to make this decision. To assist in choosing storage repositories, we developed a model that incorporated not only (8)'s criteria, but also aspects like data confidentiality, privacy, and quality of performance.

Motivation

Every Blockchain miner owns a local ledger, so this technology allows transactions to be verified and processed without the need for third parties. Verifying transactions does not require a centralized server. Document alterations cannot be guaranteed through conventional database storage and blockchain-based hash management. Data is only detectable in a blockchain if a hash pointer holds a pointer to it. Depending on the patient, personal preferences, and other factors, the sensitivity and significance of the health information are also different from repository to repository. Choosing the right repository is extremely crucial. As wearable sensors continuously stream health data, the challenges are exacerbated. In (16), the author has surveyed the importance of artificial intelligence in healthcare. The prediction of COVID-19 infected patients using artificial intelligence has been implemented in (17), but there is a need for an appropriate repository to store the data.

Contribution

In our research, we considered the variation in data sensitivity, volume, and other factors to locate the appropriate system to manage health records. The flow diagram of the paper contribution is shown in **Figure 1**. Collect the health data and health repository parameters. Evaluations of both health information and health repository parameters are given a score. The machine learning-based recommendation model for health data storage proposes a way to distribute health data among multiple repositories. A model for automated health data storage recommendation is being developed to determine appropriate storage repositories. Through correlation analysis, user preferences, and clinical heuristics, a machine learning-based classifier is used to map health data characteristics to each repository. Patients' security and privacy preferences are taken into account as well as the sensitivity of health data.

Organization

Following are the sections of the paper: section Background addresses related work. In section Model for Recommendation of Health Repositories, we present the proposal for a recommendation model for a health repository. Section Implementation describes how the system will be implemented. The results and evaluation of performance will be discussed in section Results and Discussion. Conclusions and future work will be discussed in section Conclusion.

BACKGROUND

Big Data cannot be stored, accessed, or analyzed with a single health record system. Patients can lose medical information when their electronic health records are malfunctioning (18). Due to the manual uploading of data generated by wearable sensors to personal health records, caregiver responses were delayed. For this reason, (19) developed methods for storing patient-generated health information on commercial blood glucose monitors. The electronic health record system could be made to fit the streamed data if it is filtered or compressed (20). In (21–24), a number of action plans and standards were advocated for the adoption of an electronic health record system. A selection of an electronic health record should take into account functional requirements, troubleshooting, and optimization features (22). The author provides a list of steps to follow before buying an electronic health record system. Checklists mostly cover client meetings on site, site visits, and maintaining live workflows. Health data sources such as hospitals, clinics, insurers, and patients should be integrated into

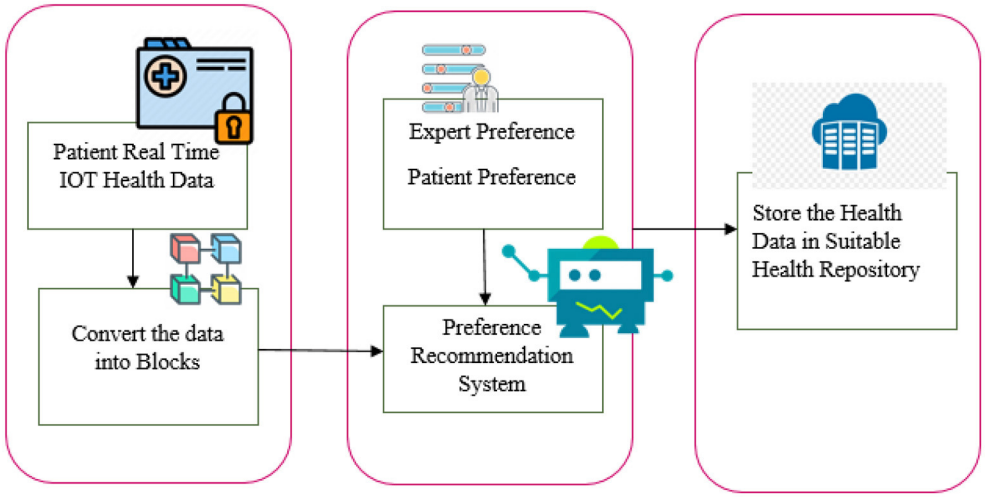

FIGURE 1 | Paper contribution flow diagram.

centralized databases, according to the author (25). In particular, patient-centered health data with high degrees of structural heterogeneity must be stored and processed quickly because of their high volume and rate. For health data, to provide useful insights, precision is essential, but some sources produce vague and inaccurate information. Distributed data storage systems do offer some relief to these issues (26). Various cloud storage mediums have been examined. A machine learning and deep learning model is used to predict the thermal sensation vote system (27). Utilization of a compression algorithm to retrieve the health repository data as fast as possible using blockchain and interplanetary file systems (IPFS) without data loss (28). Diabetic Retinopathy is efficiently classified using a deep learning and machine learning algorithm (29). Genetic algorithm with fuzzy logic is a tool to help medical practitioners diagnose heart disease at an early stage using adaptive genetic algorithm with fuzzy logic (AGAFL) (30). Health data storage systems and data properties were not considered in the selection of repositories. Furthermore, no machine learning mechanisms were developed to cater to user preferences.

In the next section, we describe how we facilitate distributed health data management.

MODEL FOR RECOMMENDATION OF HEALTH REPOSITORIES

As data streams increase, the need for storage decisions becomes more frequent, making manual consultation with patients an inefficient process that requires an automated solution. It is, however, impossible to prespecify the data storage requirements for each patient that will apply to all possible future contexts. The learning classifier may generalize to a broader range of mappings based on a manual mapping specification by an expert.

The following sections explain in detail the overall approach described in **Figures 2**, **3**. Data storage requirements - an illustration of which is displayed in layer 1 of **Figure 2**, consists of a set of variables or features that characterize the requirements for storing a chunk of data. Some of the attributes' values have been shown to be numerical [1–10] and others to be qualitative. Secondly, each instance of the dataset contains the specifications required to store each chunk of data as shown in **Figure 2**.

Health Repository Evaluation Criteria are calculated in layer 3 by adding a rating provided by an expert group. These criteria reflect the characteristics of storage repositories as shown in **Figure 2**. Three standards apply to rank five storage repositories. Medical professionals and patients themselves may create clinical heuristic rules in layer-3 of **Figure 2** and each instance in the dataset is categorized according to the preferences of the users. A storage repository can be assigned to an instance based on heuristic rules in a real-world situation. The correlation coefficient offers an inference of a class label when preferences and heuristics do not match well. The health repository requirements can be mapped to layer-4 (user and expert expectations) by a machine learning classifier, as shown in **Figure 2**. In **Figure 3**, a recommendation framework for health repositories is illustrated. There are two parts to the framework: determining which standards should be used for the storage and assessment of data and implementing machine learning.

IMPLEMENTATION

This recommendation system assumes that a patient is in full control of his or her decision regarding storage. It is impossible to make decisions manually in many cases because they are made so frequently. Hence, automated processes are essential. In the mapping process, the characteristics of a repository managed by an agent group are matched with the characteristics of data about the storage requirements of patients. Because patients' storage requirements vary so much, it is impossible to predetermine every possible scenario. By utilizing a set

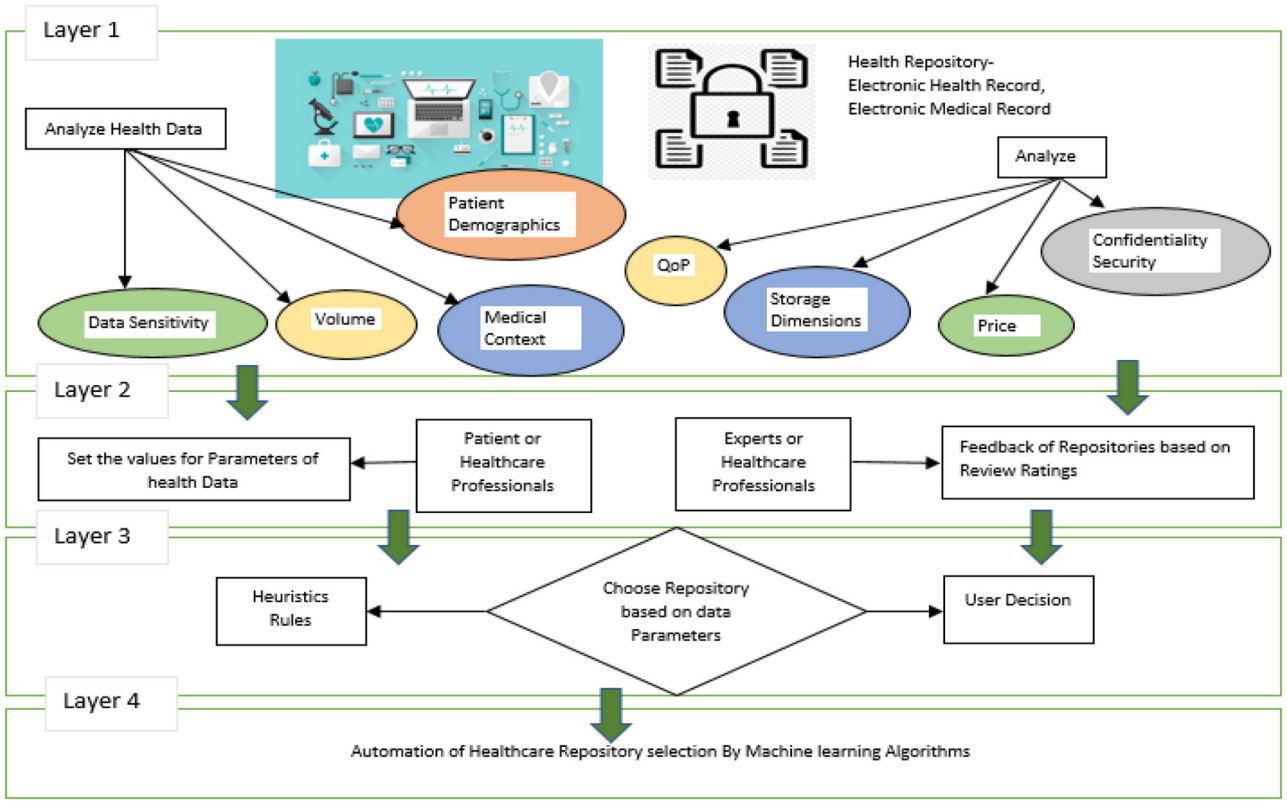

FIGURE 2 | Proposed system architecture.

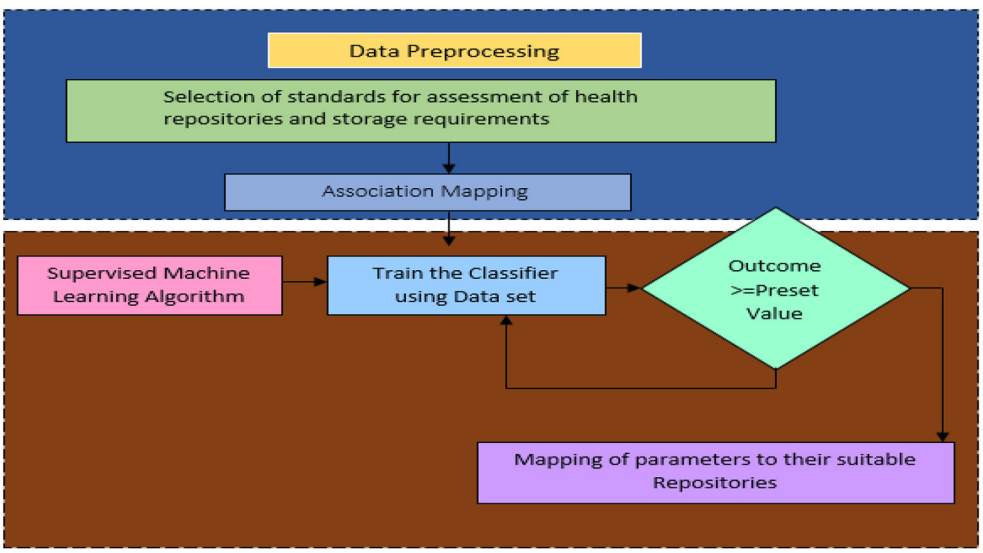

FIGURE 3 | Proposed health repository recommendation system.

of mappings that is specified manually by experts, machine learning is used to generalize a mapping over a wide range of patient contexts. This methodology involves defining a set of attributes that describe what chunk of data needs to be stored. There are numerical values and categorical values assigned to those attributes. Thus, a dataset containing these attributes will be created, with each instance representing a different set of storage requirements. A group of experts' ratings are then

used to determine the characteristics of the available storage mediums. To determine what class each instance falls into, statistical correlation and heuristic rules are employed. Based on the training datasets, the supervised machine learning classifier maps the data into a storage repository. **Figure 3** illustrates two components of the recommendation system: Data Pre-processing and Supervised Machine Learning. According to **Figure 3**, the upper portion of the framework contains the characteristics of the data storage requirements. There are a number of features that demonstrate the characteristics of health repositories. A number of associations were found between the two groups of features.

Data Preprocessing

The data collected from hospitals and patients undergoes a preprocessing process, which includes analyzing data storage requirements, identifying sensitive data areas, analyzing the volume of each record, analyzing the patient health profile, determining the demographics of patients, and analyzing health repository parameters as well as storage, cost, security, privacy, and performance.

Characteristics of Data Storage Requirements

To determine which repository is the best option, consideration is given to the sensitivity of the data, the volume of the data, medical care context, and demographics of the patient.

Sensitivity of the Data

It is imperative to prevent unauthorized access to all health-related data. Depending on the data type, some breaches are more likely than others. Depending on the individual's preferences and context, the level of data sensitivity may vary.

The Volume of the Data

Reports, medical diagnoses, and medication summaries are not frequently created, which means that their storage needs are less than those of health data sets.

Context of Medical Care

The context may be palliative care, critical care, chronic illness, or no chronic illness. The context may also differ based on the country.

Demographics of Patients

Several factors can play a significant role in determining which storage medium to use, such as socioeconomic status, occupation, education, and nationality.

Health Repository Evaluation Parameters

Evaluation parameters for health repository such as security, privacy, cost, storage capacity, and performance. **Table 1** shows the parameters and criteria of the health repository evaluation.

The Relationship Between Repository Evaluation Standards and Data Features

Medical records, in particular those generated by patients, are to be transferred to a health record system that reflects the preferences of the user and the data requirements. Health data requirements and criteria for evaluating storage are correlated in a one-to–to-many fashion as implemented in **Algorithm 1**. Some associations are strong, and some are weak. To facilitate the rapid processing of highly confidential data, a health record system may accept data blocks in plaintext format. Data with relatively low confidentiality can be highly sensitive due to the demographic characteristics of patients. Data about a patient's demographics, such as their educational background and professional experience, may affect their privacy concerns. Users can then choose from a variety of storage repositories that

TABLE 1 | Health repository evaluation.

Assessment parameters	Survey questions for health repository ratings
Storage	Can the repository be used to store Big Data?
	Regarding processing Big Data, what is the repository's role?
	Are there any benefits to storing continuously streamed data in the repository?

protect their confidentiality. The sample association mapping as shown in **Table 2**.

Supervised Machine Learning Algorithm

Dynamically suggest health repositories based on supervised learning for particular data blocks, which is implemented using **Algorithm 2**. A training dataset must be generated for every instance of the dataset in addition to the labeled training datasets. Health repositories will be assigned data blocks that have a number of attributes. Among the attributes are some that are directly linked to the data block and others that are directly linked to the patient. Attributes include data sensitivity, volume, context of care, and demographics of the patients. The health repository should consider for evaluation such as electronic health records, cloud based electronic health records, blockchain based electronic health records, patient health record, and Electronic Medical Records. We considered the following health repository parameters in this study: security, privacy, cost, storage capacity, and performance. Each repository has been assigned a rating value ranging from 1 to 10.Whenever other attributes are not significant in determining the health repository, a linear regression Y (1) is calculated to label the instance as shown in Equation 1.

$$Y = A + RX \tag{1}$$

$$\mathbf{R} = \mathbf{n}\left(\sum_{\mathbf{i}=\mathbf{1}}^{\mathbf{n}} \mathbf{xiyi}\right) - \left(\sum_{\mathbf{i}=\mathbf{1}}^{\mathbf{n}} \mathbf{xi}\right)\left(\sum_{\mathbf{i}=\mathbf{1}}^{\mathbf{n}} \mathbf{yi}\right) \tag{2}$$

$$\mathbf{A} = \frac{\left(\sum_{\mathbf{i}=\mathbf{1}}^{\mathbf{n}} \mathbf{yi}\right) - \mathbf{R}\left(\sum_{\mathbf{i}=\mathbf{1}}^{\mathbf{n}} \mathbf{xi}\right)}{\mathbf{n}} \tag{3}$$

Where R is the Coefficient which contains R1,R2,R3,R4,R5,R6,R7,R8,R9,R10 are calculated between the set of data storage requirements(DR) as shown in equation 2. Here are the evaluation criteria for Electronic health record (D1), Patient health record (D2), Cloud-based electronic health record (D3), Blockchain-based electronic health records (D4), and Electronic Medical records (D5). The calculation of health repository recommendation Di is estimated using the equation:

$$\boldsymbol{Di = High\ (R1,\ R2\ldots..Rm)} \tag{4}$$

M is the number of health repositories and n is the rating criteria. Secondly, the choice of a health data repository can be influenced by the decision of the healthcare professional, the preferences of the user, and a variety of factors such as normal or abnormal behavior patterns and patient health status, as well as other demographic factors. Patients with unusual health patterns should store their health records in a repository that health care professionals can access quickly. A less secured and less expensive repository can be used to store data which is hardly ever accessed by health care professionals. Different users may have different privacy preferences, and those preferences may change over time based on different contexts (31). The health record system for a patient should take into account a variety of factors. There are several factors involved, such as medical conditions, personal characteristics, socioeconomic status, as well as the type and significance of data. The level of privacy and security preferences of individuals may change over time as well. In contrast to patients with terminal illnesses, young individuals may be more concerned with privacy and security. By considering author preference, some of the sample user preference and health professional preference heuristic rules were implemented, as shown below:

1. If (Data= standard && volume=large)

   Then
   Storage Repository=Cloud based Health Record Management System

2. If (Data= standard && volume=low)

   Then
   Storage Repository=Blockchain enabled Personal Health Record System

3. If (Data=Unusual patterns && volume=low)

Store data in Disease Registry

RESULTS AND DISCUSSION

Research was conducted on supervised machine learning classification techniques. Using the WEKA tool, different classification algorithms were tested. The study used an Intel Core i7 6700H processor with up to 3.5 GHz and 16 GB of RAM. The dataset was divided into training and test sets. Data preprocessing is performed prior to analysis. To train the data in the recommended health repository, linear regression data blocks and user and health professional preference rules have been used. During this experiment, we determine whether the classifiers can learn how to classify data distributions. The training datasets each

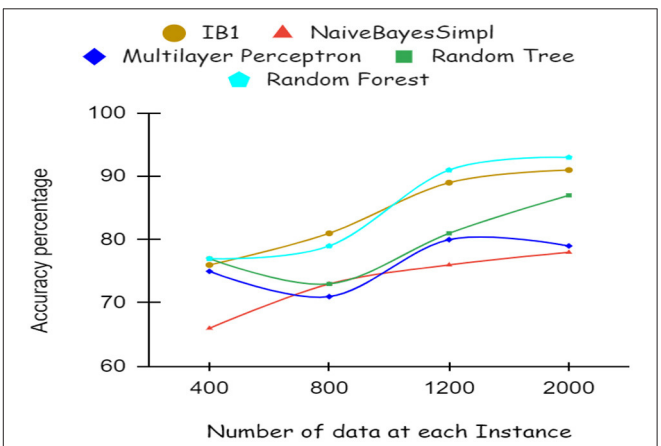

FIGURE 6 | Accuracy of percentage split dataset.

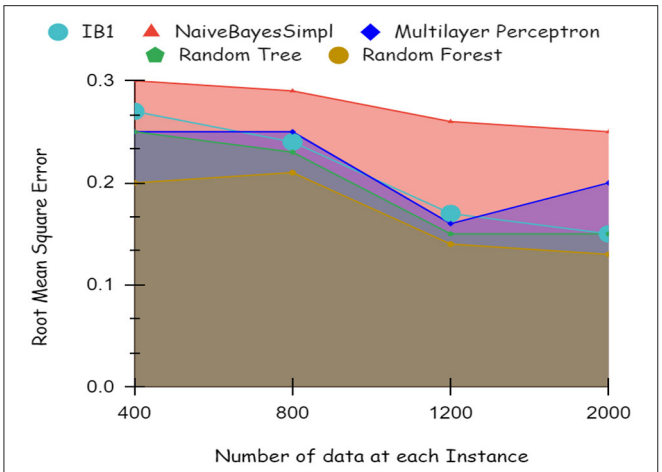

FIGURE 7 | RMSE of percentage split dataset.

FIGURE 8 | Performance loss of training and test set.

contain 400, 800, 1200, and 2000 instances. **Table 3** shows the mapped sample training dataset.

Four different classifiers were run on four datasets to test whether a machine learning algorithm could choose an appropriate storage medium, NaïveBayesSimple, Multilayer Perceptron, Random Forest Classifier, Random Tree and the IB1 algorithm are four different types of classifiers trained here. Several classification techniques were compared using Python to determine their accuracy scores (32).

Classification Model Accuracy

1. Confusion matrix.
2. Classification measure.

Confusion Matrix

In the confusion matrix, N is the number of target classes, and N is the number of rows. It is used to evaluate the performance of a classification model. Machine learning is used to predict target values from the actual values in the matrix. True Positive (TP) and True Negative (TN) rates should be high and False Positive (FP) and False Negative (FN) rates are low for a successful model. A confusion matrix as is always more appropriate as a machine learning model evaluation criterion when working with an imbalanced dataset.

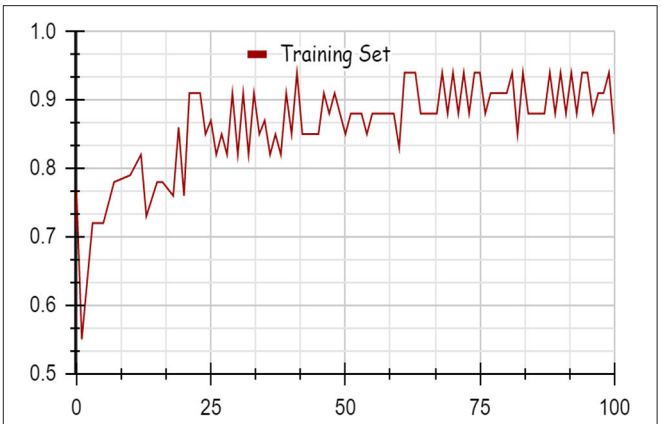

FIGURE 9 | Performance accuracy of training and test set.

Classification Measure

As an evaluation measure, the classification measure is used in addition to the confusion matrix. They are:

1. Accuracy.

$$\textbf{Accuracy} = \frac{\textbf{TP} + \textbf{TN}}{\textbf{TP} + \textbf{TN} + \textbf{FP} + \textbf{FN}} \quad \textbf{0.0} < \textbf{Accuracy} < \textbf{1.0} \tag{5}$$

2. Precision.

$$\textbf{Precision} = \frac{\textbf{TP}}{\textbf{TP+FP}} \tag{6}$$

3. Recall.

$$\textbf{Recall} = \frac{\textbf{TP}}{\textbf{TP+FN}} \tag{7}$$

4. F1-Score.

$$\textbf{F1-Scrore} = 2\frac{\textbf{Recall}^{*}\textbf{Precision}}{\textbf{Recall+ Precision}} \tag{8}$$

5. Sensitivity and specificity.

$$\textbf{Sensitivity} = \frac{\textbf{TP}}{\textbf{TP+FN}} \tag{9}$$

$$\textbf{Specificity} = \frac{\textbf{TN}}{\textbf{TN+FP}} \tag{10}$$

6. Root mean square error.

Modified Mean Square Error (MSE) is a variation of Root Mean Square Error (RMSE). Measuring the mean square error squared is equivalent to this metric. The RMSE of an ideal model is zero, just as the MSE and MAE are zero.

$$RMSE = \sqrt{\frac{1}{\mathbf{n}}\sum_{\mathbf{i=1}}^{\mathbf{n}}(\textbf{Actual Values} - \textbf{Predicted Values})^{2}} \tag{11}$$

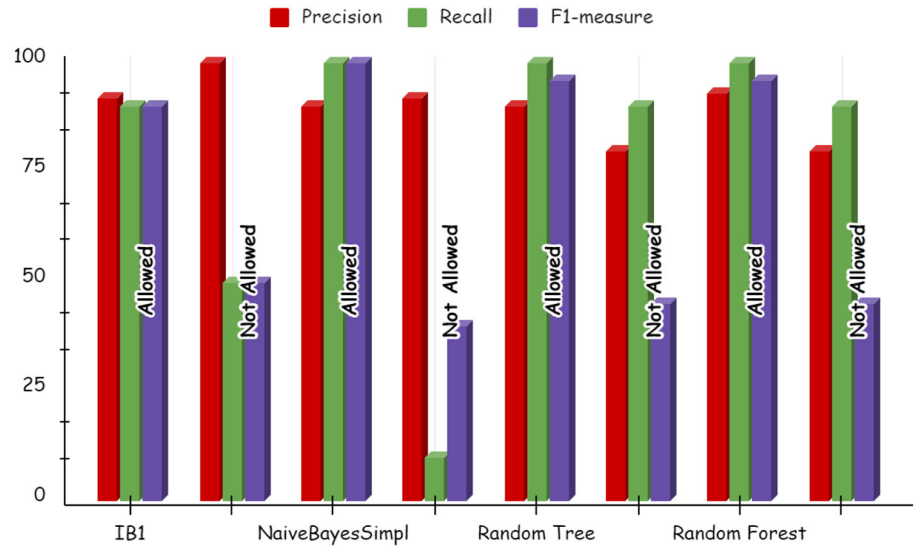

FIGURE 10 | Deep learning results for cloud electronic health record.

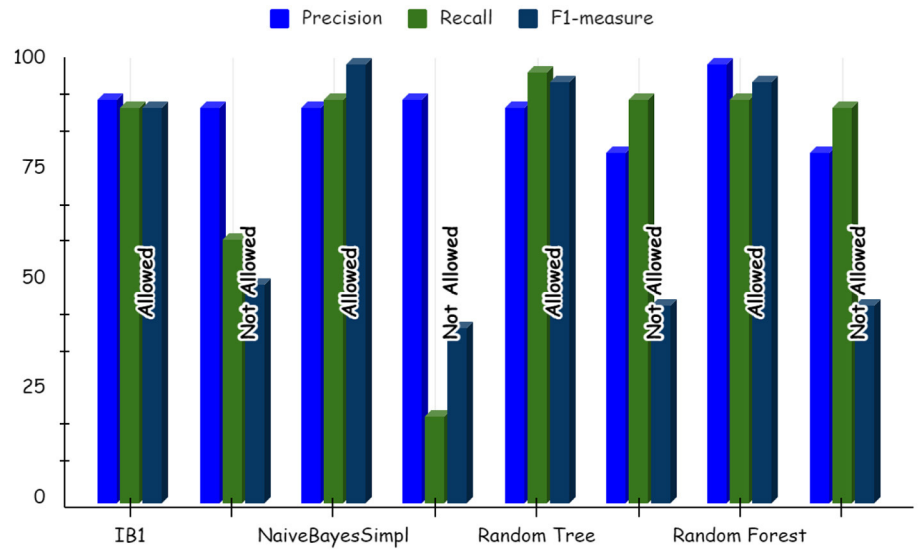

FIGURE 11 | Deep learning results for blockchain based electronic health record.

Result Analysis

As illustrated by the graph in **Figure 4**, Random Forest classifiers become more accurate as the number of instances increases, as shown by a 10-fold cross-validation analysis. A balanced ratio of each class was found in the dataset of 1,200 records, thus all classifiers performed better. The Random Forest performed best, with 98.21% accuracy. On the 2,000-record dataset, however, all classifiers had lower accuracy, largely because the dataset was skewed. Compared to other classifiers, Random Forest exhibits lower root mean square error in **Figure 5**. **Figure 6** illustrates the percentage split results, which are less accurate than the cross-validation results presented in 10-fold cross-validation.

By using a percentage split, 80% of the data were used for training and 20% for testing. The classifier is trained only once, as seen in **Figure 7**, which demonstrates low accuracy and large RMSE. Artificial intelligence is a technique for deep learning.

Using deep learning networks, unstructured or unlabeled data can be learned unsupervised. Real-world health repositories are usually recommended based on unstructured and unlabeled datasets. For our synthetic dataset, we analyzed the accuracy using a deep learning algorithm. A deep learning model is run on the synthetic dataset, and it shows 88.70 percent accuracy. It is implemented in Python. There are three hidden layers in the model; the first of these layers has 100 output nodes,

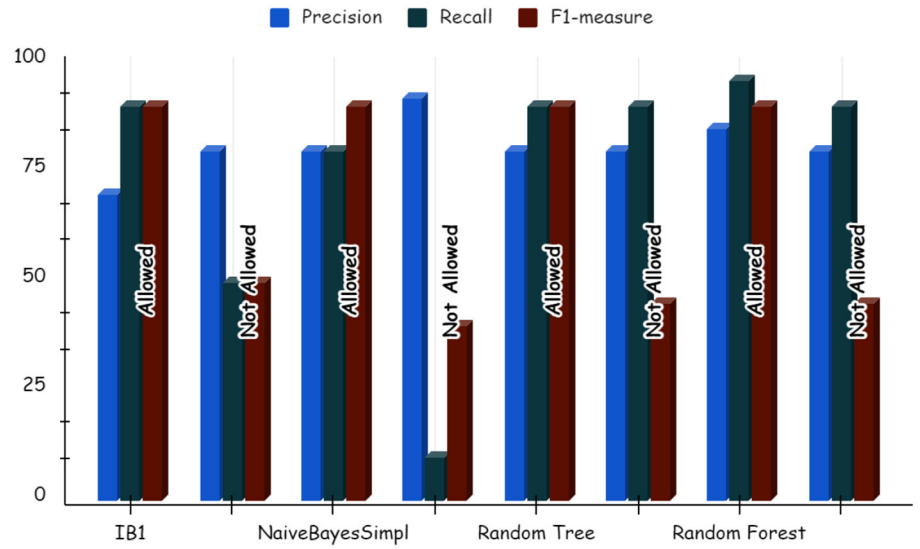

FIGURE 12 | Deep learning results for electronic medical record.

while the second and third have five output nodes each. Training is done with 100 iterations and eight batches are used. The training dataset is shown in **Figures 8**, **9**, with a Y-axis showing the loss and X-axis showing the number of iterations. A deep learning classifier and a machine learning classifier are displayed in **Figures 10–12** for the classification. With reference to recall, F1-measure, and precision, the Random Forest classifier outperformed the other tested classifiers. Classes that were allowed and those that were not were included in the experiment. In terms of recall, precision, and F1-measure, the Random classifier scored 93, 100, and 96% for cloud electronic health records, 100, 92, and 96 for blockchain-based electronic health records, and 85, 96, and 90 for electronic medical records. In terms of the allowed class, the rest of the experimented models perform well. In terms of the disallowed class, they did not perform well.

The accuracy of the classifier supports the use of machine learning to map the health storage mediums to health data blocks. Given the growing volume of health data that will need to be stored and accessed globally, this machine learning model may play a crucial role in improving storage and access arrangements in the future. This will make health data storage easy and straightforward for consumers. In addition, they would be able to ensure that the size of the data store is manageable. It can help to determine which storage solution best fits the requirements of different data assets using a machine learning model.

Mapping of Health Data Parameters to Repositories

Medical technology is expected to develop health record systems in the future. Health records are taking on novel forms as a result of the expansion of medical data. As described below, the proposed system will support various data variations and health records. First, the system requests the ratings for the latest health record on the basis of health parameters from the IT staff and healthcare professionals. Second, the system relabels instances from the entire training dataset. As soon as a new instance is created, the old instances' labels do not change.

CONCLUSION

Health data will increasingly be preserved in a variety of repositories, so patients can select the repository that best meets their needs. Patients are realistically expected to avoid using a single repository for all their health data because the context of treatment, patterns of data, and legal constraints may change. To automate the storage decision, a selection algorithm must be developed. This is especially relevant in the case of constantly streaming health data. The process of choosing the right repository is complicated. In addition to knowledge of storage features used for interoperability, data security, and privacy, regulatory concerns must also be considered. To preserve confidentiality, we propose distributing health data among various vendors. By keeping medical records together, confidentiality will also be preserved. Based on factors like data type, sensitivity level, significance, patient safety, and privacy requirements, this model can recommend which health data blocks should be stored on which storage medium. When applied to the dataset generated, random forest yielded the highest accuracy of 96.4%. Accuracy of algorithms depends on the dimension, origin, and nature of the data. As a result, we intend to evaluate these various algorithms with different characteristic datasets in the near future. In the future, we will implement a role-based access control system to store medical record information by

integrating the health repository recommendation system to allow access to the health records based on the permission of patients.

Today, disease detection automation is widespread in healthcare systems. The diabetic disease is a significant problem that has spread widely all over the world. It is a genetic disease that causes trouble for human life throughout the lifespan. Every year the number of people with diabetes rises by millions, and this affects children too. The disease identification involves manual checking so far, and automation is a current trend in the medical field. Existing methods use a single algorithm for the prediction of diabetes. For complex problems, a single model is not enough because it may not be suitable for the input data or the parameters used in the approach. To solve complex problems, multiple algorithms are used. These multiple algorithms follow a homogeneous model or heterogeneous model. The homogeneous model means the same algorithm, but the model has been used multiple times. In the heterogeneous model, different algorithms are used. This paper adopts a heterogeneous ensemble model called the stacked ensemble model to predict whether a person has diabetes positively or negatively. This stacked ensemble model is advantageous in the prediction. Compared to other existing models such as logistic regression Naïve Bayes (72), (74.4), and LDA (81%), the proposed stacked ensemble model has achieved 93.1% accuracy in predicting blood sugar disease.

INTRODUCTION

People's regular foods contain a vast amount of carbohydrates and calories. Three primary reasons that a person may suffer from diabetes are genetics, lifestyle, and environment. The first reason for diabetic positivity is genetics. Family studies proved that the children whose parents are type 2 [Muoio and Newgard (1)] diabetic have three times more chances to develop diabetic positive than the parents who don't have diabetic positive. Lifestyle is the second reason for the diabetic positive because proven studies show that the individual lifestyle causes diabetic positive even though their ancestors are not diabetic positive. The third reason for the diabetic positive is adopting intricate weight loss mechanisms. It causes kidney failure or heart issues that lead to diabetes positive in the future.

The symptoms for the diabetic positive are eye powerlessness, sudden weight loss, frequent urination, frequent hunger, and thirst. Due to these types of factors, diabetes (sugar patients) risk has increased worldwide. The diabetic disease has become a significant issue in the world. This disease is categorized into two types: type 1 and type 2. According to the International Diabetes Federation (IDF), 463 million people worldwide will have diabetes in 2019 and by 2045, this will rise to 700 million. Early detection of diabetic positives helps reduce patients' medical expenditure, death rate, and risk because they may not have proper health care facilities nearby.

The diabetic patient is categorized into two categories, namely type 1 and type 2. Type 1 diabetic patients are dependent on insulin to control the disease. Type 2 diabetic patients are non-dependent on insulin to control the disease. The diabetic-positive patient has a high risk of several problems such as cardiac arrest, kidney failure, dry skin, paralysis, eye problems, etc. Rural area people are unaware of early-stage symptoms to prevent this diabetic disease, and they are unaware of early-stage symptoms to prevent this diabetic disease.

Diabetes patients increase irrespective of age across all regions of the world, and there is no medicine (vaccine) to prevent it. The diabetic positive type 2 patient body makes gradually used insulin. The insulin increases the blood sugar to save energy into the cells for later usage. The diabetic positive diagnosis or confirmation is made at the hospital through conducting various lab/clinical tests. In this modern life, people are interested in saving their time to save money. It leads to many health complications; one of these is diabetic disease. The proposed system is one of the automated processes of early prediction of diabetic positives. There are several machine learning models were proposed for predicting the person with diabetes positively. The proposed model has outperformed in terms of prediction of diabetic positive compared to other existing models and has achieved 93% accuracy as a detection rate.

Limitations on Existing Works

The existing approaches in the prediction of diabetic positive are discussed in the next section. Most of the existing works use only a single algorithm, which is used to predict whether the patient is diabetic positive. There are two problems if one algorithm is used for predicting the output. The first problem is that a single algorithm is not sufficient for prediction. Also, the selected dataset may not fit that algorithm. These problems lead to less accuracy in output prediction. The proposed system has used multiple machine-learning algorithms to predict whether the patient has a diabetic positive or not.

Main Contributions of the Current Work

The proposed system has considered the increasing number of diabetic-positive patients, one of the common problems of all countries globally. Every country has suffered from two main problems without solutions. One is climate change and increasing diabetic positive patients. Thus this paper has investigated the common health issue, diabetic positive, which has no proper software system to predict with high accuracy. This paper has adopted several machine learning algorithms for automating the prediction of diabetic positives. Since the proposed system is a generic model for diabetic prediction, this software system can be used in any region in the world.

LITERATURE REVIEW

Dhomse Kanchan and Mahale Kishor (2) used multiple machine learning algorithms for rare disease prediction. Kavakiotis et al. (3) proposed multiple machine learning models for the diabetic positive prediction. Kononenko (4) surveyed various medical diagnoses using several artificial intelligent approaches. Kandhasamy and Balamurali (5) used various data mining models such as J48, KNN, and Random Forest, SVM, to predict diabetes mellitus under two different situations (one is before pre-processing and another is after pre-processing). Iyer et al. (6) employed two techniques, namely J48 and Naïve Bayes, to classify diabetic patients. The model J48 approach has achieved 74.87% and Naïve Bayes algorithm has obtained 76.96% accuracy in analyzing diabetes. Ashiquzzaman et al. (7) proposed a Deep Neural Network (DNN) to predict the diabetic positive. The DNN model is also adopted to reduce data overfitting.

Yuvaraj and SriPreethaa (8) adopted Hadoop clustering model for prediction of diabetic positive on big data. Sisodia and Sisodia (9) used Decision Tree, SVM, and Naive Bayes to predict diabetes. The SVM has obtained 65.10% of accuracy using SVM, and Naïve Bayes classifier has obtained 73.82%. Negi and Jaiswal (10) developed a machine learning model for diabetic prediction on different global datasets. This approach is a first attempt of diabetic prediction on global datasets. Soltani and Jafarian (11) proposed a Probabilistic Neural Network (PNN) model for diagnosing diabetes type 2 using the PIMA Indians Diabetes data set. This PNN approach has achieved 90% accuracy in analyzing diabetes. Rakshit et al. (12) used a Two-Class Neural Network to predict diabetes. This model has achieved an 83.3% detection rate of type 2 diabetes. Mamuda and Sathasivam (13) compared four machine learning approaches, Naïve Bayes, Quadratic Discriminant Analysis, Linear Discriminant Analysis, and Gaussian Process Classifier, and obtained the accuracy as 81.97% with respect to cross validation of 10.

Farran et al. (14) proposed several prediction models to predict the risk factor of diabetic two positive patients. Anand and Shakti (15) combined multiple machine learning models to predict the diabetic based on personal lifestyle indicators. Malik et al. (16) proposed a non-invasive detection model for blood glucose level using saliva. Mirshahvalad and Zanjani (17) proposed multiple ensemble techniques for diabetes prediction. Mohebbi et al. (18) developed a deep learning model to detect type 2 diabetics. Pham et al. (19) developed a deep learning model for analyzing medical records to predict the trajectories. Askarzadeh and Rezazadeh (20) proposed a neural network model to achieve an effective training novel optimization algorithm for the clinical data analysis. Rao et al. (21) developed a combined classifiers for disease diagnosis. Kopitar et al. (22) employed three techniques, namely Random Forest algorithm, Naïve Bayes classifier, and KNN, for predicting the diabetic. Apart from these machine learning algorithms for predicting

diabetic positive, they also applied XGBOOST, Glmnet, and LightGBM methods for diabetic prediction. Among these methods, the XGBOOST outperformed in diabetic prediction. It has obtained 88% accuracy. Naveen et al. (23) adopted five different machine learning algorithms, SVM, selection Tree, Naive Bayes, Logistic Regression, and KNN, to predict the diabetic positive in the PIMA dataset. This combined machine learning algorithm has obtained 75% accuracy in diabetic prediction.

Butt et al. (24) adopted LSTM to predict the diabetic positive in the PIMA dataset. The machine learning models played a major role in data analysis particularly in clinical data analysis. Thus, the proposed work has adopted machine leaning models for the diabetic positive prediction. Apart from this diabetic positive prediction, the machine learning models are also helpful in other clinical data analysis such as heart disease, cancer tumor, and COVID-19 predictions. The following recent research is evidence for the above statement. Jain et al. (25) proposed several machine learning models to predict COVID-19 positive from B-cell dataset. Shubham et al. (26) proposed deep learning based

for identification of glomeruli in the human kidney. Mohan et al. (27) employed two techniques, namely Decision Tree and Gradient Boosting machine, to predict heart disease. Kumar et al. (28) developed popular RNN model and Reinforcement learning model for COVID-19 prediction. Ngabo et al. (29) proposed several machine learning models and Reinforcement Learning Model for COVID-19 prediction. Iwendi et al. (30) proposed boosted random forest algorithm for COVID-19 disease prediction. Deepa et al. (31) developed an intelligent system based on AI with GDM approaches for healthcare analysis. Dhanamjayulu et al. (32) proposed an image processing technique to identify malnutrition from facial images.

Iwendi et al. (33) proposed a model called N-sanitization, which is used to analyse the unstructured medical datasets for various disease diagnosis. Ahmed et al. (34) used multiple machine-learning models, namely J48, Logistic Regression (LR), and Naïve Bayes (NB). The model of J48 achieved 73.5%, Logistic Regression gained 74.4%, and Naïve Bayes achieved 74.2% with 10-fold cross-validation. Kalra et al. (35) performed a detailed study on diabetic type 1 patients' medical records. **Table 1** shows the accuracy details of diabetic positive prediction with respect to existing works.

METHOD AND TECHNIQUES

Ensemble Techniques

In the conventional approach, only one machine algorithm is used for problem-solving. But the single algorithm is not enough for the complex problems. That algorithm may not fit to the input data due to parameter constraints, input data format constraints, and so on. That is the reason that combining more than two machine algorithms, called an "ensemble model," becomes popular. But the popular question on the ensemble technique is, "How do ensemble models achieve better performance than single approach?" The answer is simple. Just as diversity in nature contributes to more robust biological systems, ensembles of ML models produce stronger results by combining the strengths (and compensating for the weaknesses) of multiple sub models. The proposed system adopts multiple machine learning algorithms (ensemble) to predict the diabetic.

The Ensemble technique has three categories, bagging, boosting, shown in **Figure 1**. Each model has its merit and demerits. Among these three, the proposed system has used stacked ensemble modeling for predicting diabetic positive. **Table 2** shows the performance analysis of three ensemble models. From **Table 2**, the stacking is better compared to the other two models in improving the accuracy. In the healthcare system, prediction accuracy is a significant feature to evaluate the system. Since diabetic positive or negative prediction is under the healthcare system, the stacked ensemble approach is used in the proposed model.

Stacking

Stacking is a two-level classification technique, namely level-0, level-1, or Meta classifier. Unless conventional bagging and boosting, the stacking creates a new training dataset for the final prediction. This approach is entirely different from other multi-classifier algorithms because other multi-classifier approaches use the averaging or voting for the final prediction. But the stacking relays on the predicted probability set, which is generated from all the classifiers. In level 0, more than one algorithm is used. Level 0 works in either a homogeneous or heterogeneous algorithm set. In homogeneous, the same algorithm is used with different parameters, whereas different algorithms are used in heterogeneous. These level-0 algorithms are trained from the original dataset. After the training, the algorithms do not predict the final output. Instead, the probabilities of each class are predicted. Each algorithm predicted the probability of each class and finally generated the predicted probability set. This set will be given as the input to the level-1 algorithm. The level-1 algorithm is trained from the predicted probability set for the final prediction.

TABLE 2 | Ensemble techniques comparisons.

Bagging	Boosting	Stacked
Multiple Classifiers are trained parallelly.	Builds the new learner in a sequential way.	Multiple Classifiers are trained parallelly.
The result is obtained by averaging the responses of the N learners.	On each iteration, update the model by weights until the desired result is obtained.	The result is obtained from the second level classifier.
Reduces the variance.	Reduces the bias.	Increases the accuracy.

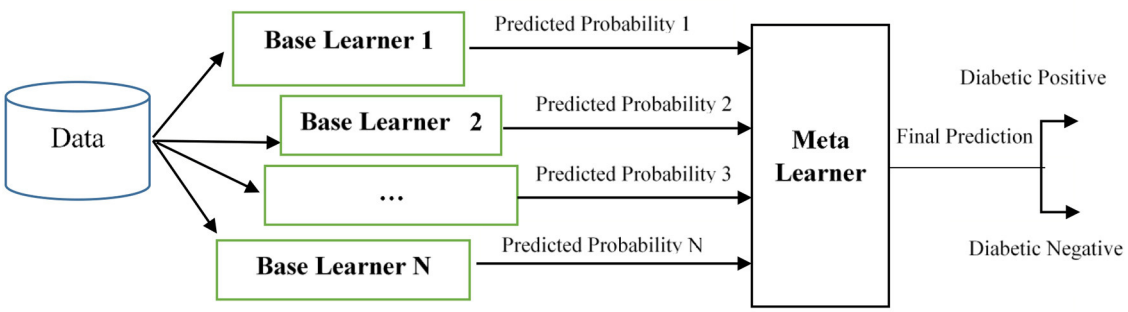

FIGURE 2 | Stacked ensemble model.

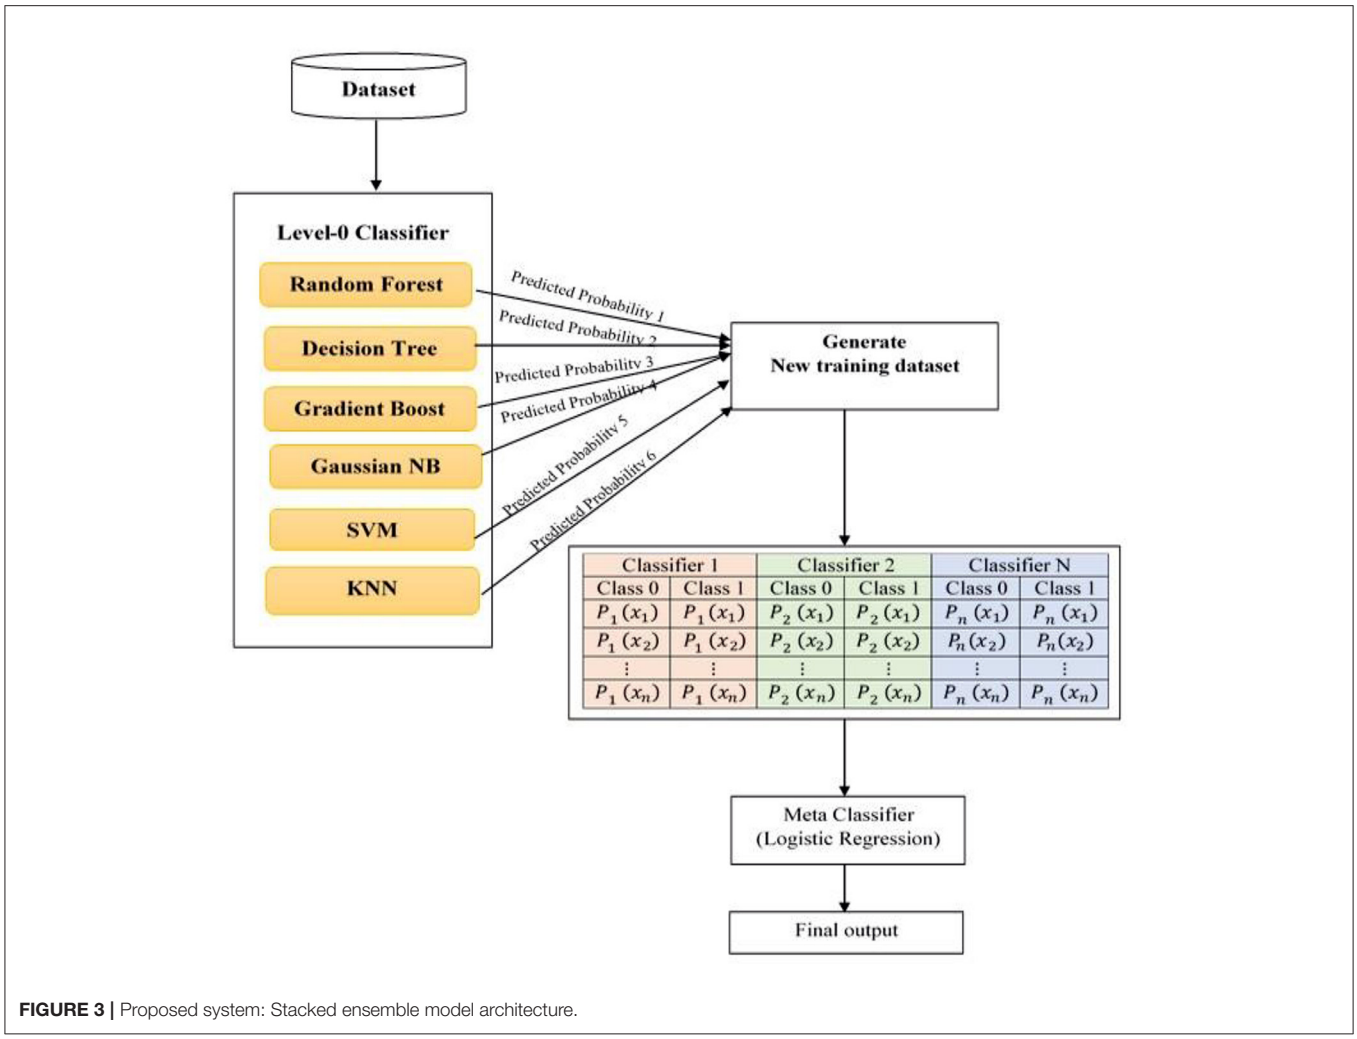

FIGURE 3 | Proposed system: Stacked ensemble model architecture.

The generic model of the proposed stacked ensemble model is shown in **Figure 2**. In **Figure 2**, the base learners 1, 2… N are level-0 classifiers, also called as weak learners. The base learners are trained from the dataset to construct the new training set. Meta learner is the level-1 classifier, and it will be trained with the newly created set. After training, the level-1 classifier will predict the test set.

Level-0 Classifier

Figure 3 depicts the proposed system architecture. The proposed system has selected six different type of machine learning models as level-0 classifiers.

The selected level-0 classifiers are Random Forest, KNN classifier, Decision tree, Gradient Boosting, SVM, and Gaussian Naïve Bayes added as base classifiers. These base classifiers are trained with the original dataset and output a new training dataset for the level-1 classifier.

The advantage of a level-0 classifier in the stacked ensemble technique is two-level classification. In the conventional approach, only one machine algorithm is used for problem-solving. The stacked ensemble learning model is called a multiple classifier system that uses base classifiers to build new training data to classify unknown data. In **Figure 3**, the level-1 classifier logistic regression is represented as a Meta classifier. The level-0 classifier predicted probability output is given as input to the logistic regression Meta classifier.

TABLE 3 | Level-0 Input Set.

Attribute Set	Target output label
$AttrVec_1$ (1st row)	y_1
$AttrVec_2$ (2nd row)	y_2
$AttrVec_3$	y_m
⋮	⋮
$AttrVec_n$ (nth row)	y_2

Level-0 Classifier Input

For the level-0 classifiers, the input is the original dataset. The dataset consists of an input vector set ($AttrVec_1$,

Classifier-1				...				Classifier-k				Actual
a1	a2	...	an	...	...	...	...	a1	a2	...	an	
$P_1(x_1)$	$P_1(x_1)$	...	$P_1(x_1)$	...	...	...	...	$P_k(x_1)$	$P_k(x_1)$	...	$P_k(x_1)$	y_1
$P_1(x_2)$	$P_1(x_2)$	...	$P_1(x_2)$	...	...	...	...	$P_k(x_2)$	$P_k(x_2)$	...	$P_k(x_2)$	y_2
⋮	⋮	⋮	⋮	...	...	...	...	⋮	⋮	⋮	⋮	y_m
$P_1(x_n)$	$P_1(x_n)$	...	$P_1(x_n)$	...	...	...	...	$P_k(x_n)$	$P_k(x_n)$	...	$P_k(x_n)$	y_2

FIGURE 4 | Level-1 classifier input set.

$AttrVec_2 \ldots$ $AttrVec_n$) and the output attribute is ($y_1, y_2, \ldots, y_n$). The format for the level-0 input is given in **Table 3**.

Proposed System Level-0 Classifiers

Random Forest

This is one of the supervised machine learning algorithms. It is used to solve classification and regression problems. The random forest builds the forest from decision trees to solve the problem and improve its performance. The decision tree consists of branches, internal nodes, and leaves. Leaf node represents the final result or class label. Internal nodes are evaluators which decide the branch selection on an attribute (e.g., whether age is eligible to vote or not). The following hyperparameters are used to build the random forest. The number of the estimator is assigned as n_estimators, maximum depth of the tree is assigned as max_depth, minimum number of the split is assigned as min_samples_split, a number of maximum features is assigned as max_features, and the number of a maximum leaf node is assigned as max_leaf_nodes. In addition, n_estimators is a hyperparameter, which indicates the number of decision trees to be generated for the prediction. A higher number of trees is recommended for better prediction, but it may increase the execution time. The default value of n_estimators is 10, and it can be increased up to 500 based on the problem. For the proposed system, the n_estimators is set to 10. That is, every attribute must have min_samples_split samples to divide into two splits. For the proposed method, min_samples_split is set as 2.

Gini index is used to generate the decision tree based on the input dataset. The equation for the Gini index is given below.

$$Gini = 1 - \sum_{i=1}^{c} (pi)^2 \quad (1)$$

C is the total number of classes in the dataset. For our problem, c is assigned as 2. In our Pima dataset, there are a total of eight input attributes and one output class label. The class labels are 1 and 0; 1 indicates the patient has diabetes, and 0 indicates that the patient has not diabetic. *pi* is the probability of selecting the branch among the branches in the ith level

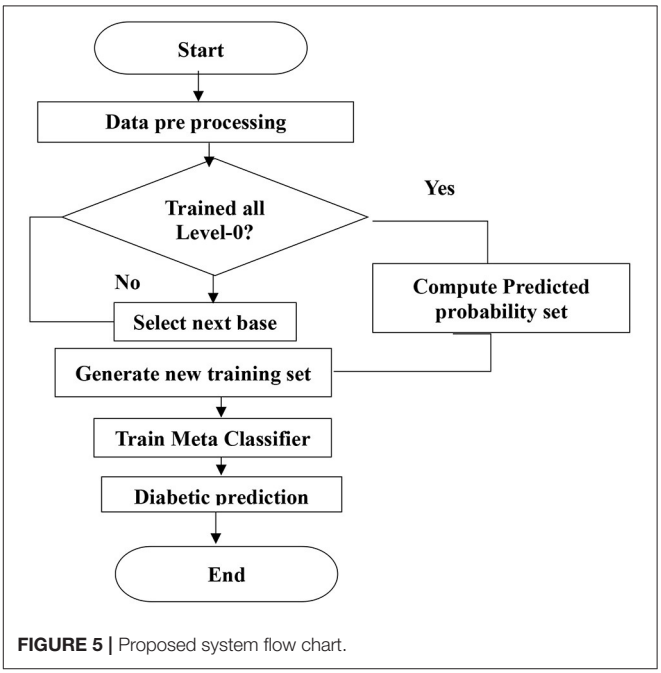

FIGURE 5 | Proposed system flow chart.

for the next level prediction. The proposed system algorithm is shown below.

K Neighbors Classifier

KNN is one of the supervised machine learning algorithms used for classification and regression problems. KNN finds the relationship between the sets X and Y, where X is the input attribute set and Y is the output data. In the KNN, similar training data points are grouped by capturing the distance between the data points. The lesser distance data points are closer than the broader distance data points. Euclidean distance method is used to compute the distance between the data. The following equation is used to calculate Euclidean distance method.

$$d = \sqrt{\sum_{i=1}^{k} (xi - yi)^2} \quad (2)$$

    end for

Decision Tree Classifier

This is a supervised machine learning model that is used for classification. It is a rule-based approach to solve the classification problem. Decision tree is built from the attribute set by applying the if-else pattern set. To create an if-else pattern set or rule set from the attribute, any one of the Gini index, entropy, or misclassification error methods is followed. The most popular approach is the Gini index. These methods are used to create the decision on the internal node and split the samples for the next level in the tree.

$$Gini = 1 - \sum_{i=1}^{c} (pi)^2 \tag{3}$$

$$Entropy = -\sum_{j} p_j \log_2 p_j \tag{4}$$

$$Misclassification\ Error = 1 - max p_j \tag{5}$$

Gradient Boosting

Gradient boosting is a tree-based machine learning algorithm. Boosting is a method that converts weak learners into strong learners. Initially, a tree is built with the dataset attributes and evaluates the model. In evaluation, the error is calculated by original error minus predicted error. This error is also called a classification error. That is, the rate of misclassification is high. This error is minimized or eliminated by building new trees in the subsequent iterations. The error and the first built tree are considered to build the second tree. The second tree is the improved version of the first model, where the misclassification is reduced while compared to the first model. The new tree is built in every iteration using the previous tree classification error

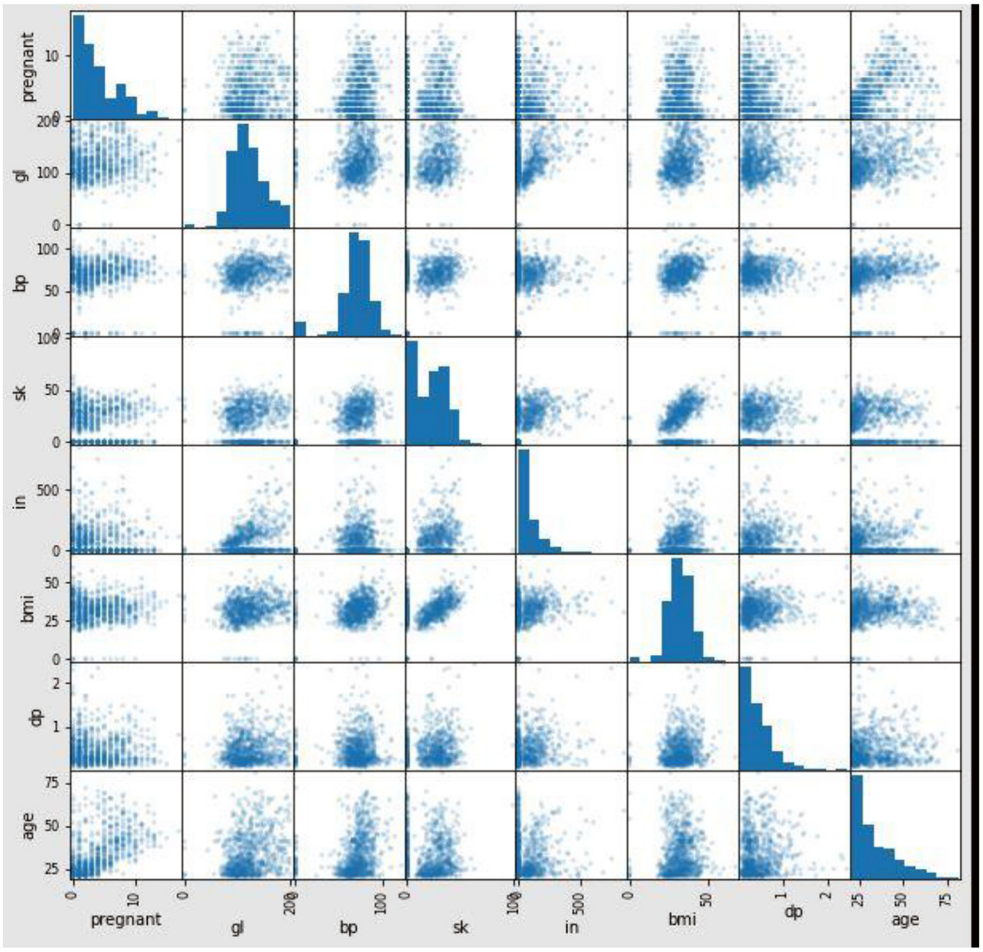

FIGURE 6 | Pearson correlation coefficient of Pima dataset input attributes.

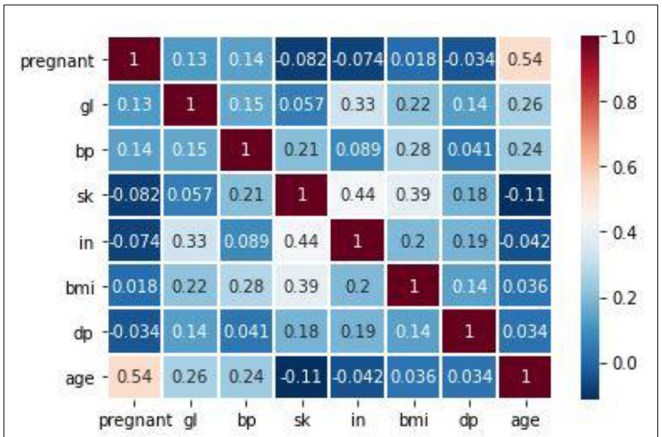

FIGURE 7 | Pearson correlation coefficient result of Pima input attribute set.

and the previous three. This new tree construction is continued until the error becomes negligible or no changes in the error. The following steps are followed for the classification in the gradient boosting approach.

1. Fit a decision tree to the data: $F_1(x)$
2. Fit the following decision tree to the residuals of the previous: $h_1(x) = y - F_1(x)$,
3. Add this new tree to our algorithm: $F_2(x) = F_1(x) + h_1(x)$,
4. Fit the next decision tree to the residuals of F_2: $h_2(x) = y - F_2(x)$,
5. Add this new tree to our algorithm: $F_3(x) = F_2(x) + h_1(x)$,
6. Continue this process until the desired output is reached.

The generic formula of GBM is given in Equation 6.

$$f(x) = \sum_{b=1}^{B} f^b(x) \tag{6}$$

Support Vector Machine (SVM)

SVM is a supervised machine learning approach used for both classification and regression problems. SVM is best suited for classification-related problem-solving approaches. In this approach, the data points are placed in the n-dimensional space, where n is the output classes or features. The SVM is well-suited for binary classification than multiclass

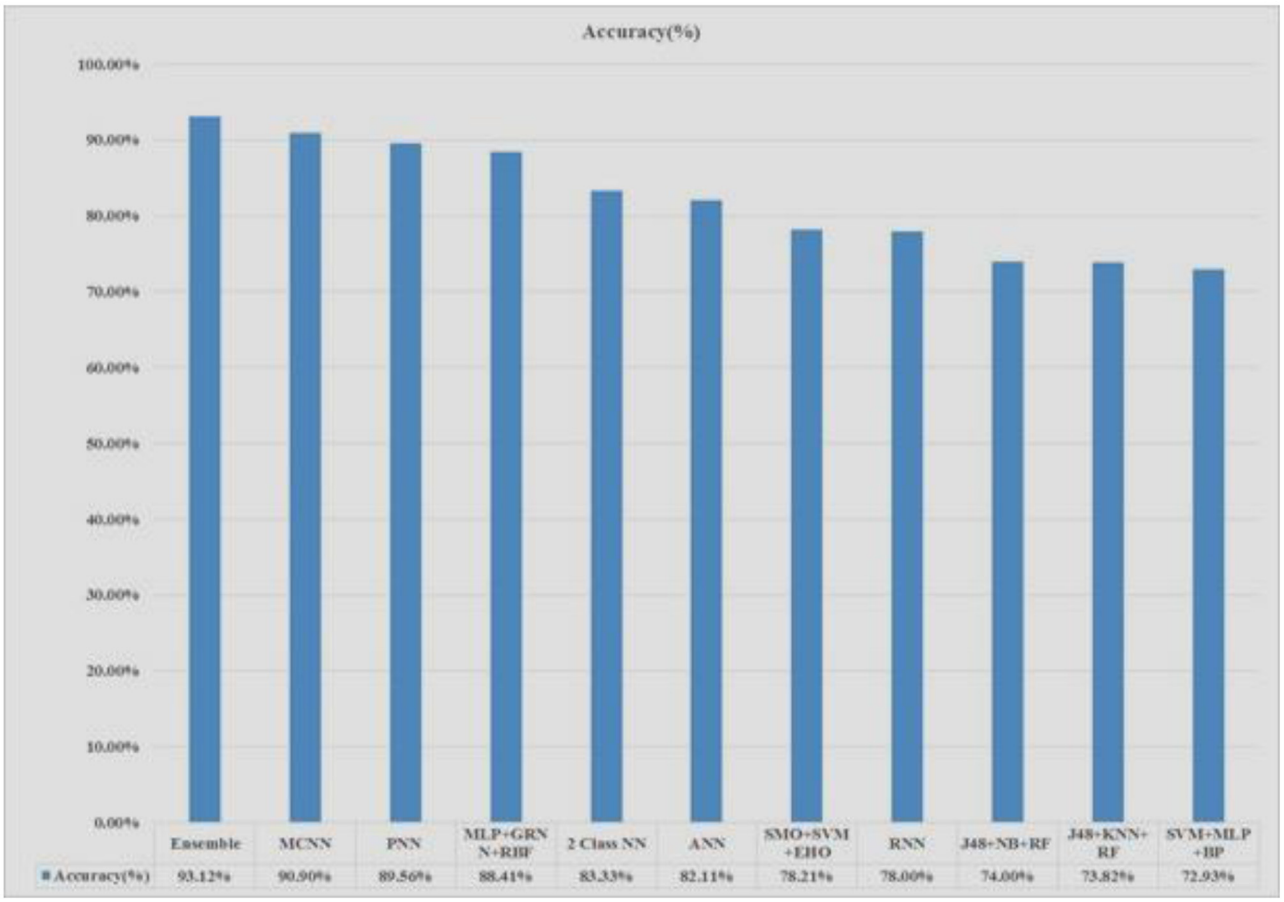

FIGURE 8 | Accuracy chart of various models and proposed model comparison chart.

classification. Equations 7 and 8 are used for computing classification output.

$$w^T X + b \geq c \tag{7}$$

$$w^T X + b < c \tag{8}$$

If the weight matrix and input vector result are higher than c, then the classification output is y1; otherwise, the classification output is y2. Here y1 and y2 are the output class labels.

Gaussian Naïve Bayes

This is a special type of Naïve Bayes approach and suitable for classification problems. It is a supervised machine learning algorithm. It works under the principle of Bayes theorem. The conditional probability calculation is shown in Equation 9.

$$p\,(Y|x_1, x_2, \ldots, x_n) = \frac{p\,(Y)\,p(x_1, x_2, \ldots, x_n|Y)}{p(x_1, x_2, \ldots, x_n)} \tag{9}$$

Level-1 Classifier or Meta Classifier

Figure 4 shows the level-1 classifier input set. For level 1, the logistic regression model is used for the final prediction; this model is trained with a new training dataset generated in level-0 classifiers. The flow chart for the proposed system is shown in **Figure 5**.

This dataset consists of set predicted probabilities of each class of each classifier. A row ri is the predicted probabilities base classifiers of each class of ith row of the original dataset. The formula for the final prediction is done by using Equation 10.

$$p = \frac{e^{b0+b1(x)}}{1 + e^{b0+b1(x)}} \tag{10}$$

$b0$, $b1$ are the constants, and x is the input vector. p is the final prediction, which is >0.5, then the patient has diabetic positive; otherwise, the patient has diabetic negative.

PIMA DATASET DESCRIPTION

Table 4 shows the Pima dataset attributes description. This dataset consists of 768 rows and nine columns. The last column is the output class, containing 1 and 0; 1 indicates diabetic positive, and 0 indicates diabetic negative.

Figure 6 shows the correlation between the attributes in the dataset. The proposed method used Pearson's correlation method, which finds the relationship between the variables in

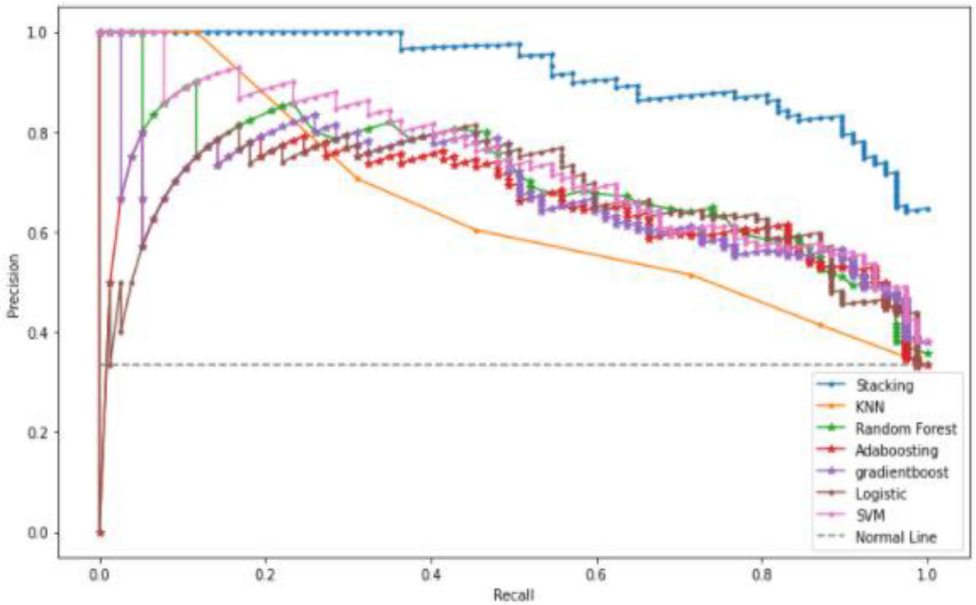

FIGURE 9 | Precision-Recall Curve of the proposed system and various machine learning models.

the Pima dataset. This correlation says how strong an association or correlation of two attributes. Pearson, correlation coefficient formula, returns a value between −1 and 1. The correlation coefficient between two attributes (X, Y) is 1; then, Y's positive value will also increase for every X positive value increase. If the correlation coefficient between two attributes is negative, then any positive value increase of X, Y's negative value will also decrease. If the correlation coefficient is 0, then there is no relation between X and Y. In **Figure 6**, for every attribute pair, the Pima dataset correlation is displayed as a scatterplot. In **Figure 7**, the coefficient value of every two attributes of the Pima dataset is displayed. These two figures depict that most of the attributes in the Pima dataset are independent. The prediction result depends on all the attributes in the dataset.

EXPERIMENTAL RESULTS AND ANALYSIS

The Pima Indians Diabetes (PID) Data Set is applied in the experimental purpose. The whole experiment is done in an Intel Core i5- 6200U CPU @ 2.30GHz 4 cores with 4 Gigabytes of DDR4 RAM with the help of python programming language (32, 33, 37). **Figure 8** shows that the proposed system stacked ensemble model obtained higher accuracy, around 93%, compared to all other existing models.

True Positive (TP) measures correctly predicted the diabetic patients.
True Negative (TN) measures correctly predicted the non-diabetic patients.
False Negative (FN) measures incorrectly predicted the non-diabetic patients.
False Positive (FP) measures incorrectly predicted the diabetic patients.

$$Precision = \frac{TP}{TP + FP} \tag{11}$$

$$Recall = \frac{TP}{TP + FN} \tag{12}$$

$$F1 - Score = 2^* \frac{Precision^* Recall}{Precision + Recall} \tag{13}$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{14}$$

A Precision-Recall Curve (PRC) is a metric used to compute the quality of the classifier model. The PRC curve is represented in a graph, where X-axis contains recall values Y-axis contains precision values. This curve depicts the compromise between precision and recall. In a graph, the PRC curve occupies a high area, which means that the obtained recall and precision rates are high. High precision leads to a less false positive rate, and high precision leads to a less false-negative rate. **Figure 9** shows that the proposed stacked ensemble model curve has occupied a higher area than other machine learning models such as KNN, Random Forest, and Gradient Boosting. The curve values are represented as TP/ (TP+FN) on the Y-axis.

The proposed system is compared with other machine learning models by quality metrics such as precision, recall, accuracy, and F1-score. These values are plotted in **Figure 10**. The proposed stacked ensemble model obtained higher results compare to all other methods. **Table 5** shows the quality metrics results. The proposed method is combination of machine

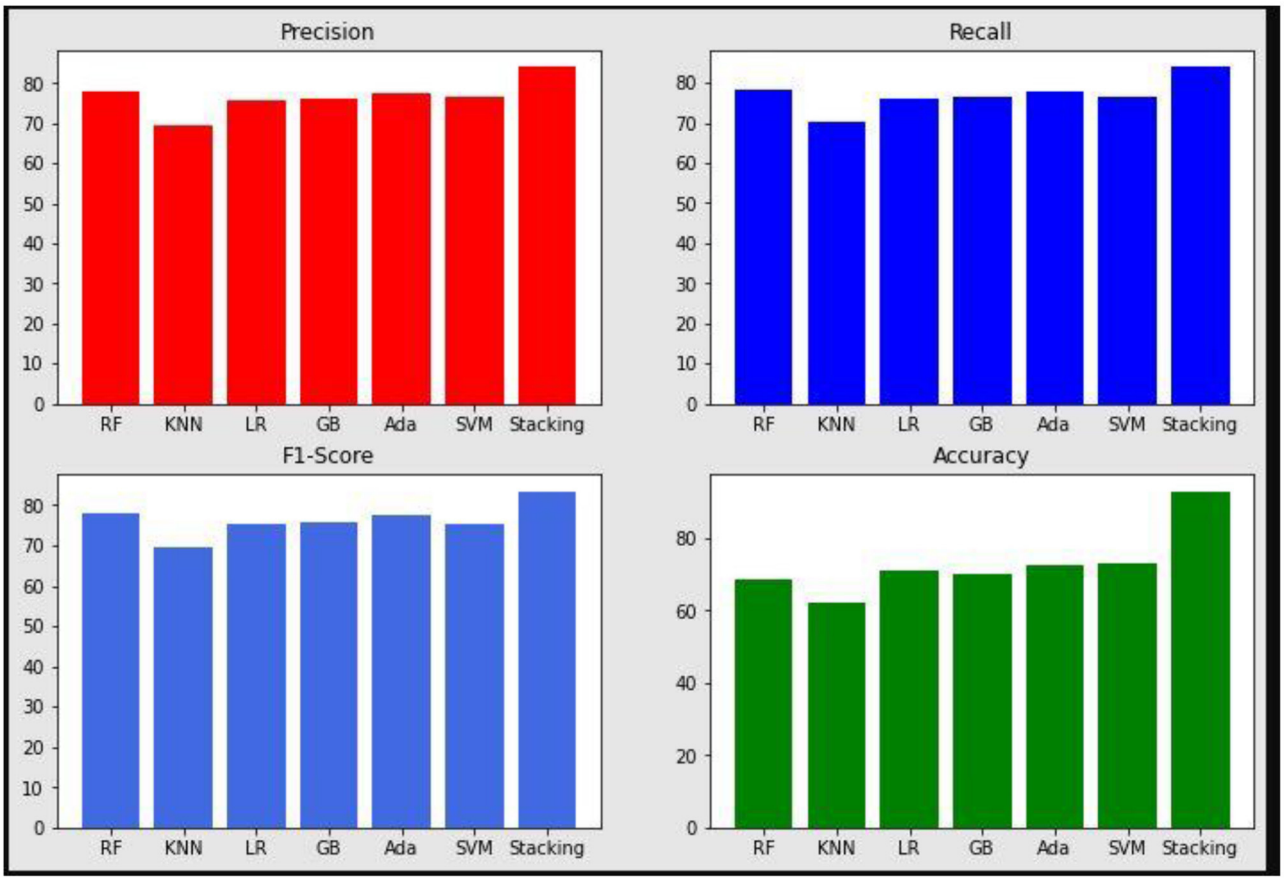

FIGURE 10 | Precision, Recall, F1-Score, and Accuracy results of the proposed system and various machine learning models.

TABLE 5 | Quality metrics results.

Methods	Precision	Recall	F1-Score	Accuracy
Random forest	78	78.3	77.8	68.5
KNN	69.3	70.1	69.5	62.4
Logistic regression	75.7	76.2	75.3	71
Gradient boosting	76.1	76.6	75.9	70
Ada boosting	77.9	77.5	77.9	72.7
SVM	76.5	76.6	75.4	73.1
Stacking	84	83.9	83.5	93.1

learning algorithms. Generally multiple algorithms for a single problem shows better performance. Each machine learning model has its own strengths and weaknesses. If more than one model is combined, then the weakness may be averaged and strength will be increased for many problems, but not all problems. Thus the ensemble techniques such as bagging, boosting, and stacking are popular. Processing time can be higher than single algorithms. The proposed work is also tested with fewer than 6 machine learning approaches with different combination in ensemble technique and obtained lesser than 93% of accuracy of proposed approach.

COMPARED WITH EXISTING WORKS

The proposed stacking ensemble model is compared with other machine learning models. The python language is used to implement the proposed model. And the popular machine learning algorithms such as Random Forest, KNN, Logistic Regression, GBM, etc., are implemented and tested with the PIMA dataset. The obtained result is given in **Table 5**. Compared to the existing models such as Aishwarya et al. (49), Singh et al. (22), and Mamuda and Sathasivam (13), the proposed stacking method has obtained a higher detection rate in detecting the diabetic positive patients.

CONCLUSIONS AND FUTURE WORKS

One of the essential approaches in the medical field is the detection of diseases in the initial stage. Today, diabetes patient increase rates are high irrespective of age across all regions of the world, and there is no medicine (vaccine) to prevent it. The diabetic disease is a big challenge throughout the world, as it affects irrespective of age. Early detection of diabetic positive helps to reduce the medical expenditure,

death rate, and risk of patients. As long as the early prediction on this disease is not famous, the proposed system initiated the prediction of diabetic positive. Experiments are carried out on the Pima Indians Diabetes Database (PIDD). A stacked ensemble model has been adopted in the proposed work and obtained 93% accuracy for a highly categorical dataset.

The existing models in the diabetic prediction used a single algorithm. But the single algorithm will not be suitable for the unstructured and large datasets. Thus, the proposed system has adopted multiple machine learning models called stacked ensemble models. The proposed prediction model has predicted diabetic patients accurately about 93% of the time. In the future, the designed system with the used stacked ensemble method can predict other diseases. The work can be extended and improved for the automation of diabetes analysis, including machine learning and deep learning algorithms.

In the pandemic of COVID-19, it is crucial to consider the hygiene of the edible and nonedible things as it could be dangerous for our health to consume infected things. Furthermore, everything cannot be boiled before eating as it can destroy fruits and essential minerals and proteins. So, there is a dire need for a smart device that could sanitize edible items. The Germicidal Ultraviolet C (UVC) has proved the capabilities of destroying viruses and pathogens found on the surface of any objects. Although, a few minutes exposure to the UVC can destroy or inactivate the viruses and the pathogens, few doses of UVC light may damage the proteins of edible items and can affect the fruits and vegetables. To this end, we have proposed a novel design of a device that is employed with Artificial Intelligence along with UVC to auto detect the edible items and act accordingly. This causes limited UVC doses to be applied on different items as detected by proposed model according to their permissible limit. Additionally, the device is employed with a smart architecture which leads to consistent distribution of UVC light on the complete surface of the edible items. This results in saving the health as well as nutrition of edible items.

1. INTRODUCTION

Health is the most critical factor in our life and majorly depends upon what we eat and what is the quality of our daily intake which includes fruits and vegetables having essential minerals, vitamins, and proteins (1). The raw vegetables and fruits may have viruses or pathogens on their surfaces even if some of them are removed by a wash. Due to the COVID-19 pandemic, this becomes essential that the things we are intaking are pathogens free and are virus-free whether it is edible items or our daily usable items. There are many products available in the market for sanitizing edible and non-edible items e.g., UVC rays (2–4). It is already proven that germicidal UVC has properties that deactivate the pathogens by exposing the surface of fruits and vegetables for a few minutes (5–8).

In recent times, it is seen that researchers are widely using UVC to perform complex operations such as scientific applications for deactivating viruses; water purification to remove viruses and bacteria from the water; air purification which deactivates the viruses and germs present in the air of the atmosphere (9); sanitizing a room. Additionally, UVC has many applications for deactivating pathogens over different surfaces and mediums. It is also being used with fluorescent which makes the viruses glow when it is seen by microscopes in presence of the UVC rays. UVC is cheap and easily available in the market which further increases its usage.

In the existing solution, there is a limitation that it damages approximately 30% of the edible items especially fruits and vegetables as its being used by industries for decades for removing the pathogens present on the surface of these items (10–12). So, the existing solution does not have an automated system that can identify the object and make optimal configuration accordingly and an existing solution does not have any filter which prevents the damage done by the exposure of the direct UVC to this item.

We have designed an Artificial Intelligence employed device to provide an automated self-learning process in which the object is identified by the device itself by using machine learning and make optimal configurations as per the class of the object classified by the object detection model. So, AI enables automation (13) with the optimal setting configuration and makes the device smarter than the existing solutions.

2. OUR CONTRIBUTION

In the view of limitations of existing solutions, we have incorporated certain changes in the proposed device so that edible items do not loose its nutrient values.

- We have used an AI-Enabled UVC sanitization device powered by raspberry pi 4, UVC light 254 nm with polarizing filters for the limited dose to the fruits and vegetables, and a camera sensor for object detection.
- We have used the rotating base to apply UVC light uniformly throughout the object.
- The vacuum pump is used to remove dust particles from inside the box which further maintains the uniform intensity of UVC.
- Inside the box, the mirror is presented on each side so total light reflection occurred when the rays from the UVC lamp strikes the mirrors at different angles.
- The aluminum sheet is also sandwiched between the outer shell and the mirror for maximum heat dissipation when the heavy dose is required by the objects.
- Bipolar fans are also present to cool down the aluminum sheets and can dissipate the heat properly out of the box.

We have used machine learning models for automated UVC sanitization. There are many different objects like vegetables and fruits which vary with proteins structure and have different molecules. It is necessary to detect the object placed inside the box so a camera sensor is used to capture the image of the object placed. This object image is passed to the machine learning model which detects the class of the object and then this class is passed to another classifier which classifies the rotation angle and the safe exposure time for that object based on the similarity.

3. LITERATURE REVIEW

UVC Sanitation is being used for many decades in the industry (14). It is not a new thing that is used for sanitizing the different edible and non-edible items. The industry is using germicidal UVC for raw fruits and vegetables to deactivate the pathogens present on the surface of vegetables and fruits (8). Germicidal UVC of 254 nm has the capability of deactivating pathogens as well as air-born virus-like h1n1 flu and also COVID-19 virus (2, 3, 6, 15). Recently, many devices have come into the market which claims that their devices can sanitize any object. There are many products available in the market like air purifiers using the germicidal UVC.

UVC Sanitization box is available in the market in different sizes which can sanitize the items using the germicidal UVC of 254 nm. There is also a UVC device available that can be used for sanitizing small electronic devices and non-electronics devices (5). These devices are good enough for sanitizing the electronic device and the non-edible items but they are not much effective for edible items like raw vegetables and fruits (3).

Some of the findings were provided in **Table 1**. As discussed in existing literature, there is a limitation that a few minutes of doses can lead to damage to edible items like fruits and vegetables. So, we proposed a novel idea to overcome this limitation.

4. METHODOLOGY: SYSTEM ARCHITECTURE OVERVIEW

4.1. Architecture

The newly built proposed design of the AI-enabled UV sanitization box, as shown in **Figures 1**, **2**, depicts the proposed architecture with the following units:

- **Processing unit:** Raspberry pie 4 would be used as a processing unit.
- **Object detection unit:** This is the unit where all the images captured by the image sensor are pre-processed and then the image of the object is passed to the AI trained model which detects the category of object and results in the category of the object. Here, we have created a machine learning model using the CNN and we trained the model with training images of the different fruits and vegetables.
- **Sensors:** We have used a camera module as an image sensor and temperature sensor along with a cooling module.
- **Alarm unit:** We have used speakers and voice enable system to alert the user.
- **Cooling unit:** The same purpose is solved with heat sink and cooling fans.
- **UVC rays filter unit:** UVC 254 nm is very harmful to the human skin as well as it can damage fruits and vegetables. So, to avoid that damage to the vegetables and fruits, the intensity of the light is controlled using the two polarized sheets (23–26). One sheet is fixed and one sheet is made to rotate on both sides directly with the help of a stepper motor. The range of the rotation varies from 0 to 180_0. Intensity can be controlled between 0 and 180_0 from total light pass to total blockage of the light through the polarizing filter (27).
  - **Parallel axis:** When two sheets are placed parallelly, they allowed the total light to passed through it.
  - **In between axis:** If one sheet is fixed and rotation of the sheet is started in either direction, it will start blocking the light as the sheets are getting crossed to each other. If further rotated, it starts allowing the light through it.

TABLE 1 | Existing findings.

Author	Objectives	Finding
Weber et al. (16)	To see how effective Ultraviolet technologies are at reducing microbial contamination on environmental surfaces in patient care environments.	UV sanitization is more likely to be unaffected in darker places.
Scotland (17)	Analyzed the scientific evidence supporting UV light disinfection systems efficiency.	The following factors influenced the effectiveness of UV light: organic load and pathogen; the strength and amount of UV light; the distance from the device; exposure time; surface to be cleaned is within direct line-of-sight or not.
Barbut et al. (18)	The eradication of bacterial spores using hydrogen peroxide sprays and sodium hypochlorite solution was studied in a prospective, randomised, prior to actually trial.	The eradication of bacterial sporesa utilising hydrogen peroxide sprays and sodium hypochlorite solution was studied in a prospective, randomised, before-and-after study. Hydrogen peroxide sprays were shown to be significantly more effective than sodium hypochlorite solution at killing Clostridium difficile spores. The later has the potential to be a viable tool for eradicating Clostridium difficile spores.
Holmdahl et al. (19)	On biological markers, the tests evaluated the effectiveness of hydrogen peroxide and sodium hypochlorite.	On G. Stearothermophilus bioindicators, hydrogen peroxide vapour generators were faster and more effective than sodium hypochlorite machines.
Fu et al. (20)	A comparison of the safety and effectiveness profile of H_2 O_2 sprays against aerosolized hydrogen peroxide on G. Stearothermophilus biological indicators with MRSA, C. Difficile, with Acinetobacterbaumannii discs	The water vapour system has demonstrated a higher level of safety, speed, and efficacy in bacterial inactivation.
Haas et al. (21)	By comparing the frequencies of hospital-acquired MDROs before and after UVD use, a retrospective analysis of the efficiency of UV light environmental decontamination as a complement to improved terminal cleaning of rooms formerly occupied with isolated patients was conducted.	Even though nearly a quarter of the disinfection chances were missed, there was a considerable drop in hospital-acquired MDRO rates during the UVD usage period compared to the previous period. UV technologies appeared to have some positive effects in this investigation.
Anderson (5)	On the surfaces of segregation units, the antibacterial capabilities of UVC light and chemical sanitisers were compared.	UVC proved ineffective in dark portions of the rooms, required further chemical decontamination.
Memarzadeh et al. (22)	The importance of UV light technology in air purification in a healthcare setting is discussed.	UV technologies cannot yet be applied to neutralise or eliminate germs as a stand-alone intervention, but they can be employed in conjunction with other traditional treatments for endpoint disinfection.

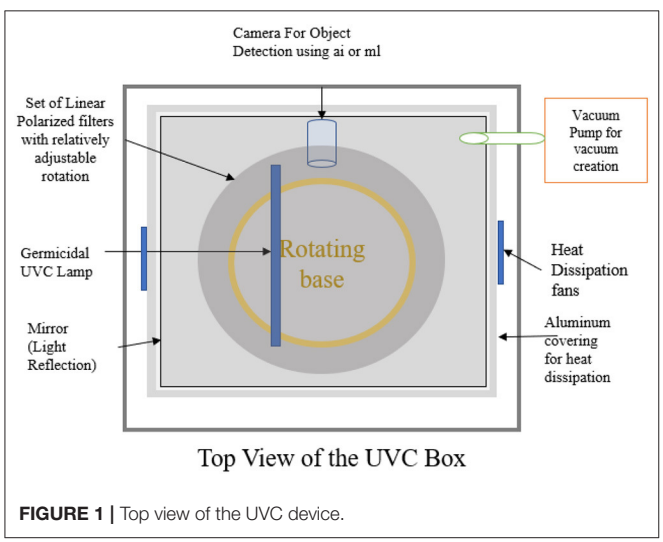

FIGURE 1 | Top view of the UVC device.

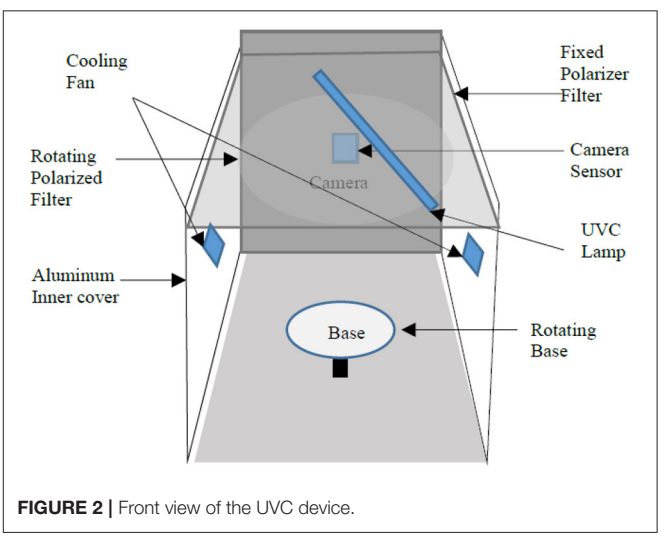

FIGURE 2 | Front view of the UVC device.

- **Crossed axis:** If two sheets are crossed then it blocks the light passing through it.

- **Rotating base unit:** A rotating base is used for the even distribution of the UVC rays to the object which is placed on the rotating base. It also prevents the direct penetration of the UVC. The base starts rotating with the start of the sanitization process.

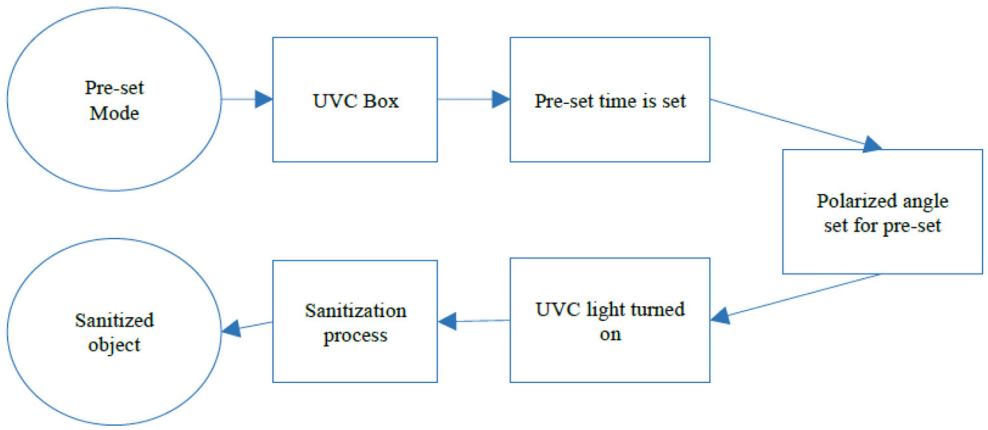

FIGURE 3 | Pre-set mode operation of UVC sanitization.

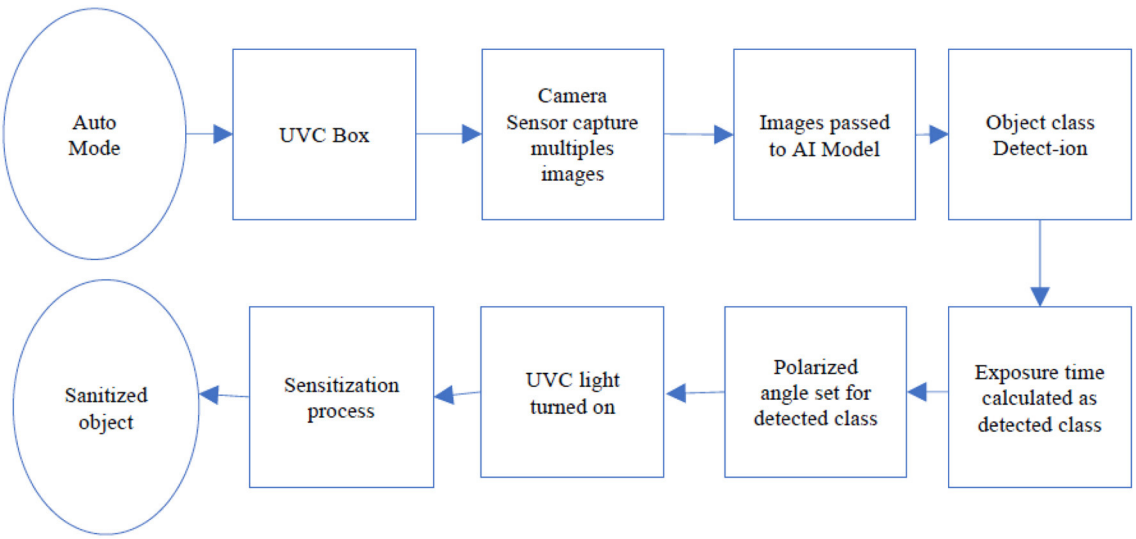

FIGURE 4 | Auto mode operation of UVC sanitization.

- **Display unit:** The display unit displays all events that occurred at the device. It starts from the device start message and mode selected and then displaying the timer set for the UVC sanitization up to the end of the sanitization process.

4.2. Mechanism of Sanitization

Smart UVC Sterilization has a special mechanism of sanitization. It is operated from 230-volt AC. There are two shields: one is the outer shell and one is the inner shell. The opening door consists of an auto cut UVC power supply mechanism which is operated using a switch. It will auto cut the power source to UVC when we open the door and a visible lamp will glow to put the objects inside the UVC box. It has a rotating plate that carries the objects. We have a few pre-set items on the operational menu. We can use those pre-sets if we know the edible item otherwise the auto mode is selected.

When the pre-set mode is selected, the UVC Box is set to the predefined fixed mode where the UVC box works on the predefined values for the UVC exposure times and the UVC box runs for the predefined time and set its polarized angle as defined for that mode (ref **Figure 3**). In the Auto mode, the UVC box uses the AI model to detect the object inside the box. The process is shown in **Figure 4**.

5. CONTROL DESIGN

Control design process of the AI-enabled UVC device consists of different process flows and control structures used in building the device and process description which defines the different sequences of processes held in the device.

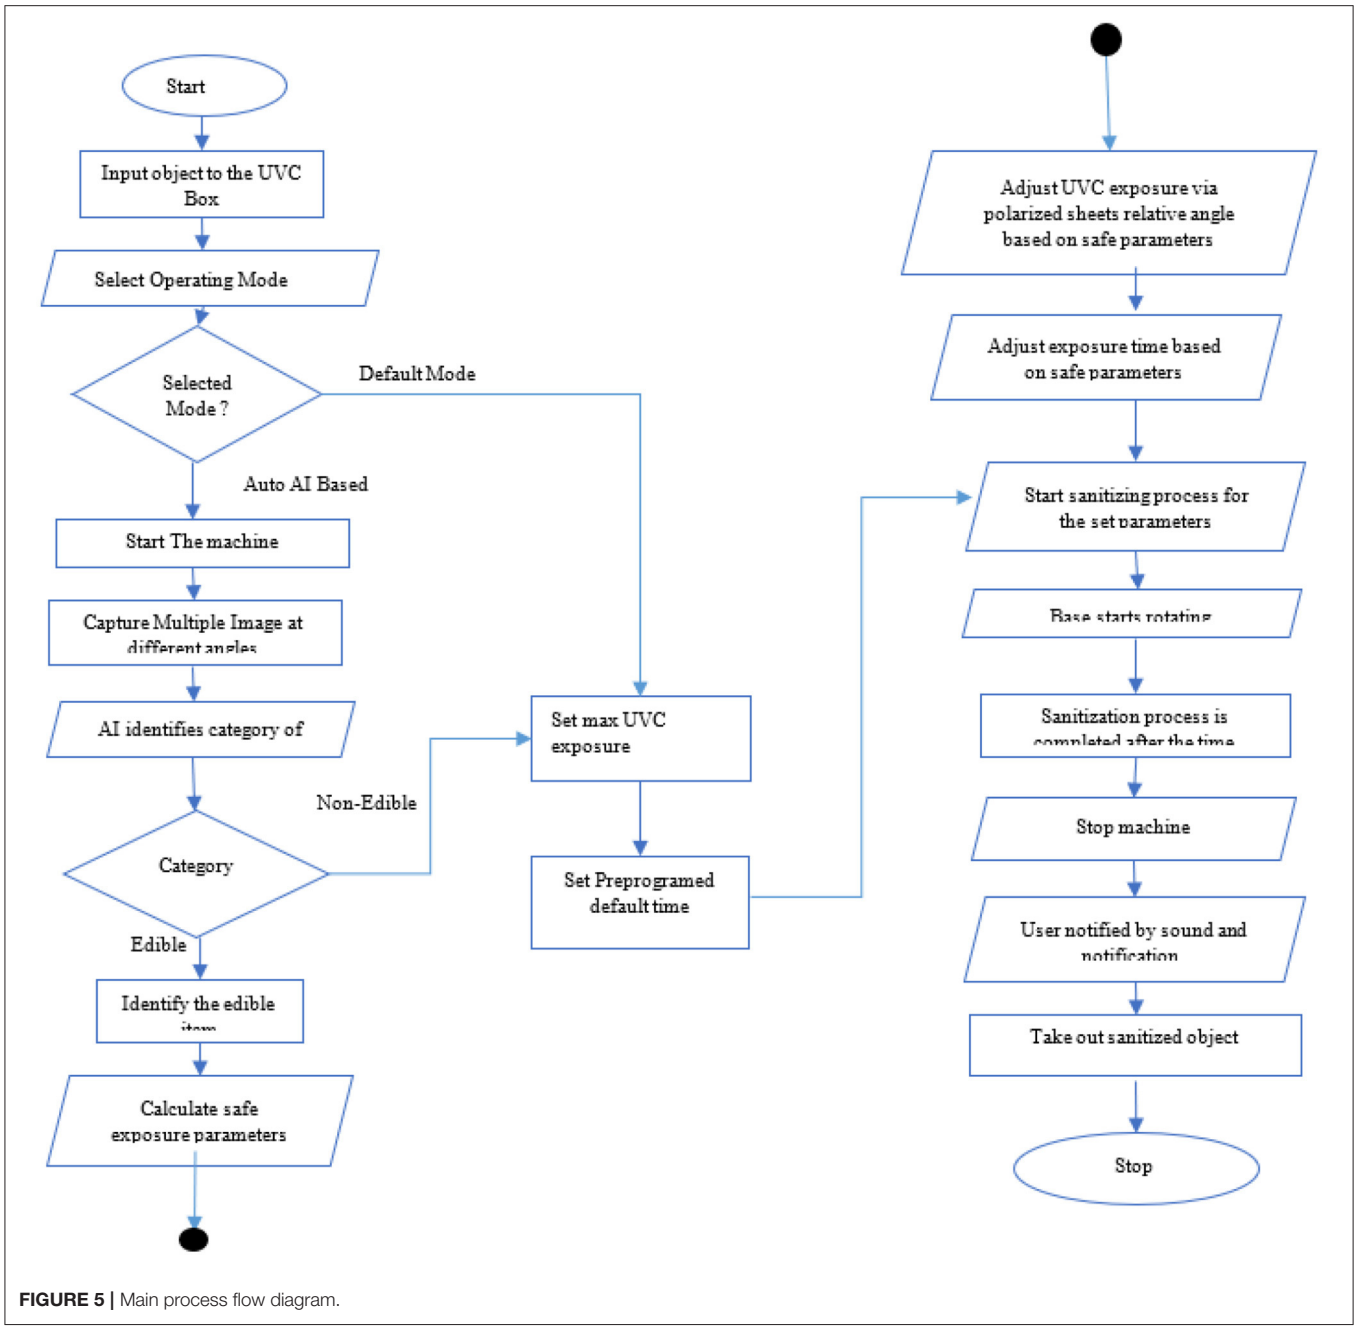

FIGURE 5 | Main process flow diagram.

5.1. Main Process Building Block

This section defines the process of the overall workflow of the AI-Enabled device (28). It defines the overall process of the device from the start to the end of the sanitization process. The main process block is defined in **Figure 5**. The process starts from inputting the edible or non-edible object inside the device and then needs to select the mode of operation of sanitization.

There are two modes: one is manual which can be used directly for the non-edible items; second mode is auto mode which once selected, it starts capturing the images of the object inserted inside the object. After successfully capturing the image, these images are passed to the object detection model which detects the class of the object and the required UVC exposure time is stored using the UVC dosage calculation formula given in equation 1. According to equation 1, we can easily determine that the total UVC dose

TABLE 2 | UV-C doses for SARS-CoV-2.

Viral inactivation (%)	UV-C dose (mJ/cm^2)	Exposure time (s)
90	0.016	0.01
99	0.706	0.32
99.9	6.556	2.98
99.99	31.880	14.49
99.999	108.714	49.42

time is calculated on the basis of the intensity of light dropped for the particular amount of time.

$$UVC_Dose = UVC_rays_Intensity(\mu W/cm^2) \times UVC_Exposure_Time(seconds). \quad (1)$$

On the basis of **Table 2**, we have calculated the expected doses for the predicted item class. If the class of the object is detected to edible items, then the safe exposure parameters are set according to the detected object, and the rotation angle of the polarizing filter and time of UVC rays exposure is measured and stored using another classifier that classifies the edible item based on the few parameters. Finally, the sanitization process gets started. The procedure is provided in **Algorithm 1**.

5.2. Control Process Flow of Camera Sensor

The Camera Sensor is used for capturing the images of the inserted object whenever the auto mode is selected. AI comes into the picture when auto mode is selected and there is a need to classify the class of the object inserted inside the device. Image captured by the camera sensor is saved to the raspberry pi and then it is transferred to the machine learning model which is already trained over the 131 classes of fruits and vegetables. The camera sensor helps to detect the class of the object inserted inside the device.

5.3. Object Detection Process Flow

The object detection process flow is the process that defines the classification of the input Image *via* a pre-trained model loaded to the raspberry pi. The object detection model is trained over 65,000 images with 131 classes. Image is passed to the model and the model predicts the class and returns the class of the object if it is predicted otherwise return nonedible.

5.4. Polarizer Filter Process Flow

The Polarizer filter process depicts the process of principle used for controlling the intensity of the UVC rays *via* changing the angle between two polarized sheets. One sheet is mounted with the stepper motor which rotates the motor in both directions. When two sheets are crossed to each other it is 180 degrees angle and zero for full light pass through the polarized sheet. The process starts with the configuration settings from the detected object class and starts rotating to the set angle for the detected class.

Algorithm 1| UVC_Process.

```
Intialise: object_class= "edible", mode=0, uvc_time=0, filter_angle=0
Select the mode of operation and set mode equal to mode selected.
if mode = manual then
    go to step 8
else if mode=auto then
    go to the step 15
end if
Set the uvc_time to 300 s
Set the filter_angle equal to 0.
Rotate the polarizer sheet to angle equal to filter_angle.
Turn on UVC Lamp.
Start Rotating Base.
Run the Sanitization process for the set uvc_time.
go to step 21.
Capture an image of the input item.
Detect the class of the object using AI model and set object_class equal to detected object class.
Detect the filter angle and optimized UVC sanitization time using optimized setting_finder_model.
Set the uvc_time equal to detected optimized detected time
Set the filter_angle equal to the detected polaroid angle of rotation.
Rotate the filter upto the filter_angle.
Start the sanitization process for the set time equal to the uvc_time.
Stop UVC light on completion of the set time.
Rotate the polarizer back to its original position.
Stop Rotating base.
```

5.5. Cooling System Process Flow

The cooling system is an essential part of the device as it takes care of the heat generated inside the device and prevents the excessive heat generated by the UVC rays. To avoid damage from the heat generated by the UVC rays, the cooling system helps the aluminum covering to act as the heat dissipation heat sink (26, 29).

The process of the cooling system consists of a heat sensor module where the auto cut relay is programmed with a temperature setting. The cooling fans control the temperature of the device. The temperature is set to the desired value. The threshold value for the temperature is set to 30^0C. Whenever the temperature reaches above 30_0C, it turns on all fans connected to the temperature module. If the temperature goes below 30^0C, it stops all the fans. This process continues whenever there is a temperature rise and down.

6. CIRCUIT DESIGN

The Circuit design includes the interfacing of the different hardwares. This section depicts the interfacing of the different hardwares used in this device.

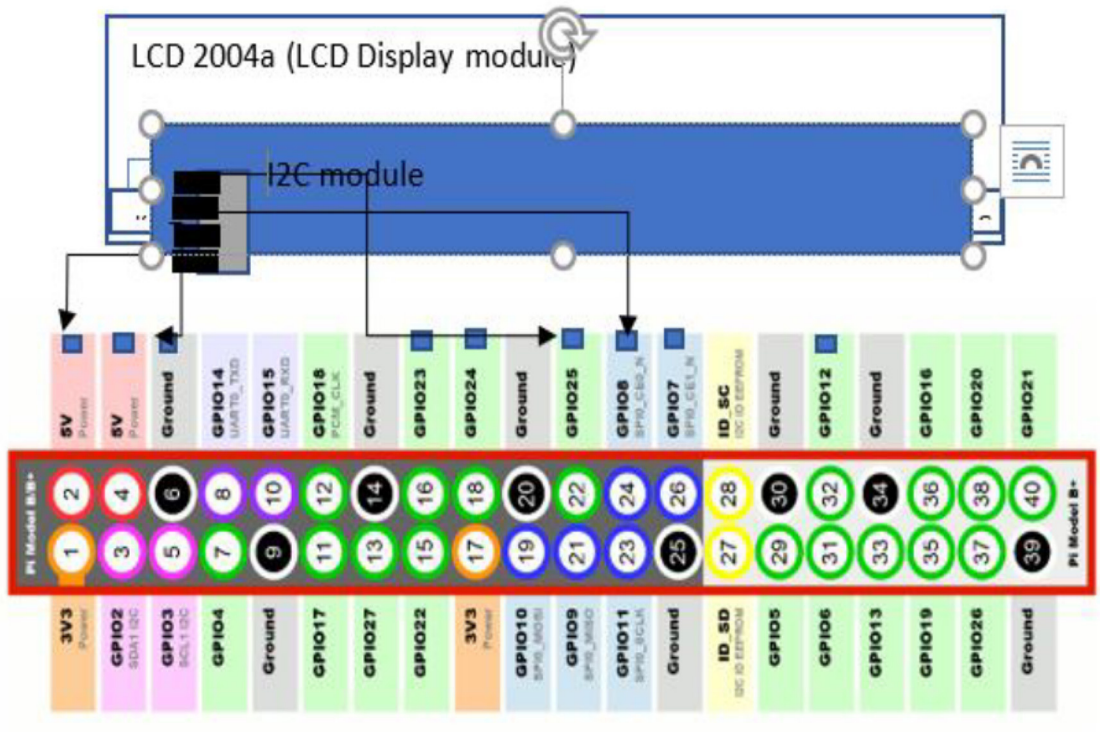

FIGURE 6 | Interfacing of 2004a display LCD with Raspberry Pi.

6.1. 2004a LCD Display Interfacing

LCD 2004 is a parallel LCD display which is simple and a cost effective solution for adding display characters on a 20×4 white and high contrast white text upon a blue background/backlight. The display has 20 characters and 4 lines. It requires 6 data pins to be interfaced with the raspberry pi GPIO pins and other 6 pins with the ground and 5 volts.

The 2004a LCD is interfaced using the i2c adapter which reduces the connection wires from 16 to only a two-wire connection to the I2C adapter. I2C adapter supports many connections to be handled at a time as defined in **Figure 6**. So, it is used here to reduce the complexity of the raspberry pi. It reduces the number of GPIO pins used by the LCD.

6.2. NEMA 17 Stepper Motor Interfacing

The Nema17 stepper motor is used for rotating the object holding base. It has high torque which can rotate weight up to 4 kgs. The L298N stepper driver is interfaced with the Nema17 stepper motor and with a raspberry pi to drive the NEMA as shown in **Figure 7**. Stepper motor drivers need to be powered with 12 volts to drive the NEMA motor.

6.3. RJ2003 Stepper Motor Interfacing

It is a stepper motor that consists of 4 coils which allow it to take very precise steps and very accurately it can rotate up to specific angles rotations. It is used for the rotation of the polarizer filter. It makes the filter from a 0-degree angle to 180-degree angle, which means from a total block of light to the total pass of the light through the polarizer filter. It is interfaced with the raspberry pi. In **Figure 8**, a stepper driver is used to drive the stepper motor that is ULN2003 which is interfaced with both the raspberry pi and stepper motor 28BY-J-48y.

7. PROPOSED TECHNIQUE

7.1. Proposed Object Detection Model

We have used the deep learning method to train the model against the fruits and vegetable dataset of images. We obtained the dataset which is freely available named Fruits-360 which can be downloaded from GitHub or available at Kaggle. It includes about 130,000 images of different categories. This dataset includes high-definition images which are essential to obtain a good classifier (30–33).

The structure of the model we used is defined in **Figure 9**. There are a total of 11 layers used in our model. There are four convolutional layers, 4max pooling layers and 2 fully connected layers, and the output layer is the SoftMax layer. The input layer is a convolutional layer where the filter of 16, 5 x 5 x 4 filter is applied and the max-pooling of 2 x 2 is used with stride=2. Convolutional layer 4 is with parameter (5 x 5 x 64) with dimension 128. The model is trained with the 131 classes of fruits

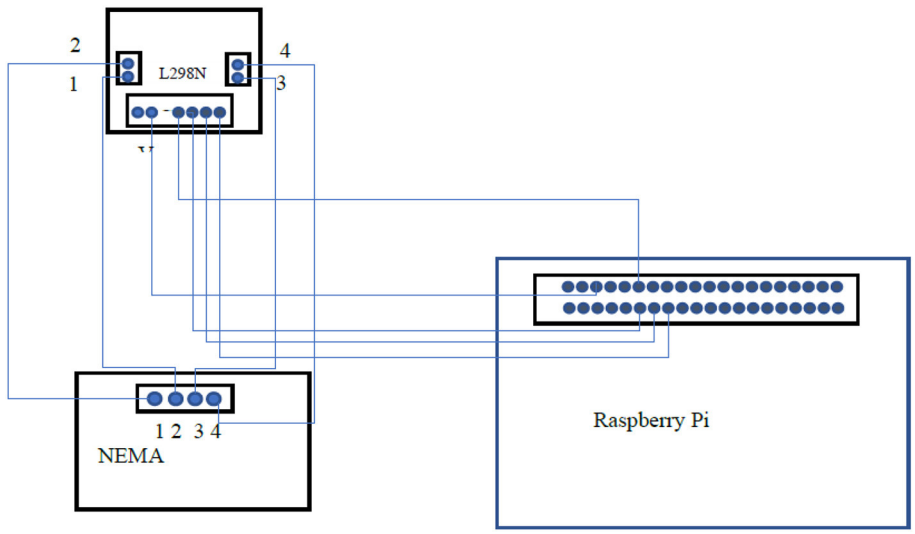

FIGURE 7 | Interfacing of NEMA 17 stepper motor with Raspberry Pi.

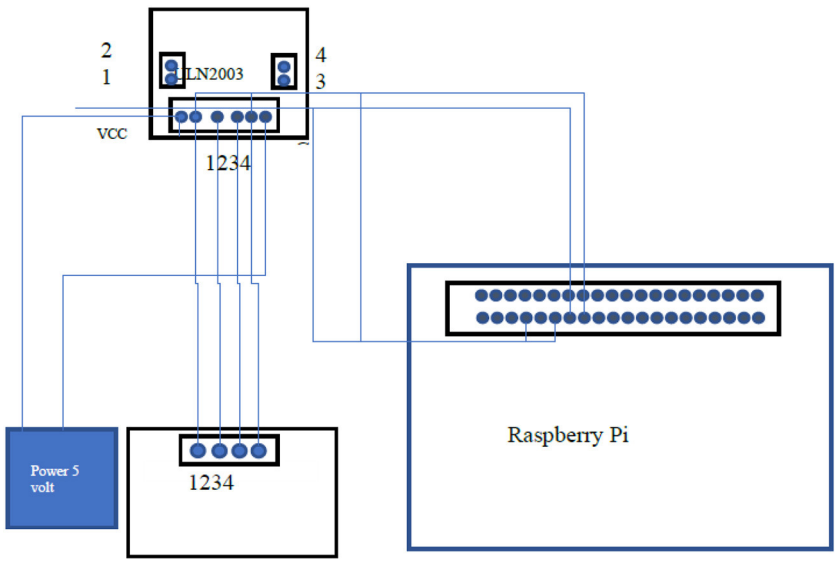

FIGURE 8 | Interfacing of RJ2003 stepper motor with Raspberry Pi.

and vegetables and it can be capable of detecting the multiclass of the image also.

7.2. Optimal Configuration Prediction Model

This is the model proposed to predict the optimal configuration for the detected object. This model makes a prediction based on the data collected through the experimentations. This collected dataset includes the entity name, its features and configuration such as time of UVC exposure and the angle of rotation of the polarizer.

The model used is a decision tree classifier and it works fine as per the requirement. We can classify the UVC exposure time and the angle of rotation of the polarizer and be able to detect the required configuration of the UVC sanitization process. This classifier gives an accuracy score of the 96.33%.

7.3. Smart Device Control

The device is controllable through a mobile app (android). There are two interface screens of the app. The use of the mobile app is to control the device using the Bluetooth communication channel and can be operatable using the mobile app interfaces (34–40). The wireless channel enables the message transfer from mobile to operate the device using the host program running on the raspberry pi and client program on the android app.

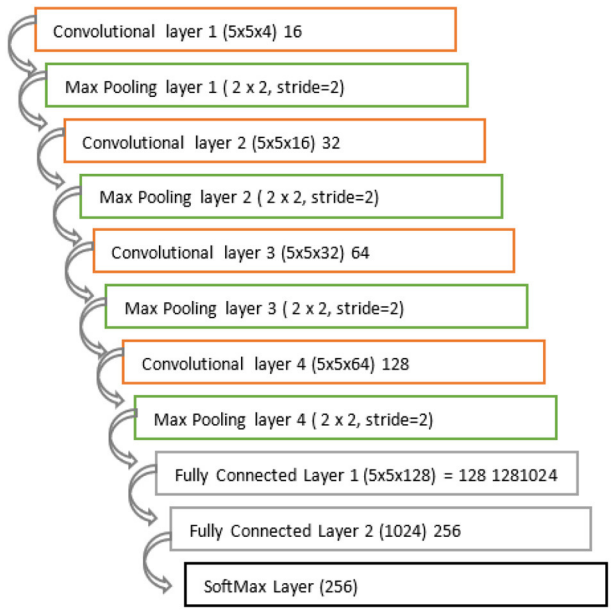

FIGURE 9 | CNN model layers.

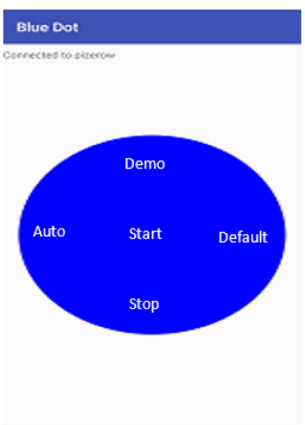

FIGURE 10 | Mobile app main screen with controls.

7.4. Control Screen

The device is configured for the following operations:

7.4.1. Mode Selection

There are two select modes

- Auto mode
- Default mode

The two modes can be selected from app as shown in the app screen in **Figure 10**. One of the mode is the auto mode where the AI comes into the picture and takes care of the rest of the process of the sanitization. The other mode is the default mode operating normally for non-edible items. Its configuration is fixed and loaded on the selection.

8. RESULTS AND DISCUSSION

The code is implemented two times, one experiment is done with 20 items with 20 iterations, another one is done with the 25 items with 20 iterations. The goal is to create an optimal configuration for the discovered items.

8.1. Data Set

In this research realm, the two data sets taken are listed below:

- Fruits 360: This dataset includes the 131 classes of images of both fruits and vegetables (41).
- Configuration mapping: This dataset is made from the experiments performed by us for optimal configuration for the different objects.

8.2. System Requirements

The code of the proposed object detection and training model is written in Python and TensorFlow libraries. The code has been implemented to detect the object class and make optimal configuration using the classification model on experiments results to assess the performance of the UVC process algorithm. The following specifications are used to implement the algorithm:

- Processor - Intel(R) i7-8750H CPU @ 2.40GHz 2.40 GHz
- GPU - NVIDIA-GeForce GTX-1050
- RAM - 8 GB DDR4
- Hard disk drive - 256 SSD
- Operating System - Windows 10 Pro x64-bit

9. RESULTS

The machine learning model used is CNN for object detection and we have used the fruits360 dataset (41) and 50 epochs for training the model which gives an accuracy of 96.2% without overfitting and underfitting as we have provided enough training data for training the model. We have trained the model on an i7 intel processor with Nvidia graphics as it is not possible to train a model over the raspberry pi. Due to limited hardware configuration, we trained it over the system and used the trained model in raspberry pi. So, the trained model gives a good result on the raspberry pi as it is trained over 131 classes of the fruits and vegetables of 65,000 images. We have run the device for the different configurations and the different filter parameters. We have run the machine for the following angle of filters as follows:

- 0^0 angle filter rotation: Here, the light passes through the filters as the normal light passes as it permits the whole rays to pass through the filters.
- 45^0 angle filter rotation: This angle of rotation allows lights to pass through the filter but with limitations as it does not allow the whole UVC light to get pass through it. It allows 75% of UVC light through.
- 90^0 angle filter rotation: At this angle of rotation of the filter, 50% of rays are blocked and 50% of rays get passed through the filters.

TABLE 3 | Experimental results.

Item	45^0 Angle time(s)	Remark	90^0 Angle time(s)	Remark	135^0 Angle time(s)	Remark
Apple	120	Ok	180	Ok	300	Ok
Banana	120	Ok	180	Ok	300	Ok
Grapes	120	Ok	180	damage	300	damage
Papaya	110	Ok	175	Ok	280	Ok
Kiwi	123	Ok	185	Ok	290	Ok

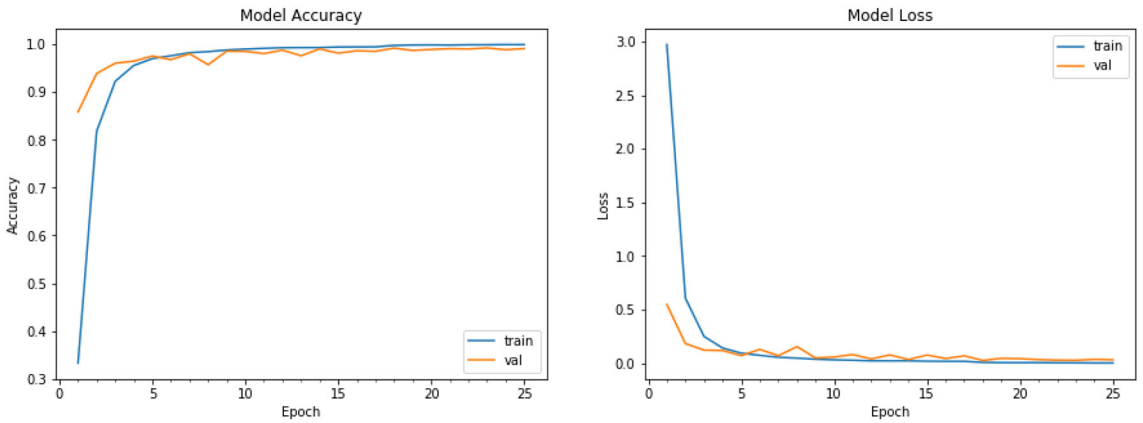

FIGURE 11 | Training accuracy vs. validation accuracy (Left) training loss vs. validation loss (Right) performance graph.

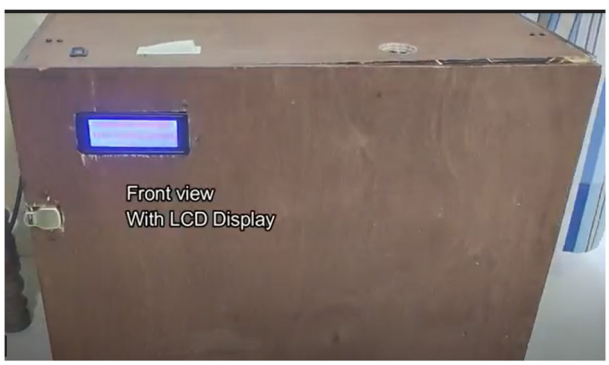

FIGURE 12 | Device front view.

FIGURE 13 | Device internal view.

- 135^0 angle filter rotation: At this angle of rotation of the filter, 70% of rays are blocked and 25% of rays get passed through the filters.
- 180^0 angle filter rotation: At this angle of rotation of the filter, 100% rays are blocked and 0% rays get passed through the filters.

So, we have used the 45-degree, 90-degree, and 135-degree rotations for our experiments and get the following results for a few of the fruits as shown in **Table 3**. We have calculated the UVC dose time using equation 1. As our UVC lamp has a UVC intensity of 300 $\mu W/cm^2$ and the length we have to use is 15 cm.

As represented in **Table 3**, the edible items (especially raw fruits and vegetables) can be sanitized without losing their quality and without any damage to the cell body of the edible item using the proposed system architecture.

9.1. Performance Plot

We have plotted the performance graph for our model for the training data and the validation data. We plot the graph between training data loss vs. validation data loss and training data accuracy and validation data accuracy (**Figure 11**) of the CNN model for object detection. The performance graph plot tells the increase in accuracy with the increase in the epochs and it also describes whether the model is trained properly or not. **Figure 11**

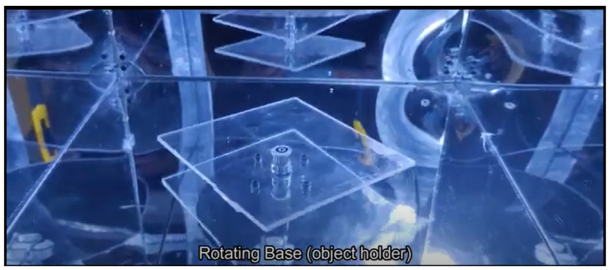

FIGURE 14 | Device internal view - rotating base.

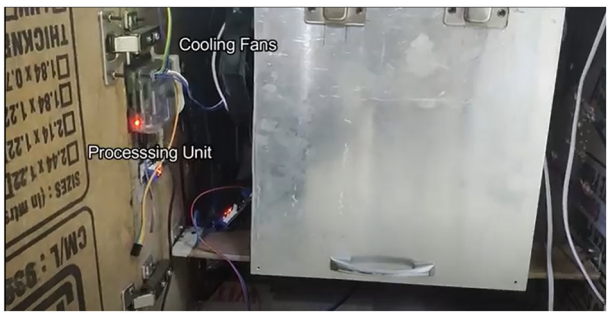

FIGURE 15 | Device internal view - processing unit and cooling fans.

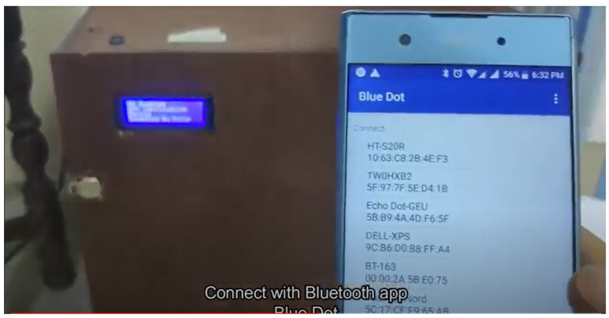

FIGURE 16 | Device connectivity.

is the graph plotted between the loss at training and loss at Validation time. As portrayed in the graph, it is nearly converging so there is no overfitting and underfitting in our model. Training accuracy vs. validation accuracy performance graph shows that the model is trained nearly perfect as there is very little difference between the validation and the training accuracy. So, our model gives an accuracy of the 96.2% which is good enough to detect the type of vegetable and fruits from an image and it works fine for the single item or single fruit or vegetable image. It is also capable of predicting the class of multiple objects too. The model works fine for 131 types of categories. It gives very accurate results for the images input to the model. Finally, **Figures 12–16** provide some additional images of the device under testing. These images are for illustration purposes only.

10. CONCLUSION AND FUTURE SCOPE

With the proposed system architecture, the edible items (especially raw fruits and vegetables) can be sanitized without losing their quality and without any damage to the cell body of the edible item. The AI-enabled device sanitizes the edible items with different optimal configurations made using object detection and automated configuration detection based on the detected class. The optimal configurations utilize the phenomenon of polarization filters which limits the expose of rays due to which the edible items get sanitized without losing their nutrition. Limited filter UVC doses are exposed uniformly throughout the surface of the item with different configurations with the optimal time.

In future, some points need to be considered to enhance the research work. The developed prototype is smart enough to detect the object inserted inside the box but the UVC 254 nm is not safe for humans as well as for edible items. So, 222 nm Germicidal UVC light can be used instead of 254 nm if it is available. Smart Home integration and API could be done to control the device using IoT, e.g., google assistant. Simultaneous sanitization could be performed for multiple items using optimal parameters.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://www.kaggle.com/moltean/fruits.

AUTHOR CONTRIBUTIONS

UB and DK carried out the experiment. DK wrote the manuscript with support from UB. DK fabricated the device with the help from RA, AB, and MH. UB supervised the project. All authors contributed to the article and approved the submitted version.

Wang J, Zhanghuang C, Tan X, Mi T, Liu J, Jin L, Li M, Zhang Z and He D (2022) Development and Validation of a Nomogram to Predict Distant Metastasis in Elderly Patients With Renal Cell Carcinoma. Front. Public Health 9:831940. doi: 10.3389/fpubh.2021.831940

Background: Renal cell carcinoma (RCC) is the most common renal malignant tumor in elderly patients. The prognosis of renal cell carcinoma with distant metastasis is poor. We aim to construct a nomogram to predict the risk of distant metastasis in elderly patients with RCC to help doctors and patients with early intervention and improve the survival rate.

Methods: The clinicopathological information of patients was downloaded from SEER to identify all elderly patients with RCC over 65 years old from 2010 to 2018. Univariate and multivariate logistic regression analyzed the training cohort's independent risk factors for distant metastasis. A nomogram was established to predict the distant metastasis of elderly patients with RCC based on these risk factors. We used the consistency index (C-index), calibration curve, and area under the receiver operating curve (AUC) to evaluate the accuracy and discrimination of the prediction model. Decision curve analysis (DCA) was used to assess the clinical application value of the model.

Results: A total of 36,365 elderly patients with RCC were included in the study. They were randomly divided into the training cohort ($N = 25,321$) and the validation cohort ($N = 11,044$). In the training cohort, univariate and multivariate logistic regression analysis suggested that race, tumor histological type, histological grade, T stage, N stage, tumor size, surgery, radiotherapy, and chemotherapy were independent risk factors for distant metastasis elderly patients with RCC. A nomogram was constructed to predict the risk of distant metastasis in elderly patients with RCC. The training and validation cohort's C-indexes are 0.949 and 0.954, respectively, indicating that the nomogram has excellent accuracy. AUC of the training and validation cohorts indicated excellent predictive ability. DCA suggested that the nomogram had a better clinical application value than the traditional TN staging.

Conclusion: This study constructed a new nomogram to predict the risk of distant metastasis in elderly patients with RCC. The nomogram has excellent accuracy and reliability, which can help doctors and patients actively monitor and follow up patients to prevent distant metastasis of tumors.

Keywords: nomogram, renal cell carcinoma, risk, distant metastasis, SEER

BACKGROUND

Renal cell carcinoma (RCC) is the most common renal malignant tumor in adults, accounting for about 3% of all human tumors (1), with more than 400,000 newly diagnosed patients each year (2). The proportion of elderly patients over 65 years old in RCC is more than 70% (3). Moreover, due to the increase of population aging and the extension of life expectancy caused by improved medical levels, the proportion is still rising (1).

According to the tumor metastasis, RCC is divided into metastatic RCC (mRCC) and non-metastatic RCC (nmRCC). Tumor metastasis is the critical factor to determine the prognosis of RCC patients. The prognosis of patients with mRCC is poor, and the median survival time is only 10.2 months (4), while the prognosis of nmRCC is good, and it is even considered to be cured entirely (5). Studies have shown that 18–30% of RCC patients have distant metastasis at the first diagnosis (6). In comparison, 33% of patients have recurrence and metastasis after surgical excision of the tumor, and it is unclear which patients are prone to metastasis (7).

The main sites of RCC metastasis were lung and bone, accounting for 43.6 and 27.6% of mRCC, respectively. Brain and liver metastasis accounted for 4.4%, respectively (8). Data processing technology has been continuously improved by continuously updating databases such as surveillance, epidemiology, and final results (SEER) of the National Cancer Institute of the United States. The nomograms prediction model represented by UISS (9), SSIGN (10), Leibovich (11) was born and provided treatment suggestions for clinicians. In terms of the RCC transfer prediction model, we found that the prediction models for each leading transfer site of RCC were reported (12–14), but the C-index of the model was 0.714–0.803, and the area under the curve (AUC) was 0.767–0.780, indicating that the relative accuracy was insufficient. And the distant metastasis prediction model for the overall large sample of the elderly has not been reported.

At present, artificial intelligence has been widely used in human health. Dhanamjayulu et al. (15) used real-time image processing and machine learning to identify malnutrition, predict BMI from facial images, and identify unhealthy people quickly. Gadekallu et al. (16, 17) used the deep learning model for the early detection of diabetic retinopathy. And the nomogram is the most commonly used prediction model. To improve the prognosis of elderly patients with RCC, we developed a risk prediction model for distant metastasis of elderly RCC. We validated its accuracy to provide treatment guidance for clinical work.

METHOD

Data Source and Data Extraction

The patient information was extracted from the Surveillance, Epidemiology, and End Results (SEER) project of the National Cancer Institute in the United States to include all elderly patients with RCC from 2010 to 2018. SEER database is the National Cancer Database of the United States, including 18 cancer registration centers, covering about 28% of the national population (18). Demographic information, clinicopathological information, and follow-up data of cancer patients can be downloaded from the SEER database. Access to http://seer.cancer.gov/ provides all the data for this study. Since the patient information in the SEER database is public and anonymous, our research does not require ethical approval and patients' informed consent. Our research method conforms to the research criteria of SEER data release.

We collected patient information, including age, sex, race, year of diagnosis, marital status, tumor histological type, histological grade, tumor side, tumor size, T stage, N stage, surgical method, radiotherapy, and chemotherapy. Inclusion criteria: (1) pathological diagnosis of RCC (ICD-O-3 code 8260, 8310, 8312, 8317); (2) Aged 65 or above; (3) The years of diagnosis were 2010–2018. Exclusion criteria: (1) the race of the patient is unknown; (2) bilateral or unilateral renal tumor; (3) TN staging is unknown; (4) incomplete follow-up information; (5) tumor size is unknown; (6) unknown surgical method; (7) survival time <1 month. The patient screening flow chart is shown in **Figure 1**.

Patients' race was divided into three categories: white, black, and others (American Indian/AK Native, Asian/Pacific Islander). The patients' years of diagnosis were divided into 2010–2014, 2015–2018. Marital status is divided into married and unmarried (including single, divorced, and widowed). Histological tumors include renal clear cell carcinoma, renal papillary cell carcinoma, chromophobe cell carcinoma, and some unclassified RCC. The histological grading of tumors is classified as grades I–IV, which are well-differentiated, moderately differentiated, poorly differentiated, and undifferentiated. Surgical procedures were classified as local excision of tumor (SEER codes 10–27), partial nephrectomy (SEER codes 30), and radical nephrectomy (SEER codes 40–80).

Construction and Validation of the Nomogram

All patients enrolled were randomly assigned to either the training cohort (70%) or the validation cohort (30%). In the training cohort, univariate, and multivariate logistic regression models were used to analyze the independent risk factors for

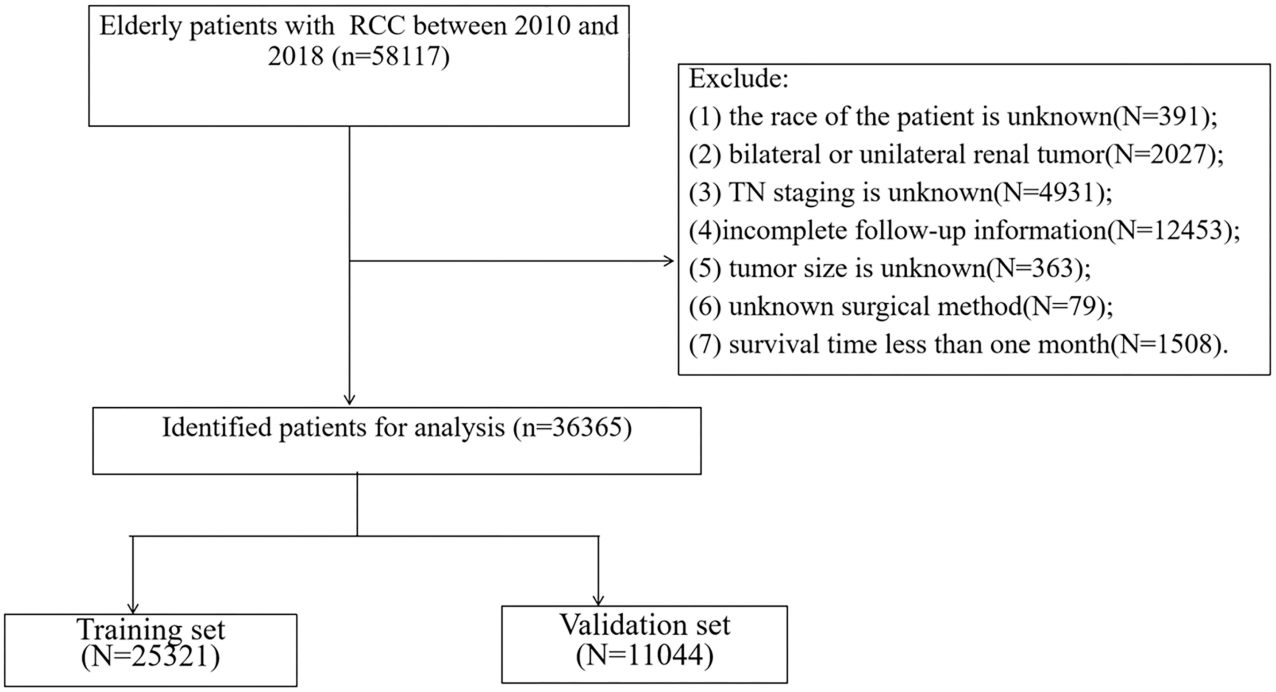

FIGURE 1 | The flowchart of including and dividing patients.

patient metastasis, and hazard ratio (HR) and 95% confidence interval (CI) were recorded simultaneously. The independent risk factors screened were used to establish a nomogram to predict the risk of distant metastasis in elderly patients with RCC. We validated the accuracy of the prediction model of the training cohort and the validation cohort by the calibration curve. We used the consistency index (C-index) to demonstrate the discrimination ability of the model. Meanwhile, We used the area under the receiver operating curve (AUC) to validate the model's accuracy.

Clinical Utility

Decision curve analysis (DCA) was used to validate the clinical value of the model. DCA is a new algorithm to evaluate the net benefit value of the model under different thresholds (19). We also used DCA to compare the ability of the nomogram and TN staging to predict patients' risk of distant metastasis. In addition, we used a risk stratification system to divide all patients into high-risk and low-risk groups based on their nomogram scores. Log-rank test and Kaplan-Meier (K-M) curve were used to compare the survival and prognosis of patients in different risk groups.

Statistical Analysis

Frequency description (%) was used for counting data, and the chi-square test or non-parametric *U*-test was used to compare groups. Measurement data (age, tumor size) were described using mean and standard deviation, and non-parametric *U*-tests were used to compare groups. Univariate and multivariate logistic regression models analyzed the risk factors of distant metastasis. The K-M curve and log-rank test compared the survival differences between groups. All statistical analyses were performed using R software 4.1.0 (http://www.Rproject.org) and SPSS 26.0 (IBM, Chicago, IL, USA). $P < 0.05$ was considered statistically significant.

RESULTS

Clinical Features

we enrolled 36,365 elderly patients with RCC based on inclusion and exclusion criteria. The mean age of the patients was 73.4 ± 6.58 years, and 29,891 (82.2%) were white, 22,760 (62.6%) were male, and 21,817 (60.0%) were married. There were 2,772 patients (7.62%), 12,432 patients (34.2%), 7,630 patients (21.0%), and 1,778 patients (4.89%) of histological tumor grade I-IV, and 20,279 patients (55.8%) of tumor histological type RCC. Papillary cell carcinoma was 5,207 (14.3%), and chromophobe cell carcinoma was 1,855 (5.10%). The mean tumor size was 49.7 ± 34.5 mm. T stage included 17,089 (47.0%) T1a, 8,320 (22.9%) T1b, 3,475 (9.56%) T2, 7,287 (20.0%) T3, and 194 (0.53%) T4. Thirty-four thousand seven hundred and fifteen (95.5%) patients had stage N0. There were 7,254 (19.9%) patients without surgery, 3,083 (8.48%) patients with local tumor excision, 3,083 (8.48%) patients with partial nephrectomy, and 16,266 (44.7%) patients with radical nephrectomy. There were 2,269 (6.24%) patients who received chemotherapy and 1,105 (3.04%) patients who received radiotherapy. The clinicopathological information of all patients is shown in **Table 1**. There was no significant difference between the training cohort and the validation cohort.

Univariate and Multivariate Logistic Regression Analysis

In the training cohort, using the univariate logistic regression model to screen a risk factor for distant metastasis, the results showed that age, gender, race, year of diagnosis, marriage, tumor histologic type, histologic grade, T stage, N stage, tumor size, surgery, radiation therapy, chemotherapy is a risk factor for RCC distant metastases. The multivariate logistic regression model analyzed these variables. The results showed that race, tumor histological type, histological grade, T stage, N stage, tumor size, surgery, radiotherapy, and chemotherapy were independent risk factors for distant metastasis in elderly patients with RCC (**Table 2**). We can incorporate these risk factors into a nomogram to predict the risk of distant metastasis.

Construction and Validation of the Nomogram

Based on independent risk factors derived from univariate and multivariate screening, we constructed a new nomogram to predict the risk of distant metastasis in elderly patients with RCC (**Figure 2**). Tumor size was the most significant risk factor for distant metastasis, followed by radiotherapy, surgery, T stage, chemotherapy, histological grade, histological type, N stage, and race. Subsequently, calibration curves were used to validate the accuracy of the nomogram in the training cohort and the validation cohort, respectively. The results showed that the model's predicted values were consistent with the actual observed values (**Figure 3**). In the training and validation cohorts, the C-index was 0.949 (95% CI, 0.945–0.953) and 0.954 (95% CI, 0.947–0.960), respectively, indicating excellent accuracy. The AUC of the training cohort and the validation cohort also suggested excellent predictive power, with 0.95 (95%CI, 0.945–0.954) and 0.954 (95%CI, 0.947–0.96), respectively (**Figure 4**).

Clinical Application of Nomogram

DCA showed good clinical utility in training and validation cohorts (**Figure 5**). In addition, the nomogram has an obvious predictive advantage over TN staging. Patients in the training cohort and validation cohort were divided into the high-risk group (total score $>$ 99.7) and low-risk group ($\leq$99.7 overall). The K-M curve indicated that the 1-, 3-, and 5-year survival rates in the high-risk group were 0.627 (95% CI, 0.613–0.642), 0.406 (95% CI, 0.389–0.423), and 0.300 (95% CI, 0.282–0.320), respectively. The 1-, 3- and 5-year survival rates of patients in the low-risk group were 0.967 (95% CI, 0.964–0.969), 0.922 (95% CI, 0.919–0.926), and 0.880 (95% CI, 0.876–0.885), respectively (**Figure 6**). The results showed that patients in the high-risk group had a higher risk of distant metastasis and a worse prognosis. We analyzed surgical procedures in the high-risk and low-risk groups. In the low-risk group, patients with partial nephrectomy had the highest survival rate, followed by local tumor excision and radical nephrectomy. Patients without surgery had the worst survival rate (**Figure 7A**). In the high-risk group, where most patients did not undergo surgery or underwent radical nephrectomy, survival was significantly higher among patients undergoing surgery than among patients who did not undergo surgery (**Figure 7B**).

DISCUSSION

RCC is a high incidence tumor, with an estimated 330,000 patients worldwide every year (20), and RCC is still a severe problem that needs to be addressed in the United States (21). Non-metastatic RCC has a good prognosis after surgical treatment, including partial nephrectomy or radical nephrectomy (22). However, 30% of patients eventually develop metastatic RCC after surgical treatment, which is incurable (23). Currently, treatment for patients with metastatic RCC is minimal, including the use of cancer-targeted surgery and immune checkpoint inhibitor drugs to treat metastatic RCC. Still, the effect is inferior (24, 25). At present, CT is mainly used to detect the metastasis of RCC. Still, CT also has its inherent limitations, and its prediction of the risk of cancer metastasis is minimal (26). Therefore, it is necessary to accurately predict the risk of metastasis in patients, strengthening doctors' active monitoring of patients and preventing distant metastasis early.

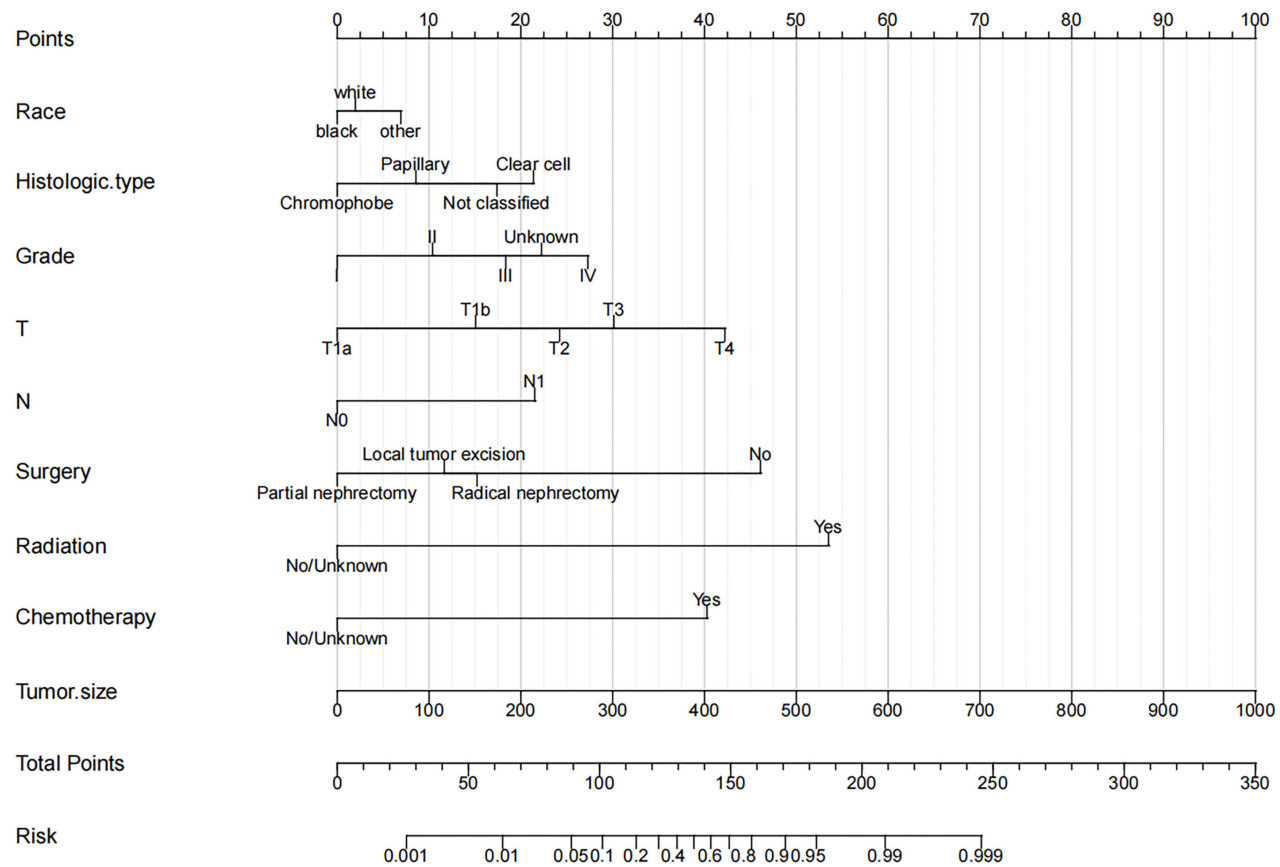

FIGURE 2 | Nomogram for distant metastasis of elderly patients with RCC.

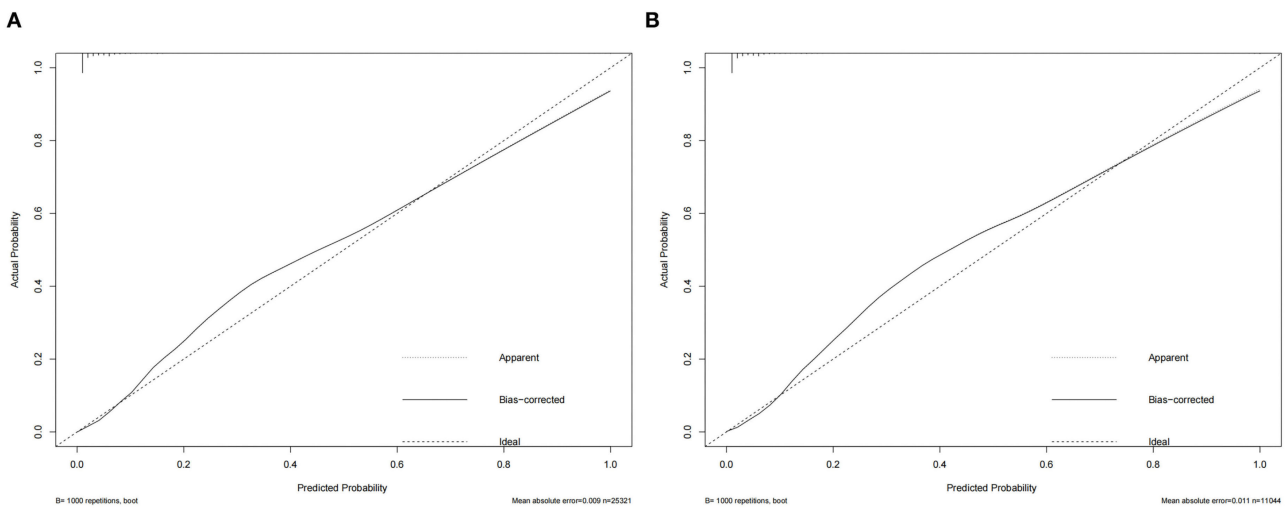

FIGURE 3 | The nomogram's calibration curve in the training cohort **(A)** and the validation cohort **(B)**.

At present, it is very limited in predicting distant metastasis of RCC. Hutterer et al. (27) collected renal cell carcinoma patients in 12 medical centers and established rosettes to predict distant lymph node metastasis, with an accuracy of 78.4%. Capitanio et al. (28) also established a prediction model to predict lymph node metastasis in RCC patients, with an accuracy of 86.9%.

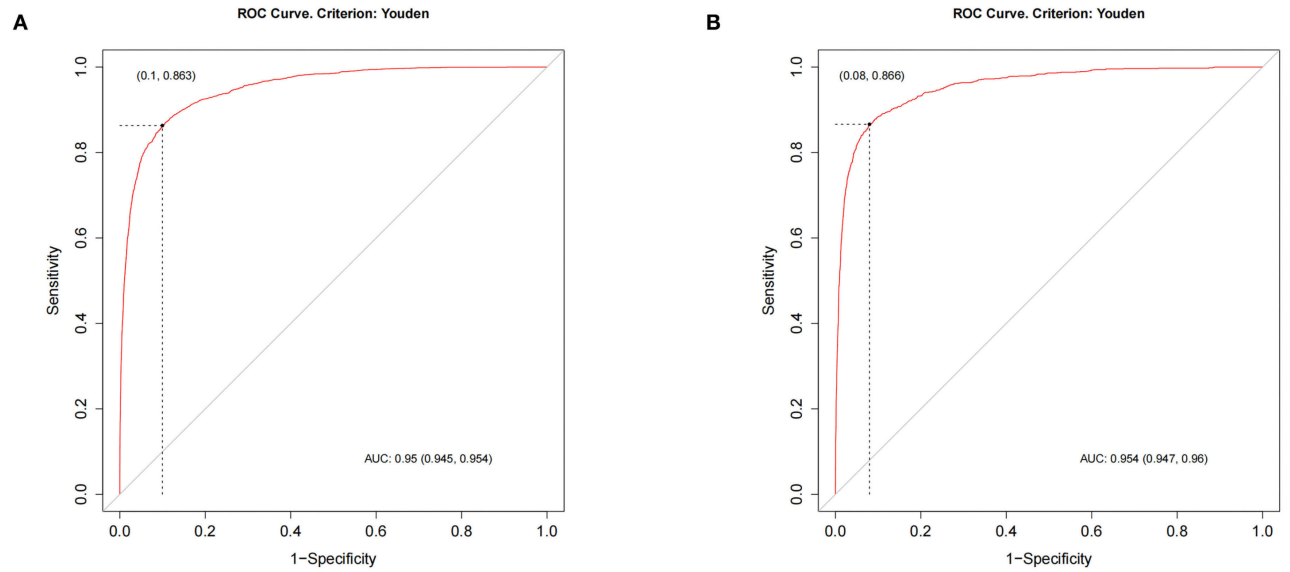

FIGURE 4 | The ROC of the nomogram of training cohort **(A)** and validation cohort **(B)**.

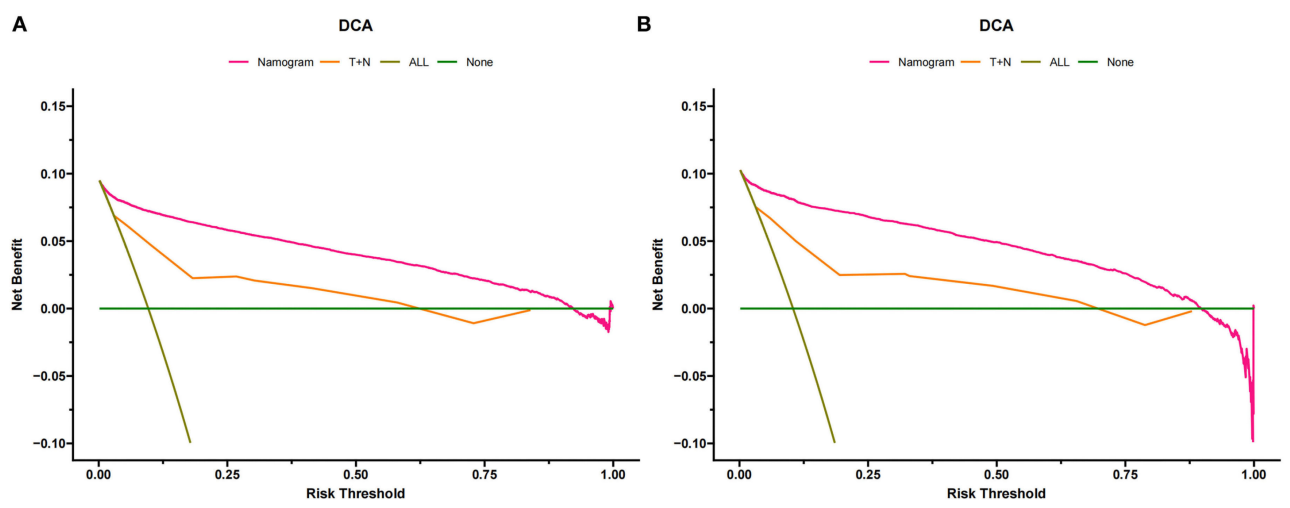

FIGURE 5 | (A) Decision curves of the nomogram predicting distant metastasis in the training cohort and **(B)** the validation cohort. The x-axis is the risk threshold, and the y-axis is the net benefit. The purple line indicates no distant metastasis of the patient, and the blue line shows that all patients have metastasis. When the threshold probability is between 0 and 100%, the net benefit of the model is the largest.

Marconi et al. (29) established a prediction model to predict the survival rate of patients with distant metastasis. Bai et al. (30) used MRI radiomic-based nomogram to predict distant metastasis of patients. Similarly, Zhao et al. (31) used CT radiomics to predict distant metastasis of patients. In addition, Li et al. (32) used patients in the SEER database to predict distant metastasis in RCC patients, but the C index was only 0.863. As far as we know, the current prediction model for distant metastases in RCC patients using nomograms has defects of a small number of patients and low prediction accuracy (**Supplementary Table 1**). Therefore, we aim to construct a highly accurate predictive model to predict distant metastases in elderly patients with RCC. The C-index of our prediction model is 0.949, which is much higher than the previous prediction models.

This study explored the risk factors for distant metastasis of elderly patients with RCC. We found that tumor size is the leading risk factor for distant metastasis of RCC, and the larger the tumor, the higher the risk of distant metastasis. Our results are similar to previous studies. Hutterer et al. (33) previously established a nomogram to predict distant metastasis of RCC and found that tumor size was a significant risk factor. Zastrow

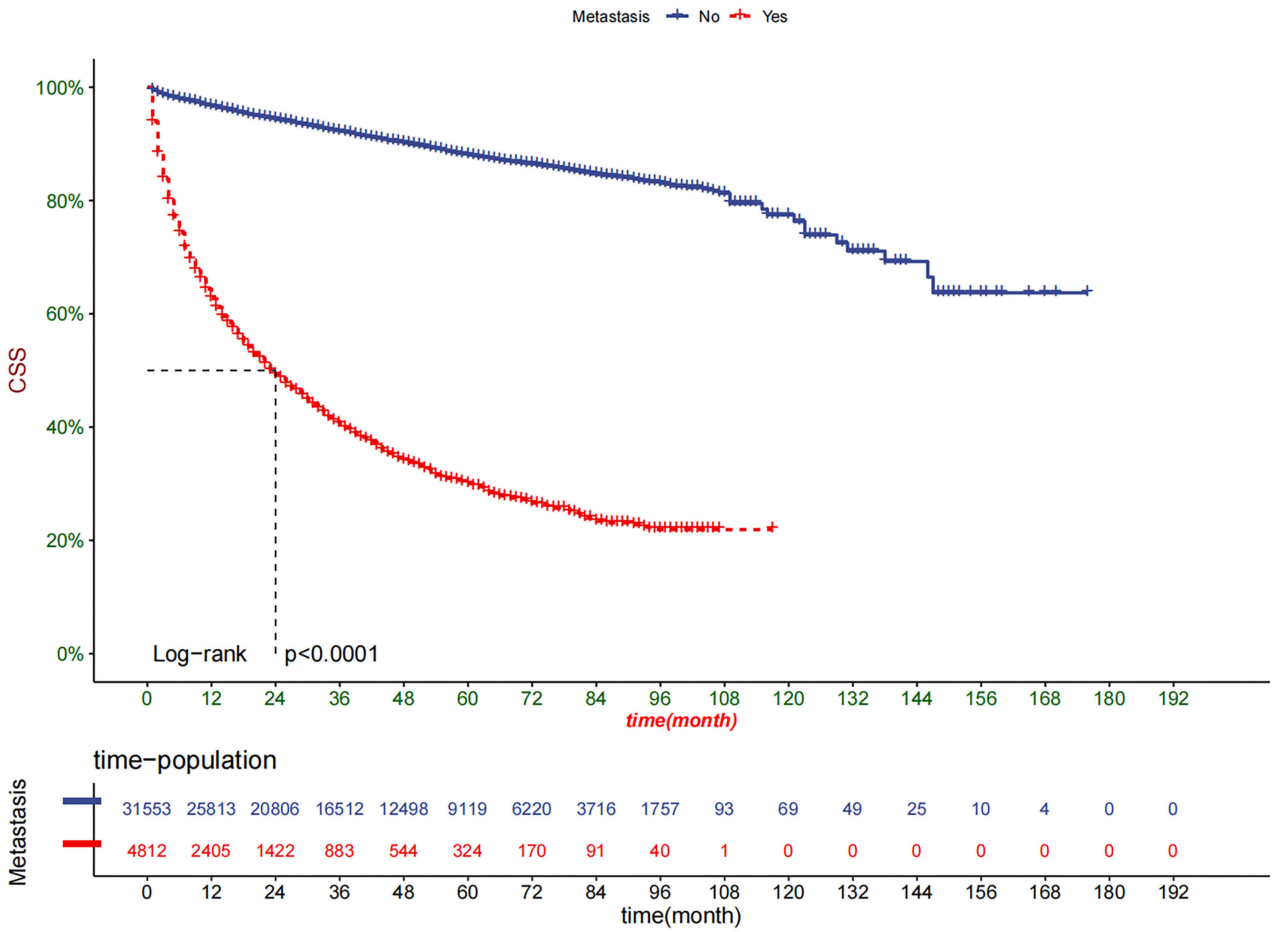

FIGURE 6 | Kaplan–Meier curves of CSS for patients in the low-risk and high-risk groups.

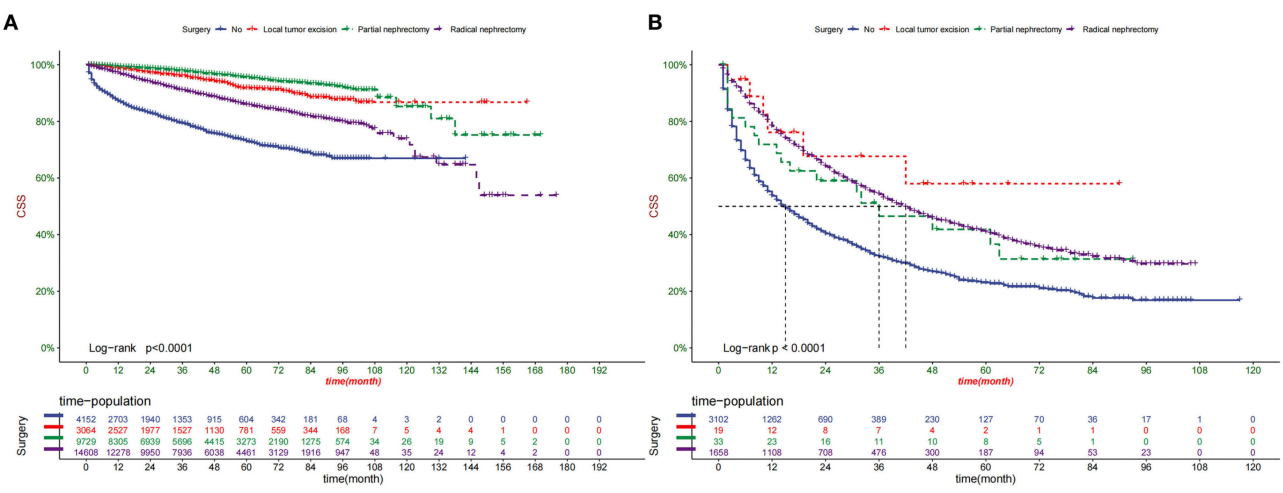

FIGURE 7 | (A) Kaplan–Meier curves of CSS for patients with different surgery in the low-risk group and **(B)** the high-risk group.

et al. (34) also found that tumor size was a risk factor for distant metastasis of renal cells. The risk of distant metastasis was significantly increased when tumor size was more significant than 3 cm. Li et al. constructed a nomogram to predict distant metastasis of RCC and found that tumors larger than 3 cm would increase the risk of metastasis (32).

Our study also found that tumor histological type and grade are important risk factors for distant metastasis. Patients with clear cell carcinoma of the kidney had the highest risk of distant metastasis, followed by papillary cell carcinoma of the kidney, and chromophobe cell carcinoma had the lowest risk of metastasis. Our results were similar to those of Zastrow et al. (34), who found that the risk of distant metastasis of renal clear cell carcinoma was the highest. In addition, we found that the degree of differentiation of RCC was associated with distant metastasis. The worse the differentiation, the higher the risk of metastasis. Previous studies have also found this phenomenon (34, 35). Because less differentiated tumors represent more aggressive biological behavior, which means they are more likely to metastasize far away.

In addition, the T stage and N stage are also crucial factors for tumor metastasis. Our study found that the higher the T stage, the greater the risk of tumor metastasis. This is understandable because the tumor invades the blood vessels and causes cancer cells to enter the bloodstream and metastasize. Lymph node metastasis is also a risk factor for distant metastasis of tumors. Previous studies have proved that regional lymph node involvement can lead to distant metastasis of tumors (6). They confirmed that regional lymph node involvement could increase the risk of distant metastasis by 50%.

In addition, surgery is also a key factor for distant metastasis of tumors. Patients without surgery are more likely to have distant metastasis than those with surgery because surgery can effectively remove or destroy cancer, thus reducing the chance of tumor metastasis. We divided patients into the high-risk metastatic and low-risk groups, and in the high-risk group, patients who underwent surgery had significantly improved survival outcomes. Patients with partial nephrectomy had the highest survival rate in the low-risk group. Because there are many complications in elderly patients, partial nephrectomy can remove the tumor with enough nephron remaining, resulting in a higher survival rate (36). Therefore, in the absence of contraindications, surgical treatment is still recommended to achieve a better outcome for patients at high risk of metastasis. For low-risk patients, partial nephrectomy is the best option.

This study explored the risk factors for distant metastasis in elderly patients with RCC. We used these risk factors to construct a graph to predict distant metastasis. After internal validation, the C-index could reach 0.95, and both the calibration curve and DCA showed the excellent accuracy of the prediction model. This prediction model can provide a practical, theoretical basis for patients' clinical decision-making and postoperative follow-up. To improve the survival rate and quality of life of elderly patients with RCC, we can better monitor the population at high risk of distant metastasis.

However, there are still some limitations to this study. First of all, this study is a retrospective study, so it is challenging to avoid selection bias. Therefore, prospective clinical trials are necessary to test the accuracy of the prediction model. Secondly, the SEER database lacks many related risk factors, such as comorbidity information, smoking, hypertension, BMI, etc. However, we included essential determinants such as tumor stage, histological type, and size so that our prediction model could achieve remarkably high accuracy. Finally, our prediction model is only validated internally, and further external validation is necessary to validate the accuracy and reliability of the model. Next, we plan to conduct a multi-center prospective clinical study to verify the accuracy of this prediction model.

CONCLUSION

This study explored the risk factors for distant metastasis in elderly patients with RCC and found that race, tumor histological type, histological grade, T stage, N stage, tumor size, surgery, radiotherapy, and chemotherapy were independent risk factors for distant metastasis. We constructed a new nomogram to predict the risk of distant metastasis in elderly patients with RCC. With good accuracy and reliability, this nomogram can help doctors and patients to carry out active monitoring and follow-up of patients to prevent distant metastasis of tumors.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://seer.Cancer.gov/.

ETHICS STATEMENT

The data of this study is obtained from the SEER database. The patients' data is public and anonymous, so this study does not require ethical approval and informed consent.

AUTHOR CONTRIBUTIONS

JW and CZ designed the study. CZ, JW, JL, LJ, and XT collected and analyzed the data. JW drafted the initial manuscript. CZ, TM, JL, ZZ, and DH revised the article critically. CZ, JL, DH, LJ, and XT reviewed and edited the paper. All authors approved the final manuscript.

FUNDING

This work was supported by Special Key Project of Chongqing Technology Innovation and Application Development (No. Cstc2019jscx-tjsbX0003).

Background: Osteosarcoma (OSC) and Ewing's sarcoma (EWS) are children's most common primary bone tumors. The purpose of the study is to develop and validate a new nomogram to predict the cancer-specific survival (CSS) of childhood OSC and EWS.

Methods: The clinicopathological information of all children with OSC and EWS from 2004 to 2018 was downloaded from the Surveillance, Epidemiology, and End Results (SEER) database. Univariate and multivariate Cox regression analyses were used to screen children's independent risk factors for CSS. These risk factors were used to construct a nomogram to predict the CSS of children with OSC and EWS. A series of validation methods, including calibration plots, consistency index (C-index), and area under the receiver operating characteristic curve (AUC), were used to validate the accuracy and reliability of the prediction model. Decision curve analysis (DCA) was used to validate the clinical application efficacy of predictive models. All patients were divided into low- and high-risk groups based on the nomogram score. Kaplan-Meier curve and log-rank test were used to compare survival differences between the two groups.

Results: A total of 2059 children with OSC and EWS were included. All patients were randomly divided into training cohort 60% (N = 1215) and validation cohort 40% (N = 844). Univariate and multivariate analysis suggested that age, surgery, stage, primary site, tumor size, and histological type were independent risk factors. Nomograms were established based on these factors to predict 3-, 5-, and 8-years CSS of children with OSC and EWS. The calibration plots showed that the predicted value was highly consistent with the actual value. In the training cohort and validation cohort, the C-index was 0.729 (0.702–0.756) and 0.735 (0.702–0.768), respectively. The AUC of the training cohort and the validation cohort also showed similar results. The DCA showed that the nomogram had good clinical value.

Conclusion: We constructed a new nomogram to predict the CSS of OSC and EWS in children. This predictive model has good accuracy and reliability and can help doctors and patients develop clinical strategies.

Keywords: nomogram, cancer-specific survival, Osteosarcoma, Ewing's sarcoma, children

INTRODUCTION

Osteosarcoma (OSC) and Ewing sarcoma (EWS) are the most common primary malignant bone tumors in children and young people (1–3). OSC is the most common tumor in children and adolescence, and its peak incidence occurs in adolescence. The annual incidence rate for children under 10 years old is 1.7 per 100,000, while the yearly incidence rate for patients between 10 and 19 is 8.2 per 100,000 (4). Although various treatments are used to improve the prognosis, the survival rate of OSC is still shallow (5–7), the 5-year survival rate of patients with localized OSC can reach 65–70% (8). In comparison, the survival rate of patients with metastatic OSC is only 19–30% (9, 10). EWS is a malignant bone tumor commonly seen in children and adolescents. Its incidence is second only to OSC, accounting for 3% of solid malignant tumors in children (2, 3). In recent years, with the improvement of treatment technology, the 5-year survival rate of EWS has reached 60% to 70%, but the prognosis of patients with metastasis and recurrence is still poor (11).

Yang et al. (12) established a nomogram to predict the cancer-specific survival (CSS) and overall survival rate of OSC. It showed that age, stage, grade, surgery, primary site, and tumor size were independent risk factors for OSC. Lu et al. (13) established a nomogram to predict the risk of distant metastasis of OSC. We found that age, tumor location, tumor grade, T stage, and surgical method were risk factors for metastasis and suggested a worse prognosis. Zhou et al. (14) established a nomogram to predict the overall survival of EWS, revealing that age, N stage and bone metastasis are independent risk factors for prognosis. However, as far as we know, no nomogram has been established for children with OSC and EWS to predict tumor-specific survival.

At present, artificial intelligence has been widely used in human health. Dhanamjayulu et al. (15) used machine learning to identify malnourished people. Gadekallu et al. (16) used a neural network to predict retinopathy in diabetic patients. Reddy et al. (17) used an artificial intelligence algorithm to diagnose heart disease. Abbas et al. (18) used a new algorithm to monitor breast cancer. Mubashar et al. (19) use artificial intelligence to manage personal health records.

The nomogram is a way to estimate the occurrence of a given event by generating corresponding values from the clinical-pathological information of the patient. At present, nomograms have been widely used in the clinical prediction of liver cancer, lung cancer, and breast cancer (20–22). As the two most common bone malignancies in children, OSC and EWS seriously endanger children's health. Revealing the prognostic factors of childhood OSC and EWS can help doctors and patients choose appropriate treatment measures, which is conducive to prolonging the survival time of patients and improving the quality of life. In other words, accurately predicting the prognosis of malignant tumors can help patients and doctors formulate treatment plans and follow-up strategies.

However, the prediction models for OSC and EWS in children are still not well established. No studies have precisely predicted CSS in pediatric OSC and EWS patients. Bone tumor in children is an essential factor endangering children's health. Accurate prediction of the survival of bone tumors in children can enhance the population's health and improve people's overall quality of life and life span. Therefore, it is necessary to construct a nomogram to predict the survival prognosis of childhood OSC and EWS.

Abbreviations: OSC, Osteosarcoma; EWS, Ewing's sarcoma; SEER, the Public Surveillance, Epidemiology, and End Results; CSS, cancer-specific survival; C-index, concordance index; AUC, area under the receiver operating characteristic curve; DCA, decision curve analysis.

PATIENTS AND METHODS

Data Source and Data Extraction

Patient data are downloaded from the Surveillance, Epidemiology, and End Results (SEER) project of the National Cancer Institute. From 2004 to 2018, all children under 18 diagnosed with OSC and EWS were collected. The SEER database is a cancer database in the United States, covering about 28% of Americans, and contains 18 cancer registries (23). The SEER database discloses patient demographic information, clinicopathological characteristics, and survival status. The clinicopathological information we used is public and anonymous, so our study does not require ethical approval and patient consent. Our study method complies with the regulations of the SEER database.

We collected patient demographic information (age, sex, race), tumor characteristics (tumor grade, size, primary location, pathological type), treatment (surgery, radiotherapy, chemotherapy), follow-up information (survival status, survival time). The selection criteria are: (1) age less than 18 years old; (2) diagnosed as OSC and EWS. The exclusion criteria are: (1) the surgical method is unknown; (2) non-primary tumor; (3) the tumor size is unknown; (4) The location of the tumor is not precise; (5) Survival time less than 1 month. The flowchart of patient screening is shown in **Figure 1**.

The race of all children was divided into white, black, and other (American Indian/AK Indian, Asian/Pacific Islander). The tumor grade was split into I (well-differentiated), II (medium differentiated), III (poorly differentiated), IV (undifferentiated). According to the SEER surgery code, the surgery methods were divided into four groups: no surgery, partial resection, radical excision, and amputation. The primary site of the tumor was divided into the limb, cranial, spine, thoracic, and pelvic.

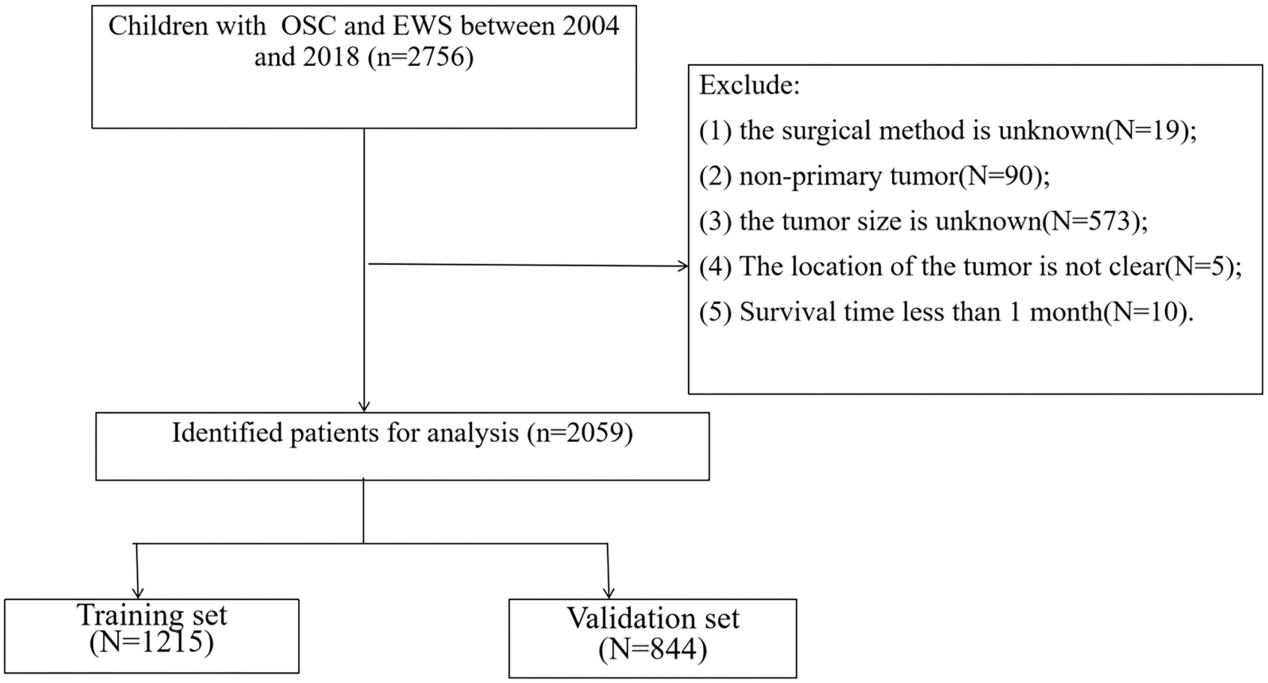

FIGURE 1 | The flowchart of including and dividing patients.

Univariate and Multivariate Cox Regression Analysis

All patients were randomly divided into a training set (60%) and a validation set (40%). Univariate Cox regression screened out related prognostic factors. Then multivariate Cox regression analysis was used to analyse the independent risk factors of the training set. And we recorded the hazard ratio (HR) and 95% confidence interval (CI) simultaneously.

Nomogram Construction

Based on the independent risk factors obtained by univariate and multivariate Cox regression, a nomogram was constructed to predict the 3-, 5-, 8-year CSS of children with OSC and EWS. Each variable is distributed on the nomogram according to its weight to get different lines, and the points of each variable correspond to a point. The sum of the points of all the variables in the nomogram can equal an overall points, thus obtaining survival rates at different points in time.

Nomogram Validation

Then a series of validation methods were used, including the consistency index (C-index), the calibration curve, and the area under the receiver operating characteristic curve (AUC). The accuracy of the nomogram was tested mainly by the calibration curve, which was used to compare the relationship between the observed value and the actual value through 1,000 bootstrap sampling. The results of the calibration curve are dotted in the **Figure 3**. If they are close to the diagonal, the model has good accuracy. Both the C-index and the AUC are used to assess the discrimination of the model.

Clinical Utility

Decision curve analysis (DCA) is a new algorithm to evaluate the clinical value of the model based on the net benefit under each risk threshold (24). DCA was used to assess the clinical potential application value of the new nomogram. Subsequently, we divided the patients into a low-risk group and a high-risk group through the nomogram score of each patient. The Kaplan-Meier curve and log-rank test were used to compare the survival differences of different risk groups. At the same time, we analyzed the surgical methods of patients in other risk groups.

Statistical Analysis

All statistics were performed using SPSS23.0 (IBM, Chicago, IL, USA) and R software (version 3.4.1; http://www.Rproject.org). Age and tumor size were continuous variables and did not follow a normal distribution; median and the inter-quartile range was used for description. All possible prognostic factors were confirmed using univariate Cox regression. Then, the relevant variables were included in the multivariate analysis and the stepwise regression method was used to select the best Cox regression model. A $p < 0.05$ was considered statistically significant.

RESULTS

Clinical Features

A total of 2,059 children with OSC and EWS were included in our study. They were divided into a training set (N = 1215) and a validation set (N = 844). The clinicopathological characteristics are shown in **Table 1**. There was no significant difference between the training set and the validation set. The median age of all children was 13 years old (interquartile range, 10–15 years old), including 1,179 males (57.3%) and 1,624 whites (78.9%). One thousand three hundred eighty-five cases (67.3%) were OSC, and 674 cases (32.7%) were EWS. Children whose primary tumors were located in limb, cranial, spine, thoracic and pelvic were 1,576 cases (76.5%), 93 cases (4.52%), 56 cases (2.72%), 118 cases (5.73%), and 216 cases (10.5%), respectively. Children with tumor grades I, II, III, and IV was 23 (1.12%), 48 (2.33%), 419 (20.3%), and 747 (36.3%), respectively. There were 673 cases (32.7%), 842 cases (40.9%), and 531 cases (25.8%) of children whose tumor stages were localized, regional and distant, respectively. The median tumor size was 90 mm (interquartile range, 62–125 mm). Most children have performed chemotherapy (1,978, 96.1%), and most have not completed radiotherapy (1,674, 81.3%). Partial resection, radical excision and amputation were performed in 230 cases (11.2%), 1,166 cases (56.6%), and 342 cases (16.6%). A total of 474 patients (23.0%) had distant metastases.

Univariate and Multivariate Cox Regression Analysis

We first established a univariate Cox regression model to screen possible prognostic factors. Then we established a Cox multivariate model to identify independent risk factors affecting OS in children. Univariate and multivariate Cox regression results are shown in **Table 2**. Finally, we found age (HR 1.030; 95% CI 1.006–1.055), tumor size (HR 1.002; 95% CI 1.001–1.003), histological type (HR 0.563; 95% CI 0.434–0.73), surgery, stage, and primary site were independent risk factors. In other words, these six factors can be used to establish a nomogram to predict the CSS of OSC and EWS in children.

Nomogram Construction for 3-Year, 5-Year, and 8-Year CCS

The six independent risk factors above were used to construct a nomogram to predict CSS in children with OSC and EWS (**Figure 2**). The nomogram accurately listed the impact of each factor on CSS. We found that tumor size was the most significant influencing factor, and a large tumor meant a higher risk of death. The second was the staging of tumors. There was no doubt that distantly metastatic tumors had a higher risk of death than in localized or regional tumors. The location of the primary tumor was also a significant risk factor. We found that tumors in the spine, pelvis, and thorax have a significantly higher risk of death than tumors in the limbs and skull. In addition, the children with radical resection of the tumor, the younger children and the children with EWS had the lowest mortality.

Validation of the Nomogram

The C-index of the training set and the validation set were 0.729 (95% CI 0.702–0.756) and 0.735 (95% CI 0.702–0.768), respectively. This showed that the nomogram has good discrimination. The calibration curves of the training set and the validation set showed that the predicted value of the nomogram is highly consistent with the observed value (**Figures 3A–F**), which proved that the nomogram has good accuracy. In the training set, the 3-, 5-, 8-year AUC of the nomogram were 74.7 (95% CI 71–78.4), 72.5 (95% CI 68.9–76.1), 68.7 (95% CI 64.5–73.0), respectively. In the validation set, the 3-, 5-, 8-year AUC of the nomogram were 73.6 (95% CI 69.0–78.2), 71.2 (95% CI 66.5–75.9), and 72.3 (95% CI 67.3–77.3), respectively (**Figures 4A,B**). The AUC results once again proved the accuracy and discrimination of the nomogram. These validations showed that the nomogram was at least 70% accurate, especially for predicting medium-term survival.

Clinical Application of the Nomogram

The DCA of the training set and the validation set showed that the clinical value of the nomogram is higher than that of the tumor stage (**Figures 5A,B**). According to the score of the nomogram, the patients were divided into two groups: low-risk group (total score $<$75.46) and high-risk group (total score $\geq$75.46). The Kaplan-Meier curve showed that high-risk patients have lower survival rates than low-risk patients (**Figures 6A,B**). In the total set, the low-risk group's 3-year, 5-year, and 8-year CSS rates were 92.2, 89.7, and 81.5%, the high-risk group were 75.7, 67.5, and 63.3%, respectively. In addition, we analyzed the impact of surgical methods in different risk groups on the survival probability of patients. In the low-risk group, radical resection was the primary surgical method, and there was no significant difference in the survival rate of various surgical methods (**Figure 7A**). In the high-risk group, patients with radical resection had the highest survival rate, followed by partial resection, amputation and no surgery (**Figure 7B**).

DISCUSSION

OSC is the most common malignant bone tumor in children. The application of neoadjuvant chemotherapy has increased the survival rate of patients with OSC from 15 to 17% of surgical treatment alone to 70% (25). However, the survival rate of patients with OSC has not improved significantly in the past 30 years. As the second most common bone tumor in children, EWS has a lower mortality rate than OSC, but metastatic EWS is still a fundamental cause of harm to children's health (26). Because it is a highly aggressive cancer, it can metastasise to bone marrow, lung and other tissues in the early stage of the disease (27–29): children's malignant bone tumors, especially OSC, hurt patients. Accurately assessing prognostic factors can improve the prognosis and help clinicians effectively evaluate survival and make treatment decisions.

We collected 2,059 children with OSC and EWS from the SEER database. The results showed that the survival rate of children with EWS was significantly higher than that of OSC. More whites than blacks and other races and more boys than girls

TABLE 1 | Clinicopathological characteristics of children with bone tumor.

	Total (*N* = 2,059)	Training cohort (*N* = 1,215)	Validation cohort (N = 844)	*p*

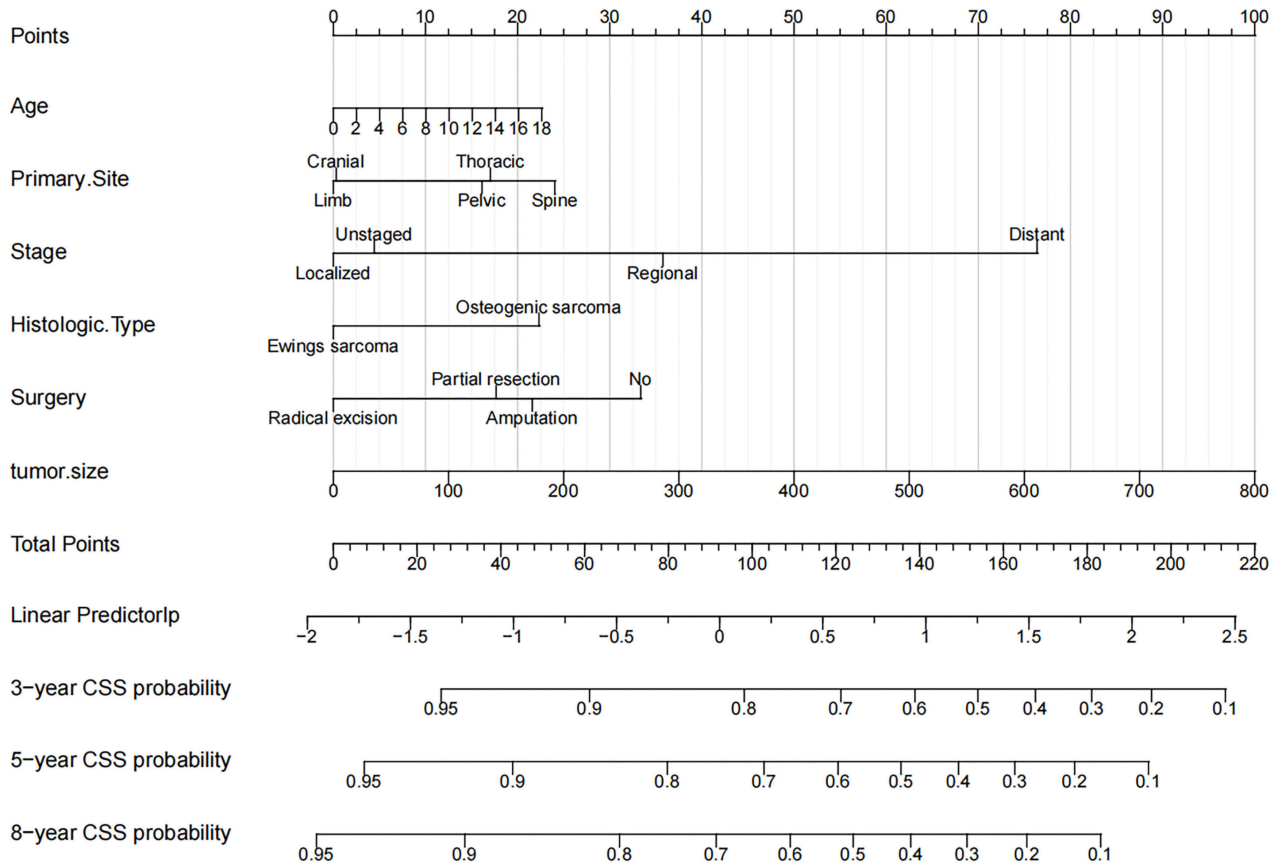

FIGURE 2 | Nomogram for 3-, 5-, and 8-year CSS of children with OSC and EWS.

in all children. The median age of all children was 13 years old, and the peak incidence was 12–15 years old. This study found six independent risk factors through univariate and multivariate Cox regression models, including age, surgery, stage, primary site, tumor size, and histological type. The nomogram includes these factors to establish a predictive model to predict the 3-, 5-, 8-year CSS of childhood OSC and EWS. We first use a nomogram to predict and validate CSS in childhood OSC and EWS. This nomogram has good accuracy and reliability and is of great significance to clinical patients. The nomogram is user-friendly and can be applied to everyone with simple learning.

Previous studies have found prognostic factors for OSC and EWS. However, no study has used these influencing factors to construct a prediction model for survival prediction of children with a bone tumor. Although the influencing factors we identified have previously been shown to be independent risk factors, we integrated these risk factors to construct a nomogram predicting long-term survival in children with OSC and EWS.

Previous studies have shown that various prognostic factors (age, tumor location, type of surgery, local recurrence) will affect the survival of patients (30–32). Our study found that age is an independent risk factor for malignant bone tumors in children, and the survival rate of older children is lower, the same as previous research results (33, 34). Lee et al. (35) found that fewer adult patients receive chemotherapy, which may also be a reason. In addition, we found that the tumor's location near the central axis (spine, pelvis, thorax) has a significantly higher risk of death than the limbs. Like previous studies, axial tumor location predicts the worst prognosis (36, 37). Wan et al. (38) also found that the survival rate of EWS of the spine and pelvis was lower. Because the tumors in the axial position are easier to infiltrate vital organs and metastases far away than the tumors of the limbs. Oberlin et al. (39) believe that bone tumors of the limbs can be removed by surgery, but it is more difficult to remove the axial bone's tumors. Similarly, as in a previous report (40), our study found that tumor size is also a significant risk factor. Large tumors are prone to metastasis, indicating a worse prognosis.

In addition, surgical treatment of bone tumors in children, especially in extremity tumors, is still an important issue. With the widespread development of neoadjuvant chemotherapy and standardized surgery, the survival rate of patients with malignant bone tumors has improved significantly, and limb salvage has become the primary surgical method in treating malignant bone tumors. This treatment model can preserve the function of the limbs and joints and effectively reduce the metastasis and recurrence of OSC (41). Whether it is the low-risk or high-risk group, radical salvage resection has the highest survival rate in our study. However, overall,

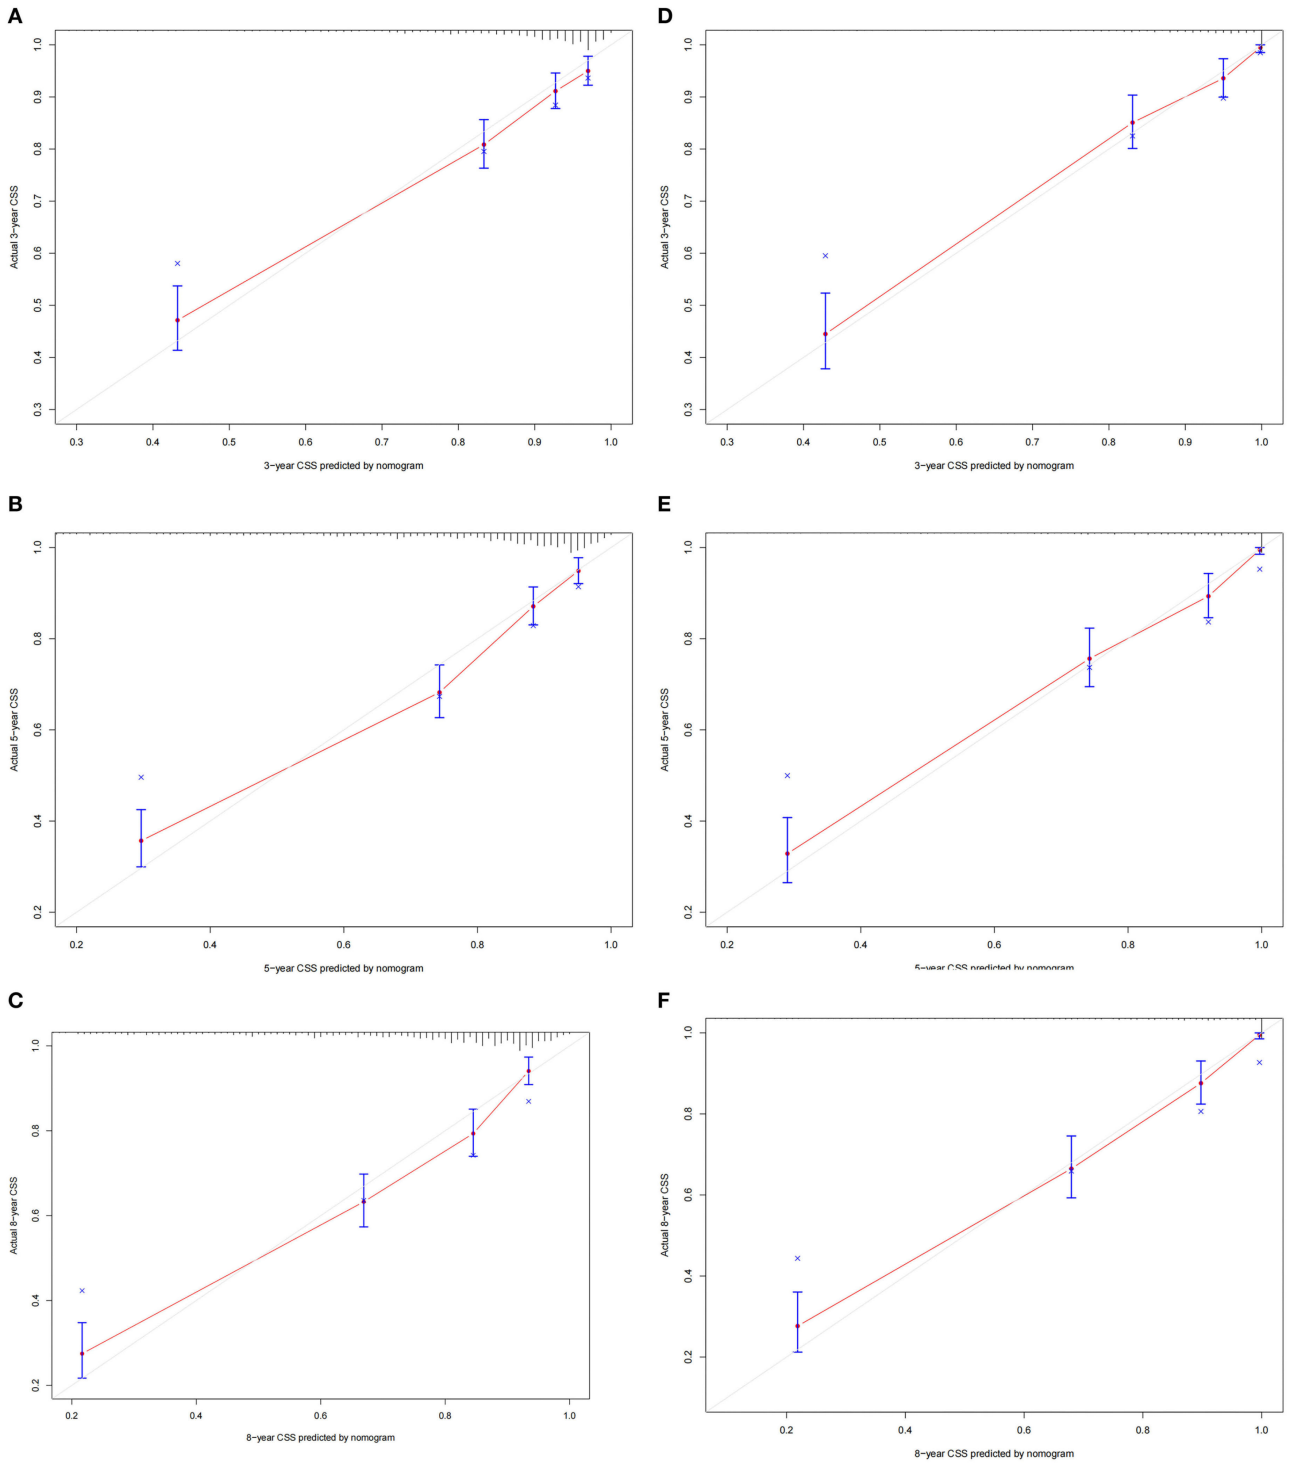

FIGURE 3 | Calibration curve of the nomogram. **(A–C)** For 3-, 5-, and 8-year CSS in the training set; **(D–F)** for 3-, 5-, and 8-year in the validation set.

patients with surgery have a higher survival rate than those without surgery.

Chemotherapy and surgery are still the main treatments for OSC (1). In our study, almost all patients received chemotherapy. In addition, radiotherapy seems to be controversial for treating bone tumors in children. Because surgery is still a radical cure for malignant bone tumors, it will only be considered if cancer cannot be removed entirely (42). For children, radiotherapy

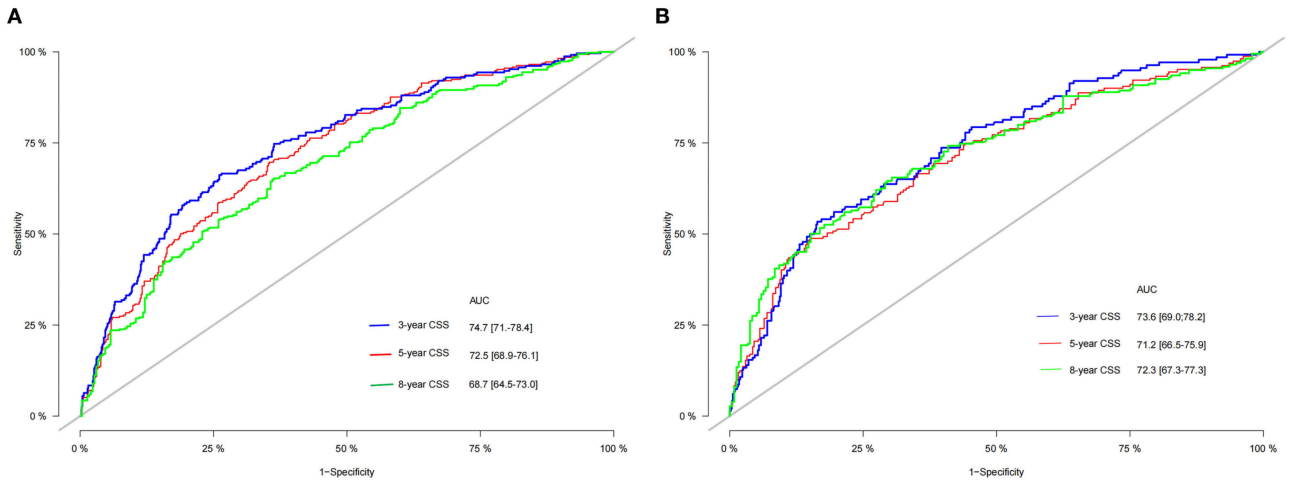

FIGURE 4 | The ROC of 3-, 5-, and 8-year of the training **(A)** and validation **(B)** sets.

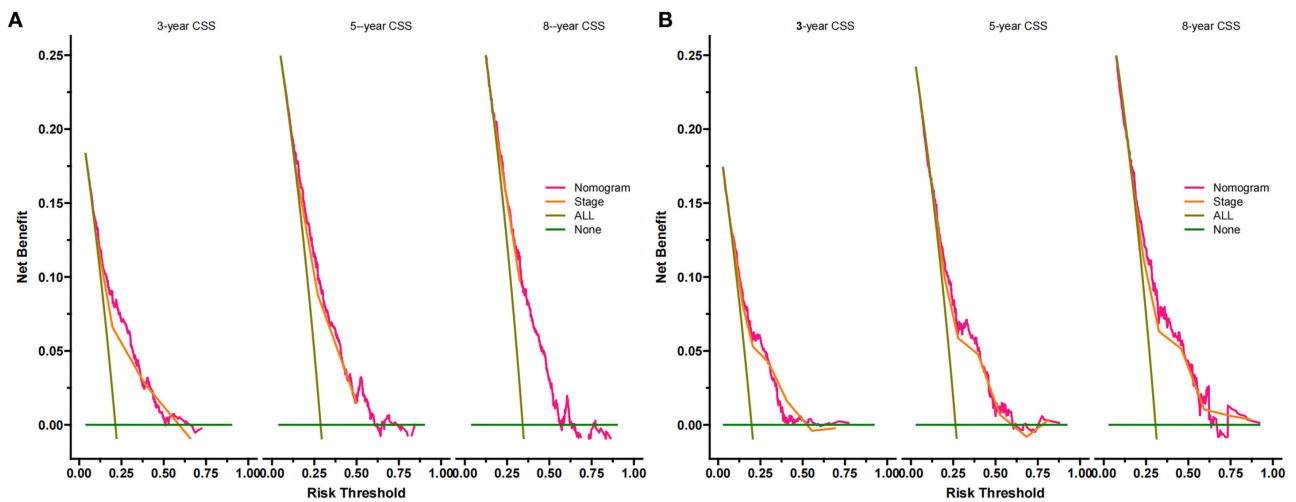

FIGURE 5 | Decision curves of the nomogram predicting CSS in the training set **(A)** and the validation set **(B)**. The x-axis is the threshold probability, and the y-axis is the net benefit. The green line indicates that no patients have died, and the dark green line indicates that all patients have died. When the threshold probability is between 10 and 50%, the net benefit of the model exceeds all deaths or no deaths.

may cause developmental delay of bones or organs. Even if it has a therapeutic effect on tumors, it will also seriously affect the quality of life in the future. Our research also found that only a few patients received radiotherapy, similar to previous studies (43).

It is worth mentioning that our analysis found that sex, race, and tumor grade are not independent risk factors. Previous studies have found that they are indeed related to the patient's survival prognosis (44–46). Regarding the grade of the tumor, it may be related to too many cases of unclear grades. Whether race and sex factors affect, the prognosis needs further research.

However, our research still has certain limitations. First, because our study is a retrospective case study based on the SEER database, some possible variables such as surgical margins, tumor recurrence, genetic factors, etc., are not available. However, we have included essential variables such as tumor size, tumor location, pathological type and other vital elements that determine the prognosis and will not cause devastating deviations. Second, we included patients from 2004 to 2018. With the improvement of treatment methods, the survival rate of patients in different years should be different. However, we stratified by the year of diagnosis and found no significant difference, indicating that it did not affect the results. Finally, all the data used in our study were downloaded from the SEER database, and the constructed nomogram lacks external data to validate. Therefore, it is necessary to use external validation further to test the accuracy and reliability of the prediction model. Next, we will conduct further prospective studies in our hospital to externally validate the accuracy of this prediction model further to promote the clinical application.

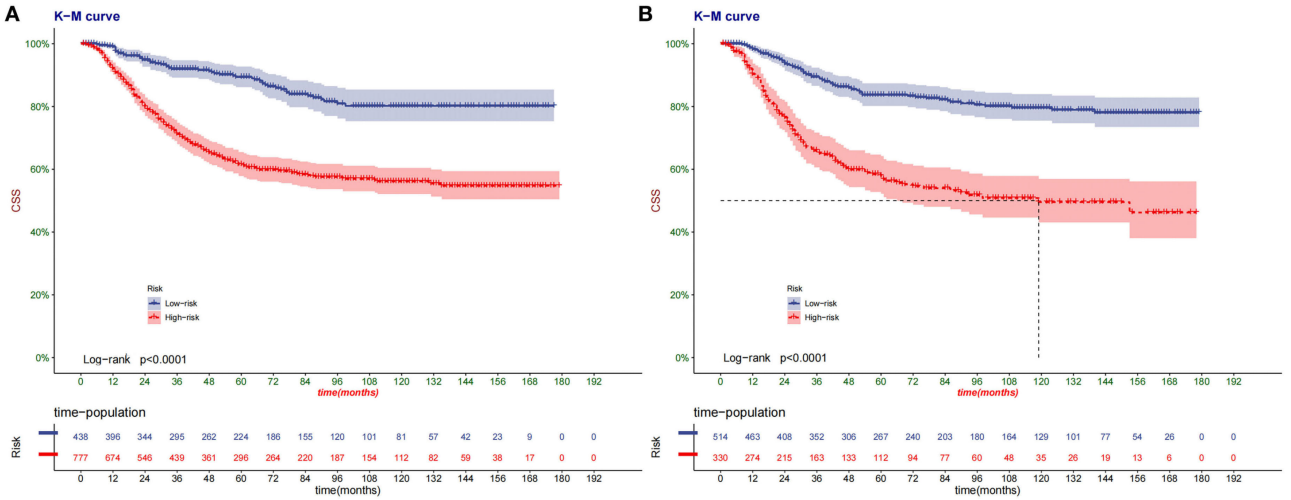

FIGURE 6 | Kaplan–Meier curves of CSS for children in the low- and high-risk groups in the training set **(A)** and validation set **(B)**.

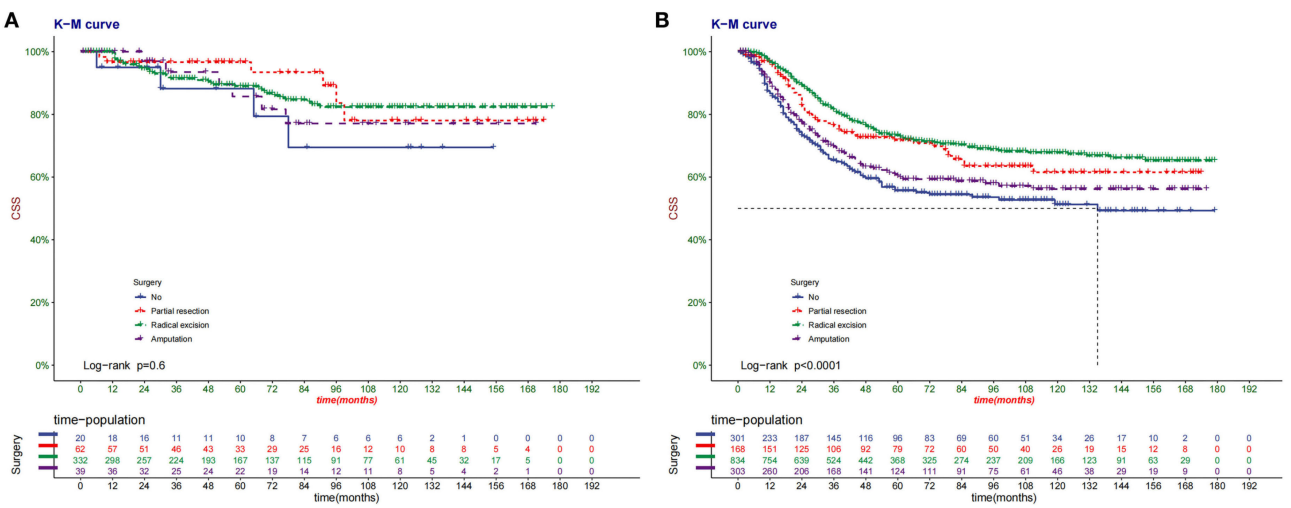

FIGURE 7 | Kaplan–Meier curves of CSS for children with different surgery in the low- **(A)** and high-risk **(B)** groups in total set.

CONCLUSION

We constructed a new nomogram to predict the CSS of children with OSC and EWS. In addition, we found that age, surgery, stage, primary site, tumor size, and histological type are important risk factors affecting children with OSC and EWS. The discovery of risk factors and the Construction of nomograms can help doctors accurately grasp the prognosis of patients, answer patient consultations and help patients make clinical decisions.

DATA AVAILABILITY STATEMENT

Publicly available datasets were analyzed in this study. This data can be found here: https://seer.Cancer.gov/.

AUTHOR CONTRIBUTIONS

JW and CZ designed the study. CZ, JW, JL, ML, LJ, and XT collected and analyzed the data. JW drafted the initial manuscript. CZ, TM, JL, ZZ, and DH revised the article critically. CZ, JL, DH, ML, and XT reviewed and edited the article. All authors approved the final manuscript.

FUNDING

This work was funded by Special Key Project of Chongqing Technology Innovation and Application Development (No. Cstc2019jscx-tjsbX0003).

Alzheimer's Disease (AD) is a progressive, neurodegenerative brain disease and is an incurable ailment. No drug exists for AD, but its progression can be delayed if the disorder is identified at its initial stage. Therefore, an early analysis of AD is of fundamental importance for patient care and efficient treatment. Neuroimaging techniques aim to assist the physician in the diagnosis of brain disorders by using images. Positron emission tomography (PET) is a kind of neuroimaging technique employed to create 3D images of the brain. Due to many PET images, researchers attempted to develop computer-aided diagnosis (CAD) to differentiate normal control from AD. Most of the earlier methods used image processing techniques for preprocessing and attributes extraction and then developed a model or classifier to classify the brain images. As a result, the retrieved features had a significant impact on the recognition rate of previous techniques. A novel and enhanced CAD system based on a convolutional neural network (CNN) is formulated to address this issue, capable of discriminating normal control from Alzheimer's disease patients. The proposed approach is evaluated using the 18FDG-PET images of 855 patients, including 635 normal control and 220 Alzheimer's disease patients from the ADNI database. The result showed that the proposed CAD system yields an accuracy of 96%, a sensitivity of 96%, and a specificity of 94%, leading to splendid performance when related to the methods already in use that are specified in the literature.

Keywords: Alzheimer's disease, accuracy, convolutional neural network, deep learning, feature extraction, image analysis, image classification and positron emission tomography

1. INTRODUCTION

Alzheimer's disease (AD) is a type of brain disease which regularly affects people over 65 years old. It is a progressive and neurodegenerative disorder, meaning that, it becomes worse with time. According to an Alzheimer's Association report, around 55 million people are living with AD worldwide and it is envisioned that the number of AD patients will reach 152 million by 2,050. The number of people with AD is progressively increasing worldwide. The prime objective of this paper is to develop a robust classification system for AD diagnosis using a convolutional neural network (CNN). In this approach, the 3D image classification problem is completely

solved by converting them into 2D images. The proposed system uses whole brain images for AD diagnosis instead of region of interest. Thus, there is no need for a segmentation algorithm. Furthermore, the proposed system uses CNN for classification. CNN learns the features from images. Pre-processing like noise removal, enhancement, and feature extraction are not needed. AD starts with impairment of memory functions followed by cognitive functions with behavioral impairments (1). Some common symptoms of AD are: memory loss, a lack of initiative, difficulty in expressing thoughts and recognizing people or relations, personality changes, and poor judgement, etc. AD is an incurable brain disorder. Currently, no effective treatment has yet been fully discovered, but it is possible to slow down the progression of AD if the disorder is identified at its initial stage. Therefore, it is of primary significance to identify AD at an early stage for patient care, as well as effective treatment. Furthermore, if the condition is diagnosed early on, some of the changes induced by AD can be reversed, allowing patients to keep their everyday lives. However, diagnosis of AD still remains a highly complicated task, especially at an early stage while the disorder offers greater opportunities to be treated (2).

Over the past few years, several neuro imaging modalities which include magnetic resonance imaging (MRI), positron emission tomography (PET) (3), and single-photon emission computerized tomography (SPECT) have been confirmed to be very powerful within the diagnosis of AD. PET is a non-invasive neuro imaging technique that uses an imaging agent like 18FDG-PET to monitor the brain's glucose intake. Brain activity is related to glucose consumption. During PET scanning, a position emitting radionuclide tracer with 18FDG is delivered in the body. The glucose uptake shows tissue enzymatic reactions when the quantities of these traces are scanned with a camera. In seriously damaged AD patients, particular brain areas showed reduced glucose intake, together with bilateral areas inside the temporal and partial lobes, posterior cingulate, frontal lobes, and entire brain (4). Research studies proved that FDG-PET is a good candidate for AD diagnosis and can be used to assist the physicians or an expert to analyze and diagnosis AD in early stages. Consequently, this paper proposes an automated computer-aided design (CAD) system for the diagnosis of AD using 18FDG-PET images. The foremost awareness of this research work is to distinguish AD patients from normal control (NC) employing CNN (5).

Classification of medical images via visual examination by an expert or a physician can be subjective and prone to errors. As a result, researchers attempted to create an automatic CAD system that could distinguish AD from NC participants using picture data attributes. Over the past few years, numerous machine learning models have evolved and are being used for examining neuro reading that allows researchers to capture the structure or functional changes related to AD including support vector machine (SVM) (6) classification in SPECT and learning vector quantization-SVM (LVQ-SVM) classification in structural MRI (7).

Wysoczánski et al. (1) investigated the strength of random forest (RF) for diagnosing AD. The authors used partial least square (PLS) for extracting features from the image. This method is tested on SPECT images downloaded from the ADNI dataset. A new CAD system for differentiating AD from NC based on PET image features was developed by Cabral and, Silveria (4). Garali et al. (8) proposed a classification system using favorite class ensembles for differentiating AD and MCI from NC using PET images. Each classifier in the ensemble uses a different set of brain voxels. Two base classifiers SVM and random forest are employed to create the ensemble classifier. Results showed that this ensemble classifier outperforms the corresponding single classifier. However, higher computational cost is the drawback of this system. Markiewicz et al. (9) presented a region-based method to classify AD from NC using 16 anatomical regions of interest (ROIs), and the first four times, as well as their entropy, are computed and used as feature vectors. The capacity of ROIs to discriminate PET images is then ranked using ROC curves. Finally, 21 capabilities are selected and fed as an input to both SVM and RF classifiers. Results proved that this method achieved high classification accuracy using 166 anatomical ROIs when compared to other methods. Poongodi and Bose (10) proposed a deep learning model for AD diagnosis from MRI images. A deep neural network is designed with a convolution layer, normalization layer, and pooling layer. The effectiveness of this method is validated on the OASIS dataset. Results showed improved performance of this particular method when compared to other methods. A boosting classifier to classify PET images was developed by Poongodi and Bose (11). It is the combination of simple classifiers, which performs segmentation, feature extraction, and feature selection in order to make the input image fit for the classification task. This classifier was validated on the ADNI dataset and achieved an accuracy of 90.97%.

2. DISTINCT FEATURES OF THE PROPOSED METHOD

In the literature, researchers have developed an automated CAD system using various soft computing models (12). Most of the researchers have used either full brain images or set features for diagnosing AD. Each method has its own merits and demerits. However, none of the methods offer a consistent outcome. Keeping this in mind, this research work intends to design and render a CAD system for discriminating AD from NC with the help of CNN. In the proposed CAD system, the first 15 slices and last 15 slices are discarded to remove unwanted regions. Dimension-reduced 18FDG-PET images are fed as input into the deep neural network. CNN is used for classifying FDG-PET snapshots into NC and AD. The efficacy of CNN is evaluated by measuring accuracy, sensitivity, and specificity, and is compared with the existing methods (13–16).

For solving the shortcomings of the methods elaborated in the literature, this paper presents a novel computer diagnosis system using a deep convolutional neural network. The conventional neural network has the potential of recognizing images with minimal processing. The novel features of the proposed system are: 3D images are transformed into 2D images so as to reduce the computational time, 2D images are further grouped at specific intervals for reducing the dimension, image segmentation is not

required in this proposed approach, and no image processing techniques are needed to extract features from the images.

From the existing literature survey, it could be seen that, in existing computer-aided diagnosis systems, in those intended to classify the brain images (5), it was observed that most of the systems employ image processing methods to classify the data, therefore, a machine learning model was designed to obtain the features. Also, few methods use only the information from regions of interest (17). However, these methods require increased computational time. In addition, the classification accuracy depends mainly upon the selected features. Researchers developed hybrid models by combining a deep learning neural network and machine learning model to increase the classification accuracy, but these models required increased memory usage and increased time (18).

To overcome these issues, the proposed CAD system employs the consideration of entire brain images instead of regions of interest. The 3D picture type problem is completely solved with the aid of converting them into 2D images. Venugopalan et al. (19) proposed a set of rules that might help in robot surgical treatment. To run on such soft tissues, software program-driven techniques and algorithms have to be extra particular in choosing the highest quality direction for attaining the procedural region. Statistical analysis has determined whether the proposed approach might be outperforming under the favorable learning rate, discount factor, and the exploration factor (20). The network is built with multiple layers to learn features through a training process, which eliminates the need for extracting the features, resulting in higher prediction performance when compared to other approaches. Reddy et al. (21) focused on classifying tomato disease with a machine learning model used to predict agricultural disaster. The features were extracted from the dataset using the hybrid-predominant element evaluation-whale optimization algorithm and the extracted features were fed into a deep neural network for classification of tomato diseases. Srinivasu et al. (22) focused on improving quality, a preprocessing technique was implemented in a multimodal stroke dataset from the Kaggle repository. To achieve homogeneity, a label encoder technique was used and dataset missing values were replaced with attribute means. Resampling techniques were used to balance the dataset and to obtain accurate results. The following is how the rest of the paper is organized: The demographic details of the dataset utilized in this work are presented in section 2. Section 3 formulates the unique features of the proposed CAD device for AD prognosis. Section 4 presents the unique evaluation of numerical results and evaluation of the results. Finally, section 5 concludes the paper with few suggestions toward future research in closer vicinity of this study.

3. DATASET DETAIL

The neuroimaging dataset that was used in this study is presented in this section.

The visual dataset used in this study was acquired from ADNI, which is publicly available (http://adni.loni.usc.edu/methods/pet-analysis-methods). The ADNI database was released in 2003 by the NIA, NIBIB, and FDA. The ADNI was designed for the diagnosis of AD at the earliest stage and tracking of progression of AD with several biomarkers such as MRI, PET, and SPECT. ADNI helps researchers to gather, collect, and use the image data including PET to measure and track the progression of AD.

TABLE 1 | Demographic details of 18FDG-PET image dataset.

Factors	Normal control	Alzheimer's disease
Number of subjects	635	220
Age	70	75
Gender (M/F)	35/15	30/20
MMSE	24–30	20–26
CDR	0	1.5 or 1

18FDG-PET images of 855 patients and their final diagnosis were collected from ADNI. The detailed procedure for 18FDG-PET scanning can be found on the website (http://adni.loni.usc.edu/methods/pet-analysis-methods). The total data have 855 samples including 635 NC and 220 AD subjects. The dataset is split into two categories: training data and validation data. Around 90% of the data, referred to as training data, was used to construct the model, while the remaining 10%, referred to as validation data, was used to validate the model. Description of 18FDG-PET images investigated in this work is provided in **Table 1**. Only subjects with CDR of 0.5 or 1 for AD and 0 for NC were chosen. Classification was based on MMSE (Mini Mental State Examination) scores of 24 to 30 for NC and 22 to 26 for AD. The resulting volumes of images have been represented by means of a matrix of size 256x256x96 yielding a total of 6291456 voxels. The values are denoted as mean plus or minus std deviation.

4. PROPOSED CAD SYSTEM

4.1. In-linestyle

The capture of 18FDG-PET images in ADNI followed a conventional methodology. The pictures were co-registered, averaged, aligned, normalized, and smoothed to a similar resolution of 8 mm FWHM 30–60 min after injection. Each image was examined for artifacts and, if needed, its orientation was changed.

Subsequently, the FDG-PET images have been normalized through an affine model with 12 parameters using SPM12 software, normalized in intensity, and converted to a uniform isotropic resolution of 8 mm FWHM. All the images were reduced to a size of 160 x 160 x 96 for analysis. **Figure 1** shows the sample of co-registration using SPM12.

4.2. Classification

Numerous methods have been proposed for AD diagnosis using various approaches like RF, SVM, and ANN. Each method has its own characteristics. In recent years, deep learning neural networks were used for medical photo evaluation and computer vision problems due to its ability to capture the features from 2D images. Additionally, CNN has the potential to recognize

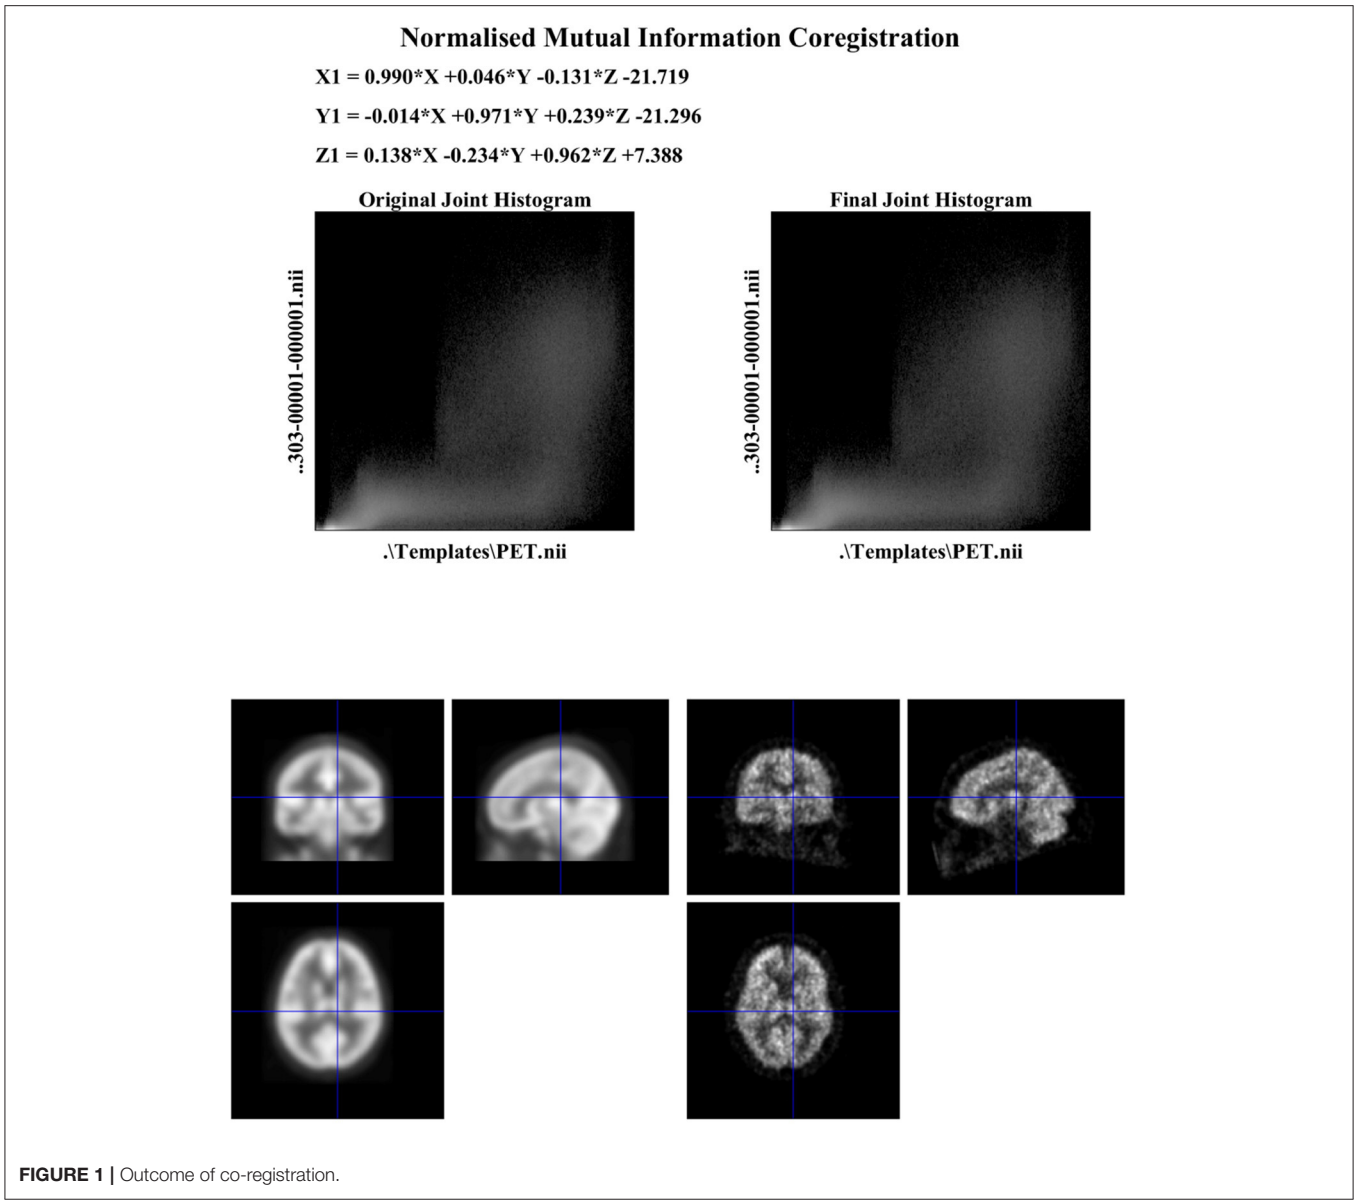

FIGURE 1 | Outcome of co-registration.

visual patterns with minimal preprocessing. CNN is robust to spatial and geometric transformations. In this paper, a 2D CNN is built to differentiate AD from NC. **Figure 2** depicts the suggested CAD system's framework. Each 3D FDG-PET image is transformed into multiple 2D images along the coronal (axial) direction, as shown in **Figure 2**. The initial 15 and closing 15 slices are discarded to do away with skull and other undesirable regions. Subsequently, the 2D slices are arranged into groups at particular intervals with some overlaps and averaged to reduce the dimension and computational overhead. CNN is developed with many layers and trained to capture useful features. The features generated by convolution layers are implemented to absolutely connected layers followed by means of a smooth max to make the final decision.

The convolution layer, pooling or subsampling layer, fully connected layer, and soft max classification layer are the layers that make up a CNN. The designed 2D CNN is composed of an input layer, three convolutional layers, two subsampling or pooling layers, a drop out layer, a fully connected layer, and a smooth max layer as shown in **Figure 3**. Parameters employed for constructing the CNN are tabulated in **Table 2**. The hyper parameters are tuned by experimentation. After many trails, the values are fixed. The designed CNN has an input layer size of 160 x 160. The sizes of receptive fields or filters for convolutional layers are set to 3 x 3 and kernel numbers are 8, 16, and 32 for C1, C2, and C3, respectively. Convolutional layers are used for extracting features from the image. The first C1 generates low level features with a size of 158 x 158. The pooling layer is used to reduce the dimension of the features. Max pooling function is adopted. Subsequent to P1, these features are reduced into 79 x 79. Then, C2 generates mid-level features with a size of 39 x 39 and these features are down-sampled into 20 x 20. Finally, C3

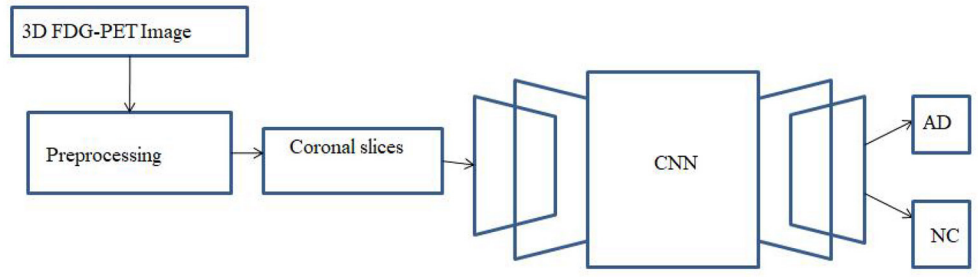

FIGURE 2 | Framework of the proposed CAD system.

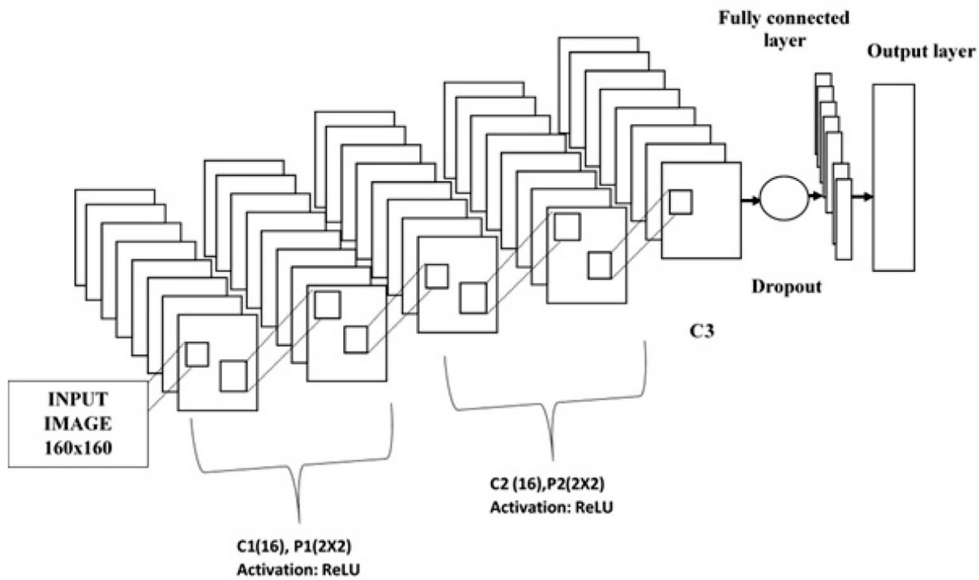

FIGURE 3 | Convolutional neural network.

generates high-level features with a size of 10 x 10. These features are concatenated and taken as the feature vector. The obtained feature vector is fed to FC followed by the soft max layer. In this work, the rectified linear unit (ReLU) activation function is adopted to introduce non-linearity. SGDM is used to train the network by minimizing the cross entropy loss, and maximum iteration is set to 500. The drop out layer is utilized to improve the generalization ability and to prevent the overfitting problem.

5. NUMERICAL RESULTS AND DISCUSSION

This section depicts the numerical results of the proposed CAD system for AD diagnosis from FDG-PET images. It also goes through the simulation environment and performance measures that were used to compare the proposed system to other existing approaches.

TABLE 2 | CNN parameters employed.

Sl.No.	Layer	Kernel size/stride	No. of kernels	Size
1	Input image			160 x 160 x 1
2	Convolution layer 1 (C1)	3 x 3/1	16	158 x 158 x 16
3	Pooling layer 1 (P1)	2 x 2/2		79 x 79 x 16
4	Convolution layer 2 (C2)	3 x 3/1	32	39 x 39 x 32
5	Pooling layer 2 (P2)	2 x 2/2		20 x 20 x 32
6	Convolution layer 3 (C3)	3 x 3/2	64	10 x 10 x 64
7	Flatten			6,400
8	Fully connected layer	512		512
9	Soft max	2		2

5.1. Simulation Platform

The main objective of simulation platform is to provide better results for visualization and interpretation. The developed CAD

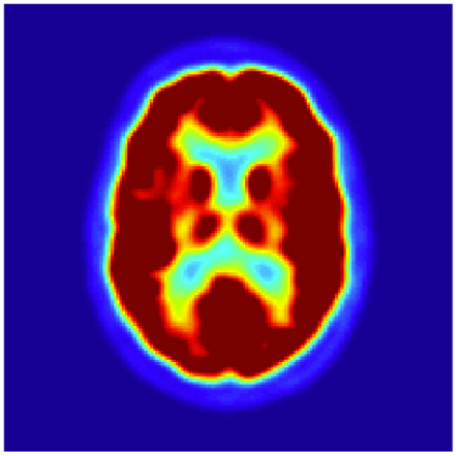

FIGURE 4 | Sample of preprocessed NC images.

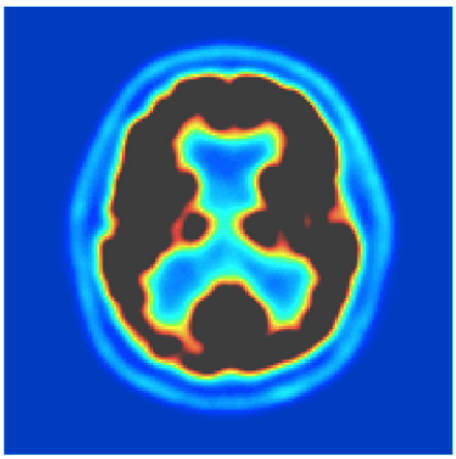

FIGURE 5 | Sample of preprocessed AD images.

system is implemented on the MATLAB 2018a platform using the deep learning toolbox and executed in an Intel core i5 processor with 2.5 GHz speed and 12 GB of RAM.

5.2. Performance Indicators

To estimate the efficacy of the proposed CAD system, this paper evaluates some widely used performance indicators, such as confusion matrix, region of curve (ROC), classification accuracy, sensitivity, and specificity. Accuracy calculates the proportion between true positive (correctly classified data) and total data, and shall be mathematically represented as given in Equation (1).

Specificity is the percentage of normal control patients who are identified as not having AD, and can be expressed as mentioned in Equation (2).

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

$$Specificity = \frac{TN}{TN + FP} \quad (2)$$

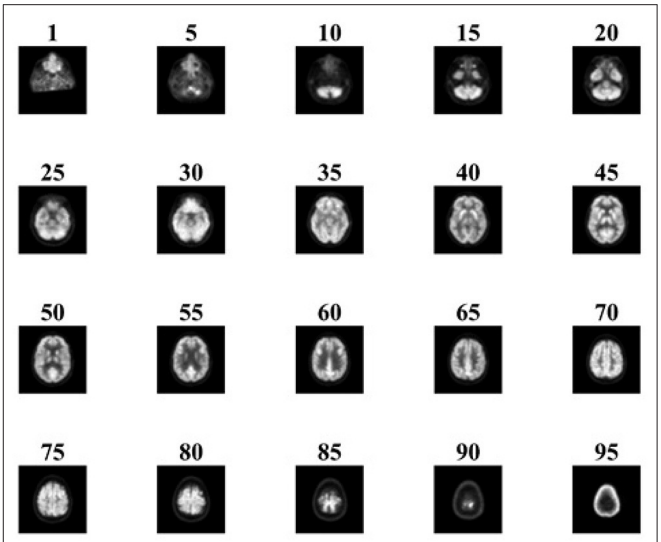

FIGURE 6 | Sample slices of NC patient.

Sensitivity computes the percentage of AD patients who are diagnosed and as such sensitivity is calculated as expressed in Equation (3).

$$Sensitivity = \frac{TP}{TP + FN} \quad (3)$$

True positive is represented by TP, true negative is represented by TN, false negative is represented by FN, and false positive is represented by FP.

5.3. Experimental Treatment

In this work, an automated CAD system for the diagnosis of brain disorders is developed and implemented accordingly. The proposed system was employed to differentiate AD patients from NC. The FDG-PET image dataset was utilized in the simulation and was gathered from the ADNI database. The FDG-PET images were acquired from 855 patients including 635 NC and 220 AD patients.

The collected images are preprocessed using SPM12. The samples of preprocessed images of NC and AD patients are given in **Figures 4**, **5**, respectively. It is obvious that hypometabolism is visible in AD patients. Moreover, the first 15 and last 15 slices have redundant information. Slices of these regions of AD and NC patients are demonstrated in **Figures 6**, **7**, respectively. These slices are discarded to remove unwanted regions and make the image fit for further processing. Preprocessed and dimension-reduced images are fed as input into the designed system. CNNs are a kind of deep learning neural network that have proven to be very effective in image classification recognition problems. The CNN learns features from the images acquired using its own convolutional layer. Additionally, CNNs can recognize patterns with extreme variability and some geometric transformations such as scaling, rotation, translation, and noise.

Figure 8 shows the training plot of the CNN. The outcome of the proposed CAD system is demonstrated in the form of a

confusion matrix as detailed in **Figure 9**. The total number of images is 855 including 635 NC and 220 AD patients.

To demonstrate the superior performance, the developed system was repeated five times and the mean values were reported. Efficacy of the developed system is evaluated by computing evaluation parameters which are given in section 2. The outcome of the proposed CAD system for the testing sample is demonstrated in the form of a confusion matrix as detailed in **Figure 9**.

In **Figure 9**, 42 images are correctly diagnosed as NC patients and 41 images are correctly classified as AD patients. A total of 2 images out 43 images are mistakenly identified as AD (2.3%). Similarly, one image is misdiagnosed as NC (1.2%). For NC patients, out of 43 patients, 48.8% are correctly diagnosed as NC and 2.3% are wrongly diagnosed. For AD patients, out of 43 patients, 47.7% are correctly classified as AD and 1.2% are wrongly classified. Overall, 96.5% of the photos are correctly

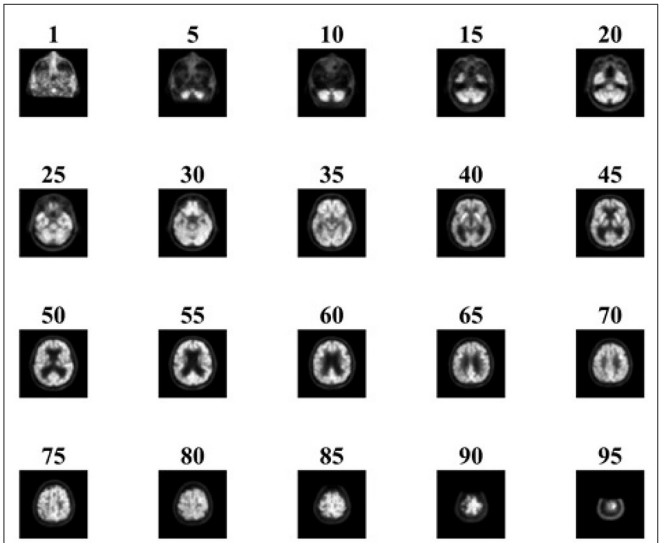

FIGURE 7 | Sample slices of AD patient.

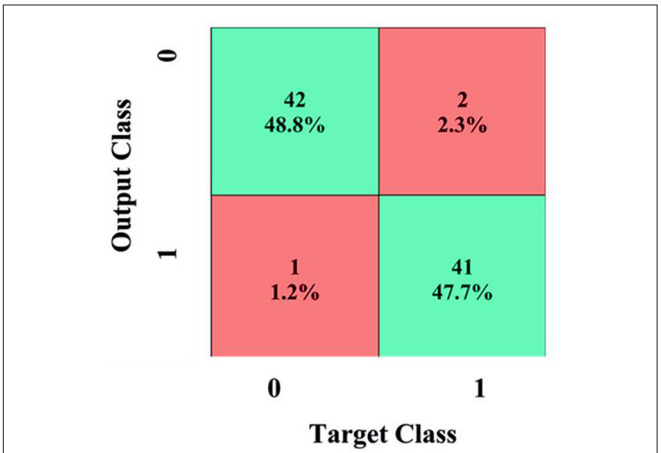

FIGURE 9 | Confusion matrix.

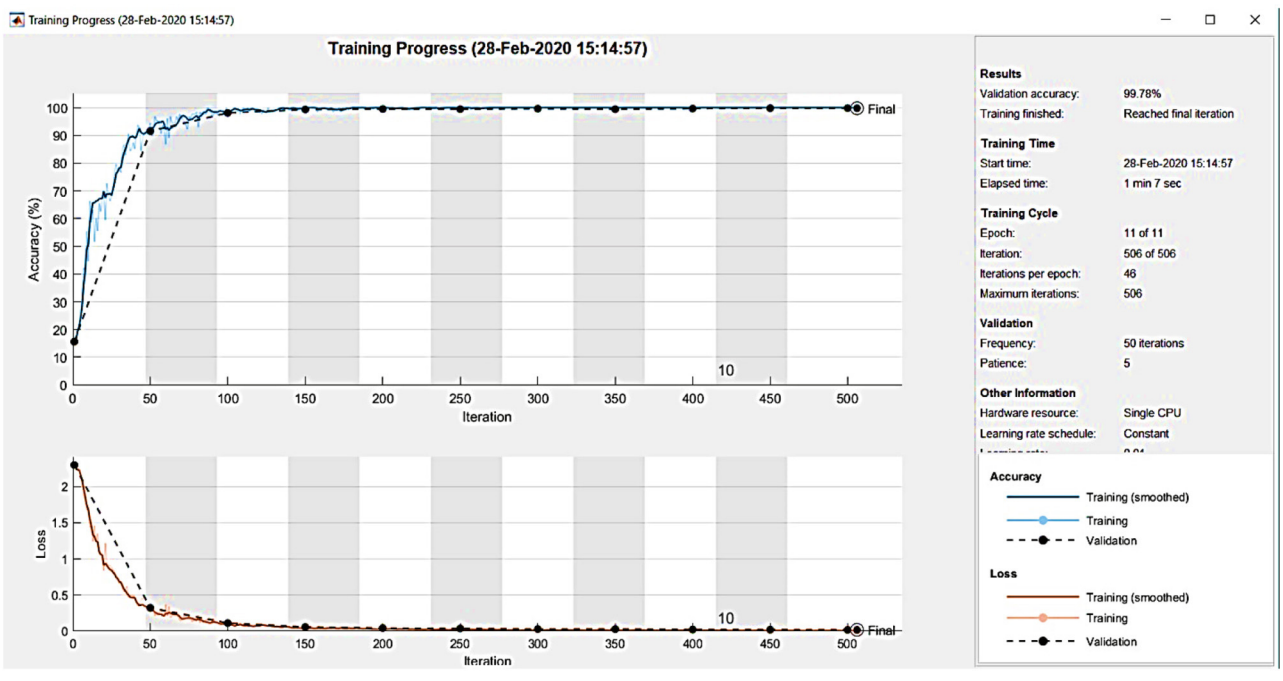

FIGURE 8 | CNN training process.

classified, whereas 4.5% are incorrectly categorized. ROC is a mathematical tool used to assess the separation ability of the classification system. The true positive rate is compared against the false positive rate in a ROC chart. It is investigated by adjusting the threshold value. **Figure 10** shows the ROC of the proposed system. The area under the curve (AUC) of the proposed system is 0.95.

5.4. Effect Analysis

In terms of accuracy, sensitivity, and specificity, this section compares the efficacy of the proposed CAD system to that of existing approaches. In particular, the experimental consequences reported in state-of-the-art methods such as Cabral and Silveria (4), Liu et al. (23), Islam and Zhang (24), Silveira and Marques (25), and Poongodi and Bose (26) are compared with the proposed system, as given in **Table 3**.

Cabral and Silveria (4) proposed a method to differentiate NC from AD using PET images. Input images were preprocessed using SPM. Feature vectors were extracted with PCA. SVM classifier discriminated NC from AD based on the feature vectors. Regional analysis-based classification system was proposed by Liu et al. (23). In this approach, the PET image was preprocessed using SPM. SVM classifier was used to carry out the classification process. Islam and Zhang (24) investigated the strength of CNN for diagnosing AD. They converted the 3D MRI images into 2D images. To increase the image's quality, a few preprocessing techniques, such as noise reduction, edge recognition, and segmentation were used. The preprocessed image was fed as an input to the CNN. The deep learning neural network provided a better result compared to the existing methods.

Silveira and Marques (25) presented a classification system based on a CNN and extreme machine learning classifier. CNN was utilized to extract characteristics from MRI images in this system. Then, with the help of free surfer, the features were mined. Extreme machine learning classifier performed the classification task. The drawback of the system is high computational overhead. A hybrid method of CNN and RNN for AD diagnosis was presented by Poongodi and Bose (26). In this method, 3D PET images were transformed into 2D slices along axial, coronal, and sagittal directions to reduce the computation time. At regular intervals, the transformed slices were divided into a number of groups. The resultant groups were fed as input to the CNN. To extract inter slice features, RNN was used. Prediction score was calculated using the weighted averaging method. However, this method needs more memory and time. **Figure 11** shows a graphic comparison of the suggested CAD system's classification with the current approaches.

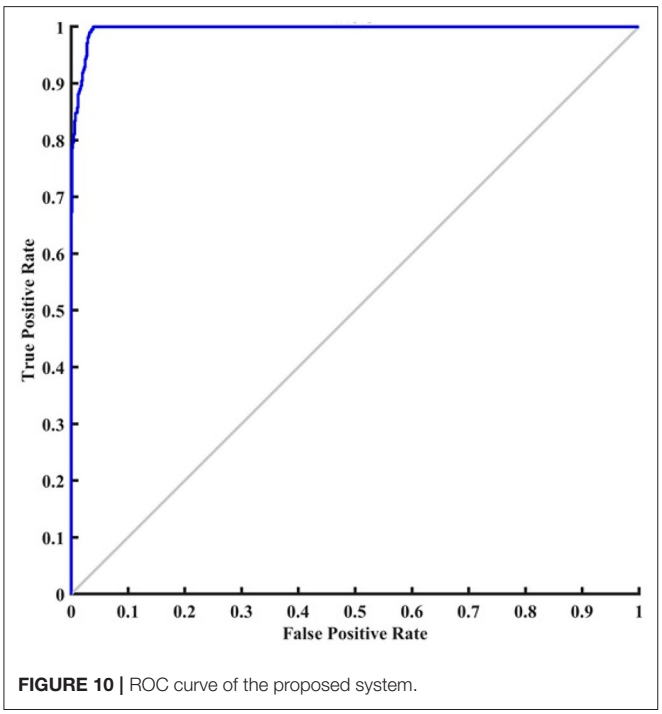

FIGURE 10 | ROC curve of the proposed system.

6. CONCLUSION AND FUTURE WORKS

In this paper, a CAD device for discriminating AD from NC patients based on features from 18FDG-PET images was proposed and investigated properly. The proposed CAD system was designed by using a convolutional neural network. The FDG-PET images were decomposed into several 2D slices for extracting the features. Subsequently, the slices were grouped at some intervals without overlaps. The proposed CAD machine was confirmed on the ADNI dataset. The obtained simulation results showed that the proposed system provided exceptional performance when compared to the existing methods. Simulation results clearly demonstrated that the proposed CNN possessed higher potential to differentiate

TABLE 3 | Performance comparison of the proposed system with existing systems.

Author	Modality	Method	Accuracy (%)	Sensitivity (%)	Specificity (%)

AD from NC with better classification accuracy and robustness. Future study will focus on improving the classification accuracy by extending the suggested CAD system to incorporate data from other sources. The overall performance of the suggested CAD system will be evaluated using a large number of samples. In addition, the potential of using different deep learning neural networks will be explored in a wider scenario.

DATA AVAILABILITY STATEMENT

Energy Expenditure Estimation of Tabata by Combining Acceleration and Heart Rate

*Yiping Yan and Qingguo Chen**

Sport Laboratory, College of Physical Education, Sichuan Normal University, Sichuan, China

Tabata training plays an important role in health promotion. Effective monitoring of exercise energy expenditure is an important basis for exercisers to adjust their physical activities to achieve exercise goals. The input of acceleration combined with heart rate data and the application of machine learning algorithm are expected to improve the accuracy of EE prediction. This study is based on acceleration and heart rate to build linear regression and back propagate neural network prediction model of Tabata energy expenditure, and compare the accuracy of the two models. Participants ($n = 45$; Mean age: 21.04 ± 2.39 years) were randomly assigned to the modeling and validation data set in a 3:1 ratio. Each participant simultaneously wore four accelerometers (dominant hand, non-dominant hand, right hip, right ankle), a heart rate band and a metabolic measurement system to complete Tabata exercise test. After obtaining the test data, the correlation of the variables is calculated and passed to linear regression and back propagate neural network algorithms to predict energy expenditure during exercise and interval period. The validation group was entered into the model to obtain the predicted value and the prediction effect was tested. Bland-Alterman test showed two models fell within the consistency interval. The mean absolute percentage error of back propagate neural network was 12.6%, and linear regression was 14.7%. Using both acceleration and heart rate for estimation of Tabata energy expenditure is effective, and the prediction effect of back propagate neural network algorithm is better than linear regression, which is more suitable for Tabata energy expenditure monitoring.

INTRODUCTION

According to the recently published World Wide Survey of Fitness Trends, high-intensity interval training (HIIT) has become increasingly popular modes of physical exercise (1). Tabata training is one of the most energetically effective high-intensity intermittent training methods (2).This exercise is relatively inexpensive, usually requires very little equipment, and is effective in promoting physical fitness. Tabata is not only useful to promote fat loss, improve blood pressure, insulin sensitivity, and glucose regulation in a relatively short time, but also enhance sports performances that depend on both the aerobic and anaerobic energy exependiture systems (2, 3). Being able to monitor energy expenditure (EE) portable and accurately during these activities is critical for weight control, physical activity adjustment and fitness goals achievement.

At present, the methods that produce the most accurate measurement of EE is direct calorimetry, indirect calorimetry and doubly labeled water (4), however, one limitation of all three methods is that they are expensive to test, which is not suitable for mass measurement of daily physical activity (5). Both accelerometer and heart rate sensor have long been recognized as the common and cheap wearable devices used for monitoring EE (6, 7). In 2001, Strath et al. (8) proposed a method for predicting EE using accelerated combined heart rate (ACC-HR), and believed that this method is better than the single acceleration (ACC) or heart rate (HR) measurement. So far, other authors have verified that this method predict the EE of some Physical activity (PA) more accurately, such as flat running and uphill running with different intensity (9, 10). In the era of big data, machine learning (ML) has been widely used in people's production and life (11–14). In terms of EE prediction algorithm, back propagate neural network (BPNN) is one of the most common used in machine learning algorithms (15), which has been applied and has significantly improved EE prediction performance in some exercises compared with linear regression (LR).

The main contributions of this paper are:

(1) We analyzed the correlation between ACC and EE, HR and EE in Tabata training.
(2) We established linear regression and back propagate neural network model based on ACC-HR to predict the EE of Tabata training during exercise and intervals.
(3) We evaluate and compare the predictive effectiveness of linear regression and back propagate neural network model.

The rest of the paper is organized as follows. Section 2 gives literature review. Section 3 describes our proposed method in detail. Section 4 presents the test results and analysis. Section 5 discuss the result. Section 6 gives conclusions and Future work.

LITERATURE REVIEW

Existing Wearable Devices

Currently, wearable devices that monitor EE can be divided into five categories: pedometer, accelerometer, heart rate sensor and multi-sensor combination (16). Pedometer is the most convenient motion sensor, and converts the PA of exercisers through the number of walking steps. However, there are significant limitations in EE predicting for slow walking, non-walking, and running (17). The accelerometer can calculate the rate of change of speed within a certain time, and the PA parameters was obtained through body acceleration, then EE is calculated based on the relationship between the known ACC and EE. Unfortunately, the accuracy of energy monitoring is limited by different acceleration wearing positions, additional load on the user and the change of moving surface (18). Heart rate sensor was estimated based on the correlation between HR and oxygen consumption (VO_2) of some physical activities of exercisers, and then the EE was reflected by oxygen intake. But the accuracy of HR monitoring was affected by exercise action, mood and health status (19). A potential and powerful energy expenditure prediction approach is to use ACC and HR simultaneously. ACC values confirm that increased HR is caused by physical activity, which is the basic principle behind the combination of these techniques (16). In addition, the heart rate is linear with the EE of medium and high intensity exercise, which can quantify the daily EE of most people, but it cannot quantify the low intensity physical activity. The deficiency is compensated by acceleration data, which can effectively predict low intensity physical activity (16). In this study, Tabata exercise EE was monitored, including high-intensity exercise and intermittent exercise. The ACC-HR measurements may improve the EE monitoring effect.

Estimation Algorithm

Most of the early research and monitoring EE models are LR models, and the most classical EE linear regression model is Freedsom regression with acceleration parameters (20). Later studies confirmed that a single variable regression could not fit all physical activities, and then some studies developed linear regression models with multiple variables such as acceleration combined with body weight and heart rate combined with body weight for achieving better prediction results (10, 21). However, the ACC, HR, and EE used for some workouts are not linearly or highly correlated. Recently, Morris et al. have shown that ACC is not effective in predicting high-intensity intermittent exercise using the previous LR model (22). Recent sudden developments in the field of machine learning has increased the potential for remote monitoring and diagnostics using data obtained from wearable devices (23). Such as standing balance estimation (24), ECG signal classification (25), and EE prediction (26), etc. Some studies have achieved good accuracy by using BPNN, random forest (RF) and other machine learning algorithms to build models (23, 27). In addition, Montoye et al. (15) has proved that BPNN is better than linear regression for predicting EE in daily physical activity and partial sports. In terms of variable selection, there is inconsistency between machine learning and traditional regression model in the selection of input variables, as shown in **Table 1**. Recently, the researchers verified that BPNN model was constructed with ACC, HR and morphological indicators as input variables, which had high accuracy in predicting walking, running and resistance movement in EE (23). BPNN is the most popularly used Artificial neural network at present, which make up for the difficulty of linear regression in modeling non-linear data or polynomial regression with correlation between data features. For EE prediction of Tabata training, BPNN model may provide a new prediction idea. In this study, acceleration and heart rate data were selected as input variables, and the EE prediction was used by LR and BPNN model.

METHOD

Participants

A sample of 45 participants were included [Female = 23, Age (AG) = 21.04 ± 2.39 years, body height (BH) = 1.67 ± 0.75 m, body weight (BW) = 59.61 ± 8.27 kg, body

mass index (BMI) = 21.17 ± 2.16 kg/m^2, body fat rate (BFR) = 18.46 ± 5.47%]. Participants were primary recruited from Si Chuan Normal University. Exclusion criteria included the following: (1) Participants had a history of respiratory, cardiovascular, neurobiological, metabolic, or lower extremity related diseases, (2) Participants were given hypnotic drugs, alcohol, caffeine, or nicotine. This study was approved by the Si Chuan Normal University institutional Research Board before participant recruitment. Immediately upon arrival at the exercise research lab, the researchers described the study details to each participant and obtained written informed consent before proceeding with the protocol.

Instrumentation

EE was measured by indirect calorimetry method with gas metabolism analyzer as calibration, and collects data in kilocalorie as the basic unit. During the Tabata test, participants wore a portable gas metabolism analyzer, four wear site accelerometer (dominant hand, non-dominant hand, right hip, right ankle), and a chest strap heart rate band, all set up according to the manufacturer's instructions. The portable gas metabolism analyzer (K4b2, Cosmed) was used as a calibration to measure the EE of Tabata motion, it was calibrated according to the manufacturer's instructions before test. HR was recorded by chest strap heart rate band (Polar wearlink) during exercise, because K4b2 comes with a synchronization sensor from Polar's heart rate band, the heart rate band synchronizes with K42b measurements. ACC was acquired from four accelerometer (Actigraph GT3X+), which is initialized to set the sampling frequency to 30HZ. Prior to the test, participants identified their dominant hand (defined as the hand with which they wrote), and GT3X + was placed on the dominant hand, non-dominant hand, right hip, right ankle for all tests, the instruments was worn as shown in the **Figure 1**. In order to ensure the synchronization of the accelerometer with k4b2 and Polar heart rate band test, calibrate the computer time of the two devices and set the acceleration start time in advance.

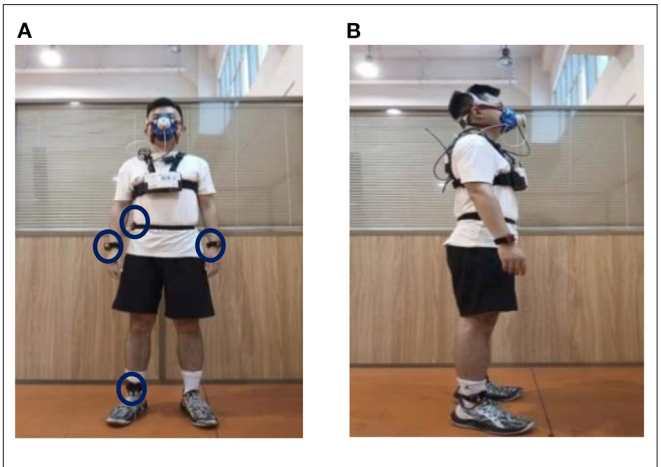

FIGURE 1 | Position of instrument wearing **(A)** Front view and **(B)** Lateral view.

Procedure

Each participant reported to the Sports Research Laboratory for one visit. To avoid discomfort and errors in EE measurement during the test, participants were forbidden to eat 2 h before the test. The testers explained the details of the test to each participant and obtained written informed consent. A PA preparation questionnaire was conducted prior to the test to ensure that participants were healthy and not participating in MVPA contraindications. If the participant answered "yes" to any of the questions on the PA questionnaire, they would have been asked to obtain physician approval before being able to participate in the study; however, whether there are rules in the questionnaire will not be tested. Next, trained research assistants measured height, weight, body fat percentage, and BMI using a human morphological indicator meter (InBody J30). In addition, the age shall be calculated in years according to the date of birth of the resident identity card. The classic Tabata training mode is 20–10 mode (20s-exercise, 10s-interval). In consideration of the simplicity of the exercise movements and the comprehensiveness of the exercise parts, this study adopts the classic Tabata training mode with multiple movement combinations. Participants were asked to learn how to perform the Tabata movements (Jumping jack, Burpees, Running in place high-knees, Side Skaters) and complete each movement 5 times after learning to get familiar with the movements, the exercise process is shown in **Figure 2**, eight movement stages were tested, each consisting of a exercise and an interval. These exercise movements not only can be full-body exercise and follow the principle of simplicity, but also have been proved by studies to achieve high intensity (28), and the intermittent movements are also common. After getting familiar with the action, participants warmed up with a 5-min warm-up in the Keep APP. Once the participant completes warm-up, Polar wearlink, Cosmed K4b2, and Actigraph GT3X fitted to the participant. Sit still for at least 15 min until heart rate stabilizes. At the beginning of the test, participants performed the

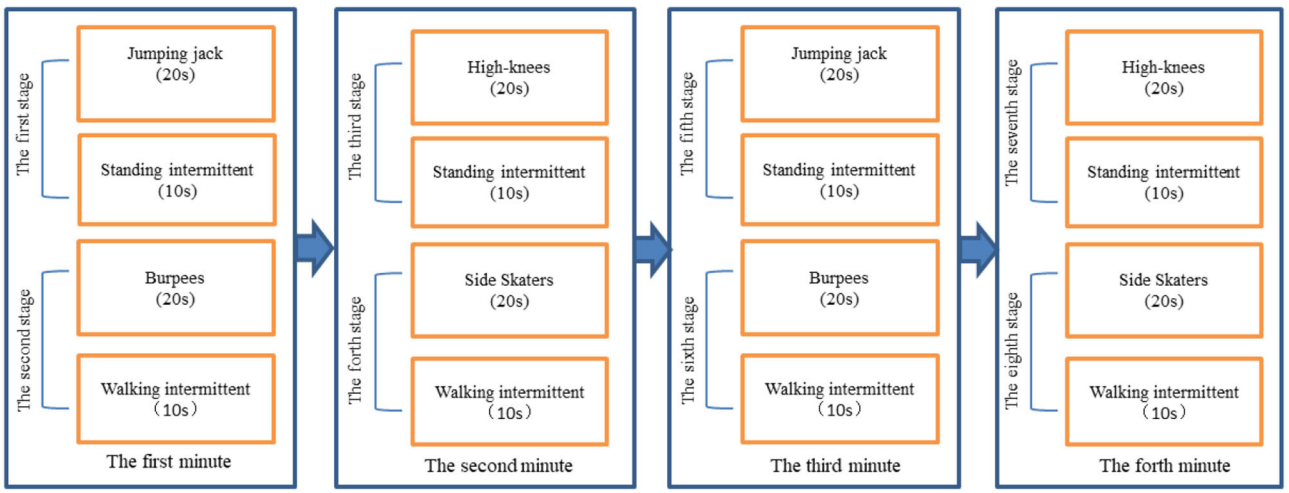

FIGURE 2 | Tabata exercise process.

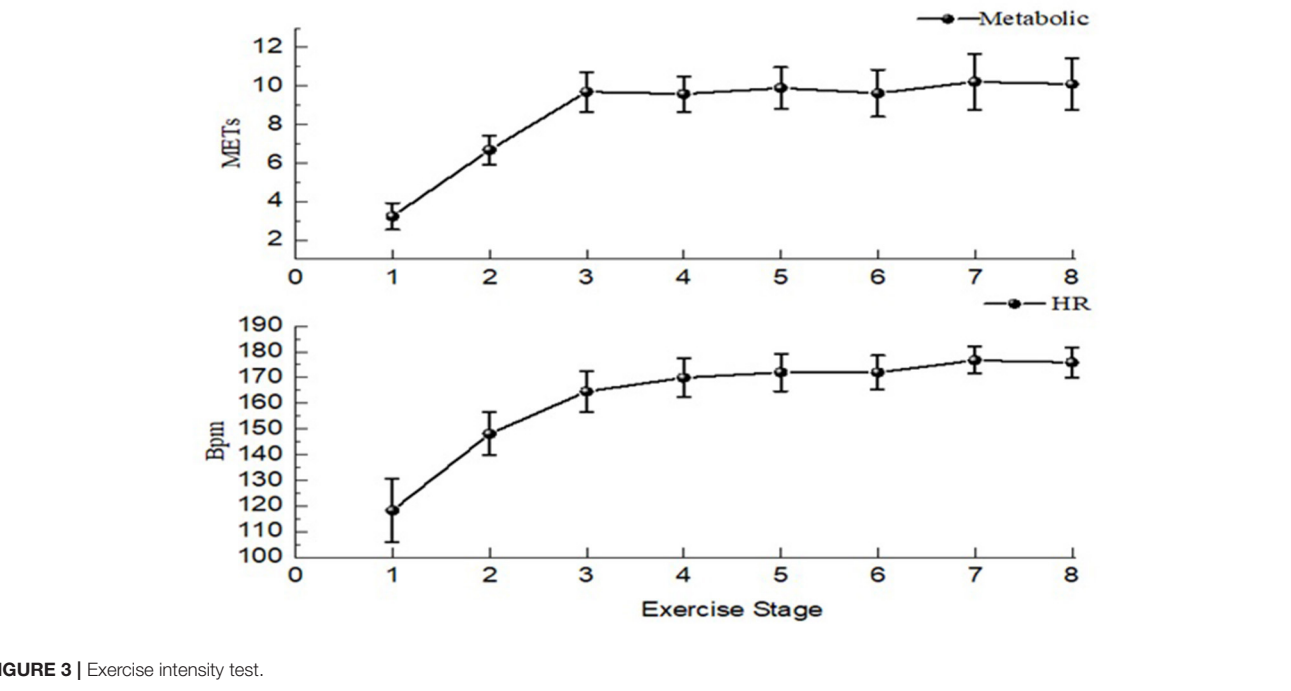

FIGURE 3 | Exercise intensity test.

maximum number of reps prompted by a Tabata video played on a computer. Relax and stretch after completing the test.

Data Processing

Tabata Exercise Intensity Monitoring

To ensure that participants reach the high intensity during the Tabata exercise test, the heart rate of participants and metabolic equivalent (METs) during each stage (exercise + interval) were collected during the test (**Figure 3**). In this study, the average HR of exercise was 165.46 ± 5.39 for men and 163.88 ± 6.88 for women, reaching 80% of the maximum heart rate. As the same time, the average of METs was 8.84 ± 0.89 for men and 8.39 ± 0.93 for women. Refer to ACSM for exercise categories and physical activity intensity (29), the exercise intensity of this test reached high intensity, Maximum heart rate 183.43 ± 7.09, almost 90% of maximum heart rate, which was in line with the exercise intensity required by Tabata exercise.

Variable Selection

The triaxial acceleration values are combined into vector acceleration, the vector magnitude (VM) can been seen in Equation 1 (the X, Y, Z is the acceleration of the three axes, N

means in unit time interval). Data of acceleration, heart rate and EE are intercepted in 10 and 30s.

$$\mathbf{VM}=\frac{\sum_{\mathbf{i=0}}^{\mathbf{N-1}}\sqrt{x_i^2+y_i^2+y_i^2}}{\mathbf{N}} \quad (1)$$

Given the difference in EE predictions between exercise and interval, the selection of linear regression and neural network variables was based on previous studies (20, 23). EE is predicted in kcal/10s. Pre-selected variables during exercise included: human morphological index, the unit of 10s corresponds to heart rate during the exercise and the unit of count/10s corresponds to the VM value of each wearing part during the exercise. Since the interval is 10 s, the VM value is the minimum or "0" during the standing interval, and the heart rate during exercise is related to the EE during the interval (31). The pre-selected variable for predicting the intermittent EE includes: human morphological, VM value during 0–10s exercise, VM value during 10–20s exercise, VM value during 0–20s exercise, VM value during entire stage, HR value during 0–10s exercise, HR value during 10–20s exercise, HR value during 0–20s exercise, HR value during entire stage, HR value in Intermittent. Pearson correlation analysis was conducted between pre-selected variables and EE in exercise and interval period, respectively. The absolute value of correlation coefficient ($|r|$) compared the correlation between each variable and EE.

Model Development

In order to build LR model, the pre-selected variables of the exercise period and the intermittent period were put into stepwise linear regression, respectively. Then the equations with significance *P*-value of variables <0.05 were selected. Finally, LR model of exercise period and intermittent period were constructed.

BP neural network is a multi-layer error feedback neural network, which consists of input layer, hidden layer and output layer. Each node represents a neuron, the upper node and the lower node are connected by weight, and the nodes between layers are fully interconnected. Before input variable selection, the temporal characteristics of the four accelerometers were extracted in the non-overlapping windows of 10 and 30 s, and the heart rate (HR) in units of 10 and 30 s was obtained. Input layer variables are selected based on the degree of correlation between EE and the variable, which can include gender, age, weight, height, average heart rate, mean, standard deviation, cova-riance of adjacent windows of data, minimum, maximum, the 10, 25, 50, 75, and 90th percentiles of the vectorial magnitude acceleration. And these variables have been proved to be effective machine learning EE prediction model can be built method (27). In order to improve the speed of convergence, in this study, momentum—learning rate adaptive adjustment algorithm was used to optimize BPNN. The number of hidden nodes was determined by trial and error method. The formula of hidden layer (32) used the Equation 2, "n_i" is the number of hidden nodes, "no" is the number of input nodes, and "c" is the number of output nodes. After the number of hidden node is determined, the number of nodes is increased step by step until the number of nodes with the lowest Root mean square error (RMSE) is found. The activation functions of the hidden layer and output layer are determined as logsig logs-type transfer functions. Sigmoid type differentiable function is strictly incremental, with solid theoretical basis, rigorous derivation process, beautiful symmetry of the obtained formula, and strong non-linear fitting ability (33), the formula is the Equation 3. The BPNN model was constructed by the variables of neural network model through Matlab software (R2018b).

$$n=\sqrt{n_i+n_0}+c \quad (2)$$

$$Log\ \mathbf{sig}\ (\mathbf{x})=\frac{1}{1+\mathbf{e}^{-\mathbf{x}}} \quad (3)$$

$$\mathbf{RMSE}=\sqrt{\frac{1}{\mathbf{n}}\sum_{\mathbf{i=1}}^{\mathbf{n}}(\hat{\mathbf{y}}_\mathbf{i}-\mathbf{y}_\mathbf{i})^2} \quad (4)$$

Statistical Analysis

Random grouping was used in which all available data are split into training and testing, at a ratio of 3:1. After grouping, the predicted values were obtained by substituting the test group data into the prediction model constructed by the training. Using Bland-Altman plot to verify the difference between the predicted and measured values, the model is effective when 95% points fall between ± 1.96 SD of the difference between predicted value and measured value. Mean percentage absolute error (MAPE) and RMSE was used to compare the accuracy of prediction between models, the specific formula is the Equations 4 and 5, "$\hat{y}_i$" is the actual measured value, "y_i" is the predicted value.

$$MAPE=\left(\frac{\mathbf{100}}{n}\right)\sum_{\mathbf{i=1}}^{\mathbf{n}}\left|\frac{\hat{\mathbf{y}}\mathbf{i}-\mathbf{y}\mathbf{i}}{\mathbf{y}\mathbf{i}}\right| \quad (5)$$

RESULT

Correlation Analysis

According to Pearson correlation analysis, we compared the correlation between each variables and EE (**Figure 4**). The heart rate band data is the significant correlated with exercise and interval EE. In the various indicators of heart rate, the highest correlation with EE during exercise period is HR value during exercise ($r = 0.758$), the highest correlation with EE during intermittent period is HR value during 0–10s exercise ($r = 0.655$). All the morphologic indicators are significantly correlated with EE, and the highest correlation between anthropometric index and EE in all stages is body weight ($r = 0.331$, $r = 0.581$). Although, the correlation between EE and ACC of multiple wear sites in all stages is significant, the highest correlation variables with EE during exercise and interval period is only moderately correlated, they are right ankle VM value during exercise and right ankle VM value during entire stage ($r = 0.352$, $r = 0.308$). Only the right ankle and hand acceleration are more than 0.300 correlated with EE during the interval. The correlation between the four wearing parts ACC and EE is different in both the exercise and the interval period, and the correlation of ankle is the largest. The measurement indexes of wearable devices with the

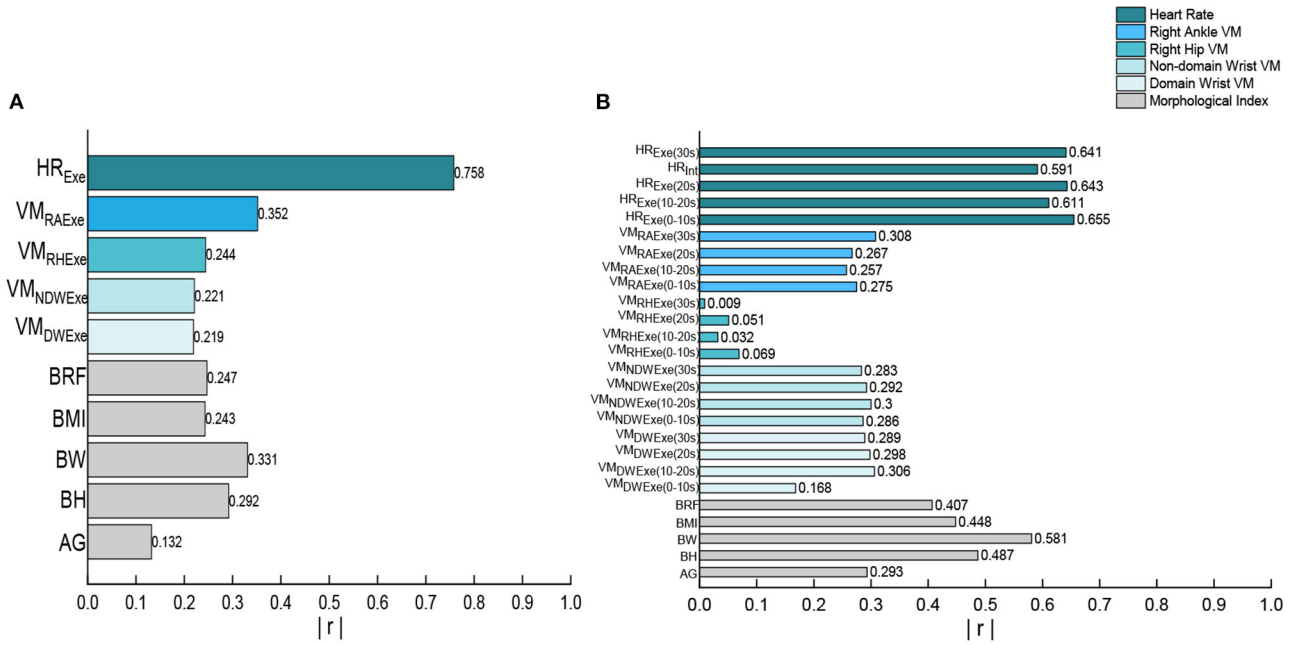

FIGURE 4 | (A) Correlation analysis of exercise period; **(B)** Correlation analysis of interval period.

greatest correlation were analyzed, as shown in **Figure 5**. There are linear correlation between heart rate measurement indexes and EE in the whole Tabata training, while all the accelerometer indexes are weakly linear correlated with EE.

Linear Regression

The variables were put into linear stepwise regression, and the LR model was established as shown in **Table 2**. right ankle VM value during exercise, HR value during exercise and body weight were took as independent variables to build LR model of EE during exercise period. VM value during entire stage, HR value during 0–10s exercise and body weight were took as independent variables to build LR model of EE during interval period. The significance *P*-values of these independent variables in the LR model are all <0.05, and they are all valid variables. The r^2 value of the EE prediction model in exercise period is 0.710, and the r^2 value of the EE prediction model in interval period is 0.730. The significance of the model is <0.05, indicating that the model is valid.

BP Neural Network

Based on the correlation between the acceleration data of each position and EE during all stages, this study decided to take the right ankle VM value during exercise as the input variable of the BPNN model during the exercise period, and the right ankle VM value during entire stage was input as the input variable of the BPNN model in intermittent period. HR in exercise period was selected as the input variable value of the neural network model during the exercise period, and HR value during 0–10s exercise was taken as the input variable of the BPNN model during the exercise period. Height, weight and gender were input into the two models as the anthropometric index and basic information of participants. After using trial and error method, we determined 4–15 hidden layers as an attempt, and finally got the hidden layers of the neural network as shown in **Figure 6**. The number of hidden layers of model in exercise period was 6, and that of model in intermittent period was 10.

Finally, the neural network model was determined as 14-6-1 in the exercise period and 14-10-1 in the interval period. The upper limit of network iteration of neural network model is 5,000 times, initial learning rate is 0.05, momentum constant is 0.9 and error rate is 0.001, as shown in **Figure 7**. "w1" and "w2" in turn represent input and sum weight vectors, "Si" means the sum of the input layers in the implicit cell, "U" indicates that the input activation function is hidden. The training group was substituted into the model for training and BPNN was finally obtained. After calculation, the time complexity of BPNN model during exercise and interval period is 20139840 and 27643680, respectively. The r^2 value of the exercise model is 0.813, the r^2 value of the intermittent model is 0.816, which indicates the model is valid.

Predictive Accuracy of Models

The variable data of the test group was substituted into each prediction model and the predicted values of each model were obtained. Then the predicted EE values and measured EE values of 15 subjects in the validation group were intercepted in 10-s increments, each subject will have 24 predicted values. The whole verification group was substituted into each model to obtain 24*15 predicted values. The forecast and measured graph was presented in **Figure 8**.

Bland-Altman Plot statistical method with MedCalc software was used to analyze the consistency of model prediction effect, as shown in **Figure 7**. The difference between the measured EE

TABLE 2 | EE prediction model of Tabata linear regression.

Use conditions	Model	r^2
Exercise	$EE_{Exe} = 0.000044*VM_{RAExe} + 0.193*HR_{Exe} + 0.23*BW-3.05$	0.71
Interval	$EE_{Int} = 0.000011*VM_{RA(30s)} + 0.0116*HR_{Exe(0-10s)} + 0.030*BW-1.99$	0.73

value of K4b2 and the predicted EE value of each model was used as the Y-axis, and the mean value of the predicted EE value of each model and the measured K4b2 was used as the X-axis. **Figure 9** showed that 95% of the scatter points of the two prediction models were within the range of ± 1.96 SD during the exercise period and interval period, they all have good consistency.

The predicted and measured values of the validation group were substituted into the MAPE formula for calculation, and the MAPE of the two models in the exercise period and the intermittent period were compared. The MAPE of LR model is 16.95% in EE prediction during exercise period, which is 2.65% higher than BPNN model. In the intermittent EE prediction, the MAPE of BPNN model is 9.28%, which is lower than LR model. At the same time, the error dispersion degree of LR model is larger, and its standard error of MAPE is 1.70% and 1.22%, which proves that the stability of LR prediction effect is lower than that of BPNN (**Figure 10**).

In order to compare the prediction effect of the Tabata training during each movement stage, the two models were compared in each exercise stage, as shown in **Figure 11**. In the LR model, the MAPE of three exercise stages is >15%, while the BPNN model has two. In addition, the MAPE and RMSE predicted by tow EE model in entire Tabata training was calculated. The MAPE of BPNN model was 12.6%, which is 2% lower than that of LR model, and the RMSE of LR model was 0.238, which is 0.011 higher than that of BPNN model. Both LR and BPNN models can effectively predict the EE of Tabata, but BPNN model has better prediction performance than the LR model regardless of the comparison of each part or the whole movement.

DISCUSSION

In this study, the correlation of pre-selected variables was analyzed. The highest correlation with the EE in the exercise and the intermittent period is HR, which basically shows a linear relationship with the EE. The linear correlation between HR and EE in high-intensity exercise can also be confirmed in Tabata training (16). Bazuelo et al. (30) has shown that intermittent heart rate is related to intermittent EE. But this study found

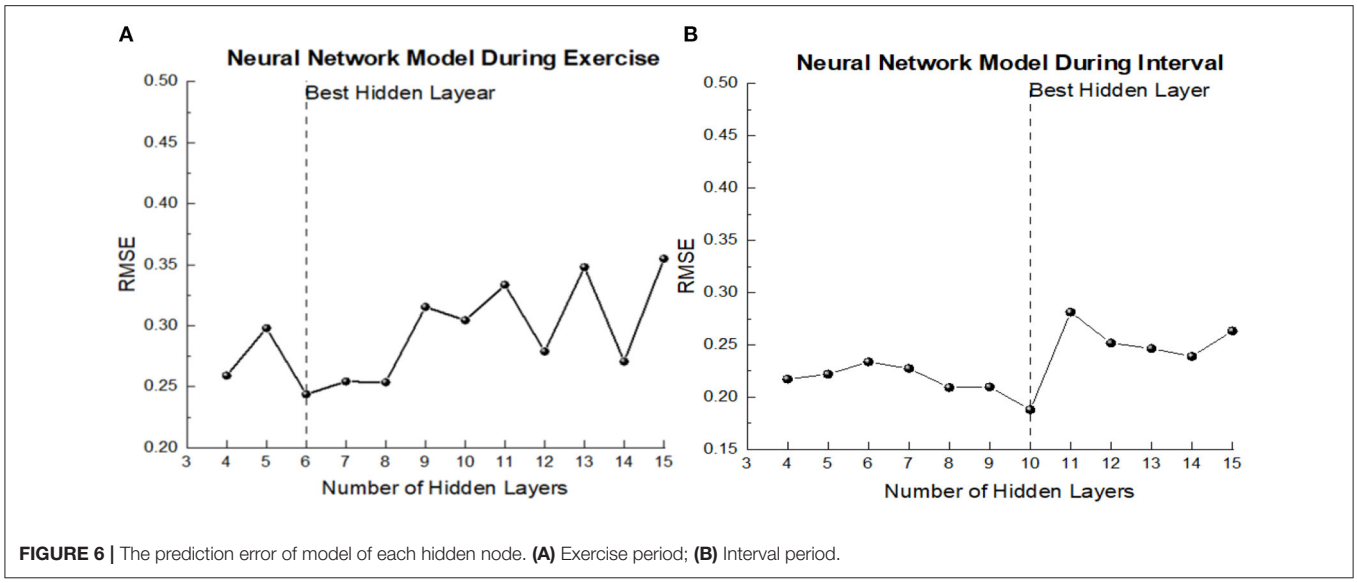

FIGURE 6 | The prediction error of model of each hidden node. **(A)** Exercise period; **(B)** Interval period.

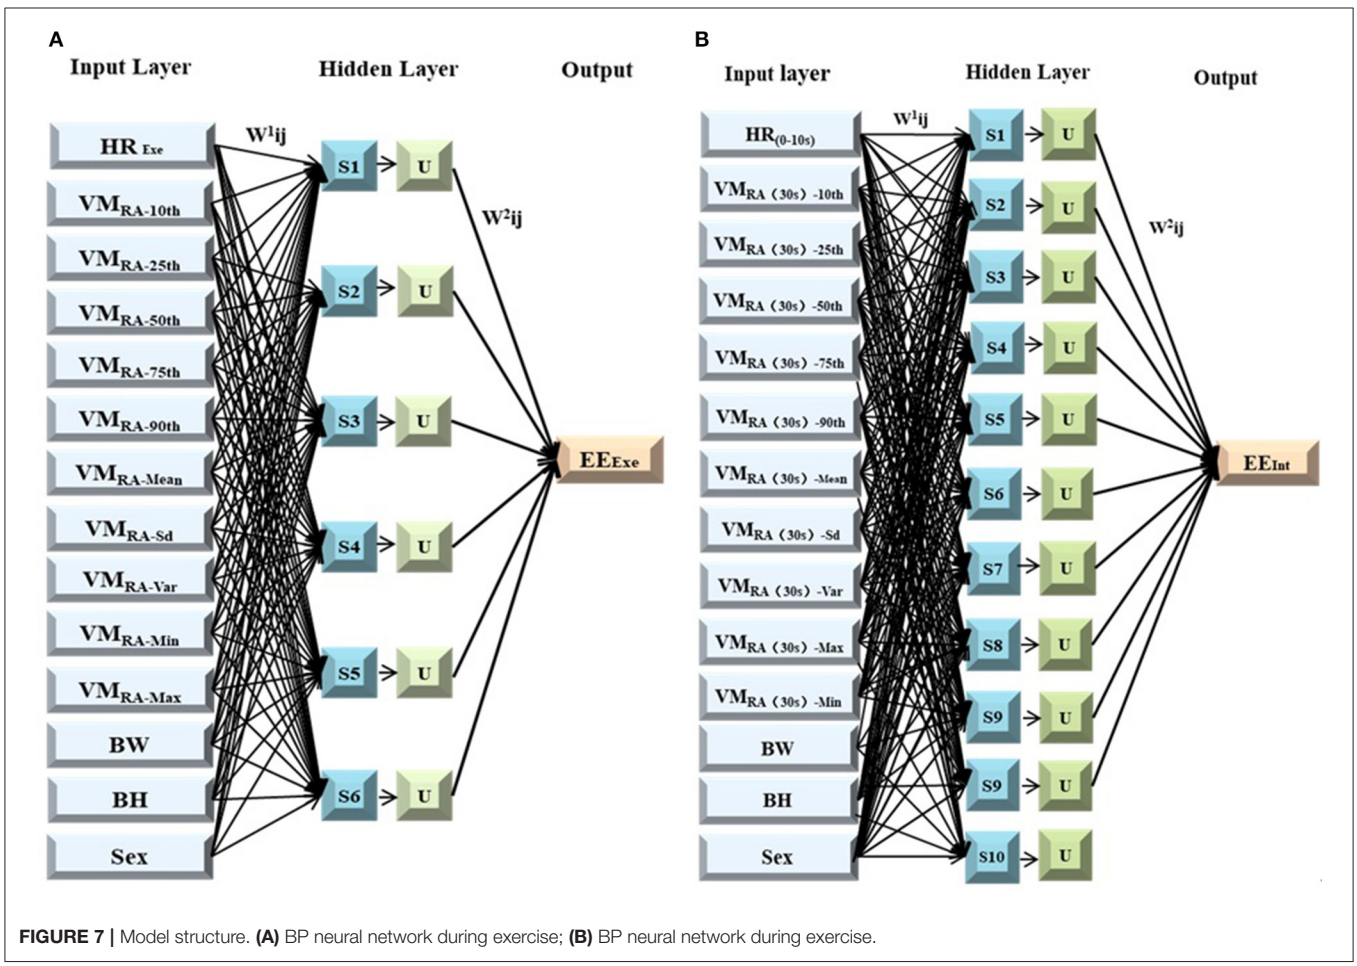

FIGURE 7 | Model structure. **(A)** BP neural network during exercise; **(B)** BP neural network during exercise.

that intermittent EE not only correlate with intermittent heart rate, but also with exercise heart rate, the highest correlation with intermittent EE was the HR value during 0–10s exercise, and the correlation was basically linear. Meanwhile Dugas et al. show the similar result (31), the exercise they tested was set-up exercise (45s-exercise, 15s-interval), the significant correlation of

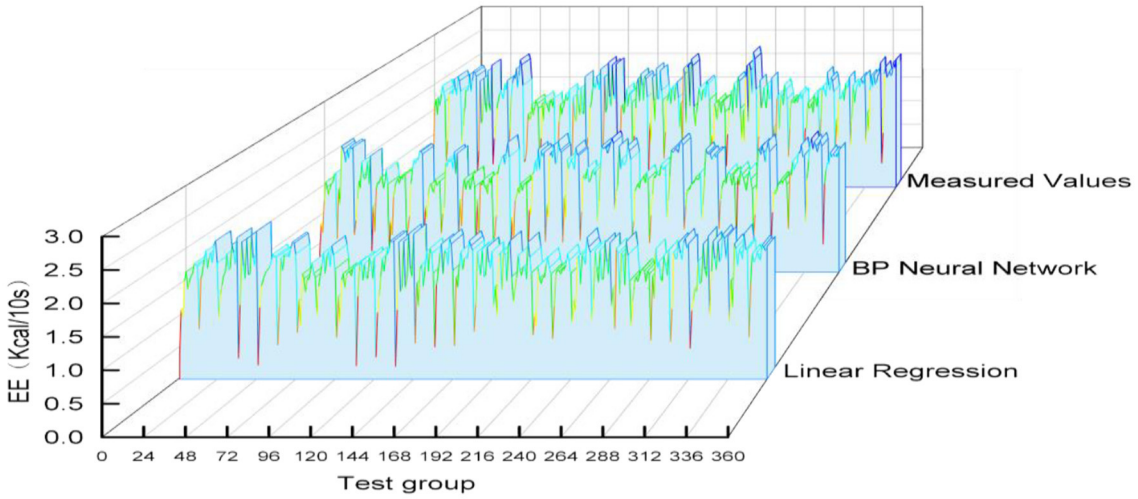

FIGURE 8 | Predicted values and Measured values.

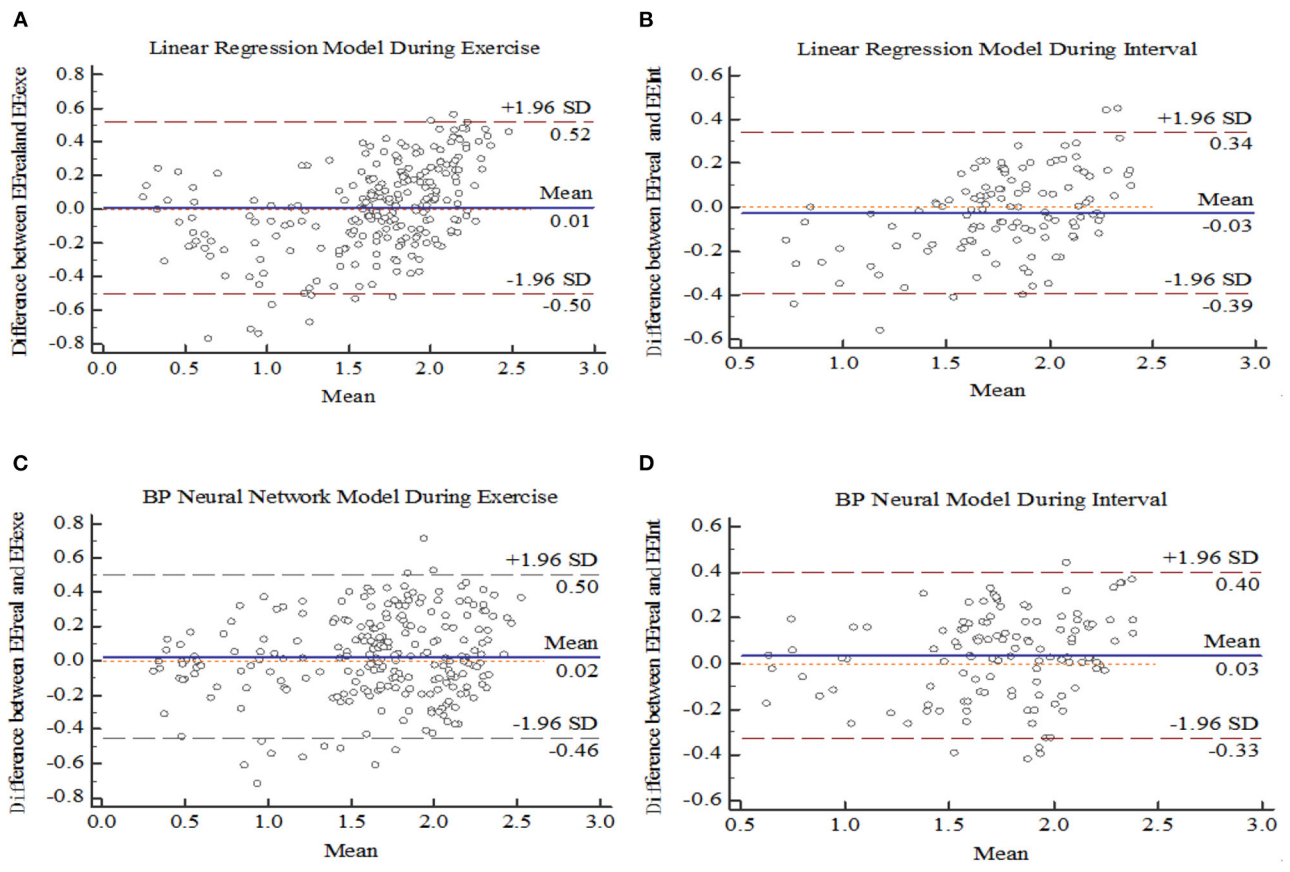

FIGURE 9 | Bland Altman plot for models. **(A)** Linear regression during Exercise. **(B)** Linear regression during interval. **(C)** BP neural network during Exercise **(D)** BP neural network during interval.

intermittent EE is exercise HR 1 min before the interval. Due to a temporal dissociation be-tween HR and VO2 (EE) during intermittent-type activity, the relationship between resting heart rate and oxygen uptake was not strong during partial exercise intervals (34), Therefore, the HR value during 0–10s exercise was selected as the input variable in this study. At present, there are

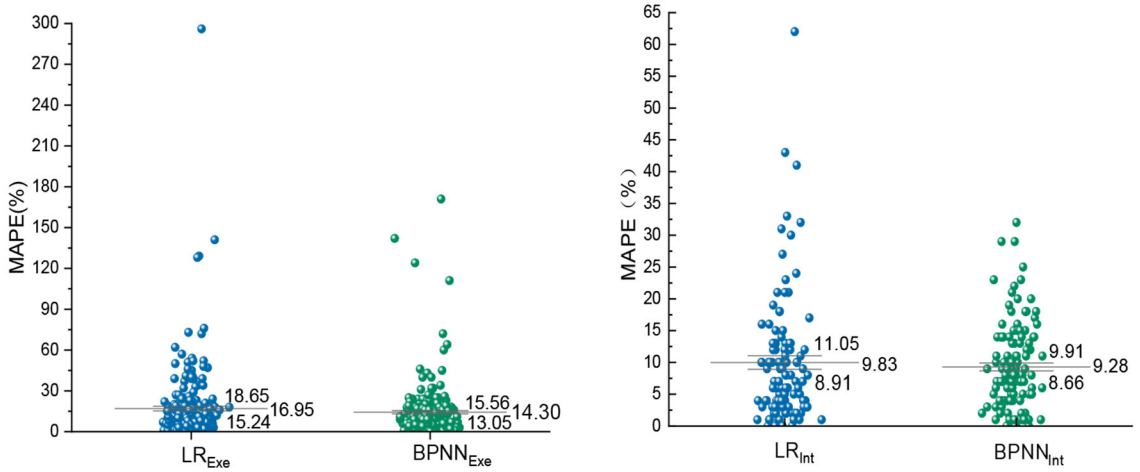

FIGURE 10 | Prediction error of EE during exercise and interval period.

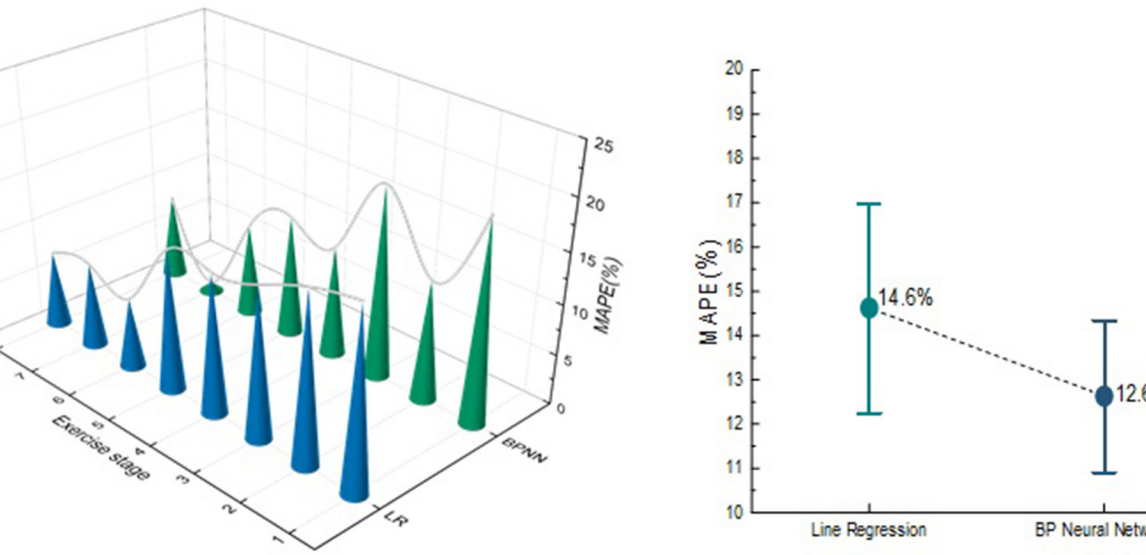

FIGURE 11 | MAPE comparison of the EE of total exercise.

few studies on the correlation between exercise heart rate and intermittent energy, and the correlation between other exercises and intermittent energy expenditure is not clear, which needs to be verified in the future.

Throughout the Tabata training, the ACC has a moderate correlation with EE, showing a weak linear correlation with EE, and the ankle ACC is the highest correlation among all the wearing parts. Tabata tested in this study included high-intensity and complex movements. In this exercise mode, the ACC values of each part of the body are vary a lot and do not show periodic changes, and the different parts of the body show different physical activity. This is similar to the study by Morris et al. (22), who validated smart devices with built-in accelerometers worn on the hip and wrist. The high intensity intermittent motion was carried out, the prediction efficiency of the acceleration values of the two wear parts is not good after substituting into the existing linear model. Although some studies suggest that accelerometers worn on the hip can better predict EE, most of these studies tested continuous periodic motion (35). Some studies have also suggested that ankle is the most suitable wearing part for sports with high speed and intensity, because the acceleration signal vector of human motion changes with different postures (36). Therefore, the ankle acceleration can be used as a prediction variable in EE prediction in this study.

Some studies have also shown the correlation between EE and anthropometric indexes (37). In this study, the correlation between body weight and EE was the highest among anthropometric indexes. Therefore, body weight is also considered a variable of EE prediction.

After the correlation analysis of the pre-selected variables, the LR model was constructed with the heart rate, the right ankle VM value and body weight as independent variables through stepwise regression of the predictive variables. Referring to input variables selected in past studies, BPNN is constructed by combining relevant variables significantly related to EE with subject characteristics information.

In terms of model establishment, Bland-Altman method is used to test that LR and BPNN model are consistent. The feasibility of predicting EE with heart rate combined accelerometer was confirmed, which was consistent with the results of previous studies by Brage and Crouter (38, 39). A recent study evaluated the effectiveness of accelerometers in predicting the EE of High Intensity Functional interval Training (HIFT), which is similar to the Tabata model. But, the effect of accelerometer alone on the EE prediction by linear regression model is not ideal, and the MAPE of energy expenditure in the whole movement process is more than 15%, and the errors in predicting EE during exercise and interval period have not been specifically evaluated (22). In accordance to the statement made by Lee et al. (40) that the reasonable error of energy expenditure prediction is 10–15%. Compared with the recent study, the overall prediction errors of the two ACC-HR models constructed in this study are both lower than 15%, which has improved the prediction effect in EE prediction of high intensity intermittent exercise. By comparing LR and BPNN model, the MAPE of BPNN model is higher than 15% in two stages, while the MAPE in LR model is higher than 15% in three stages. In addition, the RMSE and MAPE predicted by BPNN in the whole exercise process were lower than those predicted by LR model (0.227 and 12.6%), which proved that BPNN model based on machine learning algorithm in the era of big data could provide exercisers with more accurate prediction of EE than LR, which was similar with the result of Montoya et al. (15).

LIMITATION

Firstly, Limitations of test contents, this study selected classic and representative Tabata exercise pattern and movement for testing. Although the model cannot predict the EE of all Tabata exercises, it can be used to predict EE in the classical pattern. Future research can further enrich the testing of Tabata exercises and modes, so as to improve the accuracy of Tabata EE prediction. In addition, Limitations of the applicability, the subjects selected were 45 young adults. Therefore, the generalization of the models established in this study to other age group further research and confirmation.

CONCLUSION AND FUTURE WORK

In this paper, a linear regression and neural network model were constructed to predict the EE of Tabata training using accelerometer combined with heart rate data. The two models have good consistency by bland-Alterman test, and the prediction performance is evaluated by MAPE and RMSE, which proves that the error of back propagate neural network is lower than linear regression. Overall, the empirical results showed that: (i) the effectiveness of acceleration combined with heart rate data in predicting Tabata exercise EE. (ii) Back propagate neural network model constructed by acceleration combined with heart rate has higher prediction accuracy than linear regression model, reflecting the feasibility of machine learning algorithm in predicting EE of complex intermittent exercise. The ACC-HR Back propagate neural network model provides exercisers with a portable and more accurate tool for predicting Tabata EE, so as to help exercisers adjust their physical activities and set up their exercise plans, thus improving their exercise benefits. In the future, more novel and useful machine learning algorithms will be used to predict the EE of high intensity interval exercise. In addition, this study will test more Tabata exercise patterns and movements to more fully and accurately predict Tabata exercise EE.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author/s.

ETHICS STATEMENT

The studies involving human participants were reviewed and approved by Chengcheng Cai, Sport Laboratory, College of Physical Education, Sichuan Normal University. The patients/participants provided their written informed consent to participate in this study.

AUTHOR CONTRIBUTIONS

YY participated in research concepts, design, subject data collection, manuscript writing, and chart making. QC contributed to the research concept and made critical revisions to the research design and manuscript. All authors contributed to the paper, the manuscript was constantly revised, and the authors unanimously agreed on the version submitted.

FUNDING

The work was supported by the Physical Education Institute of Sichuan Normal University, which provided the venue for the testing.

ACKNOWLEDGMENTS

The authors would like to thank Junsong Pu, Yubing Zhou and Junrong Zhang for their assistance with test data collection.

Diabetes has been recognized as a global medical problem for more than half a century. Patients with diabetes can benefit from the Internet of Things (IoT) devices such as continuous glucose monitoring (CGM), intelligent pens, and similar devices. Smart devices generate continuous data streams that must be processed in real-time to benefit the users. The amount of medical data collected is vast and heterogeneous since it is gathered from various sources. An accurate diagnosis can be achieved through a variety of scientific and medical techniques. It is necessary to process this streaming data faster to obtain relevant and significant knowledge. Recently, the research has concentrated on improving the prediction model's performance by using ensemble-based and Deep Learning (DL) approaches. However, the performance of the DL model can degrade due to overfitting. This paper proposes the Extra-Tree Ensemble feature selection technique to reduce the input feature space with DL (ETEODL), a predictive framework to predict the likelihood of diabetes. In the proposed work, dropout layers follow the hidden layers of the DL model to prevent overfitting. This research utilized a dataset from the UCI Machine learning (ML) repository for an Early-stage prediction of diabetes. The proposed scheme results have been compared with state-of-the-art ML algorithms, and the comparison validates the effectiveness of the predictive framework. This proposed work, which outperforms the other selected classifiers, achieves a 97.38 per cent accuracy rate. F1-Score, precision, and recall percent are 96, 97.7, and 97.7, respectively. The comparison unveils the superiority of the suggested approach. Thus, the proposed method effectively improves the performance against the earlier ML techniques and recent DL approaches and avoids overfitting.

INTRODUCTION

In a survey made by IDF and WHO, nearly half a billion of the population worldwide have diabetes and posing about $13,700 financial burden per year. Moreover, the statistics increasing in years to come. Diabetes is a persistent disease caused when the blood sugar level crosses certain levels and can have adverse consequences on other organs of the human body and severely affect the entire body. If it is not diagnosed at the right time and remains untreated, it can increase the risk of other

disorders. In addition, diabetes may lead to other problems like kidney failure, weak eyesight and heart problem.

Furthermore, diabetic persons are at higher risk of infection and death from COVID-19 (1). Hence, concerning its severe complications, prior diagnosis of the disease is very significant to take timely steps to avoid other health risks and complications. Patients with diabetes can benefit from the Internet of Things devices such as CGM, intelligent pens, and other similar devices, according to the American Diabetes Association (ADA). These devices help in collecting medical data in real-time. Data collected from the smart devices needs to be processed immediately for dissemination of information to practitioners to provide prompt medical attention. Health care data comes from various sources, including medical history and records of patients in hospitals, medical diagnosis reports, medical examination reports by doctors, real-time data from multiple IoT devices and health-related Apps, and data streams from social networking sites. Dealing with such heterogeneous healthcare data has become increasingly difficult in recent years, owing to the large volume of data, security issues, incompetence in wireless network application development, and the rapidity with which it is being generated. As a result, to improve the healthcare industry's efficiency, accuracy, and workflow, data analytics tools are required to manage such complex data (2). Therefore, it is necessary to process this streaming data faster to obtain relevant and significant knowledge using an adaptive model. In the recent past, many algorithms have been employed in handling the classification of real-time data streams. Gaining insights and knowledge from such streaming data is a crucial challenge. Machine Learning (ML) is an analytical method for mechanized learning. It learns from knowledge and skill gained during the training process and applies the experience to improve the performance to make more accurate predictions. ML plays a significant role in discovering hidden and new patterns in the medical data stream. These patterns provide fascinating insights into the knowledge gained.

Further, researchers and medical practitioners use it for assistance in various ailment diagnoses and treatments. Latest advances in this field can also be applied for discovering unknown and latent patterns for detecting diabetes in prior stages. The advancement in ML techniques resolves this censorious problem of an early diabetes diagnosis.

Only health professionals are permitted to process health data because it is sensitive and not readily available. In addition, it is subject to strict usage rules due to the obligation of medical secrecy. As a result, only health professionals are permitted to process it. ML algorithms frequently underperform in prediction accuracy when there is insufficient data to train the model. The data obtained from heterogeneous sources can be either structured or unstructured, depending on the source. Conventional ML techniques cannot process unstructured data; on the other hand, DL can analyze images, videos, and unstructured data in ways that traditional ML techniques cannot. Deep understanding, as opposed to ML, typically necessitates less ongoing human intervention. DL models for prediction and classification are becoming increasingly popular as a means of avoiding these pitfalls.

DL is a subset of Artificial Intelligence with similar architecture as a neural network but has extra hidden layers. The extra layers, therefore, make DL more powerful in data processing than shallow architecture. DL methods showed more accuracy in results than traditional rule-based methods in various domains, including eHealth systems (3–5). A study proposed a hypothesis that further improving the accuracy of DNN feature selection techniques can be used (6, 7). Feature selection is the process of acquiring relevant information and discarding irrelevant ones (8). The feature selection methods can be either supervised or unsupervised, and the supervised method can be divided into the wrapper, filter or intrinsic methods.

Furthermore, a single feature selection method may produce a local optimal or sub-optimal feature subset for which a learning method's performance is compromised. Therefore, multiple feature subsets are combined in the ensemble-based feature selection method to select an optimal subset of features using a combination of feature ranking that improves classification accuracy. The normalized total reduction is the mathematical criteria used in the split decision during the forest construction when the extra tree ensemble method performs feature selection. In addition, in the proposed work Gini Index is computed for each feature known as the Gini Importance of the feature. Then, each feature is ordered in descending order based on its Gini Importance, and the user selects the top k features based on the preferences to perform feature selection. This process selects the optimal feature subset from the high dimensional feature space.

However, the DNN has a disadvantage because it overfits small data sets (9, 10). Overfitting occurs when the accuracy with the training dataset is greater than the accuracy with the testing data set, and the model is not generalized. Dropouts can avoid this problem where a certain number of neurons at a layer are deactivated from firing during training. This deactivation of neurons prevents overfitting, and the network's performance on test data improves (11).

The novelty of the proposed work is as follows:

i. The Extra tree ensemble feature selection technique reduces the feature space by selecting the optimal feature subset. Thus, improving the prediction accuracy and reducing model complexity.
ii. When presented to the DL network, the optimal feature subset further enhances its performance and prevents overfitting.
iii. Previous works are either complex or prone to overfitting. Both these issues are fixed in the proposed work.

Following are the key contributions of the Novel ETEODL framework.

i. The proposed algorithm predicts diabetes at a very early stage using a framework that combines an extra-tree ensemble feature extraction technique used to extract relevant features and a deep neural network to improve prediction accuracy.
ii. Valuable metrics: prediction accuracy, Precision, Recall, F1-score, and computation time are evaluated for performance comparison.
iii. The proposed algorithm is compared with state-of-the-art techniques.

iv. The proposed algorithm shows no instances of overfitting or underfitting.

LITERATURE REVIEW

Alić et al. (12) studied several diverse ML techniques to detect diabetes and concluded that the most common type of ANN used is multilayered feed-forward and the Naïve Bayesian network, which shows higher possibilities of get-ting accurate predictions. In their work, Sisodia and Sisodia (13) experimented with Decision Tree, SVM, and Naive Bayes and concluded that Naive Bayes has the highest accuracy compared to other algorithms and verified it using ROC metrics. Maniruzzaman et al. (14) used Gaussian process classification (GPC) to diagnose diabetes and concluded that the model's performance is comparatively better than other models. In their work, Kaur and Kumari (15) analyzed different models for the detection of diabetes. Wei et al. (16) explored the popular techniques to detect diabetes and data pre-processing techniques. Kamble et al. (47) proposed a DL-based Restricted Boltzmann machine approach for detecting diabetes. Swapna et al. (17) used DL-based methods to classify diabetic and HRV signals by extracting dynamic features from HRV data using a combination of LSTM and CNN. However, LSTM has high computational complexity and is prone to overfitting (18). Yahyaoui et al. (19) compared traditional classifiers with DL-based classifiers, Random Forest (RF) shows more accurate results in predicting diabetes than DL and SVM methods. DL (DL) techniques like CNN and RNN improve performance compared with classic designs (20). Naz and Ahuja (21), in their work, concluded that DL approaches perform better for early detection of diabetes as compared to Artificial Neural Network (ANN), Naive Bayes (NB), and Decision Tree (DT). The DL techniques also facilitate the latest trending techniques like Edge AI applications (22). A regularization layer called dropout can be used in fully connected layers of DNN to address the problem of overfitting (23). Rubaiyat et al. (24) used feature selection and used the selected features with traditional ML techniques like Random Forest, Logistic Regression, and MLP neural network classifier. Iwendi et al. (25) proposed a system to improve intrusion detection using a combination of correlation-based feature selection techniques and machine learning ensemble models. Reddy et al. (26) proposed ensemble-based ML algorithms, compared the proposed performance against the individual ML algorithms and concluded their superiority over the unique ML algorithms. Bashir et al. (27) used ensemble techniques for diabetes detection and inferred that the Bagging ensemble outperforms other ensemble techniques.

Similarly, Tama and Rhee (28) concluded that a tree-based classifier is better than other approaches. Recent research has been concentrated on enhancing the performance of ensemble-based methods for the prediction of disease. In addition, the neural network-based models can further reduce the cost (29). Deepa et al. (30) proposed RASGD to improve the regularization of the classification model. It is done by employing weight decay methods, such as the least absolute shrinkage and selection operator. In addition, ridge regression methods are used to achieve better regularization. Gadekallu et al. (31) were motivated by the fact that previous work had neglected the aspects of data pre-processing and dimensionality reduction, which had resulted in skewed results. Consequently, in their work, the raw dataset is normalized using the Standardscalar technique and Principal Component Analysis (PCA) is used to extract the most significant features from the dataset. In addition, the Firefly algorithm is used to reduce the dimensionality of the data. Finally, this condensed dataset is fed into a Deep Neural Network Model, used to classify the data. Gadekallu et al. (32), in their work, use a principal component analysis-based deep neural network model with the Gray Wolf Optimization (GWO) algorithm. The application of GWO allows for the selection of the most optimal parameters for training the DNN model.
